GUIDELINES TO READ THE ABSTRACT BOOK

The scientific program is divided into 5 main topic tracks:

Track A: Immune development and differentiation
Track B: Tumor immunology and therapy
Track C: Autoimmunity, allergy and transplantation
Track D: Infections and microbial immune regulation
Track E: Immunomics – Technical advances and big data

There are 10 types of sessions generated from invited and submitted abstracts:

Keynote Lectures (KL): oral presentations by invited keynote speakers
Symposia (S): oral presentations by invited speakers
Joint Symposium (JS): oral presentations by invited speakers
Educational Sessions (EDU): oral presentations by invited speakers
Men and Women in Immunology (MWI): oral presentations by invited speakers
EFIS President's Symposium (EP): oral presentations by invited speakers
Bright Sparks Workshop (BS): oral presentations from selected abstracts
Workshop (WS): oral presentations from selected abstracts
Late Breaking Hot Topics (HT): oral presentations from selected abstracts
Guided Poster Session (P): poster presentations from selected abstracts

How to read the presentation numbers – for example: WS.B1.06.04

WS.B1.06.04: **WS** stands for one of the following session types

KL:	Keynote Lecture	EP:	EFIS President's Symposium
S:	Symposium	BS:	Bright Spark
JS:	Joint Symposium	WS:	Workshop
EDU:	Educational Session	HT:	Late Breaking Hot Topic
MWI:	Men and Women in Immunology	P:	Poster Session

WS.B1.06.04: **B** stands for one of the following tracks:

A:	Immune development and differentiation
B:	Tumor immunology and therapy
C:	Autoimmunity, Allergy and Transplantation
D:	Infections and microbial immune regulation
E:	Immunomics - Technical advances and big data

WS.B1.06.04: **1** indicates the subtopic within the respective track

WS.B1.06.04: **06** indicates the chronological order of sessions within the respective subtopic

WS.B1.06.04: **04** indicates the chronological order of presentations within the respective session

Thus, WS.B1.04.04 indicates the fourth talk in workshop 04 of subtopic B1!

ANNOTATIONS

In the following we are publishing the abstracts as submitted by the authors.
Missing session numbers represent sessions with no abstracts associated. Missing presentation numbers represent withdrawn or embargoed abstracts which have not been received as per date of publication.

KL.01 Serendipities of acquired immunity

KL01.1
Serendipities of acquired immunity

***T. Honjo**;*
Kyoto University Institute for Advanced Study, Kyoto, Japan.

In 1992, we started working on PD-1 and found that this acts as a brake in the immune system. Then, in 2002, we discovered that PD-1 inhibition could be effective in treating cancer in animal models. After 22 years of study, this idea has borne fruit in a new, breakthrough immunotherapy that is being hailed as a 'penicillin moment' in cancer treatment. I believe that, just as a number of antibiotics developed in the wake of the discovery of penicillin now protect humans against threats of infectious diseases, this discovery will play a leading role in advancement of cancer immunotherapy so that in the future the fear of dying from cancer will cease to exist. Through evolution, vertebrate animals have developed immunity against infection by microorganisms. In the process, they incidentally acquired a sophisticated system for diversifying genomic information by combining gene fragments. It was doubly fortunate that the success in cancer treatment via PD-1 inhibition brought the realization that immunity, a "weapon" against infectious diseases, could also serve as a "shield" against cancer. It has been said that, whereas humankind's greatest enemies in the 20th century were infectious diseases, cancer is the major foe in the 21st century. It is a pleasant surprise to discover that the acquired immunity system holds the keys to overcoming both of these difficult medical challenges.

KL.02 Trained immunity: reprogramming innate immunity to protect against infections

KL02.1
Trained immunity: reprogramming innate immunity to protect against infections

***M. G. Netea**;*
Radboud University Medical center, Nijmegen, Netherlands.

The inability of innate immunity to build an immunological memory, considered one of the main characteristics differentiating it from adaptive immunity, has been recently challenged by studies in plants, invertebrates, and mammals. Long-term reprogramming of innate immunity, that induces adaptive traits and has been termed *trained immunity* characterizes prototypical innate immune cells such as natural killer cells and monocytes, and provides protection against reinfection in a T/B-cell-independent manner. In contrast, *trained immunity* has been shown to be able to induce protection against reinfection in a lymphocyte-independent manner. Non-specific protective effects dependent on *trained immunity* have also been shown to be induced after BCG vaccination in humans. Specific signaling mechanisms including the dectin-1/Raf1 and NOD2-mediated pathways induce trained immunity, through induction of histone modifications (methylation, acetylation) and epigenetic reprogramming of monocyte function. Complex immunological and metabolic circuits link cell stimulation to a long-term epigenetic reprogramming of its function. The concept of *trained immunity* represents a paradigm change in immunity and its putative role in infection and inflammation may represent the next step in the design of future vaccines and immunotherapeutic approaches.

KL.07 Microbiota and cancer therapeutics

KL07.1
The unsuspected role of gut microbiota in cancer therapies

***L. Zitvogel**;*
INSERM, Gustave Roussy Cancer Center, University Paris Saclay, Villejuif, France.

We recently highlighted the crucial role of gut microbiota in eliciting innate and adaptive immune responses beneficial for the host in the context of effective therapies against cancer (chemotherapies, immunotherapy based on immune checkpoint blockers).
1/ *Context of cyclophosphamide (CTX):* Chemotherapeutic agents, by compromising, to some extent, the intestinal integrity, facilitate the gut permeability and selective translocation of Gram positive bacteria in secondary lymphoid organs. There, anti-commensal pathogenic TH17 T cell responses are primed, facilitating the accumulation of TH1 helper T cells in tumor beds post-chemotherapy as well as tumor regression. Importantly, the redox equilibrium of myeloid cells contained in the tumor microenvironment is also influenced by the intestinal microflora, contributing to tumor responses. Hence, the anticancer efficacy of alkylating agents is compromised in germ-free mice or animals treated with antibiotics. These findings represent a paradigm shift in our understanding of the mode of action of many compounds having an impact on the host-microbe mutualism (Viaud S, *Science* 2013). These findings have been extended to platinum salts (oxaliplatine, cis-platine) as well as to a combination of anti-IL-10R mAb+CpG for Iida et al. Science Nov 2013 (Trinchieri's group at the NIH, USA).
2/ *Context of CTLA4 blockade :* The immune checkpoint blocker (ICB) anti-CTLA4 Ab is a first-in class compound approved for reinstating cancer immunosurveillance and prolonging survival in metastatic patients. However, this clinical benefit is often associated with immune –related side effects at sites exposed to commensal flora such as the large intestine. Uncoupling efficacy from toxicity is a challenging issue for the future development of ICB. Her team showed (and submitted to Science) that the antitumor effects of CTLA4 blockade, largely dependent upon Toll like receptor (TLR)2/TLR4 receptors, markedly rely on the regulatory commensal *Bacteroides fragilis (Bf) (*in coordination with *Burkholderia cenocepacia).* Innate signaling induced by specific TLR2/TLR4 agonists failed to compensate the lack of tumoricidal activity mediated by CTLA4 blockade in germ free (GF) or antibiotics-treated mice while the IL-12-dependent cognate immunity directed against *Bf* could do so. Hence, anti-CTLA4 Ab elicited protective *Bf*-specific Th1 immune responses in specific pathogen free (SPF) mice that could be substituted, in GF animals, by oral *Bf*, purified *Bf*-associated polysaccharides or a *Bf*-specific adoptive T cell transfer, without triggering overt colitis. Ipilimumab could also restore *Bf*-specific Th1 immune responses in a fraction of advanced melanoma patients. This study unravels the key role of *B.fragilis* in the immunostimulatory effects of anti-CTLA4 Ab, opening up novel strategies to safely broaden its clinical efficacy (Vétizou et al. *Science Nov. 2015*). At the same time, Gajewski's group in Chicago showed that *Bifidobacteria* from the gut influence the tumor microenvironment in such a way that anti-PDL-1 Ab can induce a prominent anticancer immune responses (Sivan et al. Science Nov. 2015).
3/ *Setting of PD-1/PDL-1 blockade:* In September 20 2017, the demonstration of the deleterious role of antibiotics in the clinical efficacy of PD-1 blockade in lung, kidney and bladder cancer patients was brought up, highlighting the role of *Akkermansia muciniphila* as the main player in the immunomodulatory effects of pembrolizumab or nivolumab (Routy et al. Science 2017 Nov2). The mechanisms by which *A. muciniphila* restores gut dysbiosis will be discussed, involving CCR9 and IL-12.
From these findings, we infer that oncomicrobiotics and/or fecal microbial transplantation could be considered as adjuvants to the current oncological armamentarium in dysbiotic cancer bearers.

KL.08 The maintenance and mobilization of resident immune memory cells

KL08.1
The maintenance and mobilization of resident immune memory cells

***A. Radbruch**[1,2];*
[1]Deutsches Rheumaforschungszentrum, Berlin, Germany, [2]Charité University Medicine, Berlin, Germany.

Populations of memory T lymphocytes and memory plasma cells residing in epithelial tissues and in the bone marrow provide first-line protection and longterm memory to prevailing antigenic challenges of the environment. We have now also identified memory B lymphocytes of the bone marrow as a population distinct from their splenic counterparts in terms of repertoire and phenotype. Apparently the resident memory lymphocytes are not maintained by homeostatic proliferation. For memory plasma cells of the bone marrow, we could demonstrate that they are maintained individually by stromal cells. Their survival is dependent on cell contact to the stromal cell, inducing PI3K signaling, and on the cytokines April or BAFF from their environment, inducing NFkB signaling. In synergy, both signaling pathways in plasma cells upregulate expression of the vital transcription factor IRF4 and prevent caspase-induced apoptosis. Memory T and B lymphocytes of the bone are maintained individually on stromal cells as well, and sensitive to inhibition of the PI3K pathway, suggesting that stromal cells play a pivotal role for immunological memory, by inducing vital, cell-contact dependent PI3K signaling. In secondary immune reactions, resident quiescent T and B lymphocytes obviously have to be mobilized from their memory niches. We could show for resident CD4+ memory T lymphocytes that this mobilization leads (a) to the formation of "Immune clusters" in the bone marrow, resulting in amplification of the specific memory lymphocytes, and (b) to the emigration of specific resident memory T lymphocytes into the blood, and their participation in the secondary immune reaction.

SYMPOSIA

S.A2 Immune development and aging from the cradle to the grave

S.A2.01
Dissecting blood and immune cell lineages by endogenous barcoding

***H. Rodewald**, W. Pei, T. Feyerabend, K. Klapproth, K. Busch, A. Schuon, T. Benz, X. Wang, J. Rössler, T. Höfer;*
German Cancer Research Center (DKFZ), Heidelberg, Germany.

Deconvolution of cell lineage origins and relationships remains a major challenge. Once achieved, this would allow deep insights into understanding not only the formation and maintenance of tissues but also of stem and progenitor cell fates and clone sizes. Genetic fate mapping enables the tracing of the origins and lineages but numbers of available fluorescent markers have been limiting. Within the immune system, hematopoietic stem (HSC) and progenitor cells have been studied in cellular and molecular details, but information on the physiological behavior of HSC under non-perturbed or challenge conditions is limited. We have developed an endogenous genetic HSC fate mapping system that revealed differentiation rates of HSC in the bone marrow and the differentiation flow from stem cells via progenitors in vivo (Busch et al. Nature 2015; reviewed in Hoefer and Rodewald Blood 2018). To combine fate mapping with high resolution barcoding of individual cells we devised a barcoding system, in which an artificial recombination locus (termed *Polylox*) serves as Cre recombinase-dependent substrate in cells in vivo (Pei, Feyerabend et al. Nature 2017). We have introduced barcodes in embryonic HSC progenitors and in adult HSC and studied the lineage outputs from HSC clones, as well as their sizes in the bone marrow. The data demonstrate common myeloid-erythroid, and common lymphocyte pathways as fundamental structures of the hematopoietic system. These endogenous barcoding studies are now exploited to unravel at high resolution lineage relationships of tissue resident macrophages of embryonic origins.

S.A2.02
Implications from monogenic autoimmunity

***K. Kisand**;*
University of Tartu, Tartu, Estonia.

Autoimmunity caused by single gene defects is a rapidly growing group of hereditary diseases. Autoimmune tissue damage is often accompanied by susceptibility to certain infectious agents highlighting the dual function of the immune system - to recognize pathogens and secure tolerance to own tissues. APECED (autoimmune polyendocrinopathy candidiasis ectodermal dystrophy) is caused by *AIRE* gene mutations resulting in defective central T cell tolerance. However, the most striking feature of APECED patients is the presence of multiple high-titer autoantibodies that target cytokines: type I interferons and Th17 cytokines. Monoclonal auto-antibodies isolated from patients' B cells show extremely high affinity which has permitted their application for diagnostic and potentially therapeutic purposes. STAT1 gain-of-function (GOF) mutation is another gene defect that leads to chronic mucocutaneous candidiasis and variable manifestations of autoimmunity. In these patients the development of Th17 cells, that are indispensable for fungal protection, is impaired. The precise molecular mechanisms causing STAT1 signalling imbalance in STAT1 GOF cells are still unclear. We have applied ChIP-Seq to shed some light on these processes. In spite of the rarity of monogenic autoimmune diseases their impact on unfolding of the processes that shape and regulate the immune responses is immense.

S.A2.03
Strategies for enhancing human immunity during ageing

***A. N. Akbar**;*
University College London, London, United Kingdom.

Older people suffer from increased incidence and severity of infections and also cancer. In addition, vaccination therapies becomes less efficient with age. It is possible to enhance the function of immune cells during ageing in both humans and mice by blocking the function of a group of proteins called the sestrins
(Lanna et al Nature Immunology 2017). The sestrins were found to form a molecular complex, termed sMAC (sestrin-induced MAPK activation complex), with p38 and also the other two classes of MAPKs namely ERK and JNK in these cells. This for the first time provides a mechanism for integrated activation of all three classes of MAPK within a single cell type. The inhibition of sestrins in human T cells or in genetically modified mice that are sestrin-deficient, enhanced the function of T lymphocytes. Moreover, when old sestrin deficient mice were vaccinated against influenza, the response was considerably enhanced as compared to old sestrin replete animals. Therefore temporary immune enhancement by short-term inhibition of sestrins can boost immune function that could be beneficial during anti-ageing immunotherapy, for instance during vaccination of older humans.

S.A3 Immunomonitoring and biomarkers

S.A3.03
CD Maps - antigen density measurements of CD1-CD100 on human lymphocytes and thymocytes

***T. Kalina**[1], J. Stuchlý[1], D. Kužílková[1], K. Fišer[1], M. Cuenca[2], E. Blanco Álvarez[3], S. J. W. Bartol[4], N. Brdičková[1], M. Andres-Perez[3], M. C. van Zelm[5], P. Engel[2];*
[1]Charles University, Prague, Czech Republic, [2]University of Barcelona, Barcelona, Spain, [3]University of Salamanca, Salamanca, Spain, [4]Erasmus MC, Rotterdam, Netherlands, [5]Monash University, Melbourne, Australia.

Leucocyte receptors have been characterized using antibodies validated by the human leucocyte typing HLDA/HCDM organization (www.hcdm.org). However, expression information is outdated or incomplete. CD Maps project aims at quantitative mapping of expression of all CD molecules across the spectrum of leucocyte subsets. We measured PE conjugated CD1-CD100 antibodies in the context of four standardized 8-color panels on cells from three tissues (blood, thymus and tonsil). We attempted to re-map CD markers expression in thymocytes using a 37 marker mass cytometry panel (29 surface markers and 8 transcription factors). We expert gated 9 thymocyte stages based on canonical markers (CD34, CD1a, CD3, CD4, and CD8). We developed fast time and paths inference algorithm, which involves branching and also accounts for possible alternative developmental paths. We processed the thymocytes through computational algorithm in parallel to expert gating. The simulated paths reached the canonical CD4 helpers end in 79% and the canonical CD8 end in 19% respectively. The CDMaps project generates a broad and updated online database containing the expression profiles of all CD markers on human leukocyte subsets present in blood, tonsil, and thymus. Quantitative information on receptor expression is important for mechanistic studies as well as flowcytometric panel design and design of novel biological therapeuticals. Therefore it will serve as a useful resource to widen and advance studies into basic, translational and clinical immunology. CD Maps project is supported with reagents by BD Biosciences, BioLegend, Exbio and Fluidigm. TK is supported by Ministry of Health Czech Republic grant 15-26588A and LO1604.

S.A4 Germinal centers and B cell differentiation

S.A4.01
Germinal centers under the lens: Differentiation of plasma cells and memory B cells from germinal center precursors

***R. Brink**[1,2];*
[1]Garvan Institute, Darlinghurst NSW, Australia, [2]UNSW Australia, Darlinghurst NSW, Australia.

Germinal centers form in secondary lymphoid organs in response to challenge with T-cell-dependent antigens. After extrafollicular and follicular interactions with cognate antigen and T helper cells, responding B cell clones can enter the germinal center response, where they undergo iterative cycles of proliferation, somatic hypermutation and selection such that clones acquiring increased affinity for the eliciting antigen preferentially accumulate. This process is also associated with the differentiation of long-lived memory B cells and antibody-secreting plasma cells from germinal center B cell precursors. These two populations facilitate long-term immunity against infectious pathogens and underpin the efficacy of almost all current vaccines.
Although the importance of memory B cells and plasma cells to long-term immunity is well established, the processes that regulate their production during the germinal center response have been difficult to identify due to the dynamic nature of the geminal center and the difficulty of tracking the antigen specificity and fate of responding B cells. We have used a high resolution in vivo model in which B cells respond to a low affinity variant of the model antigen hen-egg lysozyme, to identify the precursors of both memory B cells and plasma cells in the germinal center. A fundamental dichotomy in the differentiation of these two critical germinal center outputs was revealed in terms of both antigen affinity and cell cycle status. This system not only optimises the specificity and potency of the antibody response but provides response flexibility within the long-term memory B cell pool.

S.A5 Initiation of immune responses

S.A5.01
Regulation of cytotoxic responses

***G. Guarda**;*
IRB, Bellinzona, Switzerland.

Natural Killer (NK) cells are cytotoxic lymphocytes that contribute to the elimination of virally infected or transformed cells. Their cytotoxic activity is regulated by two complementary sets of receptors; the activating receptors, which are engaged by stress-induced molecules, and the inhibitory ones, recognizing MHCclass I molecules.NK lymphocytes are extremely powerful and several efforts are undertaken in order to to harness their full potential for therapeutic purposes. A deeper understanding of the mechanisms regulating their development, survival, and activity, is therefore needed. Recently, the study of mechanisms specifically regulating their activation as well as their metabolism has revealed new pathways and players relevant to NK cell-mediated immunity. Advances in our understanding of such mechanisms and the consequences on innate cytotoxic immunity will be discussed.

S.A5.02
Dendritic cells in HIV-1 sensing and restriction

***T. B. H. Geijtenbeek**[1,2];*
[1]Amsterdam UMC, Amsterdam, Netherlands, [2]Amsterdam Infection & Immunity Institute, Amsterdam, Netherlands.

Sexual transmission is the primary route of infection by HIV-1 and mucosal dendritic cell (DC) subsets are amongst the first targets for HIV-1.Although DCs are paramount to the induction of antiviral immunity to HIV-1, it is becoming evident that HIV-1 subverts DCs for dissemination to T cells as well as escape from antiviral immunity. HIV-1 productively infects submucosal DCs but this does not lead to an antiviral type I Interferon (IFN) immune response as HIV-1 escapes viral sensing in DCs. We identified the dead-box helicase DDX3 as a RNA sensor for HIV-1 and our recent data strongly suggest that HIV-1 blocks this viral sensor in DCs, preventing triggering of antiviral immunity Strikingly, interfering with the inhibitory pathway, leads to efficient DC maturation, type I IFN and cytokine responses, which limits HIV-1 replication in vitro and in vivo. Here, we will discuss the importance of DDX3 in sensing HIV-1 replication and induction of innate and adaptive immunity. Furthermore, we will discuss how synthetic DDX3 ligands can be used as adjuvants in immunotherapy to induce innate and adaptive immune responses. However, not all DC subsets become infected by HIV-1 as our data show that mucosal Langerhans cells (LCs) are resistant to HIV-1 infection. LCs efficiently capture HIV-1 and route the virus into a autophagy-mediated degradation pathway, which prevents infection. Here I will discuss the molecular mechanisms underlying the distinct functions in DC subsets in HIV-1 infection and how we can harness these mechanisms to prevent infection and enhance antiviral immunity.

S.A5.03
The role of Complement in Tolerance

***M. Botto**;*
Imperial College London, London, United Kingdom.

Complement has been shown to contribute to the immunopathology of several autoimmune diseases including systemic lupus erythematosus (SLE). Paradoxically, however, complement also appears able to protect against autoimmunity since complement deficiencies, particularly C1q deficiency, strongly predispose to the development of SLE. There are currently several proposed mechanisms whereby deficiency or low levels of complement might lead to break of tolerance, and these are not mutually exclusive.One of the hypotheses to explain the heightened susceptibility to the development of SLE in the absence of C1q invokes an important role for complement in the waste-disposal mechanisms of dying cells. However, impaired clearance of such cells is, on its own, insufficient to induce autoimmunity. The data available from knockout mice emphasize that the break of tolerance depends on many factors in addition to the defective removal of dying cells. Recent findings have highlighted that C1q and C3 can modulate both adaptive and innate immune responses. In addition, C1q may not only act as initiator of the classical complement pathway, but can also mediate multiple immune responses in a complement activation independent manner. In particular, C1q can restrain autoimmunity by acting as a metabolic regulator of effector $CD8^+$ T cells. In summary,the traditional view of the role of complement in tolerance needs revision as evidence is emerging of an important interplay between complement and immunometabolism in autoimmunity

S.B1 Tumor vaccination principles and immuno therapy

S.B1.02
Next generation Immunotherapies

***E. Vivier**;*
Aix Marseille Univ, CNRS, INSERM, APHM, CIML, Innate Pharma,, Marseille, France.

Immuno-oncology, including checkpoint inhibitors targeting the PD-1/PD-L1 (PD-x) axis in particular, has revolutionized cancer treatment. However, only a subset of patients respond to these immunotherapies, and the development of drug resistance is frequent. Here, we report that the blocking of the inhibitory NKG2A receptor enhances tumor immunity by promoting both Natural Killer (NK) and $CD8^+$T-cell effector functions in mice and humans. Monalizumab, a humanized anti-NKG2A antibody, enhanced NK cell activity against various tumor cells and rescued $CD8^+$ T-cell function in combination with PD-x axis blockade. Monalizumab also stimulated NK-cell activity against antibody-coated target cells. We also established proof-of-principle for the use of combined immunotherapy with monalizumab and cetuximab in a phase II clinical trial, in which the combination showedpromise for the treatment of patients with squamous cell carcinoma of the head and neck (SCCHN). NKG2A targeting with monalizumab is thus a novel checkpoint inhibitory mechanism promoting anti-tumor immunity by enhancing the activity of both T and NK cells, which may complementthe first-generation immunotherapies against cancer.

S.B1.03
Intratumorally produced immunoglobulin repertoires

***D. M. Chudakov**[1,2,3];*
[1]Institute of Bioorganic Chemistry, Moscow, Russian Federation, [2]Privolzhsky Research Medical University, Nizhny Novgorod, Russian Federation, [3]Central European Institute of Technology, Brno, Czech Republic.

The emerging data shows that B cells may play an essential role in the immune response to cancer - as antigen-presenting cells, and by cytokines and antibodies production. Been present at limited counts in a tumor infiltrate, B cells may participate in generation of tertiary lymphoid structures, convert to the plasma cell phenotype and produce huge amounts of antibodies, which specificity and isotype-determined functional activity may influence on either cancer surveillance or immunosuppression. From this point, repertoire of intratumorally produced antibodies represents yet poorly explored component of cancer-immunity interaction that could play its role as a biomarker or as a source of tumor-specific receptors for precise immunotherapy. I will briefly summarize current knowledge on tumor-infiltrating B cells and immunoglobulin repertoire they produce, complementing it with our recent experience on antibody repertoire profiling with high-throughput sequencing. In particular, I will cover full-length nearly error-free immunoglobulin repertoire profiling using 5'RACE with UMI, extraction of immunoglobulin repertoires from RNA-Seq data with MiXCR, and provide guidelines for repertoire diversity/clonality analysis.

S.B2 Environmental regulation anti-tumor responses

S.B2.03
Dissecting immune complexity of metastatic breast cancer

***K. E. de Visser**;*
the Netherlands Cancer Institute, Oncode Institute, Amsterdam, Netherlands.

Metastasis formation is a key challenge in cancer patient care that urgently needs solutions. It is now well established that cells and mediators of the immune system influence these processes. Historically, our immune system has been considered to form an intrinsic defense mechanism against cancer and metastasis. Yet, the majority of cancer types exploit a myriad of strategies to successfully evade destruction by the immune system. In fact, mounting evidence supports the notion that cancer cells hijack the immune system for their own benefit, allowing them to escape from immune attack, maintain limitless proliferation, survive under dire circumstances and spread to distant organs. The overall goal of our research is to understand how the immune system influences metastasis formation. To achieve this, we utilize pre-clinical mouse models that faithfully recapitulate human breast tumorigenesis in combination with immune profiling studies in breast cancer patients. We have previously discovered that breast tumors elicit a systemic inflammatory cascade to dampen anti-tumor T cells and promote metastasis formation. Current efforts are underway to dissect how the genetic make-up of breast tumors dictates activation of systemic immunosuppressive inflammation. Our findings provide novel mechanistic insights into the thus far poorly understood metastatic cascade, and open new avenues for the development of therapeutic strategies to unleash anti-tumor immunity and to inhibit metastatic disease.

S.B3 The Yin and Yang of T-cell regulation

S.B3.03
Maintaining T cell tolerance via the CTLA-4 pathway

***L. S. K. Walker**;*
University College London, London, United Kingdom.

The immune system provides vital protection from infection and cancer but needs to be tightly regulated to prevent the development of autoimmune diseases such as type 1 diabetes and rheumatoid arthritis. The ability to augment or diminish the immune response in a controlled fashion holds the promise of boosting anti-tumour responses or silencing autoimmune diseases respectively. A major checkpoint controlling immune responses involves the T cell molecule CTLA-4 that is expressed at high levels in FoxP3+ regulatory T cells. CTLA-4 controls engagement of the T cell costimulatory receptor, CD28, by binding to their shared ligands and removing them from antigen presenting cells by a process of trans-endocytosis. Our lab seeks to understand how this mechanism operates in the steady state to maintain tolerance and allow appropriate immune responses to develop in a timely manner. Understanding the molecular basis of the CTLA4 checkpoint will ultimately empower us to manipulate the immune response in a more precise manner.

S.B4 T cell activation and exhaustion

S.B4.02
Immunodeficiencies associated with increased T cell senescence

***S. Kracker**, L. Heurtier, M. Deau, L. Chentout, A. Bouafia, A. Durandy, M. Cavazzana;*
INSERM UMR 1163, Imagine Institute, Paris, France.

Activated PI3Kδ syndromes 1 and 2 (APDS1 and 2) are primary immunodeficiencies caused by either gain-of-function mutations in the *PIK3CD* gene encoding p110δ (the catalytic subunit of PI3Kδ) or heterozygous mutations in the *PIK3R1* gene encoding p85α, p55α and p50α (regulatory subunits of PI3Kδ). The disease causing mutations lead to hyper-activated PI3Kδ -signalling in lymphocytes. APDS1 and 2 are combined immunodeficiencies with variable clinical phenotypes. The clinical symptoms include recurrent respiratory infections, bronchiectasis, lymphoproliferation and hypogammaglobulinemia frequently associated with elevated IgM serum level. Both diseases appear to predispose to B cell lymphomagenesis especially diffuse large B cell lymphoma and Hodgkin lymphoma. Abnormalities of B lymphocyte subpopulations, e.g. B cell lymphopenia and higher frequency of transitional B cells, and of T cell subpopulation, e.g. decreased number of naive CD4 and CD8 T cells and increased frequency of effector/effector memory CD8 T cells and CD8CD57 positive (senescent) T cells, are frequently observed in both diseases. Immunoglobulin replacement therapy, rapamycin, allogeneic hematopoietic stem cell transplantation and selective PI3Kδ-specific inhibitors (currently on clinical trials) are possible treatment options. The work was supported by the Institut National de la Santé et de la Recherche Médicale (INSERM), the Agence National de la Recherche as part of the "Investment for the Future" program: ANR-10-IAHU-01 and by ANR-15-CE15-0020 (ANR-PIKimmun), the Ligue Contre le Cancer - Comité de Paris, the Fondation ARC pour la recherche sur le Cancer, and the Centre de Référence Déficits Immunitaires Héréditaires (CEREDIH).

S.B4.03
Maintenance of "exhausted" T cells in chronic infection

***D. Zehn**;*
Munich, Germany.

Failure to clear an infection can coincide with the appearance of T cells which express low amounts of cytokines and high levels of inhibitory receptors (PD-1, Lag-3, Tim-3). This phenotype has so far been viewed to mark exhausted and terminally differentiated effector cells. Nonetheless, "exhausted" T cell populations in chronic infections and tumors are long-living and can be expanded upon blocking inhibitory receptor ligand systems. This raised the questions how these populations are maintained and which mechanisms act in case of therapeutically induced re-expansion. We and others identified recently that both long-term T cell maintenance in chronic infections and re-expansion following blockade of PD-1 signaling are depending on a small subpopulation of T cells, which express the transcription factor Tcf-1. We showed that Tcf-1 positive T cells share key features with conventional memory T cells while they co-express markers of "exhausted T cells" (i.e. PD-1). These memory-like T cells are capable of undergoing self-renewal while they are continuously generating terminally differentiated effector cells. Given the presumed central role of the memory-like population for therapeutic purposes, we will report recent advances on molecules and mechanisms that control size and function of this subset.

S.C1 Maintenance and local regulation of tissue specific immunity

S.C1.02
Functions of Resident Memory T Cells

***D. Masopust**;*
University of Minnesota, Minneapolis, MN, United States.

Resident memory T cells, often abbreviated T_{RM}, occupy tissues without recirculating and provide a first response to infections reencountered at body surfaces, where they accelerate pathogen clearance. T_{RM} also likely play critical roles in tumor immunosurveillance, and may contribute to immune disorders, allergies, and autoimmunity. This talk will share recent and ongoing investigations of T_{RM} function. Evidence will be presented that T_{RM} are capable of autonomously regulating the expansion of local immunosurveillance independently of central memory or proliferation in lymphoid tissue. Data will be communicated that reveal a nonlymphoid origin of secondary lymphoid organ T_{RM} and that suggest vaccination strategies by which memory CD8 T cell immunosurveillance can be regionalized to specific lymph nodes. Experiments supporting developmental plasticity among T_{RM} will be reviewed. Lastly, evidence will be presented that natural antiviral T_{RM} can be repurposed to control or eliminate tumors.

S.C1.03
Activation of Ca2+ regulated pathways downstream of Pattern Recognition Receptors

***F. Granucci**[1,2], L. Marongiu[2], L. Gornati[2], I. Artuso[2], F. Mingozzi[2], I. Zanoni[2];*
[1]Milan, Italy, [2]University of Milano-Bicocca, Milan, Italy.

Microorganism invasions are perceived by pattern recognition receptor (PRR)-expressing cells of the innate immune system. Among PRR, TLRs and their co-receptors are the best characterized. CD14, with LPS binding protein (LBP), TLR4 and MD-2 forms the multi-receptor complex for LPS. CD14 is a glycosylphosphatidylinisitol (GPI)-anchored protein abundantly expressed on DCs and macrophages. CD14 concentrates the LPS signal, mediates the relocation of TLR4 and MD2 to the endosome for the initiation of the TRIF signaling pathway and is responsible for Ca^{2+} mobilization and NFAT signaling pathway activation in DCs. Ca^{2+} mobilization is one of the first events for the initiation of the NFAT signaling pathway. We have investigated the mechanism of Ca^{2+} mobilization leading to NFAT activation in myeloid mouse and human DCs following LPS stimulation. Following LPS stimulation, IP_3 second messenger induces a SOCE through IP_3 receptor 3 channels co-localized with CD14. For this process to occur, Ins(1,3,4,5)P_4 generation by the IP_3 kinase (ITPK) B is required to antagonize IP_3 dephosphorylation and increase IP_3 availability. ITPKs pharmacological inhibition restrains inflammatory events (such as increased vessel permeability or inflammatory arthritis) regulated by NFATs in the presence of LPS, similar to the direct inhibition of NFATs by nanodrugs. ITPKB represents a new target for anti-inflammatory therapies aimed at inhibiting specific DC functions. The NFAT-controlled phenomena and the consequences of NFAT activation in innate immune cells will be discussed in models of microbial infections and sterile inflammation.

S.C2 Immune signalling and therapy in autoimmunity

S.C2.01
Myeloid and glial cells collaborate to regulate neuroinflammation

***T. Owens**[1], G. Webster[2], R. Khorooshi[1], J. Marczynska[1], A. Wlodarczyk[1], A. Benmamar-Badel[1], R. Dieu[1];*
[1]University of Southern Denmark, Odense, Denmark, [2]Innate Immunotherapeutics, Auckland, New Zealand.

Tissue macrophages and blood-derived regulatory myeloid cells play important roles in development and normal homeostasis. In the neonatal central nervous system (CNS) a subset of tissue-resident $CD45^{low}CD11b^{+}$ microglia that express CD11c dramatically expand, and are a critical source of myelinogenic IGF1. Transfer of such cells to adult mice alleviated experimental autoimmune encephalomyelitis (EAE) which identifies an anti-inflammatory role for this microglial subset in the developing CNS, whose mechanism remains to be established. We have also examined how innate signaling can direct anti-inflammatory myeloid cell programs in the adult CNS. Microglia as well as extraparenchymal $CD45^{high}CD11b^{+}$ macrophages were induced to produce interferon-alpha and -beta by intrathecal TLR3/RIG-I ligand poly-I:C, and this alleviated EAE. Intrathecal administration of a bi-specific NOD2 and TLR9 microparticle (MIS416) induced marked influx from blood of $CD45^{high}F4/80^{+}GR\text{-}1^{-}CD11b^{+}CD11c^{+}$ monocytes as well as $CD45^{high}Gr\text{-}1^{high}Ly6G^{high}CD11b^{+}CD11c^{-}$ neutrophils, as early as 2h after injection.

Both populations phagocytosed MIS416, produced IFNβετα and expressed PDL1. Intrathecal MIS416 alleviated EAE and this was dependent on IFNAR signaling. RNAseq analysis showed upregulation in the CNS of NFκB, Jak-STAT, TLR and NLR signaling pathways, as well as IFNgamma and neutrophil- (CXCL1, CXCL2) and monocyte-attracting (CCL2, CXCL10) chemokines. Microglia were a prominent source of chemokines. These studies collectively show that CNS-intrinsic signals promote and recruit endogenous and exogenous myeloid programs that collaborate to maintain CNS homeostasis in development, and in response to infection or tissue damage.

S.C2.03
How to modulate TCR signalling for peptide therapy in autoimmunity

***D. C. Wraith**;*
University of Birmingham, Birmingham, United Kingdom.

Control of autoimmune and allergic conditions can be reinforced by tolerance induction with peptide epitopes; this presentation will focus on the mechanisms involved. Peptides must mimic naturally processed epitopes and be designed to target tolerogenic, steady-state dendritic cells (DCs). Steady-state DCs express low levels of costimulatory molecules and induce 'abortive' activation of T cells whereby T cells undergo initial cell division but do not differentiate. $CD4^+$ T-cells become anergic following their first encounter with peptide. This depends on strength of signal via the T cell receptor (TCR) and the balance between TCR and costimulatory signalling. Continuation of peptide therapy results in the generation of anergic, IL-10 secreting $CD4^+$ T-cells with regulatory function. The loss of proliferative capacity correlates with a cytokine switch from a pro-inflammatory to a phenotype characterised by secretion of the anti-inflammatory cytokine IL-10. The IL-10 secreting Tr1-like cells suppress dendritic cell maturation, prevent Th cell differentiation and create a negative feedback loop for Th driven immune pathology. This mechanism leads to bystander suppression whereby Tr1-like cells specific for one antigen can suppress T cells specific for other antigens derived from the same tissue. Tolerance induction involves upregulation of transcription factors controlling IL-10 and inhibitory receptors limiting T cell signalling. The peptide therapy approach is a highly selective approach for prevention and treatment of autoimmune diseases in humans. Results from clinical trials of peptide immunotherapy in multiple sclerosis and Graves' disease will be described.

Transplantation, T cell engenering

***C. Bonini**;*
UNIVERSITA' VITA SALUTE SAN RAFFAELE, Milan, Italy.

Transplantation, T cell engineering
Chiara Bonini, Università Vita-Salute San Raffaele
Ospedale San Raffaele Scientific Institute
Milano
Adoptive T cell therapy represents an innovative and promising therapeutic approach, which relies on the ability of T lymphocytes to recognize and destroy specific targets on microbes or tumors through their T cell receptors (TCR), to obtain efficient killing of cancer cells. Ideally, adoptively transferred T cells should be: 1. Specific for tumor antigens, 2. Able to expand and persist long enough to mediate a long lasting clinical response, 3. Able to counteract the immunosuppressive tumor microenvironment.
TCR genetic engineering represents a suitable approach to generate large numbers of tumor specific T cells. The core of this approach is the transfer in patients' T cells of genes encoding for rare tumor-specific TCR. The simple transfer of tumor specific TCR genes into T cells is affected by some limitations: genetically modified T cells shall express four different TCR chains, that might mispair, leading to unpredictable toxicity and to an overall dilution of the tumor specific TCR on lymphocyte surface, thus limiting the efficacy of therapeutic cellular product. To overcome these issues, we can adopt a TCR gene editing approach, based on the concomitant disruption of the endogenous TCR genes and introduction of the tumor specific TCR genes. Different protocols to generate high numbers of TCR edited memory stem T cells and central memory T cells, able to overcome the immunosuppressive tumor microenvironment will be discussed.

S.C4 Manipulation of tolerance

S.C4.01
Engineered Dendritic Cells to re-establish Antigen-Specific Tolerance in T-cell Mediated Diseases

***S. Gregori**;*
San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milan, Italy.

The design of novel approaches to control antigen (Ag)-specific pathogenic T cell responses and restore tolerance represents an ambitious goal for the management of autoimmune diseases. The prominent role of dendritic cells (DC) in promoting T-cell tolerance and the development of methods to generate clinical grade products allowed the clinical application of tolerogenic DC-based therapies for the control of unwanted immune responses. The concluded clinical trials demonstrated the safety and feasibility of this approach. However, the stability of the infused DC products and the maintenance of their tolerogenic properties *in vivo* remain open issues to be tackled for improving the safety and the efficacy of DC-based cell therapies. Our hypothesis is thatinfusion oftolerogenic DC genetically modified by newly developed tolerogenic lentiviral vectors (LV) encoding autoAg-derived epitopes (tolLV-DC) will promote the *in vivo*generation of Ag-specific tolerance *via*down-regulation of autoAg-specific pathogenic T cell responses and induction of long-living autoAg-specific Tregs. To this aim we developedLV-platforms that allow the expression of specific autoAg epitope and pro-tolerogenic molecules. Our preliminary data show that tolLV-DC can modulate T cell responses both *in vitro*and *in vivo*and that infusion of tolLV-DC dampens Ag-specific T cell responses *in vivo*. The success of our strategies will help designing a safer tolDC-based cell therapy, abrogating the boosting of autoimmunity, and to stably preserve the tolerogenic properties of *in vivo* transferred DC.

S.C4.02
The role of cell metabolism in Treg biology and function

***B. Salomon**, R. Vallion, J. Divoux, S. Gregoire, E. Ronin;*
CIMI-Paris, Sorbonne Université, Inserm, CNRS, Paris, France.

Foxp3 regulatory T cells (Treg) play a major role in regulation of immune responses. Cellular metabolism of conventional T cells (Tconv) has been intensely studied revealing, among other findings, that their activation requires a switch from AMPK to mTOR driven metabolic pathways. We know little about cell metabolism on Treg homeostasis and function and published data are quite controversial. Thus, we have investigated the role of AMPK (coded by *Prkaa*) and mTOR in Treg by generating mice that have a conditional knockout of these molecules specifically in Treg. Whereas the *Foxp3^{cre} x Prkaa1^{lox}* (AMPKΔTreg) mice looked healthy, the *Foxp3^{cre} x mTor^{lox}* (mTORΔTreg) mice developed a systemic inflammatory disorder with massive immune cell infiltration, activation of Tconv, increased levels of inflammatory cytokines and immunoglobulins and died by 10 weeks of age. Interestingly, mTORΔTreg mice had increased Treg frequency in lymphoid organs but decreased Treg frequency in non-lymphoid organs, which was correlated with lower proliferation, migration and stability of mTOR-deficient Treg. In the healthy AMPKΔTreg mice, AMPK deficient Treg had decreased OXPHOS activity. In a cancer model, tumor growth was reduced in these mice, which was correlated with decreased proportion of tumor-infiltrating Treg and higher activation of Tconv. Thus, AMPK seems critical for the homeostasis of Treg infiltrating tumors but dispensable at steady state. Our results reveal a new role of the AMPK/mTOR metabolic balance in Treg biology.

S.C4.03

Tolerogenic dendritic cells as a therapeutic strategy to induce tolerance in multiple sclerosis

***E. Martinez-Caceres**;*
Germans Trias i Pujol Hospital. Universitat Autònoma Barcelona., Badalona (Barcelona), Spain.

Multiple sclerosis (MS) is a chronic, inflammatory, and neurodegenerative disease of the central nervous system. Its prevalence is increasing worldwide, and is now considered, after traumatisms, the main cause of disability in young people. Current treatments in MS do reduce disease activity, do not decrease long-term disability and progression and must be administered lifelong, causing relevant side effects. Therefore, safer and more effective treatments are needed. In this context, a promising strategy for the attenuation of pathogenic T cells is an autologous therapy with tolerogenic dendritic cells (tolDC). Our group has developed an antigen-specific cell therapy based on autologous monocyte-derived tolDC differentiated in the presence of vitamin D3 (VitD3), loaded with a group of myelin peptides (vitD3-tolDC), to induce tolerance in MS patients. *In vitro* studies in co-culture experiments demonstrated a potent immune-regulatory activity of vitD3-tolDC, reducing lymphocyte proliferation and IFN-γ production and producing low levels of IL-10. Moreover, *in vivo* studies in the animal model of MS - experimental autoimmune encephalomyelitis - revealed a beneficial effect of vitD3-tolDC, ameliorating the severity of the disease. These pre-clinical results, as well as, reported outcomes from previous clinical trials using tolDC, have led to a Phase I/IIa clinical trial in patients with active MS as approved by the Spanish regulatory Agency (AEMPS) which is currently ongoing (Nº EudraCT: 2015-003541-26, available at ClinicalTrials.gov Identifier: NCT02903537, Tolervit-MS).

Spontaneous protein crystallization in asthma : a new pathway for intervention

***B. Lambrecht**[1], E. Persson[2];*
[1]VIB Inflammation Research Center, Ghent, Belgium, [2]VIB, Ghent, Belgium.

Asthma is a chronic inflammatory airway disease rich in eosinophils. As early as 1853, Charcot and von Leyden described extracellular deposits of morphologically diverse crystals in airways of asthmatics. Charcot-Leyden crystals (CLC) are made from Galectin-10 (Gal10), one of the most abundant yet least understood proteins in eosinophils. A pathogenic role for CLC or Gal10 in airway inflammation has not been established. Here, we show that the *ex vivo* crystal packing interface of CLC obtained from the upper airways of patients is identical to recombinant Gal10 crystals, and could be mutated to prevent auto-crystallization. Only in the crystalline state could inhaled Gal10 induce airway inflammation. Remarkably, Gal10 crystals when co-administered with harmless antigens could stimulate humoral and cellular immunity, promoting Th2 sensitization and airway eosinophilia *in vivo* in a mouse model. To target this type of crystal-induced inflammation in humans, we generated llama antibodies against crystalline Gal10 that rapidly dissolved preformed Gal10 crystals and CLC in the mucus of patients. In a humanized severe combined immunodeficiency model of allergic airway inflammation, administration of crystal dissolving antibodies suppressed lung inflammation, human IgE synthesis and airway mucin production. As a mechanism of action, the crystal dissolving antibodies targeted the key crystal packing contacts underlying the intrinsic auto-crystallization behavior of Gal10. Together, our data demonstrate that beyond serving as markers of eosinophilia, CLC actively promote inflammation and adaptive immunity. As protein crystallization is reversible by antibody treatment, antagonizing the crystalline state of pro-inflammatory proteins in a new intervention strategy.

S.C5.02

Isotype-specific regulation of BCR signal transduction

***J. Wienands**, N. Engels, M. Engelke;*
Institute for Cellular & Molecular Immunology, University Medical Center Göttingen, Göttingen, Germany.

The key role of the B cell antigen receptor (BCR) in triggering antibody-mediated immune responses is well established. However, it has become clear more recently that BCR ligation does not deliver an all-or-nothing signal for B cell activation. Multiple levels of BCR-intrinsic fine tuning exist that can amplify or attenuate the primary 'Go Signal' provided by phosphorylated Immunoreceptor Tyrosine-based Activation Motifs (ITAMs) and the associated kinase Syk. While ITAMs reside in the cytoplasmic segments of the canonical BCR signal elements, Ig-α and Ig-β, a second phosphorylation module is accommodated in membrane-bound IgG and IgE on class-switched memory B cells. It is called the Ig Tail Tyrosine (ITT) motif and recruits the versatile signaling protein Grb2. The phospho-ITT/Grb2 axis provides a co-stimulatory signal that renders antigen-experienced B cells less dependent on T cell help during recall responses. Indeed, memory B cell responses are dominated by class-switched Ig isotypes, most notably IgG. Given the anaphylactic properties of IgE antibodies, activation of IgE-positive B cells is tightly regulated. The long isoform of membrane-bound IgE on human B cells encompasses an ER retention motif in its extracellular membrane-proximal domain that restricts surface IgE-BCR expression and concomitant downstream signaling events. BCR-autonomous signal inhibition can also be brought about by linking up with negative regulatory modules such as lipid phosphatase SHIP known to limit BCR activation through inhibitory coreceptors. In summary, the BCR can regulate its signal output by various mechanisms to promote protective humoral immunity or keep potentially harmful B cells in check.

Genetic restriction of antigen-presentation dictates allergic sensitization and disease in humanized mice

*A. Neunkirchner[1], B. Kratzer[1], C. Köhler[1], U. Smole[1], L. Mager[1], K. Schmetterer[1], D. Trapin[1], V. Leb-Reichl[1], E. Rosloniec[2], R. Naumann[3], L. Kenner[1], B. Jahn-Schmid[1], B. Bohle[1], R. Valenta[1], **W. Pickl**[1];*
[1]Medical University of Vienna, Vienna, Austria, [2]Memphis Vetrans Affairs Medical Center, Mamphis, TN, United States, [3]Max Planck Inst Molecular Cell Biology Genetics, Dresden, Germany.

IgE-associated allergies result from misguided immune responses against usually innocuous environmental or food antigens. $CD4^+$ T lymphocytes are critical for initiating and perpetuating that process, yet the crucial factors determining whether an individual gets allergic are largely unknown. We here created a novel human TCR and HLA-DR1 (TCR/DR1) transgenic mouse model of asthma, which specifically reacts to the human-relevant major pollen allergen from *Artemisia vulgaris* (mugwort) to examine these critical factors upon natural allergen exposure via the airways in the absence of systemic priming and adjuvants. We discovered that acute allergen exposure led to IgE-independent airway hyperreactivity (AHR) and Th2-prone lung inflammation in TCR/DR1, but not DR1, TCR or WT control mice, that was alleviated by prophylactic IL-2/αIL-2 mAb complex-induced expansion of Tregs. In contrast, chronic allergen exposure sensitized one third of single DR1 transgenic mice, however, without impacting on lung function. Similar treatment led to AHR and Th2-driven lung pathology in >90% of TCR/DR1 mice. Prophylactic and therapeutic expansion of Tregs with IL-2/αIL-2 mAb complexes blocked the generation and boosting of allergen-specific IgE associated with chronic allergen exposure. Our findings reveal allergen-specific T effector and Treg cell frequencies next to genetic restriction of allergen-presentation, as important factors for allergy.

S.C6 Innate control of inflammation and tissue repair

S.C6.01

The yin yang of phagocyte regulation and inflammatory cytokines

***A. Mantovani**;*
Istituto Clinico Humanitas, Humanitas University, Rozzano, Italy.

The tumor microenvironment (TME) is a complex network, which includes soluble factors and components of the extracellular matrix as well as stromal, endothelial and immune cells. Immune cells and, among them, myeloid cells, play important roles in cancer development and can promote or inhibit cancer initiation and progression. Among tumor-infiltrating immune cells, macrophages are well-known determinants of cancer-related inflammation and are typically characterized by their remarkable plasticity. This consists in the ability to acquire a wide spectrum of activation states in response to various signals derived from the microenvironment. Classical M1 and alternative M2 macrophages represent the paradigm of this property. Tumor-associated macrophages (TAMs) usually display a so-called "M2-like" phenotype that can foster tumor progression in different ways, namely by promoting genetic instability, angiogenesis and metastasis and by restraining anti-tumor adaptive immunity. Notably, TAMs can also play a dual role in the response to conventional anti-tumor therapies: they can enhance the anti-neoplastic effect or, in contrast, they can sustain a tumor-promoting response and so foil the anti-cancer power of these drugs. We recently identified IL-1R8, which we had cloned as TIR8 and is also known a SIGIRR, as a checkpoint in NK cells, which negatively regulates response to myeloid derived IL-18. Unleashed NK cells mediate resistance to liver carcinogenesis and metastasis at NK rich anatomical sites. Thus the organ immunological context is a key determinant of the role of innate and adaptive immunity in tumor progression.

S.C6.02
Extracellular DNA traps: neutrophils, eosinophils, basophils

***H. Simon**;*
Institute of Pharmacology, Bern, Switzerland.

Extracellular DNA traps represent an important element of the innate immune response and they are seen in association with many infectious, allergic, and autoimmune diseases. They are able to kill bacteria and can be formed by neutrophils, eosinophils and basophils. Although the functional importance of extracellular DNA traps is generally accepted, the origin of the DNA scaffold, as well as the mechanism of their generation, remains unclear and a matter of dispute. In my presentation, I will focus on the role of Optic Atrophy 1 (OPA1), a mitochondrial inner membrane protein known for its role in mitochondrial fusion and structural integrity. Dysfunctional OPA1 mutations cause atrophy of the optic nerve leading to blindness. We demonstrate that lack of OPA1 reduces the activity of mitochondrial electron transport complex I in neutrophils, which, owing to lowered NAD^+ availability, causes a decline in adenosine-triphosphate (ATP) production through glycolysis. OPA1-dependent ATP production in these cells is required for microtubule network assembly and for the formation of neutrophil extracellular traps (NETs). Moreover, conditional knockout mice lacking *Opa1* in neutrophils ($Opa1^{N\Delta}$) exhibit a reduced antibacterial defense capability against *Pseudomonas aeruginosa*. Hence, these findings establish an impact of OPA1 function on the innate immune system.

S.C6.03
Mitochondrial failure in monocytes immunocompromise the NLRP3 inflammasome in human sepsis

***P. Pelegrin**;*
Biomedical Research Institute of Murcia-Hospital Virgen de la Arrixaca, Murcia, Spain.

Sepsis is the leading cause of death in critical-care units. Systemic infection in sepsis induces the release of pro-inflammatory cytokines by monocytes, causing an uncontrolled inflammatory response damaging different tissues and organs. This inflammatory response is followed by an acute immunoparalysis due to broad defects in monocytes metabolism after the infection. In this study, we aim to characterize potential mechanisms leading to mitochondrial metabolism downregulation in monocytes and its implication in the immunoparalysis response of septic patients. We analyzed monocytes from patients with abdominal origin sepsis compared with control groups of healthy donors and patients undergoing abdominal surgery but not developing sepsis. We found that the cell surface expression of the ion channel P2X7 receptor increased in septic monocytes when compared with the control groups. Despite the increase of P2X7 receptor, in septic patients ATP failed to induce NLRP3 inflammasome activation in monocytes measured by ASC aggregation and IL-1beta release. In septic patients, P2X7 receptor expression in monocytes correlated with a lack of mitochondrial membrane potential. P2X7 receptor stimulation in human monocytes from healthy individuals before LPS-priming, induced a decrease of mitochondrial membrane potential and impaired the respond of the monocytes to LPS and the engagement of the NLRP3 inflammasome. Our results suggest that during sepsis P2X7 receptor expression increases in monocytes and damage mitochondria contributing to the immunoparalysis of these patients.

S.D2.01
Using super-resolution microscopy to watch immune cells kill

***D. M. Davis**;*
University of Manchester, Manchester, United Kingdom.

Natural Killer (NK) cells can directly kill diseased cells by secretion of cytolytic granules across an immune synapse. The molecular choreography that leads to assembly of the synapse and the secretion of granules has widely been studied. However, a long-standing gap in our understanding of this process is how disassembly of the synapse occurs, allowing NK cells to dissociate from target cells. Using microscopy to visualize degranulation from individual NK cells, we found that the outcome of sequential stimulation depended upon the order in which different NK receptors were ligated. Moreover, we found that shedding of the Fc receptor CD16 increased NK cell motility and facilitated detachment of NK cells from opsonized target cells. Disassembly of the immune synapse caused by CD16 shedding aided NK cell survival and boosted serial engagement of target cells. Thus, counter-intuitively, shedding of CD16 can positively impact immune responses. In a separate line of research, using super-resolution microscopy, we have found that inhibitory Killer Ig-like receptors (KIR) encoded by different genes and alleles organise differently at the surface of primary human NK cells. KIR which are expressed at a low level at the cell surface assemble in smaller clusters than KIR which are highly expressed. Upon receptor triggering, lowly expressed receptors generate more phosphorylated Crk than highly expressed receptors. Thus, genetic variation modulates the nanoscale organisation of inhibitory KIR, which in turn impacts receptor signalling. This identifies a new way in which genetic diversity could impact immune responses.

S.D3 Novel approaches to vaccinology

S.D3.01
Viral vaccine delivery systems

***S. Gilbert**;*
Jenner Institute, University of Oxford, Oxford, United Kingdom.

Viral vectored vaccines are in development for many different vaccines to prevent infections, and also as therapeutic vaccines against cancer. As platform technologies they have many advantages, including reduced development timelines, ease of manufacture and the ability to employ thermostable formulations. This talk will include some recent developments in the use of adenoviral vectored vaccines against emerging pathogens, covering both preclinical and clinical data. The Jenner Institute has established a pipeline for early stage vaccine development with all activities from vaccine design, pre-clinical production and testing, GMP manufacturing and phase I clinical trials all taking place on the same campus in Oxford.
This approach has facilitated the early development of multiple novel vaccines.

S.D3.03
Therapeutic monoclonal antibodies

***A. Lanzavecchia**;*
Institute for Research in Biomedicine, Bellinzona, Switzerland.

We use cell culture-based high-throughput screens to isolate monoclonal antibodies selected for neutralizing potency and breadth. Recently, we focused on the antibody response to *P. falciparum*. In one study (Pieper et al, *Nature* 2017), we discovered that up to 10% of malaria-infected individuals produce a new type of antibodies that contain templated DNA insertions encoding the extracellular domain of LAIR1, a collagen binding inhibitory receptor encoded on chr19. These insertions are found either at the V-DJ junction or in the switch region, leading to the positioning of the LAIR1 domain on the tip of HCDR3 or in the VH-CH1 elbow. The inserted LAIR1 domain is necessary and sufficient for binding to infected erythrocytes and somatic mutations abolish collagen binding and modulate binding activity to the parasite antigens, which we identified as distinct RIFINs. Templated insertions are frequently found in memory B cells of healthy individuals, suggesting that this represents a new mechanism of antibody diversification. In another study (Tan et al *Nat Med* 2018), we analysed the antibody response of African individuals immunized by repeated injection of irradiated sporozoites. All antibodies isolated bound to the circumsporozoite protein (CSP) and recognized distinct epitopes. Strikingly, the most effective antibodies bound not only to the NANP-repeat region, but also to an N-terminal NPDP peptide that is not present in the RTS,S vaccine. These dual-specific antibodies were isolated from different donors and were encoded by certain VH3-30 alleles and provide relevant information for lineage-targeted vaccine design and passive immunization strategies.

S.D4 Exploiting host pathogen interaction

S.D4.01
Immune suppression by Salmonella

***D. Holden**;*
Imperial College, London, United Kingdom.

Salmonella enterica can cause persistent infections such as typhoid fever. Following bacterial entry into host cells, the pathogen replicates in a membrane-bound compartment called the *Salmonella*-containing vacuole (SCV). Bacteria respond to nutritional deprivation and the acidic pH in the vacuole lumen by activating the expression of the SPI-2 type III secretion system (T3SS). After assembly of a T3SS-linked pore in the vacuole membrane, bacteria sense the near-neutral pH of the host cell cytoplasm. This triggers the translocation of bacterial virulence proteins (effectors) into the host cell. Approximately 30 different effectors are translocated by the SPI-2 T3SS. These have been implicated in several physiological activities, including the control of SCV positioning within the host cell, maintenance of vacuole membrane integrity, bacterial replication, interference with lysosome function and innate immune signaling. I will discuss our recent progress on the characterization of a unique effector that suppresses the development of adaptive immunity by inhibiting antigen presentation by MHC class II molecules. This effector is likely to contribute to the ability of *Salmonella* to persist in mammalian tissues.

S.E1 Visualizing immune responses

S.E1.02
Neuronal regulation of innate lymphoid cells

***H. Veiga-Fernandez**;*
Champalimaud Centre for the Unknown, Lisboa, Portugal.

Innate lymphoid cells (ILC) are the most recently defined cell family to be included to the increasingly complex atlas of the immune system. ILC have a lymphoid morphology, lack rearranged antigen receptors and are abundantly present at mucosal surfaces. The combined expression of lineage-specific transcription factors with discrete cytokine profiles led to the identification of distinct ILC subsets. ILC development and function have been widely perceived to be programmed. However, emerging evidence indicates that ILC are also controlled by complex environmental signals. Here, we will discuss how ILC perceive, integrate and respond to their environment, notably to nutritional and neuronal cues.

S.E1.03
Spatiotemporal dynamics of CD8$^+$ T cells undergoing intrahepatic priming

***M. Iannacone**;*
San Raffaele Scientific Institute, Milan, Italy.

CD8$^+$ T cell responses to hepatotropic intracellular pathogens such as hepatitis B virus (HBV) range from tolerance to full differentiation into effector cells endowed with antiviral potential. However, the molecular and cellular mechanisms underlying these distinct outcomes are incompletely understood. Here, we used multiphoton intravital microscopy, RNA-seq and ATAC-seq to interrogate the motility, transcriptional and epigenetic changes of naïve HBV-specific CD8$^+$ T cells undergoing intrahepatic priming. We found that intrahepatic priming can lead to both effective or dysfunctional CD8$^+$ T cell responses. Priming by Kupffer cells leads to differentiation into effector cells that are indistinguishable from those primed in secondary lymphoid organs; these effector cells form dense, poorly perfusable clusters that are scattered throughout the liver and are composed by largely immotile cells. By contrast, priming by hepatocytes leads to local activation, vigorous proliferation but lack of differentiation into inflammatory cytokine-producing and cytolytic effector cells; these dysfunctional cells accumulate in looser, intravascular clusters that coalesce around portal tracts and are composed by more motile cells. Transcriptome and epigenome analyses of these dysfunctional cells reveal a signature that is distinct from that of exhausted cells, including the lack of modulation of genes that are downstream of the cytokine IL-2; accordingly, CD8$^+$ T cells primed by hepatocytes are refractory to anti-PD-L1 treatment but can be rescued by interleukin-2. These findings reveal the dynamic behavior of naïve CD8$^+$ T cells undergoing intrahepatic priming and suggest potential strategies for the therapeutic restoration of dysfunctional CD8$^+$ T cells during chronic HBV infection.

S.E2 How to handle big data and can we do this?

S.E2.01
Human Systems Immunology - Cell by Cell

***J. L. Schultze**;*
LIMES-Institute, University of Bonn, Bonn, Germany.

During the last three decades, immunology was characterized by work mainly in murine model systems, gene knockout technologies and a focus on single pathways or single genes. However, to understand the immune system as a system, we actually have to develop multi-science approaches interacting and collaborating with experts from other fields including genomics, cell biology, bioinformatics, the computational sciences and even mathematics. Furthermore, with increasing knowledge about regulatory elements that are not evolutionary conserved between species, we need to switch to research in humans to better understand major human diseases. I will lay out and exemplify the path towards a truly human systems immunology strategy as the basis to better understand inflammatory conditions throughout the major human diseases. Single cell genomics technologies will play an important step forward to better describe and understand the role of certain immune cells in organ homeostasis, but even more so during the development and progression of major diseases. For example, by single cell RNA-sequencing, multi-color flow cytometry and functional testing we are currently mapping the human immune system in healthy and diseased lungs with highest resolution currently possible. Such approaches allow us now to define whether organ-resident immune cells or natural immigrants are major players during immunopathologies such as asthma or chronic obstructive pulmonary disease. Furthermore, the combination with therapeutic interventions allows us even to study immune system response under perturbation conditions. Collectively, the technological revolution in genomics towards single cell resolution will greatly impact on our possibilities to directly study disease in humans.

S.E2.02
How to make sense out of big data in immunology: The single cell genomics revolution as an example

***R. Zinkernagel**;*
University of Zurich, University Hospital, Zurich, Switzerland.

I shall try to illustrate how immunological research may be divided into 1) Surprising observations motivating experimental analysis or 2) Experiments begging for a question (P.Medawar). As long as we know little, new findings only rarely can be placed properly within a co-evolutionary context, because our methods of measurement are inadequate. Once we know almost everything any new detail (also from big data) can be interpreted much more adequately. Disease and death are excellent motivators for the analysis of aetiology and rate limiting steps by using adequate methods (including big data) as a starting point to improve our understanding of immunology, immunity and evolution. Big data analysis alone is a waste of money, but as a method will help to make observation-driven analysis quicker and medically helpful, if kept within an evolutionary context.

S.E2.03
How to make sense out of big data in immunology: The single cell genomics revolution as an example

***J. J. C. Neefjes**;*
Leiden University Medical Center, Leiden, Netherlands.

MHC class II molecules control many immune responses by presenting antigenic fragments acquired in the endosomal system to CD4+ T cells. Both tissue selective expression and the cell biology are complex and involve many different factors and systems. I will present how multi-dimensional screens can help placing proteins in pathways controlling MHC class II expression in an unbiased manner. This will be illustrated by a number of examples showing new pathways in control of MHC class II release in immature DC (effectively generating a mature DC phenotype), factors in control of MHC class II expression and the control of MHC class II expression in non-APC cells. In the latter case, a genetic and chemical screen was integrated that yielded both pathways and drugs in control of MHC class II expression with impact for associated diseases.

S.E4 Cell communication and signaling in the immune system

S.E4.01
Common and distinct Immune functions of exosomes and other extracellular vesicles

***C. Thery**, M. Tkach;*
INSERM U932, Institut Curie, Paris, France.

Cells secrete into their environment different types of extracellular vesicles (EVs) that have distinct properties depending on their intracellular site of origin. Exosomes are a subtype of EVs with a mean diameter lower than 150 nm that are formed inside multivesicular compartments of the endocytic pathway. Exosomes secreted by dendritic cells (DCs) have been shown to bear functional MHC class I and class II molecules able to activate cognate T lymphocytes and induce anti-tumor immune responses. These findings motivated the use of DC-derived exosomes in cancer clinical trials, although with limited clinical effects. Other EVs also bear functional immune molecules and may thus represent alternative immunotherapy tools. In our recently published work, we have isolated different subtypes of EVs simultaneously released by live human primary DCs to characterize their protein composition, and their abilities to activate T lymphocytes. We have observed that all EVs activate T cells as efficiently, but that the resulting functionality of T cells is different. Interestingly, exosomes were not the most efficient T-cell-activating EVs. Differences in the relative levels of surface co-stimulatory proteins in the different EV subtypes can explain differences of activities. We are now analysing the common and different abilities of EVs secreted by tumor cells to induce immune responses. Our results highlight the need to determine the respective roles of exosomes and other EVs, in cancer-immune system cross-talk but also in many other patho-physiological systems, to identify the best therapeutic or diagnostic EV-based tools.

S.E4.03
Metabolic programs controlling immune cell function

***T. Sparwasser**;*
Institute of Medical Microbiology and Hygiene, Johannes Gutenberg-University, Mainz, Germany.

Recent advances in the field of immunometabolism support the notion that essential processes in T cell biology, such as TCR-mediated activation and T helper lineage differentiation, are closely linked to changes in the cellular metabolic programs. Although the main task of the intermediate metabolism is to provide the cell with a constant supply of energy and molecular precursors for the production of biomolecules, the dynamic regulation of metabolic pathways also plays an active role in shaping T cell responses. Key metabolic processes such as glycolysis, fatty acid and mitochondrial metabolism are now recognized as crucial players in T cell activation and differentiation, and their modulation can differentially affect the development of T helper cell lineages. We only begin to understand the diverse metabolic processes that T cells engage during their life cycle from naïve towards effector and memory T cells. Many milestone discoveries in this active area of research are based on the use of chemical inhibitors that have been shown to possess off-target effects, emphasizing the importance of genetic models to study immunometabolism. Following activation, T cells switch to fatty acid synthesis, demonstrating that *de novo* lipid synthesis actively supports T cell proliferation and differentiation. We could show previously that pharmacological or genetic ACC1 inhibition impairs T helper cell induction, with the strongest impact on Th17 development. Here we discuss the molecular mechanisms that link metabolic changes with the control of gene expression.

Novel vaccines against old foes: Dengue, Zika, Ebola & Co

F. X. Heinz;
Medical University of Vienna, Center for Virology, Vienna, Austria.

Emerging viruses pose great challenges to global health and require enormous efforts for their control, as exemplified by the recent outbreaks of Ebola and Zika viruses and the continuous fight against dengue viruses, causing by far the highest number of arbovirus infections in tropical and subtropical regions worldwide. In addition to other means of outbreak control, vaccines cannot only contribute to manage acute emergencies but also provide long-term immunity to populations at risk. Probably the best example for a highly successful vaccine against an emerging virus is the live-attenuated yellow fever vaccine, which was developed ingeniously about 80 years ago in the absence of detailed knowledge of viral molecular biology, immunology and pathogenesis. Today, the armamentarium in the search for vaccines has increased impressively and led to the establishment of so-called vaccine platforms that can be readily exploited for developing vaccines against a variety of viruses, including Zika virus. These platforms include vector vaccines, recombinant immunogens produced in soluble or particulate forms, DNA and RNA vaccines, genetically engineered attenuated viruses, and chimeric viruses that can be used as live vaccines. Such chimeric replication-competent viruses are currently used and further evaluated as Ebola and dengue vaccines. Results have been encouraging, but especially in the case of dengue also provided evidence for potential negative side effects, related to an intrinsic problem of dengue pathogenesis that interferes with vaccine performance. New technologies like structure-based vaccine design may be starting points for developing more effective immunogens.

JS.01.03
A new generation of vaccines: for each target group its own adjuvant?

E. C. Lavelle;
Trinity College Dublin, Dublin, Ireland.

The effectiveness of vaccines and their capacity to promote and direct adaptive immunity depends on the induction of specific types of innate immune responses. As we increasingly adopt subunit vaccines which depend on adjuvants for their immunostimulatory potential, there is scope to refine vaccine formulations for specific conditions and defined target groups. Innovative adjuvant approaches can allow vaccines to be targeted at specific groups, for example the elderly or neonates. However, detailed knowledge of the nature of immune regulation in such groups and of the expression of specific innate immune sensors is required to facilitate rational vaccine design. Innate immune factors such as type 1 interferons and inflammasomes can play key roles in promoting adaptive immunity and identifying how adjuvants can regulate these and other such pathways which direct adaptive immunity can provide valuable targets for vaccine design. Adjuvants can also facilitate a move from injectable to oral vaccines which are attractive for the many enteric infections we are faced with. In conclusion, advances in our understanding of how innate immunity impacts on adaptive responses and in the design and formulation of adjuvants allows greater potential for a targeted approach to vaccination in future.

JS.02 Systems Immunology for stratifying patients with autoimmune diseases

JS.02.03
The Stratification of Lupus

M. Alarcòn Riquelme;
Center for Genomics and Oncological Research (GENYO), Granada, Spain.

Objectives: The highly heterogeneous clinical presentation of lupus is characterized by the unpredictable appearance of flares of disease activity and important organ damage. Attempts to stratify lupus patients have been limited to clinical information, leading to unsuccessful clinical trials and controversial research results. Our aim was to develop and validate a robust method to stratify patients with lupus according to longitudinal disease activity and whole-genome gene expression data in order to establish subgroups of patients who share disease progression mechanisms. **Methods**: We applied a clustering-based approach to stratify SLE patients based on the correlation between disease activity scores and longitudinal gene expression information. Clustering robustness was evaluated by bootstrapping and the clusters were characterized in terms of clinical and functional features. **Results**: Using two independent sets of patients, one pediatric and another adult, our results show a clear partition into three different disease clusters not influenced by treatment, race or other source of bias. Two of the clusters differentiate into a neutrophil correlated disease group and a lymphocyte correlated disease group, while the third that correlated to a lesser extent with neutrophils, was functionally more heterogeneous. The neutrophil-driven clusters were associated with increased development towards proliferative nephritis. **Conclusions**: We found three subgroups of patients that show different mechanisms of disease progression and are clinically differentiated. Our results have important implications for treatment options, the design of clinical trials, the etiology of the disease, and the prediction of severe glomerulonephritis.

JS.03 Antigen Presentation in Health and Disease

JS.03.02
Antigen processing and presentation in cancer immunosurveillance

R. Binder;
University of Pittsburgh, Pittsburgh, PA, United States.

Binder, Robert
University of Pittsburgh, Pittsburgh PA

The immune system recognizes aberrant cells and eliminates them prior to emergence of nascent tumors. This prevents progression of many malignancies. In the absence of such immunity in mice or humans, multiple and frequent tumors are generated. Current immunosurveillance model involves the priming of T cell and NK cell immunity. The gap in knowledge in this model is raised in two questions; (1) What is the molecular mechanism for cross-priming T cell responses in the context of the negligible amount of antigen available at the early stages of nascent tumor development? (2) What is the stimuli for co-stimulation of T cell priming and activation of NK cells. Both of these questions are unanswered. Our work has demonstrated that tumor-derived heat shock proteins (HSPs), introduced during vaccination, are super-efficient at cross-presentation of limited amounts of their chaperoned tumor (peptide) antigen. HSPs are also capable of initiating signals for co-stimulation. Both events require the HSP receptor, CD91, expressed on dendritic cells and together allow for priming potent tumor-specific T cells. The release of cytokines by DCs stimulated with HSPs enhances the T cell responses and activates NK cells. Our data shows that when tumor antigen levels are limiting, as in nascent emerging tumors, the HSP-CD91 pathway is essential for cross-priming of anti-tumor immune responses. The HSP-CD91 pathway represents a novel mechanism for initiating responses for cancer immunosurveillance.

JS.03.03
Generating peptide-MHC ligands for immune surveillance of foreign and self

N. Shastri[1,2], C. Park[1], J. Guan[1], T. Ding[1], F. Gonzalez[1];
[1]University of California, Berkley, CA, United States, [2]Johns Hopkins University School of Medicine, Baltimore, MD, United States.

The normal peptide repertoire presented by classical and non-classical MHC class I molecules is regulated by ERAAP, the endoplasmic reticulumaminopeptidase associated with antigen processing. Loss of ERAAP's peptide trimming function in cells causes dramatic changes in the peptide repertoire. The changes in the peptide repertoire enhance the immunogenicity of ERAAP-deficient cells and elicit potent immune responses in otherwise syngeneic wild-type mice. Because changes in ERAAP activity can cause abnormal immune responses, normal ERAAP function is monitored by an unusual subset of semi-invariant CD8+ T cells. These T cells recognize the QFL ligand that consists of a conserved peptide presented by the non-classical Qa-1^{b}MHC Ib molecule displayed only on surface of ERAAP-deficient cells. We show that these QFL-specific CD8+ T cells (QFL-T cells) bear unique and semi-invariant αβ TCRs. Genetic manipulation of the expression of the self-QFL ligand and functional characteristics of QFL-T cells shows that in addition to monitoring ERAAP function, QFL-T cells may also regulate metabolic activity.

JS.04 HLA in Transplantation and Autoimmunity

JS.04.03
HLA in Autoimmune Diseases

***L. M. Sollid**;*
Department of Immunology, Rikshospitalet, University of Oslo, Norway.

More than 50 years have passed since the first HLA association with disease was described, and in recent years genome wide association studies have taught us that HLA typically is the chief genetic determinant for autoimmune disorders. Yet, for most of the autoimmune diseases the underlying mechanism for their HLA association is elusive. There is strong linkage disequilibrium in the HLA gene complex making is hard to determine the primary HLA associations. Notwithstanding, for many diseases there is accumulating evidence that the primary associations are with classical HLA molecules. The principal role of these molecules to present peptides to T cells suggests an involvement of T cells in the pathogenesis. It is striking that autoimmune diseases with autoantibodies typically are primarily associated with HLA class II alleles, whereas seronegative diseases most often are associated with HLA class I alleles. HLA class II associations and presence of autoantibodies speak to involvement of B cells in addition to T cells. Celiac disease has a strong association to certain HLA-DQ allotypes and is hallmarked by very disease specific autoantibodies to the enzyme transglutaminase 2. I will present data on the molecular mechanisms for the HLA association of this disease highlighting the role of T cell and B cell interaction in the pathogenesis.

JS.05.03
Novel insights into membrane targeting of B cell lymphoma: lessons learned from tetraspanins

***A. van Spriel**;*
Radboud university medical center, Nijmegen, Netherlands.

The plasma membrane of immune cells contains thousands of different proteins including receptors, enzymes and signalling molecules. A tight spatiotemporal organisation of these membrane proteins is essential for immune cell function including pathogen recognition, antigen presentation and migration. The superfamily of tetraspanin proteins plays a central role in organising membrane proteins and signalling molecules into the 'tetraspanin web'.
We discovered that tetraspanins CD37 and CD53 control B cell function. *Cd37*-deficient mice have reduced numbers of IgG+ antibody-secreting cells in lymphoid organs, which is a B-cell intrinsic defect as demonstrated in chimeric mice. In contrast, IgA+ B cell numbers are increased, and deficiency of CD37 induces the spontaneous development of B-cell lymphoma in vivo. We identified that CD37 interacts with suppressor of cytokine signalling 3 (SOCS3), and when absent drives tumour development through constitutive activation of the IL-6 signalling pathway. Moreover, loss of CD37 on neoplastic cells in patients with diffuse large B-cell lymphoma is directly correlated with worse progression-free and overall survival.
Together, this study identifies CD37 as novel tumour suppressor that protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with CD37-negative B cell malignancies as therapeutic intervention.

JS.07 Subversion of phagocytosis in innate immunity: from efferocytosis to pathogen interaction

JS.07.01
Neutrophils as targets for host-directed therapy against tuberculosis

***T. Dallenga**[1,2], U. Repnik[3], R. Reimer[4], G. Griffiths[5], U. E. Schaible[1,2];*
[1]Research Center Borstel, Borstel, Germany, [2]TTU-TB, German Center for Infection Research, Munich, Germany, [3]Max Planck Institute of Molecular Cell Biology & Genetics, Dresden, Germany, [4]Heinrich Pette Institute, Hamburg, Germany, [5]University of Oslo, Oslo, Norway.

With multi drug-resistant *M. tuberculosis* variants on the rise, novel approaches to tackle the global tuberculosis epidemic are needed. Neutrophils represent the main infected cell population in lungs of patients with active tuberculosis. Here we show that *M. tuberculosis* induces necrosis of human neutrophils in an ESX-1-dependent manner. Necrosis was a prerequisite for mycobacterial growth in human macrophages after subsequent removal of infected, necrotic neutrophils. After identification of reactive oxygen species (ROS) as drivers of necrosis, we were able to prevent necrosis by pharmacological inhibition of myeloperoxidase. Thereby, we restored the capability of efferocytic macrophages to control mycobacterial growth, highlighting ROS and ROS-producing enzymes as putative targets for host-directed therapy. Taken together, host cell necrosis represents the starting point for a vicious circle leading to subsequent uptake of infected necrotic cells by other phagocytes, mycobacterial growth therein and, again, induction of host cell necrosis, a scenario that is very likely to take place in patients. Interruption of this vicious circle by inhibition of necrosis and subsequent restoration of the anti-mycobacterial functions represent an intriguing approach for host-directed therapy.

JS.07.02
Differential signaling through TLR7 or TLR8 determines the phenotype of human monocytes during RNA viral infection

*M. de Marcken, K. Dhaliwal, A. Gautron, **M. Dominguez-Villar**;*
Yale University, New Haven, CT, United States.

Despite being one of the major cellular targets of many RNA
virus infections in peripheral blood, the early events that occur after interactions between human monocytes and RNA viruses, and the signaling pathways responsible for the activation of these cells during infection are not well understood. Toll-like receptors (TLR) are a major family of pattern recognition sensors that trigger specific activation pathways in cells of both the innate and adaptive arms of the immune system. There are at least 10 TLRs in humans, from which TLR7 and TLR8 recognize single-stranded RNA. Despite both recognizing the same generic ligand, we and others have demonstrated different phenotypic outcomes on cells stimulated through either TLR7 or TLR8. We have recently observed fundamental differences in the phenotype and function of monocytes stimulated via either TLR7 or TLR8, in the context of RNA virus infections, and specifically, in terms of type I IFN responses and effector cytokines they produce, as well as general differences in cell surface markers. We have defined the molecular mediators that are responsible for these differences in phenotype by performing *ex vivo* experiments with human monocytes isolated from blood and we have shown the relevance of these data in common RNA virus infections, demonstrating that TLR7 and/or TLR8 stimulation by RNA virus infections of human monocytes account for much of the phenotype the cells acquire upon virus interaction.

JS.07.03
Efferocytosis induces a novel SLC program to promote glucose uptake and lactate release

***J. S. A. Perry**[1], S. Morioka[1], M. H. Raymond[1], C. B. Medina[1], L. Zhou[2], V. Serbulea[1], S. Onengut-Gumuscu[1], N. Leitinger[1], J. C. Rathmell[3], L. Makowski[3], K. S. Ravichandran[1];*
[1]University of Virginia, Charlottesville, VA, United States, [2]University of North Carolina, Chapel Hill, NC, United States, [3]Vanderbilt University, Nashville, TN, United States.

On a daily basis, we turnover billions of apoptotic cells that are removed by professional and non-professional phagocytes. While characterizing the transcriptional program of phagocytes, we discovered a novel solute carrier family (SLC) gene signature (33 SLC members) that is specifically modified during engulfment of apoptotic cells (efferocytosis) but not during antibody-mediated phagocytosis. When we assessed the functional relevance of these SLCs, we noted robust induction of an aerobic glycolysis program in engulfing phagocytes, initiated by SLC2A1-mediated glucose uptake, and suppression of oxidative phosphorylation program. Interestingly, the different steps of phagocytosis, i.e. smell ('find-me' signals / sensing factors released by apoptotic cells), taste (phagocyte- apoptotic cell contact), and ingestion (corpse internalization), activated different molecules to promote this glycolytic process. Further, lactate, a natural byproduct of aerobic glycolysis, was released from engulfing phagocytes via SLC16A1, an SLC member activated after corpse uptake. While glycolysis within phagocytes was needed for the continued uptake of corpses, the lactate released via SLC16A1 contributed to the establishment of an anti-inflammatory environment. Collectively, these data reveal a novel SLC program activated during efferocytosis, identify a previously unknown reliance on aerobic glycolysis during apoptotic cell uptake, and show that glycolytic byproducts of efferocytosis can also influence other cells in the microenvironment.

JS.08 Cytometry building bridges

JS.08.01
Cytometry of aging of the immune system

***A. Cossarizza**;*
University of Modena and Reggio Emilia, Modena, Italy.

In most developed and rich countries, human life span has dramatically increased because of great advances in preventing, delaying, or curing several pathologies. In all mammals, the aging process is characterized by profound changes in immunological responses that can be identified either analyzing the phenotype of lymphocytes (typically, collected from peripheral blood in the case of donors) or their functionality. For these purposes, several techniques have been developed in the last decades, but with no doubts flow cytometry has assumed the main role, due to the possibility to analyze several parameter (at present, up to 27 by using fluorescent dyes, more than 40 by mass cytometry) at the single cell level. Thus, a very fine characterization of age-related changes is occurring, and, for example, researchers are clarifying the importance of exhaustion markers among different subsets of T cells as predictors of morbidity and mortality, building a new immune risk profile. Not only cytometry is now allowing to identify such a huge amount of parameters, but also to identify rare cells, i.e. those present in a percentage that is much less than 1 in one thousand, like those specific for a given antigen. So, for example, the identification of responding cells is crucial for a better understanding of the effect of vaccines in the elderly. The talk will present some recent advancement in the field of immunology of aging that have been obtaining by studies at the single cell level.

JS.08.03
Standardizing cytometry of primary immunodeficiencies

***T. Kalina**;*
Charles University, Prague, Czech Republic.

EuroFlow consortium has developed and validated an set of 8-color flow cytometry panels for the initial evaluation of patients with the clinical suspicion of a Primary Immunodeficiency (PID). We have analyzed 96 PID patients and additional 21 severe PID diagnosed until the age of 2 years.
I will aim to illustrate following objectives:
•How and why to do standardized measurements in an international collaboration
•Investigation of lymphocyte subsets (incl. their maturation status) in one tube can be used to asses abnormalities in primary immunodeficiency
•Approach to comprehensive visualisation of results
•Search for hallmarks
•Present an example of diagnostic utility of the two tube test for sever PID (SCID, Omenn syndrome, CID and other PIDs with molecular lesion at the age 0-2 years)
In summary, out of the 96 PID patients we failed to uncover lymphocytes' subsets abnormality only in 2 patients with Chronic Granulomatous Disease and 4 patients with complement deficiencies (in line with literature), but we were able to find at least one abnormality in all remaining patients with PID. Furthermore the T-cell directed tube revealed accurately all SCID and Omenn syndrome patients even in cases with maternal engraftment. This is the first approach to a standardized PID diagnostic test that should reveal all alterations in patient lymphocytes' compartment without a correct a priori assumption about the PID nature (a universal test).
Acknowledgement: Supported by EuroFlow and a grant 15-28541A and LO1604.

JS.09 The gut microbiota and the IgA antibody production in health and disease

JS.09.03
The regulatory microenvironment in Peyer's patches leading to synchronized gut IgA responses

***N. Lycke**[1,2], M. Bemark[2], R. Komban[2], A. Strömberg[2], Z. Shulman[3];*
[1]Gothenburg, Sweden, [2]University of Gothenburg, Gothenburg, Sweden, [3]The Weizmann Institute of Science, Rehovat, Israel.

The majority of activated B cells differentiate into IgA plasma cells at mucosal sites, with the gut being the largest producer of immunoglobulin in the body. Secretory IgA antibodies have numerous critical functions of which protection against infections and the role for establishing a healthy microbiota appear most important. Expanding our knowledge of the regulation of IgA B cell responses and how effective mucosal vaccines can be designed are of critical importance. I will discuss recent developments in this field that shed light on the uniqueness and complexity of the gut mucosal IgA inductive site, the Peyer's patches. In particular, I will describe a novel B cell dependent pathway for bringing luminal antigens from the M cell to the germinal centers in the Peyer's patches. In addition, single cell RNAseq data on the composition of antigen-specific B cells in the Peyer's patches following oral immunizations will be presented.

JS.10 Innate host pathogen interactions

JS.10.01
Protective role of Mincle in Gram-positive bacterial infection

***S. Yamasaki**;*
Osaka University, Osaka, Japan.

C-type lectin receptors (CLRs) comprise a large family of proteins that share a common structural motif and are involved in various immune responses. Among them, ITAM-coupled CLRs are recently identified as pattern recognition receptors (PRRs) for pathogens. Mincle (Macrophage-inducible C-type lectin) is an FcRγ-coupled activating receptor that recognizes mycobacterial glycolipid, trehalose dimycolate, to promote protective immunity against mycobacteria. Recently, we found that Mincle also recognizes Gram-positive bacterial pathogen, Group A *Streptococcus* (GAS). GAS causes fatal invasive infections and thus called "flesh-eating bacteria"; however, the mechanism by which our immunity react this pathogen is not well understood. Within GAS components, we purified and identified unique glycolipids as Mincle ligands. Upon invasive GAS infection, Mincle-deficient mice exhibited impaired cytokine production of pro-inflammatory cytokines, severe bacteremia and rapid lethality. These results indicate that Mincle plays a central role in protective immunity against acute GAS infection.

JS.10.02
LILR family receptors in host pathogen interactions

***H. Arase**[1,2];*
[1]Research Institute for Microbial Diseases, Osaka University, Suita, Japan, [2]Immunology Frontier Research Center, Osaka University, Suita, Japan.

Immune cells express various kinds of paired receptors that consist of inhibitory and activating receptors. Although their extracellular domains are highly homologous between inhibitory and activating receptors, inhibitory receptors possessing ITIM at cytoplasmic domain downregulate activation of immune cells, whereas activating receptors deliver activating signals via ITAM positive adaptor molecules like DAP12. LILR family receptors are one of representative paired receptors mainly expressed on innate immune cells.
From the analysis of LILR family receptors, we found that inhibitory LILRB1 is used by *Plasmodium falciparum* for immune evasion. Furthermore, immune evasion of *Plasmodium falciparum* via LILRB1 was associated with severe malaria (*Nature* 2017). On the other hand, we have found that LILRA2, one of activating LILR family receptors, specifically recognizes immunoglobulin cleaved by bacterial protease whereas LILRA2 does not recognize normal immunoglobulin. This suggested that activating LILRA2 plays an important role in host defense by sensing immunoglobulin abnormalities (*Nature Microbiology* 2016). These studies suggest that LILR family receptors play an important role in host-pathogen interaction.

JS.10.03
ILC2 and type 2 immune diseases

***K. Moro**;*
RIKEN IMS, Yokohama, Japan.

Recent studies have revealed new types of lymphocytes functioning in innate immune responses that are collectively called innate lymphoid cells (ILCs). Unlike T and B lymphocytes, ILCs lack Rag-dependent antigen-specific receptors and are activated by cytokines produced by other innate immune cells or epithelial cells. ILCs have been divided into 3 groups based on their cytokine production profiles; group 1 ILC including NK cells and ILC1 produce IFNγ, group 2 ILC (ILC2) including natural helper cells, nuocytes and innate helper type 2 cells produce type 2 cytokines such as IL-5, IL-6 and IL-13, and group 3 ILC including lymphoid tissue inducer (LTi) cells and ILC3s produce IL-17 and IL-22. ILCs play important roles in protection against various invading microbes including multicellular parasites, and in the maintenance of homeostasis and repair of epithelial layers. ILC2 produce a large amount of IL-5 and IL-13 in response to IL-25 or IL-33, and induce eosinophilia and goblet cell, both of which act to protect against helminth infection and exacerbation of allergy. Since we discovered ILC2 in 2010, many other research groups have joined this research field and identified new immune responses that are regulated by ILC2. In particular, the importance of ILC2 in allergic diseases has received a fair amount of attention and new evidence indicates that allergic disorders occur not only from allergen-specific pathways but are also induced by allergen non-specific pathways due to ILC2 activation.

EDU.01 Systems Biology for Immunology: Help with the Complexity

EDU.01.03
Systems Immunology: Making sense of the Yins and Yangs

H. V. Westerhoff*;*
AIMMS and SILS and MCISB, Amsterdam and Manchester, Netherlands.

Thousands of molecules are discussed at this conference. The good news is that most can now be measured quantitatively: Immunology must thereby be the most challenging science for which most of the building blocks of complexity can be measured. How can they be understood however? Will the Biology that draws diagrams and arrows, suffice? The interactions between immunological factors and phenotype or disease appear to be determined by multiple networks that work positively and multiple that work negatively. For what we want, i.e. to understand and then cure, the usual schemes with plusses and minuses won't do. In an analogy with Deep Sequencing, this conference brings 'Deep Immunology' to the fore, i.e. a strategy that collects 'all' data and then puts these into a 'machine' that helps understand what they imply. Such a 'machine' is a new type of mathematical model, i.e. a 'watchmaker model', which is able to assimilate all mechanisms into a coherent and predictive whole; a whole that may not be greater than the sum of its parts, but actually smaller (simpler), and certainly different from that sum. This presentation will present one such model, which deals with multiple concatenated regulatory networks of various signs and strengths that affect the innate immune response. It will show how the model gives a handle on understanding the dichotomy between acute and chronic inflammation and what this has to do with supplementation of stem cells in immune therapies. And it will show how immunologists can now use this Deep Immunology.

EDU.02 The Utility of Theories in Immunology

EDU.02.02
The "two-niche" theory of T cell Memory

F. Di Rosa*;*
Institute of molecular biology and pathology, Italian National Research Council (CNR), Rome, Italy.

The concept is emerging that the bone marrow (BM) sustains life-long persistence of memory T cells, as it does for long-lived plasma cells. The majority of BM memory CD8 T cells are recirculating cells in constant exchange with blood, although some may permanently reside in the BM, thus resembling tissue-resident memory CD8 T cells of extra-lymphoid organs (e.g. gut, skin, etc.). Indeed, it has been suggested that the BM provides "niches" for memory CD8 T cell self-renewal, thus controlling the maintenance of memory CD8 T cell number in the body. However, many gaps remain unfilled, and in particular how memory CD8 T cells are steadily maintained as seemingly quiescent cells, and yet are poised to promptly generate a huge progeny of effector CD8 T cells upon secondary response. In an active debate on the regulation of memory T cell quiescence, I have built upon my own and others' data to propose a novel hypothesis: namely, that the BM offers two types of niches for memory T cells: one driving self-renewal, the other supporting quiescence, thus echoing the duality of niches for hematopoietic stem cells. While self-renewal would stably preserve memory T cell numbers, maintenance in a quiescent state would preserve a capacity to promptly mount secondary responses. Hence, testing this hypothesis is key to considering how CD8 T cell responses to discrete challenges may be beneficially manipulated.

EDU.02.03
The Discontinuity Theory of Immunity

E. Vivier[1]*, T. Pradeu*[2]*;*
[1]*Aix Marseille Univ, CNRS, INSERM, APHM, CIML & Innate Pharma, Marseille, France,* [2]*Unité d'immunologie (ImmunoConcEpT, UMR5164), Université de Bordeaux, France.*

Similar to many other biological systems, the immune system can be seen as a change-detection system. According to the **discontinuity theory of immunity**, the immune system responds to sudden changes in antigenic stimulation and is rendered tolerant by slow or continuous stimulation. The immune system can adapt to these slow or long-lasting modifications in the host, which it then treats as a new reference point. This basic principle, which is supported by recent data on immune checkpoints in viral infections, cancers, and allergies, can be seen as a unifying framework for diverse immune responses. The mechanisms underlying the recognition of patterns, the absence of a pattern, tissue damage, and functional modifications have been considered separately, but the **discontinuity theory of immunity** explains these mechanisms as instances of the more general rule that immune systems have been selected by evolution to respond to sudden modifications within the host.

EDU.02.04
The Equilibrium Model of Immunity

G. Eberl*;*
Institut Pasteur, Paris, France.

The classical model of immunity states that the immune system reacts to pathogens and injury and restores homeostasis. Indeed, a century of research has uncovered the means and mechanisms by which the immune system recognizes danger and regulates its own activity. However, this classical model does not fully explain complex phenomena, such as tolerance, allergy, the increased prevalence of inflammatory pathologies in industrialized nations and immunity to multiple infections. I propose a model of immunity that is based on equilibrium, in which the healthy immune system is always active and is in a state of dynamic equilibrium between antagonistic types of response. This equilibrium is regulated both by the internal milieu and by the microbial environment. As a result, alteration of the internal milieu or microbial environment leads to immune disequilibrium, which determines tolerance, protective immunity and inflammatory pathology.

EDU.03 Immunology of extracellular vesicles

EDU.03.01
Extracellular vesicles in acute and chronic Inflammation

E. I. Buzàs*;*
Semmelweis University, Budapest, Hungary.

Extracellular vesicles are phospholipid membrane enclosed structures released by cells in an evolutionarily conserved manner. These subcellular structures are secreted even under steady state conditions as part of the homeostatic cell-cell communication. Importantly, upon cell activation, induction of cellular stress or different types of cell death, both the number and the molecular composition of extracellular vesicles are altered. In innate and adaptive immune reactions, extracellular vesicles convey intercellular messages by delivering their molecular cargo (proteins, lipids, nucleic RNA and DNA and metabolites). Extracellular vesicles are important carriers of danger signals. There are numerous examples showing that PAMPs and DAMPs are associated with extracellular vesicles and are recognized by the innate immune system. Furthermore, by carrying a wide variety of cytokines and surface-associated tissue degrading enzymes, extracellular vesicles are important players in both acute and chronic inflammation. They have the ability to stimulate antigen-specific T cells, and they participate in cross-dressing and cross-presentation of APCs. The role of extracellular nuclear molecules in the pathogenesis of autoimmune diseases is increasingly recognized. Rapidly growing number of data supports that extracellular vesicles are complex packages of autoantigens which often represent the focus of autoimmune reactions. Finally, they are not only promising biomarkers of diseases but also have significant therapeutic potential in diseases with immune pathomechanism.
Grants: NVKP_16-1-2016-0017, OTKA11958 & 120237, VEKOP-2.3.2-16-2016-00002 and VEKOP-2.3.315201600016, the Institutional Higher Education Excellence Program of the Ministry of Human Resources in the theme "Therapeutic development" and H2020-MSCA-ITN TRAIN-EV.

EDU.03.02
Isolation and detection of extracellular vesicles

***R. Nieuwland**;*
Amsterdam UMC, Amsterdam, Netherlands.

Human body fluids contain cell-derived membrane-enclosed vesicles. The cellular origin, concentration, composition and function of vesicles in body fluids differ in health and disease. Therefore it is not surprising that the scientific and clinical interest in EVs is growing exponentially because vesicles potentially behold the promise of an entirely new set of biomarkers.
Body fluids contain multiple types of vesicles, which are involved in intercellular communication, cellular waste management, and host defence (inflammation, coagulation). Because the types of vesicles are difficult to distinguish from each biochemically (composition) or biophysically (size, density), the umbrella term “extracellular vesicles” was introduced by the International Society of Extracellular Vesicles (ISEV).
Most EVs in body fluids are extremely small and spherical, and the bulk of EVs have a diameter of less than 200-300 nm. Blood, which is the most commonly studied body fluid for biomarker research, contains not only EVs but also high concentrations of soluble proteins and lipoprotein particles / chylomicrons which overlap in size and density with EVs. Consequently, the isolation, detection and biochemical characterization of EVs is not trivial, and only recently several major methodological pitfalls and hurdles have been overcome.
In this presentation, an overview will be given about the progress that has been made regarding isolation of EVs, and the detection of single EVs by flow cytometry.

EDU.03.03
Extracellular vesicles in immunity

***S. Gabrielsson**;*
Karolinska Institutet, Dept of Medicine, Stockholm, Sweden.

Exosomes from antigen presenting cells are interesting as potential cancer immunotherapy vehicles due to their capacity to stimulate tumor-specific activity in mice. However, clinical trials using peptide-loaded autologous exosomes showed only moderate T cell responses, suggesting a need for optimization of exosome-based therapy. We are using dendritic cell derived exosomes to induce antigen-specific immune responses with the aim to cure cancer. We have seen that exosomes need to carry whole protein, and not only peptide/MHC complexes, to induce a strong T cell response in vivo. We showed that the reason for this was that B-cells needed to be activated to induce a strong T cell response to exosomes. This has led us to test allogeneic exosomes in a B16 melanoma model, and our results demonstrate that allogeneic exosomes are as efficient in inducing immune responses as syngeneic exosomes. This greatly increases the feasibility of exosome-based immunotherapy. Currently we are working on different ways to further boost immunogenicity of exosomes and data from these studies will be presented.

EFIS PRESIDENT'S SYMPOSIUM

EP.01 T Cell immunity in the front line

EP.01.03

Differentiation of tissue-resident memory T-cells in primary and secondary immune responses

K. van Gisbergen*;*
Sanquin Research, Amsterdam, Netherlands.

Tissue-resident memory T-cells (Trm) form populations of memory T-cells in barrier tissues including the epithelial compartments of lungs, skin, and gut. Trm are emerging as one of the most potent immune weapons against reinfection, prompting great interest in the development of therapeutic strategies for their elicitation. We have previously identified Hobit as a central regulator of Trm differentiation in mice. We found that the transcription factor was universally expressed in Trm populations of the skin, gut and liver, but not in circulating memory populations. Hobit together with related Blimp-1 was essential for the formation of Trm through suppression of the expression of tissue exit receptors such as S1PR1 and CCR7. Therefore, our findings indicate that Hobit and Blimp-1 mediate a universal program of tissue-residency. The restricted expression pattern of Hobit within resident lymphocytes is a characteristic that we deemed highly valuable for the development of novel tools to study Trm. Therefore, we generated a transgenic mouse model that contained a "knock-in" within the Hobit locus of an "all-in-one" construct of the tdTomato reporter, CRE recombinase and the diphtheria toxin receptor (DTR). We confirmed that expression of tdTomato and functional activity of the CRE recombinase and the DTR was nearly uniformly present and largely restricted to Trm in the transgenic mice. These findings suggest that we have established a novel model system to address Trm development *in vivo*. We aim to resolve the development and the potential of Trm through the further characterization of T-cell differentiation in Hobit reporter mice.

LATE BREAKING HOT TOPICS

HT.04 Late Breaking Hot Topic 4

HT.04.01

Smoking induces recruitment of monocytes into the alveolar space and contributes to accelerated growth of Mycobacterium tuberculosis

B. Corleis[1], *J. L. Cho*[2], *A. Linder*[1], *A. Yan*[1], *A. Dickey*[1], *A. E. Schiff*[1], *B. D. Medoff*[2], *D. S. Kwon*[1];
[1]*Ragon Institute of MGH, MIT, and Harvard, Cambridge, United States,* [2]*Division of Pulmonary and Critical Care Medicine, Massachusetts General Hospital, Boston, United States.*

20-30% of active tuberculosis (TB) cases worldwide are associated with tobacco smoking. Extensive monocyte recruitment in small animal models of human TB is associated with a higher total lung bacterial burden, suggesting that monocyte-derived macrophages may be more permissive to *Mycobacterium tuberculosis* (*M tb*) growth relative to resident macrophages in the lung. We recruited healthy current- and never-smokers for collection of bronchoalveolar lavage (BAL). Monocytes, BAL macrophages or monocyte-derived macrophages (MDMs) were analyzed using flow cytometry, and infected with *M tb in vitro* and bacterial growth monitored over time by CFU. We examined numbers of macrophages, T cells and granulocytes in BAL and found a significant increase in a population of small macrophages in BAL from smokers compared to non-smokers. Half of the small macrophages expressed surface CD93, a marker which distinguished circulating monocytes from large alveolar macrophages and suggests that these small macrophages are derived from newly recruited monocytes. BAL fluid from smokers recruited blood monocytes *in vitro* and significantly higher concentrations of the chemokine CCL11 in BAL fluid correlated with the number of CD93+ small macrophages in BAL. Virulent *M tb* induced a hyper-inflammatory response in human BAL monocytes with significantly higher intracellular growth compared to MDMs or large alveolar macrophages *in vitro.* In conclusion, our data indicate that smoking leads to higher numbers of total BAL macrophages due to CCL11 mediated recruitment of circulating CD93+ monocytes into the alveolar space. Importantly, monocytes were highly susceptible to M tb intracellular growth, suggesting that extensive monocyte infiltration plays a significant role in smoking associated risk for active tuberculosis.

Quantitative shotgun proteo-/transcriptomics shows how human regulatory T cells protect their identity

D. Amsen[1,2];
[1]*Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands,* [2]*University of Amsterdam, Amsterdam, Netherlands.*

Inflammation is both a requirement and a challenge for regulatory T cell (Treg) function. Inflammatory cues direct Tregs to inflamed sites where they limit tissue destruction and promote repair. Under pathological conditions, inflammation can however coerce Tregs into assuming functions normally performed by conventional T cells (Tconvs), such as production of pro-inflammatory cytokines. Here, we have studied how Tregs generally protect their identity from such destabilization. For this, we first established a molecular definition of Treg identity by performing whole cell shotgun proteomics and transcriptomics on multiple human populations of Tregs and Tconvs. We found that proteome and transcriptome compositions markedly differ from one another, but are complementary, underscoring the importance of analysis at both levels. Core and subset-specific Treg signatures reveal that these cells have specific adaptations in cytokine-, TCR- and costimulatory receptor signaling pathways. We show that strategic deficiencies in individual pathways allow inflammatory cytokines to mobilize select functions in Tregs (such as expression of transcription factors and homing receptors) without compromising Treg identity. Genetic alterations in individual signature molecules however suffice to allow conversion of Tregs into Tconvs by inflammatory cytokines. Our results therefore identify molecular nodes that determine the unique response characteristics of Tregs to inflammation.

A cautionary note for using pharmacological inhibitors challenges the role of long-chain fatty acid oxidation on immune cells

L. Berod[1], *B. Raud*[1], *D. G. Roy*[2], *A. S. Divakaruni*[3], *T. N. Tarasenko*[4], *R. Franke*[5], *M. Brönstrup*[5], *A. N. Murphy*[6], *P. J. McGuire*[4], *R. G. Jones*[2], *T. Sparwasser*[1];
[1]*Twincore, Hannover, Germany,* [2]*Goodman Cancer Research Centre, McGill University, Montreal, Canada,* [3]*David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, United States,* [4]*National Human Genome Research Institute, NIH, Bethesda, United States,* [5]*Helmholtz Centre for Infection Research, Braunschweig, Germany,* [6]*University of California, San Diego, La Jolla, United States.*

Long-chain fatty acid oxidation (LC-FA0) has been suggested to play an important role supporting CD4+Foxp3+ regulatory T cells as well as CD8+ memory T cell differentiation and survival. Similarly, LC-FAO has been associated with IL-4-driven macrophage polarization towards the alternative M2 phenotype. However, previous research leading to these conclusions is based on the pharmacological inhibition of carnitine palmitoyltransferase-1, the rate-limiting enzyme for LC-FAO, with high concentrations of the drug etomoxir. Using genetic mouse models to target Cpt1a on specific immune cell populations, we dissected the role of LC-FAO in primary, memory, and regulatory T cell responses. Challenging previous concepts, we here show that LC-FAO and Cpt1a are largely dispensable for effector, memory, or regulatory T cell formation, and that the effects of high dose etomoxir on immune cell differentiation and function are independent of Cpt1a expression. Together our data argue that metabolic pathways other than LC-FAO fuel CD8+ memory or Treg differentiation and suggest off-target effects of etomoxir on mitochondrial respiration.

BRIGHT SPARKS WORKSHOPS

BS.A.01 Bright Sparks A

BS.A.01.01
Developmental origin of osteoclasts and their functional maintenance by nuclear chimerism

E. Mass[1,2], *C. E. Jacome-Galarza*[2], *G. I. Percin*[3,4], *T. Lazarov*[2], *J. Eitler*[3,4], *M. Rauner*[4], *L. Crozet*[2], *M. Bohm*[2], *C. Waskow*[3,4], *F. Geissmann*[2];
[1]*Life & Medical Sciences Institute (LIMES), Bonn, Germany,* [2]*MSKCC, New York, United States,* [3]*Institute for Immunology, Dresden, Germany,* [4]*Leibniz-Institute on Aging-Fritz-Lipmann-Institute, Jena, Germany.*

Osteoclasts are multinucleated macrophages that continuously remodel the bone marrow hematopoietic niche. Excess osteoclast activity contributes to bone loss and osteoporosis, while decreased activity leads to osteopetrosis and bone marrow failure. Osteopetrosis can be partially treated by bone marrow transplantation in human and mice, which is in accordance with in vitro studies suggesting that osteoclasts develop by fusion of hematopoietic stem cell (HSC)-derived monocytic precursors. However, the developmental origin and lifespan of osteoclasts, and the mechanisms that ensure their maintenance and function in vivo remain largely unexplored. Here we report that osteoclasts are long-lived cells that originate from erythro-myeloid progenitors (EMP) in the yolk sac. Using genetic fate-mapping and knockout models we show that EMP-derived osteoclasts colonize ossification centers during embryogenesis and are required for normal bone development and teeth eruption. However, after birth osteoclasts depend on HSC-derived cells. Parabiosis and transfer experiments indicate that an iterative fusion of osteoclasts with circulating monocytes sustains their function is thus indispensable for the maintenance of the bone marrow niche during aging. Altogether, our results identify a dual origin of osteoclasts in vivo, and nuclear chimerism as a mechanism that enables long-term maintenance and function of these multinucleated cells, thereby suggesting new strategies to modulate osteoclast activity.

BS.A.01.02
Uncovering the regulatory T cell transcriptional signature in the human thymus

M. Ângelo-Dias*, A. Godinho-Santos, Y. Tokunaga, A. Serra-Caetano, H. Nunes-Cabaço, A. E. Sousa, A. A. Raposo;*
Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal.

Thymic committed regulatory CD4 T cells (Treg) are essential to maintain self-tolerance and immune homeostasis, yet there are no genome-wide data defining their expression profile in the human thymus. Although FoxP3 is known as a master regulator of Treg differentiation and function, many other factors remain to be uncovered.
To this purpose, we sorted mature CD4 single-positive thymic Tregs (tTreg) and their conventional counterparts (tTconv) based on the expression of CD27, CD25, and CD127, from three human thymuses collected during routine corrective pediatric cardiac surgery, and generated their respective expression profiles by RNA-seq.
Our comparative transcriptomic analysis identifies 1047 genes significantly differentially expressed between tTreg and tTconv subsets. We confirm the prominent expression of Treg associated genes (*FoxP3, IL2RA, CTLA4, LRRC32*, *IKZF2, IKZF4)* in tTreg relative to tTconv. Of note, 45 amongst the 648 tTreg highly-expressed genes encode for known transcription factors, including those involved in T cell activation and differentiation (*RORA, AHR, TBX21, STAT4*), and NF-kB pathway (*NFKB2*, *RELB*, and *REL*). To identify novel factors and pathways, we selected 196 transcripts uniquely expressed in tTreg and not expressed in tTconv. Remarkably, we uncovered groups of genes with a strong statistical association with the regulation of cell migration *(FN1, CCL22, LMNA, LAMA2, ICAM1, CXCR3)*, cytokine pathways (*CCR8, IRF5, TNFRSF8, IL12RB2, IL1RL1, EBI3*), and ion homeostasis (*RYR1, ACTN2, HMOX1, CHRNA6, TMPRSS6, CAV1, KCNS3, CASQ1*).
Our data open several new lines of research to further clarify pathways of Treg lineage commitment in the human thymus, and determinants of the human tTreg signature.

BS.A.01.03
Human T-bet$^+$ B cells: induction and effector functions from a multiple sclerosis perspective

J. van Langelaar[1], *L. Rijvers*[1], *M. Janssen*[1,2], *I. de Groot*[1], *L. Kalden*[1], *A. F. Wierenga-Wolf*[1], *S. Koetzier*[1], *T. A. Siepman*[2], *H. E. de Vries*[3], *P. Unger*[4], *M. S. van Ham*[4], *R. Q. Hintzen*[1,2], *M. M. Luijn*[1];
[1]*Dept. Immunology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands,* [2]*Dept. Neurology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands,* [3]*Dept. Molecular Cell Biology and Immunology, VU University Medical Center, Amsterdam, Netherlands,* [4]*Dept. Immunopathology, Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

In multiple sclerosis (MS), peripheral B-cell tolerance checkpoints are defective and meningeal B-cell follicle-like structures are present in the central nervous system (CNS). Both these critical events link to the function of IFN-γ-induced autoreactive T-bet$^+$ B cells in mice. However, the exact B-cell subpopulations and mechanisms contributing to disease activity in MS patients are underexplored. Here, we found increased STAT1 phosphorylation in IFN-γ-triggered human B cells carrying a recently identified coding MS risk variant, *IFNGR2*. In 3T3-CD40L/IL-21 based cultures, B cells from MS patients revealed higher T-bet and enhanced ASC differentiation in the presence of IFN-γ compared to matched controls. When CpG-ODN was added, T-bet and CXCR3 were further upregulated and caused enhanced switching to IgG1. *Ex vivo* FACS analysis of B cells showed that CXCR3$^+$IgG$^+$ and not naive or non-class-switched cells were reduced in untreated MS versus control blood and were enriched in paired cell suspensions from MS brain tissue, meninges and cerebrospinal fluid. CXCR3 and not CXCR5, was selectively upregulated on accumulating IgG$^+$ B cells in natalizumab-treated MS blood (pre- versus 1-year post-Tx). Correspondingly, the abundance of CXCR3 on IgG1$^+$ B cells led to superior transmigration across human brain endothelial monolayers *in vitro*. Finally, CXCR3^{high}T-bet^{high} IgG1$^+$ B-cell frequencies correlated to those of IFN-γ^{high} Th17.1 and not Th17 cells in MS blood. This work demonstrates that T-bet is synergistically upregulated by IFNGR and TLR9 in B cells, probably underlying preferential CXCR3-mediated recruitment to the CNS and enhanced IgG1 responses to local antigens in MS.

BS.A.01.04
Extracellular Vesicles derived from licensed Mesenchymal Stem Cells: a tunable approach to regulate inflammatory angiogenesis

R. Angioni[1,2,3], *S. Herkenne*[1], *C. Liboni*[1,2], *R. Sanchez-Rodriguez*[1,2,3], *B. Cali*[3], *G. Borile*[3], *A. Viola*[3];
[1]*Padova University, Department of Biomedical Sciences, Via Ugo Bassi, 58/b, 35131- Padova, Italy, Padova, Italy,* [2]*VIMM- Venetian Institute of Molecular Medicine, Padova, Italy,* [3]*Fondazione Istituto di Ricerca Pediatrica Città della Speranza, Padova, Italy.*

Angiogenesis is the process that leads to the formation of new blood vessels from a pre-existing vascular network, playing a key role in many physiological and pathological processes. Consequently, targeting angiogenesis represents a very interesting therapeutic approach. We have already shown that mesenchymal stem cells (MSCs) stimulated with pro-inflammatory cytokines (st-MSCs) block angiogenesis through the release of soluble factors. Thus, we highlighted the endothelium as a novel target during the MSC immunosuppressive effect. However, the therapeutic employment of MSCs to control inflammation is far to be clinically translated. The development of a cell-free therapeutic approach could represent a better cost-effective and safer procedure. Here, we demonstrate that extracellular vesicles derived from stimulated MSC conditioned medium (EV stMSC-CM), but not from their unstimulated counterparts (EV unstMSC-CM), affect angiogenesis, thus recapitulating the MSC effect. EV stMSC-CM, expressing high levels of the ecto-5'-nucleotidase CD73, generate extracellular adenosine. We demonstrated that the EV stMSC-CM generated adenosine inhibits the endothelial cell migration, by inducing an excessive intracellular ROS accumulation, both *in vitro* and *in vivo*. These results indicate that EVs derived from st-MSCs display anti-angiogenic properties and could be exploited for cell-free therapeutic strategies. Additionally, they pave the way for a better understanding of the MSC physiological role *in vivo.*

BS.A.01.05
Lymph node stromal cell function upon immune activation is modulated by dynamics between podoplanin and its binding partners on the plasma membrane

C. M. de Winde*, A. C. Benjamin, L. Millward, V. G. Martinez, S. E. Acton;*
MRC Laboratory for Molecular Cell Biology, London, United Kingdom.

Lymph node expansion is a pivotal process during activation of an immune response, and is controlled by contractility through the fibroblastic reticular cell (FRC) network. Interactions between CLEC-2 expressed on dendritic cells (DCs) and podoplanin on FRCs results in rapid loss of actomyosin contractility and subsequent elongation of FRCs allowing lymph node expansion. Directly downstream, this interaction results in decreased membrane binding and phosphorylation of ezrin-radixin-moesin (pERM) proteins. We sought to understand the molecular mechanisms controlling podoplanin activity.
Podoplanin remains at the plasma membrane even when inhibited by CLEC-2. We hypothesized that podoplanin function is regulated by specific binding partners in different membrane compartments. Protein clustering within membranes is tightly controlled by specialized membrane structures, including lipid rafts and tetraspanin-enriched microdomains. Upon CLEC-2 binding, podoplanin preferentially clusters into cholesterol-rich membrane domains, containing CD44, a known podoplanin binding partner. We show a link between podoplanin and CD44 expression in FRCs. Knockdown of podoplanin coincides with decreased CD44 expression, and in contrast, CLEC-2 stimulation of FRCs increases CD44 expression. RNAseq analysis identified tetraspanins CD9 and CD82 as potential interaction partners of podoplanin. Similarly to CD44, expression of both CD9 and CD82 was altered by contractility, podoplanin knockdown and CLEC-2 stimulation.
Our data support a model whereby podoplanin on FRCs resides in tetraspanin-enriched microdomains, and that CLEC-2 binding may orchestrate a switch between active and inactive complexes. This molecular switch allows for rapid yet reversible inhibition of contractility in FRCs, allowing the lymph node to undergo continuous cycles of remodelling during immune responses.

BS.A.01.06

Autoimmune associated gene PTPN22 is a novel negative regulator of dendritic cell homeostasis and function

H. A. Purvis[1], *F. Clarke*[1], *G. H. Cornish*[1], *T. J. Peel*[1], *C. Sanchez-Blanco*[1], *D. J. Rawlings*[2], *R. Zamoyska*[3], *P. Guermonprez*[1], *A. P. Cope*[1];
[1]*CMCBI Kings College London, London, United Kingdom,* [2]*University of Washington School of Medicine, Seattle, United States,* [3]*Institute of Immunology and Infection Research, Edinburgh, United Kingdom.*

Classical CD11c$^+$MHCcII$^+$ dendritic cells (DC) are divided into functionally distinct phenotypes including the SIRPα$^+$ DC2 subset. Splenic DC2 activate CD4$^+$ T-cells and are potent inducers of follicular helper T-cells (T_{FH}) stimulating germinal center (GC) formation. A single nucleotide polymorphism within the phosphatase *PTPN22* confers an enhanced risk of developing multiple autoimmune diseases including rheumatoid arthritis and type 1 diabetes. PTPN22 negatively regulates multiple immunoreceptor signalling cascades and *Ptpn22*$^{-/-}$ mice display an expanded T_{FH} repertoire and increased GCs. We observed a specific expansion in the number and proportion of splenic ESAM^{HI} DC2 within *Ptpn22*$^{-/-}$ and *Ptpn22*^{R619W} (orthologue of the human autoimmune associated variant) mice compared to WT. Competitive adoptive bone marrow transfers revealed that PTPN22 negatively regulates DC2 development in a DC intrinsic manner. PTPN22-mediated DC2 expansion occurred post-DC precursor development and was not conferred by enhanced responsiveness to Flt3L or GM-CSF. Our data indicate that PTPN22 regulates lymphotoxin β receptor responsiveness to expand ESAM^{HI} DC2. To assess if expanded DC2 were capable of mediating enhanced T_{FH}, CD4$^+$ OT-II T-cells were co-cultured with splenic DCs derived from WT and *Ptpn22*$^{-/-}$ mice immunised with ovalbumin targeted to DC2 via receptor DCIR2 (anti-DCIR2-ova) and sheep RBC adjuvant. Interestingly, the expansion of DC2, conferred by *Ptpn22*$^{-/-}$, was sufficient to induce enhanced T_{FH} responses, and therefore may contribute to the expanded T_{FH} and GCs observed in Ptpn22 variant mice *in vivo*. Together these data provide a new insight into how perturbations to PTPN22 contributes to generate pathogenic autoimmune responses by altering DC2 homeostasis and function.

Immunotargeting of acute myeloid leukemia by highly polyclonal Delta One T cells

B. Di Lorenzo[1], *A. E. Simões*[2], *F. Caiado*[1], *P. Tieppo*[3], *D. V. Correia*[1], *J. Déchanet-Merville*[4], *T. Schumacher*[5], *H. Norell*[1], *I. Prinz*[6], *S. Ravens*[6], *D. Vermijlen*[3], ***B. Silva-Santos***[1];
[1]*Instituto de Medicina Molecular, Lisboa, Portugal,* [2]*Lymphact S.A., Coimbra, Portugal,* [3]*Université Libre de Bruxelles, Brussels, Belgium,* [4]*Université de Bordeaux, Bordeaux, France,* [5]*Netherlands Cancer Institute, Amsterdam, Netherlands,* [6]*Hannover Medical School, Hannover, Germany.*

The adoptive transfer of CAR-T cells has transformed the treatment of B-cell acute lymphoblastic leukemia, but acute myeloid leukemia (AML), the deadliest of all hematological cancers, remains a major challenge due to absence of a targetable tumor-specific antigen. We are considering the potential of Vdelta1+ gamma-delta T cells, which are known to associate with improved survival of transplanted patients, but have never been applied as adoptive cell therapy. Having recently developed a clinical-grade protocol for expansion and differentiation of cytotoxic Vdelta1+ T cells, termed "Delta One T" (DOT) cells, we characterized here their anti-AML reactivity on the path to therapeutic application. DOT cells were highly cytotoxic against a large panel of AML primary samples and cell lines, including cells selected for resistance to standard chemotherapy. Interestingly, DOT cell targeting did not select for particular AML lineages, suggesting a very broad recognition domain. Indeed, next-generation sequencing of the CDR3 regions in *TRGV* and *TRDV* genes showed a striking polyclonality of DOT cells compared to ex vivo Vdelta1+ T cells, notably approaching that of naïve Vdelta1+ thymocytes. By establishing (single cell-derived) DOT cell clones we demonstrate that the vast majority display potent anti-AML cytotoxicity, which at bulk level translates into efficient AML targeting in vitro and in vivo. In particular, the adoptive transfer of DOT cells markedly reduced AML load in the blood and target organs of human AML xenografts; and significantly prolonged host survival. This works thus provides the pre-clinical proof-of-concept for application of highly polyclonal DOT cells in AML treatment.

Broad tumor microenvironment remodelling after oncolytic Adenovirus coding for TNFa and IL-2 enable T-cell therapies to deliver complete responses in solid tumors

V. Cervera-Carrascon[1,2], *R. Havunen*[1,2], *J. M. Santos*[1,2], *M. Siurala*[1,2], *S. Sorsa*[1,2], *A. Hemminki*[1,2,3];
[1]*TILT Biotherapeutics, Helsinki, Finland,* [2]*University of Helsinki, Helsinki, Finland,* [3]*Comprehensive Cancer Center, Helsinki Universitary Hospital, Helsinki, Finland.*

Besides the considerable potential of T-cell therapies for the treatment of cancer, their clinical outcome is unimpressive on solid tumours. One likely limitation here is the tremendous complexity of the tumour microenvironment, which render inefficient the treatments through multiple suppressive mechanisms. An oncolytic adenovirus engineered to express tumour necrosis factor alpha and interleukin-2 (Ad5/3-E2F-d24-hTNFa-IRES-hIL2, a.k.a. TILT-123) was empirically designed to tackle tumour immune suppression and enable T-cell therapies against solid tumours. A subcutaneous pancreatic tumour model in Syrian hamsters provided the means to study the antitumor efficacy of TILT-123 in combination with tumour infiltrating lymphocyte (TIL) transfer since it supports adenoviral replication in addition of the immune competency of the animals. More studies were performed focusing on safety parameters, abscopal effect, trafficking of the TILs transferred towards the tumour or the fact that TILT-123 can replace lympho-depleting preconditioning and postconditioning with recombinant interleukin-2 systemically. Other studies were carried out in a subcutaneous melanoma model (B16.OVA) in mice (with a murine version of the viruses) exploring other T-cell therapies such as adoptive cell transfer of T cells with OVA-specific TCR or even checkpoint blockade. From those studies, all the animals got complete responses when treated with adoptive cell transfer or checkpoint blockade, combined with the viral therapies. Analysing the biological samples from those experiments revealed a broad tumour microenvironment remodelling, including higher presence of CD8+ lymphocytes, NK cells and mature DCs, while a decreased M2 macrophage manifestation. Based on these results a Phase-I clinical trial will start in 2019.

BS.B.01.03

NF-kB c-Rel is crucial for the regulatory T cell immune checkpoint in cancer

Y. Grinberg-Bleyer[1,2], *H. Oh*[2], *A. Desrichard*[3], *T. Chan*[3], *R. Schmid*[4], *M. Hayden*[2], *U. Klein*[5], *S. Ghosh*[2];
[1]*Centre de Recherche en Cancerologie de Lyon, Lyon, France,* [2]*Columbia University Medical Center, New York, United States,* [3]*Memorial Sloan Kettering Cancer Center, New York, United States,* [4]*Technische Universität Munich, Munich, Germany,* [5]*University of Leeds, University of Leeds, United Kingdom.*

Cancers use a wide variety of mechanisms to dampen tumor immune response. Among them, CD4+Foxp3+ regulatory T cells (Tregs) are largely described to inhibit the function of effector cells. Therefore, precisely understanding the mechanisms governing Treg homeostasis may be a valuable strategy to enhance immune responses against cancer. Here we have examined the roles of the p65 and c-Rel subunits of the NF-kB family of transcription factors in Treg biology. We found that specific ablation of one or both NF-kB subunits in Tregs drove a gradual autoimmune syndrome. This was associated with profound changes in the molecular signature of NF-kB deficient Tregs. Remarkably, c-Rel specifically maintained gene expression pattern in activated Tregs, which are potent inhibitors of anti-tumor immunity. This led us to explore the role of NF-kB in Treg homeostasis during tumor growth. Strikingly, melanoma growth was drastically reduced in mice lacking c-Rel, but not p65, in Tregs. This was associated with an increased effector T cell activation. Moreover, chemical inhibition of c-Rel delayed melanoma growth and potentiated anti-PD-1 checkpoint-blockade therapy by impairing the Treg transcriptional program. Our data demonstrate a specific role for each NF-kB subunit in Treg function and homeostasis, and highlights a new therapeutic opportunity for the treatment of cancer. *Reference: Grinberg-Bleyer et al, "NF-kB c-Rel is crucial for the regulatory T cell immune checkpoint in cancer."* ***Cell****, 2017 Sep 7;170(6):1096-1108*

Mitochondrial DNA shapes metabolism in immune response

A. V. Lechuga-Vieco[1,2], *G. Prota*[3], *U. Gileadi*[3], *A. Latorre-Pellicer*[1], *J. Pellico*[1], *J. Ruíz-Cabello*[4,5,2], *V. Cerundolo*[3], *J. A. Enriquez*[1,6];
[1]*Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain,* [2]*Centro de Investigación en Red de Enfermedades Respiratorias (CIBERES), Madrid, Spain,* [3]*MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom,* [4]*CIC biomaGUNE, San Sebastián-Donostia, Spain,* [5]*Universidad Complutense, Madrid, Spain,* [6]*Centro de Investigación Biomédica en Red Fragilidad y Envejecimiento Saludable (CIBERFES), Madrid, Spain.*

All mitochondrial DNAs (mtDNA) of a given cell in our organism are essentially identical, a situation termed homoplasmy. Animal models with identical nuclear genomes but with different mtDNA haplotypes (conplastic mice) generate functionally different OXPHOS systems that shape the organismal metabolism[1], supporting the conclusion that different mtDNA haplotypes are phenotypically relevant.
There is an unsolved controversy regarding the possible functional consequences of different physiological haplotypes of mtDNA in inflammatory processes. To address this issue, we have characterised conplastic mice throughout their lifespan through transcriptomic, metabolomic, biochemical and phenotypical studies. We have also applied *in vivo* imaging techniques for non-invasive assessment of tissue metabolism and inflammatory processes. We find that the mtDNA haplotype profoundly influences reactive oxygen species (ROS) generation, energy homeostasis metabolism, immune response and ageing among others, resulting in different healthy longevities of conplastic and heteroplasmic strains. Elucidating the role of mitochondrial genetics in immune cell metabolism and function combined with an understanding of the mechanisms regulating this process is quite challenging. To address these questions, we engineered heteroplasmic mice, with two wild-type mtDNA variants co-existing in the same cytoplasm, which provided an opportunity to demonstrate mtDNA segregation in T cells, upon their in vivo and in vitro activation. In addition, we observed how differences in OXPHOS performance and ROS production can modulate T cell function and differentiation. MtDNA haplotype profoundly impacts on the way immune cells respond to and influence their environment, ultimately shaping immune cell function and fate.

***Milieu Interieur*: defining immunological variability through systems biology for a better understanding of disease**

D. Duffy[1], *E. Patin*[1], *C. Posseme*[1], *B. Charbit*[1], *J. Bergsted*[2], *H. Quach*[1], *V. Rouilly*[1], *M. Hasan*[1], *J. Fellay*[3], *J. Di Santo*[1], *M. Albert*[4], *L. Quintana Murci*[1], *Milieu Intérieur Consortium;*
[1]*Institut Pasteur, Paris, France,* [2]*Lund University, Lund, Sweden,* [3]*EPFL, Lausanne, Switzerland,* [4]*Genentech, San Francisco, United States.*

Immune responses are highly variable between individuals and populations, with this variance driven by genetic and environmental factors. To better define this inherent variability and to dissect its causes the *Milieu Interieur* cohort was established consisting of 1,000 healthy donors stratified by age (20-70 years old) and sex (50:50). From these donors we have characterized baseline immune phenotypes by multi-parameter flow cytometry, and induced immune responses in standardized whole blood stimulations systems. We have previously shown how innate immune cells are preferentially shaped by genetics, while adaptive immune cells are more impacted by environmental factors. More recently we have defined key immune stimuli that capture the full breadth of induced immune responses and characterized these responses at transcriptional and proteomic levels. We are currently integrating this rich data set with complementary cellular, genetic and epigenetic data sets in a systems immunology approach. Classical statistical approaches as well as machine learning techniques are being applied to define immune response networks and determine which components of these pathways are controlled at the genetic level. In parallel disease specific immune perturbations in infection and autoimmunity have been identified utilizing the same standardized approach. Direct comparison with our well defined 1,000 healthy donor cohort is allowing for a new understanding of these mechanisms in disease. In summary, these results will lay the foundations for the integration of immune response variability in smart clinical study design and eventually precision medicine strategies.

BS.B.01.06

T cell - target cell communication is determined by glycosphingolipid-mediated shielding of cell surface proteins

A. A. de Waard[1], *M. L. Jongsma*[1], *T. Zhang*[2], *S. Holst*[2], *M. Wuhrer*[2], *C. E. van der Schoot*[1], *R. M. Spaapen*[1];
[1]*Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands,* [2]*Leiden University Medical Center, Leiden, Netherlands.*

Receptor-ligand interactions are essential for immune cell function. Using state-of-the-art genome-wide screens we identified that physical accessibility of surface MHC class I (MHC-I) can be restricted by a subtype of glycosphingolipids (GSLs), so-called (neo-)lactoseries GSLs. Moreover, tumor cells expressing these GSLs have a reduced capacity to activate CD8+ T cells. Here, we hypothesized that also cell surface proteins other than MHC-I are shielded by GSLs preventing the binding of their natural receptors.
Using CRISPR/Cas9 we generated various cell lines with a different GSL composition as confirmed using mass spectrometry. These cells and control cells were fluorescently barcoded to analyze in a single well by flow cytometry. We then screened the various cell lines for new cell surface proteins with a restricted physical accessibility, just like MHC-I, using a custom monoclonal antibody array. Out of 26 proteins analyzed, the accessibility of 18 cell surface proteins was specifically reduced by the (neo-)lactoseries GSL subtype. Although GSLs are described to be enriched in specific membrane microdomains, both proteins within and outside of these microdomains were affected by GSLs. Importantly, next to restricting accessibility of surface proteins for antibodies, the (neo-)lactoseries GSLs largely blocked the ligation of the receptors LIR-1 and SIRP-α to their ligands, MHC-I and CD47 respectively.
To conclude, the GSL repertoire regulates shielding of several surface proteins which affects the interaction with CD8+ T cells. Tumors and viruses may thus specifically corrupt intercellular communication with the immune system through alterations in the cellular GSL signature.

Tissue resident memory T-cell (T_{RM}) maintenance is regulated by tissue damage

R. Stark[1,2], *T. H. Wesselink*[1], *F. M. Behr*[1,2], *N. A. Kragten*[1], *K. P. van Gisbergen*[1,2], *R. A. van Lier*[1,2];
[1]*Sanquin Research, Amsterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands.*

Tissue resident memory T cells (T_{RM}) are non-circulating immune cells that contribute to the first line of local defense against reinfections. Their location at hot spots of pathogen encounter frequently exposes T_{RM} to tissue damage. This history of danger-signal exposure is an important aspect of T_{RM} mediated immunity that has been overlooked so far. RNA-sequencing revealed that T_{RM} from liver and small intestine express P2RX7, a damage/danger associated molecular pattern (DAMP)-receptor that is triggered by extracellular nucleotides (ATP, NAD). We confirmed that P2RX7 protein was expressed in CD8 T_{RM} but not circulating cells (T_{CIRC}) across different infection models. Tissue damage induced during the routine liver preparation led to P2RX7 activation and resulted in selective cell death of T_{RM} but not T_{CIRC}. P2RX7 activation *in vivo* by exogenous NAD led to a specific depletion of T_{RM} while retaining T_{CIRC}. The effect was absent in P2RX7 deficient mice and after P2RX7-blockade. TCR-triggering down-regulated P2RX7 expression and made T_{RM} resistant to NAD-induced cell death. Physiological triggering of P2RX7 by sterile tissue damage during drug-induced liver injury lead to a loss of previously acquired pathogen-specific liver T_{RM} in WT but not P2RX7KO T cells of mixed bone marrow chimeras.
Our results highlight P2RX7-mediated signaling as a novel pathway for the regulation of T_{RM} maintenance. Extracellular nucleotides released during infection and tissue damage could deplete T_{RM} locally and free niches for new and infection-relevant specificities. This suggests that the recognition of tissue damage promotes persistence of antigen-specific over bystander T_{RM} in the tissue niche.

BS.C.01.02

***TLR7* escapes X chromosome inactivation in immune cells**

J. Guéry;
INSERM U1043, CPTP, Toulouse, France.

Toll-like receptor 7 (TLR7), an endosomal sensor of exogenous and autologous single-stranded RNA, is critical to the induction of antiviral immunity. TLR7 is also a pathogenic factor in systemic lupus erythematosus (SLE), where it senses RNA-containing immune complexes. Disease severity in lupus-prone mice depends on *Tlr7*. Like other autoimmune disorders, SLE is strongly sex-biased, and female-to-male incidence peaks at 9:1 in adulthood. However, men with Klinefelter syndrome (47,XXY) carry a similar risk of SLE compared to women, suggesting a gene-dose effect of X chromosome loci. *TLR7* localizes to Xp outside the pseudoautosomal regions and we investigated whether TLR7 gene might escape X-inactivation in primary immune cells of women, such as B cells, pDCs and monocytes. Our results show that *TLR7* escapes X chromosome inactivation in distinct populations of pDCs, B cells and monocytes from women and 47, XXY men. Cells exhibiting bi-allelic expression of *TLR7* were observed in all donor tested, with frequencies ranging from 7-45%. Using RNA-FISH, we show the presence of primary *TLR7* transcripts on both X chromosomes in a subset of B lymphocytes and pDCs from women. Focusing on women's B lymphocytes, we show that bi-allelism is associated with increased gene dosage and imparts a selective advantage at key TLR-dependent development checkpoints of effector B cells. Taken together, our work show that *TLR7* bi-allelism defines a new women-specific functional subset of B cells, and mechanistically connects TLR7-driven B-cell responses to sex bias in SLE and other autoimmune disorders. Human regulatory T cells suppress CD4+ T cells by rapidly altering the phosphoproteome

R. N. Joshi[1], *F. Marabita*[1], *N. Binai*[2], *Z. Sui*[3], *A. Altman*[3], *A. J. Heck*[2], *J. Tegner*[1], *A. Schmidt*[1];
[1]*Karolinska Institute, Stocholm, Sweden,* [2]*Utrecht University, Utrecht, Netherlands,* [3]*La Jolla Inst. for Allergy and Immunology, La jolla, United States.*

Regulatory T cells (Tregs) control key events of immunity primarily by suppression of effector T cells, and Treg dysfunction is involved in the pathogenesis of autoimmunity, allergy and cancer. We previously revealed that Tregs rapidly suppress T cell receptor (TCR)-induced calcium store depletion in conventional CD4+CD25− T cells (Tcons) independently of IP3 levels, consequently inhibiting NFAT signaling and effector cytokine expression.
Here, we study Treg suppression mechanisms through unbiased phosphoproteomics of primary human Tcons upon TCR stimulation and Treg-mediated suppression, respectively. We have demonstrated that Tregs suppress the signalling cascade in Tcons by inducing a state of overall decreased phosphorylation as opposed to TCR stimulation. Further we also discovered novel phosphosites (T595_S597) in the DEF6 (SLAT) protein that were phosphorylated upon TCR stimulation and conversely dephosphorylated upon coculture with Tregs. Mutation of these DEF6 phosphosites abrogated interaction of DEF6 with the IP3 receptor and affected NFAT activation and cytokine transcription in primary Tcons. Additionally, we also discovered a phosphatase inhibitor from our phosphoproteomic screen, the loss of which rendered the Tcons to be resistant to Treg-mediated suppression. These novel mechanisms and phosphoproteomics data resource may aid in modifying sensitivity of Tcons to Treg-mediated suppression and contribute to improve treatment of autoimmunity and cancer, particularly considering the frequently observed resistance of target Tcons to Treg-mediated suppression in human autoimmune disease.

BS.C.01.04

Prophylactic treatment with novel forms of allergen-laden virus like-nanoparticles (VNP) induces specific tolerance in a mouse model of allergy

B. Kratzer[1], *C. Köhler*[1], *S. Hofer*[1], *U. Smole*[1], *D. Trapin*[1], *J. Iturri*[2], *D. Pum*[2], *P. Kienzl*[3], *A. Elbe-Bürger*[3], *P. Gattinger*[4], *I. Mittermann*[4], *B. Linhart*[4], *Y. Dorofeeva*[4], *B. Jahn-Schmid*[4], *A. Neunkirchner*[1], *R. Valenta*[4], *W. F. Pickl*[1];
[1]*Institute of Immunology; Center for Pathophysiology, Infectiology and Immunology; Medical University, Vienna, Austria,* [2]*Department of Nanobiotechnology, Institute for Biophysics, University of Natural Resources and Life Sciences, Vienna, Austria,* [3]*Department of Dermatology, Laboratory of Cellular and Molecular Immunobiology of the Skin, Medical University, Vienna, Austria,* [4]*Institute of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Medical University, Vienna, Austria.*

In high-risk populations, allergen-specific prophylaxis could protect from sensitization and subsequent development of allergic diseases. However, such treatment might itself induce sensitization and allergies. Therefore, new non-allergenic vaccine formulations, such as virus like nanoparticles (VNP) are needed. We here targeted the major mugwort allergen Art v 1 either to the surface or to the inner side of VNP by genetic engineering and subjected the vaccine candidates to biochemical and immunological analyses *in vitro,* as well as in a humanized mouse model of mugwort allergy *in vivo*. Degranulation of RBL cells sensitized with Art v 1-specific IgE occurred exclusively upon incubation to VNP expressing surface-exposed but not shielded allergen, whereas both VNP versions induced proliferation and cytokine production of allergen-specific T cells *in vitro.* Upon intranasal application in mice, VNP expressing surface-exposed allergen induced allergen-specific antibodies, including IgE, which was not observed for VNP expressing shielded allergen, making them promising candidates for prophylactic application. Preventive treatment with VNP expressing shielded allergen protected mice from subsequent sensitization with mugwort pollen extract. Protection was associated with a Th1/Treg-dominated cytokine response, increased Foxp3$^+$ Treg numbers in lungs and reduced lung resistance. *In vivo,* fluorescently labeled VNPs were predominantly taken up by alveolar macrophages but also CD103$^+$ DCs, which are known to be strong inducers of Foxp3$^+$ Treg. Allergen-laden VNPs represent a novel and versatile *in vivo* allergen delivery platform to selectively target T cells that can be used for immunotherapy without inducing de novo sensitization. *Supported by Austrian Science Fund (FWF) DK-W1248, SFB-F4609, F4605.*

BS.C.01.05

Macrophages require CD200 receptor to resolve inflammatory pain

R. Raoof*, M. van der Vlist, H. Willemen, J. Prado Sanchez, L. Meyaard, N. Eijkelkamp;*
University Medical Center Utrecht, Utrecht, Netherlands.

Pain is a cardinal symptom of inflammation. The resolution of pain is presumed to be the result of discontinued inflammatory processes, yet in various diseases such as rheumatic diseases pain persists even when inflammation has subsided. Here we investigated the contribution of macrophages in the regulation of inflammatory pain. Transient inflammatory pain was induced by injection of carrageenan in mouse hind paws. In this model, monocytes/macrophages infiltrated the dorsal root ganglia (DRG) that are distant from inflammation and contain the cell bodies of sensory neurons innervating the hind paw. Unexpectedly, monocyte/macrophage-depleted mice failed to resolve inflammatory pain whilst the duration of carrageenan-induced inflammation was unaffected. During transient pain, DRG-infiltrating macrophages expressed the M2 marker CD206, but not M1 marker iNOS. Intrathecal injection of CD115$^+$ monocytes, M0 macrophages, or *in-vitro* M2-polarized macrophages in monocyte/macrophage depleted mice resolved inflammatory pain, whilst M1 macrophages were unable to resolve pain. M2 Macrophages express high levels of the immune inhibitory CD200-Receptor (CD200R). Similar to macrophage depleted mice, CD200R$^{-/-}$ mice failed to resolve inflammatory pain. Resolution of inflammatory pain required CD200R expression on monocytes: in monocyte/macrophage depleted mice, administration of WT, but not CD200R$^{-/-}$ monocytes, rescued resolution of pain. Moreover, injection of WT monocytes in CD200R$^{-/-}$ mice restored the capacity to resolve inflammatory pain.
In conclusion, we show that monocytes/macrophages require CD200R to drive the resolution of inflammatory pain in the DRG, and thereby prevent development of chronic pain. These data indicate that monocyte/macrophage function extends beyond control of inflammation to the regulation of pain-sensing neurons.

BS.C.01.06

Tissue-resident memory CD8$^+$ T cells form systemic effector and memory responses but 'remember' their site of origin

F. M. Behr*, T. H. Wesselink, L. Parga Vidal, N. A. Kragten, R. Stark, K. P. van Gisbergen;*
Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands.

Tissue-resident memory CD8$^+$ T cells (T_{RM}) are non-circulating memory T cells localizing to peripheral (barrier) tissues. T_{RM} provide efficient early protection against local reinfection through rapid cytokine production and local proliferation. However, the contribution of T_{RM} to systemic secondary effector and memory responses remains unclear.
In order to investigate T_{RM} responses after re-challenge *in vivo*, we established an adoptive transfer model of memory CD8+ T cells arising after acute viral infection. Intestinal T_{RM} and circulating effector memory (T_{EM}) and central memory CD8$^+$ T cells (T_{CM}) were isolated from immune mice, and co-transferred into naïve recipients. Unlike their circulating counterparts, T_{RM} cells were confined to non-lymphoid peripheral tissues following transfer and retained a resident phenotype. After viral challenge, T_{RM} cells, similar to circulating memory subsets, gave rise to a systemic recall response, albeit of reduced magnitude. Upon viral clearance, T_{RM} formed circulating and resident secondary memory cells, but did not give rise to T_{CM} cells. Interestingly, the intestine-derived T_{RM} were superior at re-generating secondary T_{RM} in the intestinal compartment, but not at other sites. This was consistent with their selective re-expression of the intestine-homing receptor CCR9. In contrast, re-activated liver T_{RM} lacked the capacity to access the intestine, preferentially accumulated in the liver and upregulated receptors associated with liver-homing.
Our findings demonstrate that T_{RM} have the potential to generate body-wide effector and memory responses, but retain an intrinsic preference for their tissue of origin. This may pose important implications on future cell therapy and vaccination strategies that employ T_{RM}.

BS.D.01.01

Intestinal IgA shows specific broad binding to phylogenetically non-related bacteria

J. Kabbert[1], *H. Wardemann*[2], *O. Pabst*[1];
[1]*Uniklinik RWTH Aachen, Institute of Molecular Medicine, Aachen, Germany,* [2]*German Cancer Research Center, Division of B cell Immunology, Heidelberg, Germany.*

Secretory immunoglobulin A (SIgA) is a key component in gut homeostasis. SIgA binds to luminal and gut epithelial surface associated bacteria, thereby contributing to intestinal host defense against pathogens and maintaining a stable microbiota composition. Considering the vast changes in the microbiota consortium depending on diet, medical treatment and infection, it remains elusive how the host immune system can generate and regulate beneficial SIgA responses to a highly dynamic commensal setting.
This study sought to profile the binding spectrum of monoclonal IgA antibodies (mABs) derived from human healthy donors and inflammatory bowel disease (IBD) patients by flow cytometry. Screening of almost 200 monoclonal IgA antibodies revealed an unexpected high frequency of mABs with substantial microbiota reactivity. In order to determine the binding spectrum of microbiota reactive mABs, we used these mABs to stain bacteria isolated from RAG$^{-/-}$ feces with subsequent 16S rDNA sequencing of bound and unbound bacterial fractions. Individual mABs bound a diverse spectrum of commensals rather than showing reactivity to single taxa. This suggests that single monoclonal mABs functionally bind a relevant fraction of different intestinal bacteria *in vivo*. Unlike recent reports, we did not observe a correlation of high microbiota reactivity and polyreactivity of respective mABs. In addition, while mABs with microbiota reactivity showed frequent somatic mutations, germ-line variants of previously high binding mABs showed decreased microbiota binding or an altered binding profile. We therefore speculate that ongoing somatic hypermutation selects for intestinal IgA with broad, yet specific binding to different bacterial taxa.

BS.D.01.02

Oxysterol sensing through the receptor GPR183 promotes the lymphoid tissue-inducing function of innate lymphoid cells and colitis

J. Emgård[1], *H. Kammoun*[1], *B. García-Cassani*[2], *J. Chesné*[2], *S. Parigi*[1], *J. Jacob*[3], *H. Cheng*[4], *E. Evren*[1], *S. Das*[1], *P. Czarnewski*[1], *N. Sleiers*[1], *F. Melo-Gonzalez*[5], *E. Kvedaraite*[1], *M. Svensson*[1], *E. Scandella*[4], *M. Hepworth*[5], *S. Huber*[6], *B. Ludewig*[4], *L. Peduto*[3], *E. Villablanca*[1], *H. Veiga-Fernandes*[2], *J. Pereira*[7], *R. Flavell*[7], ***T. Willinger***[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Champalimaud Centre For The Unknown, Lisbon, Portugal,* [3]*Institut Pasteur, Paris, France,* [4]*Institute of Immunobiology, St. Gallen, Switzerland,* [5]*University of Manchester, Manchester, United Kingdom,* [6]*University Hospital Eppendorf, Hamburg, Germany,* [7]*Yale University, New Haven, United States.*

Innate lymphoid cells (ILCs) sense environmental signals and are critical for healthy organ function in the intestine. Yet, which signals are sensed and what receptors control ILC function remains poorly understood. Here we demonstrate that group 3 ILCs (ILC3s) sense hydroxylated metabolites of cholesterol (oxysterols) through the G protein-coupled receptor (GPR183), which was highly expressed by ILC3s with a lymphoid tissue-inducer phenotype. GPR183 and its oxysterol ligand 7α,25-hydroxycholesterol (7α,25-OHC) directed the migration of ILC3s to lymphoid structures in the colon and ablation of the *Gpr183* gene in ILC3s caused a defect in the formation of colonic cryptopatches and isolated lymphoid follicles. The same phenotype was observed in mice lacking *Ch25h*, demonstrating a requirement for oxysterols in lymphoid tissue organogenesis. Fibroblastic stromal cells found in intestinal lymphoid structures expressed 7α,25-OHC-synthesizing enzymes and provided the local source of oxysterols. In contrast, GPR183 and its ligand 7α,25-OHC were dispensable for lymphoid tissue formation in the small intestine. Furthermore, 7α,25-OHC was increased by inflammatory signals and GPR183 controlled inflammatory cell recruitment during colitis. Consequently, *Gpr183*-deficient mice were less susceptible to colitis in an innate model of intestinal inflammation. Our results identify oxysterols as a novel class of molecules that control ILC function and establish an unexpected link between cholesterol metabolism, ILC3 migration, lymphoid tissue development, and intestinal homeostasis.

BS.D.01.03

Eomes broadens the scope of CD8 T cell memory by inhibiting apoptosis in low-affinity cells

I. Kavazović[1], *E. Slinger*[2], *G. Balzaretti*[3], *P. Klarenbeek*[3], *H. Han*[4], *N. A. Lemmermann*[5], *A. ten Brinke*[6], *J. Koster*[7], *S. Jonjić*[1], *N. de Vries*[3], *Y. Bryceson*[4], *B. Polić*[1], *E. Eldering*[2], *F. M. Wensveen*[1];

[1]*School of Medicine, University of Rijeka, Rijeka, Croatia,* [2]*Dept. of Experimental Immunology, AMC Amsterdam, Amsterdam, Netherlands,* [3]*Dept. of Clinical Immunology & Rheumatology, AMC Amsterdam, Amsterdam, Netherlands,* [4]*Center for Hematology and Regenerative Medicine, Karolinska University Hospital Huddinge, Stockholm, Sweden,* [5]*Institute for Virology and Research Center for Immunotherapy (FZI) at the University Medical Center of the Johannes Gutenberg University, Mainz, Germany,* [6]*Dept. of Immunopathology, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands,* [7]*Dept. of Oncogenomics, AMC Amsterdam, Amsterdam, Netherlands.*

The memory CD8 T cell pool must select for high-affinity clones to efficiently counter re-infection, yet must retain a level of clonal diversity to allow recognition of pathogens with mutated immuno-dominant epitopes. How this is mediated is unclear, especially in the context of a selective drive for antigen-affinity. We find that two distinct mechanisms of memory cell selection operate. Using an inducible system in which we can time elimination of Eomes by Poly(I:C) injection we show that low-affinity memory exclusively depends on the transcription factor Eomes in the first days after antigen encounter. Eomes is induced at low activating signal strength and directly drives transcription of the pro-survival protein Bcl-2. At higher signal intensity T-bet is induced which suppresses Bcl-2, generating a survival advantage for low-affinity cells. In contrast, high-affinity cells form memory independent of Eomes, but have a proliferative advantage over low-affinity cells, which compensates for their survival deficit. The Eomes-deficient CD8 T cell memory population therefore lacks low-affinity cells, resulting in a strongly reduced capacity to target antigen with point mutations in its immuno-dominant epitope. By specifically targeting Bcl-2 with a small molecule inhibitor early during the immune response we could increase the specificity of the CD8 T cell response. In summary, we demonstrate on a molecular level how sufficient diversity of the memory pool is established in an environment of affinity-based selection. Moreover, we demonstrate that the Eomes/Bcl2 axis may be exploited therapeutically to modify the scope of T cell based vaccines.

BS.D.01.04

Pentraxin3 Regulates IL-17A Mediated Immunity to *Leishmania*

G. Gupta*, P. Jia, J. E. Uzonna;*
University of Manitoba, Winnipeg, Canada.

Cutaneous leishmaniasis (CL), caused by the protozoan parasite *Leishmania (L) major*, results in ulcerative skin lesions at the sites of infection. Studies show that the nature of immune response plays a crucial role in resolution of skin lesions during infection. The long Pentraxin 3 (PTX3), a soluble pattern recognition molecule, is critical for wound healing by regulating tissue repair and innate and adaptive responses during infection and inflammation. Here, we show that PTX3 contributes to susceptibility to CL. PTX3$^{-/-}$ mice were highly resistant to primary and secondary *L. major* infections. Interestingly, the enhanced resistance of PTX3$^{-/-}$ mice to *L. major* was not associated with enhanced IFN-γ or decreased IL-4 response. Instead, L. *major*-infected PTX3$^{-/-}$ mice displayed strong IL-17 response and *in vivo* neutralization of IL-17A abolished their enhanced resistance and resulted in elevated parasite burden compared to their untreated controls. In *in vitro* polarization studies, more naïve CD4^{+} T cells from PTX3$^{-/-}$ mice significantly differentiated into Th17 cells compared to those from WT mice. This was associated with increased expression of Th17-specific transcription factors like RORγt and STAT3. Addition of recombinant PTX3 into Th17 polarizing cultures of PTX3$^{-/-}$ CD4^{+} T cells led to significant reduction in the expression of Th17-specific transcription and the frequency of Th17 cells. Collectively, our results show that PTX3 contributes to pathogenesis of CL by negatively regulating inflammation via enhancing IL-17 response.

BS.D.01.05

Imaging the host-pathogen interaction in tuberculosis in a bioelectrospray 3D cell culture model

E. Konstantinopoulou[1], *L. B. Tezera*[1], *S. Mahajan*[2], *P. T. Elkington*[1];
[1]*University of Southampton, Faculty of Medicine, Southampton, United Kingdom,* [2]*University of Southampton, Chemistry, Southampton, United Kingdom.*

Introduction: Tuberculosis is a deadly infectious disease caused by the bacterium *Mycobacterium tuberculosis* (*Mtb*). Traditional animal models as well as conventional 'two-dimensional' cell cultures do not accurately mimic human tuberculosis infection *in vivo*, such as the formation of caseating granulomas and degradation of extracellular matrix. Materials and Methods: We study a bioelectrospray-generated 3D cell culture model of tuberculosis, using diverse imaging techniques. In the 3D culture, *Mtb*-infected PBMCs (strains: H37Rv, 0414B) are mixed with an alginate-collagen gel. We investigated the host-pathogen interaction at high resolution at various stages of infection using Transmission Electron Microscopy (TEM). We used Micro-Computed Tomography (μCT) to show distribution of PBMCs in 3D in comparison to a human tuberculous lung biopsy. This was then correlated to traditional H&E, and matrix staining of the sectioned lung block. Using label-free microscopy [Coherent Anti-Stokes Raman Scattering (CARS), Second Harmonic Generation (SHG)], PBMC aggregation and collagen fibers were imaged.
Results: More lipid bodies were detected by TEM in the *Mtb*-infected samples than the uninfected controls. TEM and SHG imaging revealed collagen fibres attached to the surface of PBMCs. CARS microscopy showed that infection with *Mtb,* as well as the presence of collagen in the 3D matrix, influence the number of PBMC aggregates forming within the 3D culture. Preliminary data from μCT indicate that this technique can provide quantitative data on PBMC aggregates in 3D that can be cross-correlated with human biopsies.
Conclusion: A combination of traditional and emerging imaging modalities can provide new insight into the host-pathogen interaction in tuberculosis.

Introduction: Cellular heterogeneity emerges as a key feature of type I IFN-mediated antiviral immunity. Little is known about the factors involved in modulating cellular heterogeneity and the influence of the microenvironment. We investigate how cellular heterogeneity and the microenvironment orchestrate the type I IFN response in plasmacytoid dendritic cells (pDCs). Materials and Methods: We developed a droplet-based microfluidic platform and investigated type I IFN production in human pDCs at single-cell level. Furthermore, our platform warrants functional analysis of live single cells under omission of a microenvironment and we combined this with single cell RNA-seq. Results: For the first time in an unbiased approach, we show here in primary human immune cells that an additional deeper level of functional heterogeneity arises upon stimulation of dendritic cells. We demonstrate that type I IFN production by primary human pDCs is stochastically regulated when stimulated individually with pathogen analogues. Less than 1% of pDCs produced type I IFN despite secretion and expression of other activation markers. Importantly, we determined a crucial role for the microenvironment as a paracrine feedforward loop is able to amplify the type I IFN production leading to the well-described robust type I IFN response that pDCs are so famous for.Conclusions: Our unique technology platform revealed that the inflammatory state of the microenvironment and not the stimulus concentration perceived by pDCs determines the response strength. This has important implications for pDC-focused treatment approaches as the main focus of regulation should be in modifying the type I IFN-based paracrine regulatory system.

WS.A1.01 Myeloid lineage specifications

WS.A1.01.01
Tissue resident mast cells are of dual hematopoietic origin

R. Gentek;
Centre d'Immunologie de Marseille-Luminy (CIML), Marseille, France.

Hematopoiesis occurs in spatio-temporally distinct waves. The aorta-gonado-mesonephros (AGM) gives rise to 'definitive' hematopoietic stem cells (HSC) with the potential for all blood lineages. At earlier stages, hematopoietic progenitors emerging in the yolk sac (YS) generate erythrocytes and megakaryocytes, while YS derived erythro-myeloid progenitors give rise to macrophages (Mac). Whether HSC independent YS progenitors also significantly contribute to other lineages is currently unknown. This is at least partially due to the limitations of current lineage tracing models. Here, we established a novel model that enables fate mapping of both HSC independent YS and definitive hematopoiesis in an efficient and precise, temporally defined fashion (Cdh5-CreERT2 fate mapping). Using this tool, we revealed that embryonic mast cells (MC) initially derive from YS precursors, but get progressively replaced by definitive MC. Replacement of YS derived MC occurs with tissue specific kinetics. YS derived embryonic and definitive adult MC differ substantially phenotypically and transcriptomically. Moreover, adult MC are largely independent from the BM at steady state and during replenishment following depletion. These findings challenge the current dogma that MC originate from the BM. Instead, their developmental kinetics are highly reminiscent of Mac. Our work adds MC to the list of lineages with dual origin. Key questions that have remained unanswered or controversial for other lineages thus also apply to MC, such as the relative influence of ontogeny and (micro)environment and the establishment of immune cell niches. Cdh5-CreERT2 fate mapping represents a powerful tool to address these questions and further dissect hematopoiesis.

WS.A1.01.02
Determining dendritic cell ontogeny across organs by cellular barcoding

***T. Tak**, A. Magniez, L. Perié;*
Institut Curie, Paris, France.

Dendritic cells (DCs) are rare cells that are widely distributed throughout the body. A multitude of functions, origins and cellular markers have been attributed to DCs, resulting in a complicated classification. We aimed to determine the ontogeny of the different DC subsets across different organs in the mouse using cellular barcoding, a technique that simultaneously traces the differentiation of many cells *in vivo*. Murine hematopoietic stem and progenitor cells (HSCs and MPPs) were infected with a lentivirus containing DNA barcodes of 100 random nucleotides. This resulted in uniquely barcoded progenitors whose progeny inherit the barcode. HSCs/MPPs were transferred into sub-lethally irradiated C57BL/6 mice. After 2-6 weeks, DC subsets (pDC, cDC1 and cDC2), B cells and neutrophils were isolated from, bone marrow, spleen liver and lungs. Barcodes were identified by PCR and deep sequencing. Since daughter cells from the same progenitor share the same barcode, cell ontogeny could be analysed using hierarchical clustering. After HSC transplantation, detected barcodes were shared across a wide range of cell types, indicating that a single HSC can produce a wide variety of cells. Samples obtained after transplantation of MPPs showed a large proportion of barcodes being shared between different DC subsets within each organ and between DC subsets in liver and lungs. Only few barcodes were shared between DC subsets from spleen and liver/lungs, however, suggesting a different developmental origin of DC subsets in lungs and liver compared to the spleen.

WS.A1.01.03
Bone marrow-resident dendritic cells play an important role in anti-fungal immunity by boosting granulopoiesis upon recognition of yeast particles

*M. Goedhart, E. Slot, M. F. Pascutti, S. Geerman, T. Rademakers, B. Nota, C. Voermans, **M. A. Nolte**;*
Sanquin, Amsterdam, Netherlands.

Systemic infections with yeast and fungi are major causes of morbidity and mortality following hematopoietic stem cell transplantations and in patients with bone marrow (BM) failure. As BM is enriched for memory T cells specific for fungal antigens, we hypothesize that BM is important for anti-fungal immunity.
Here, we focused on dendritic cells (DCs) in murine BM, which largely belong to the IRF4-regulated subtype that is associated with Th2/Th17 immunity. We found that these cells are localized around sinusoids and rapidly activated upon intravenous endotoxin injection. Gene-expression profiling revealed that BM-resident DCs are, compared to the spleen, highly enriched for several c-type lectins, including Dectin-1, which can bind beta-glucans expressed on fungi and yeast. Indeed, DCs in BM were much more efficient in phagocytosis of both yeast-derived zymosan-particles and conidia of Aspergillus compared to their splenic counterparts, which was highly dependent on Dectin-1. DCs in human BM were also able to efficiently take up zymosan, which depended on β1-integrins. Given their localization inside the body's hematopoietic organ, we examined whether BM-resident DCs can also regulate hematopoiesis. Strikingly, we found that zymosan-stimulated BM-resident DCs enhanced the differentiation of hematopoietic progenitor cells towards neutrophils, while also boosting the maintenance of functional progenitors.
Our findings demonstrate that BM-resident DCs play an important role in anti-fungal immunity. The ability of BM-resident DCs to boost granulopoiesis is highly relevant from a clinical perspective, and contributes to our understanding of the susceptibility for fungal infections under conditions of BM damage.

WS.A1.01.04
Common monocyte progenitors are novel antimycobacterial effector cells

***P. Henneke**, A. Lösslein;*
CCI, Freiburg, Germany.

Mycobacterial tissue infections are characterized by the formation of a multicellular granuloma containing specialized immune cells. Granulomas compromise a unique macrophage species, so called multinucleated giant cells (MGC). In this work we dissected the origin of MGC, which has remained largely exclusive, so far. Accordingly, we isolated different monocyte precursor subsets from murine bone marrow (BM) and found the common monocyte progenitor (cMoP) to have the highest potential to form MGC in response to mycobacterial glycolipids or whole bacteria. Next to the established high proliferative activity, cMoP showed striking effector cell characteristics, e.g. robust formation of TNFα and nitric oxide in response to mycobacterial glycolipids. Furthermore, cMoP showed a distinct differentiation pattern *in vitro*. They rapidly downregulated CD117 expression and upregulated CD11b and F4/80 expression, which is in line with the differentiation into macrophages. However, in contrast to the immunophenotype of differentiated macrophages they maintained high potential to form MGC. Transcriptome analysis revealed an increase in cholesterol and fatty acid metabolism in cMoP, representing a metabolic profile, which allows for the formation of lipid bodies and nucleation of mycobacteria in the cytosol. Fatty acid synthase inhibition impaired MGC formation by cMoP, indicating that the metabolic changes are a prerequisite for the transformation program. We hypothesize that cMoP serve as MGC progenitors in local mycobacterial infections. Together, we herewith provide firm evidence that cMoP, which have been hitherto defined as precursors committed to renew monocytes only, act as specific effector cells in antimycobacterial immunity.

WS.A1.01.05
Identification of the unique functional phenotype of iMATE-defining monocytes that drive hepatic T cell proliferation

***K. Pawelka**[1], P. Knolle[1], M. Heikenwälder[2];*
[1]Institute of Molecular Immunology, Munich, Germany, [2]DKFZ, Heidelberg, Germany.

Intrahepatic myeloid-cell aggregates form in response to Toll-like-receptor 9 (TLR9) signaling in a TNF-dependent fashion to provide a unique anatomic structure that drives local proliferation of cytotoxic CD8 T cells (iMATEs) and confers protection against viral infection. Yet, the identity of the iMATE-defining myeloid cell population remained elusive.
We systematically analyzed the phenotype of myeloid cells in the murine liver after TLR9 activation using a set of different methodologies. Initial flow cytometric phenotypic characterization and tSNE analysis revealed a complex composition of monocytes and newly differentiating macrophages that hinted towards a sequential replacement of liver-resident macrophages followed by repopulation through bone marrow derived inflammatory monocytes. Laser-capture microdissection and genome wide analysis of gene expression identified a set of marker proteins that were validated by flow cytometry and led to the definition of a particular phenotype of monocyte-derived macrophages exclusively found in iMATEs but not elsewhere.
Functional assays of these iMATE-defining monocyte-derived macrophages revealed a high potency in the induction of CD8 T cell proliferation, in the differentiation towards GzmB expression rendering them efficient killer cells and in cross-presenting soluble antigens to CD8 T cells. Liver macrophages, in contrast, failed to provide any support for T cell proliferation and did not show significant cross-presentation capacity.
The transient presence of iMATE-defining monocyte-derived macrophages in the liver indicates that protective hepatic T cell immunity is determined by the dynamics of the changes in inhibitory vs stimulatory macrophage populations, which do not fall into the conventional M1/M2 categories but are related to iMATE formation.

WS.A1.01.06
C/EBPα is crucial in early dendritic cell development

A. Muralikrishnan[1], *A. Rosenberger*[1], *E. Schwarzenberger*[2], *H. Strobl*[2], *A. Zebisch*[1], *H. Sill*[1], *A. Wölfler*[1];
[1]*Division of Hematology, Graz, Austria,* [2]*Institute for Pathophysiology and Immunology, Graz, Austria.*

Background: Dendritic cells (DC) are crucial effector cells of the immune system, which are derived from hematopoietic stem cells via distinct progenitors. Briefly, in presence of FLT3L, myeloid progenitors differentiate to monocyte/DC progenitors (MDP) and subsequently to common DC precursors (CDP), which differentiate into all subsets of mature DC. C/EBPα is a crucial transcription factor in myelopoiesis, however, its role in DC development is not well defined. **Methods/Results:** FLT3L-induced DC formation was studied *in vitro* using bone marrow progenitors (BMP) from inducible BM-specific knockout (ko) mice for C/EBPα. In contrast to wildtype (wt) cells, BMP from ko mice exhibited a profound reduction in numbers of formed DC. Specifically, in ko BMP we observed a reduction in the formation of MDP and a block in their transition to CDP, whereas wt BMP nicely underwent transition towards mature DC. Gene expression analysis revealed a significant change in transcription factors associated with DC development like IRF8, inflammatory cytokines like TNFα and IL1β and several genes related to the NFκB pathway. Interestingly, addition of TNFα and, even better, a combination of TNFα and IL1β to BMP cultured *in vitro* with FLT3L restored formation of functionally mature DC in ko cells. **Conclusions:** C/EBPα plays a critical role in early DC development enabling the formation of MDP and their transition to CDP. Activation of the NFκB pathway as well as induction of IRF8 are likely involved in this C/EBPα-dependent mechanism, since inflammatory cytokines, like TNFα, can overcome this early developmental block observed in BMP lacking *Cebpa*.

WS.A2.01 T cells in aging

WS.A2.01.01
Characherisation of IL 10 producing CD4$^+$ T cells in aged mice

I. M. Ogunsulire[1], *M. Almanan*[2], *D. Hildeman*[2], *C. Hölscher*[1];
[1]*Division of Infection Immunology, Research Centre Borstel, Germany, Sülfeld, Germany,* [2]*Division of Immunobiology, Cincinnati Children's Hospital Medical Centre, USA, Cincinnati, United States.*

One of Mankind's greatest triumphs is prolonged life-expectancy. Conversely, this increase in lifespan is accompanied with its own set of problems. One such problem is a weakened or dysregulated immune state that the leads to an increased susceptibility to infections and diseases in the elderly. A major component of immune dysregulation is chronic inflammation, referred to as "inflammaging", and is characterised by elevated systemic level of interleukin (IL)-6. However, mechanisms controlling inflammaging and its effects on the immune system remain unclear. Recent data show that IL6 promotes the accumulation of FoxP3$^-$ CD4$^+$ T cell which produce a major antiinflammatory cytokine, IL-10. So far, the origin and the type of IL-10-producing cells are yet to be determined. Based on cells described in the literature, we envisioned four potential origins of these IL-10-producing cells, namely exTh17, exTregs, type 1 regulatory (Tr1) cells and T-follicular helper (Tfh) cells. Using IL-17 fate mapping reporter mice, we found that roughly 2% of the IL-10-producing cells were exTh17 cells. Again, using FoxP3 fate mapping reporter mice, roughly 25 % of the IL-10 producing cells were exFoxP3$^+$ cells, although this frequency was similar in young and old mice. Next, we characterised the CD4$^+$ FoxP3$^-$ IL-10$^+$ population and found that some expressed canonical markers of Tr1 cells while others expressed TfH markers, with both of these T cell populations producing the most IL10 with age (over 30% in old mice). Future experiments will determine mechanisms by which IL6 promotes accrual of these cells and their impact on immuneaging.

WS.A2.01.02
Peripheral Antibody titers are affected by highly differentiated, senescent, and exhausted T cells, and pro-inflammatory changes in the human Bone Marrow

E. C. Naismith[1], *L. Pangrazzi*[1], *C. Miggitsch*[1], *M. Grasse*[1], *B. Weinberger*[1], *K. Trieb*[2], *B. Grubeck-Loebenstein*[1];
[1]*Institute for Biomedical Aging research, Innsbruck, Austria,* [2]*Klinikum Wels, Wels, Austria.*

Many antigen-experienced immune cells migrate back to the bone marrow (BM), where they can remain in BM niches for an extended period. In this study, a detailed phenotypical and functional characterization of immune cells isolated from human BM was analyzed to determine if the accumulation of highly-differentiated cells limit the accumulation of other immune cells. CD8$^+$ T cells which no longer express the CD28 co-stimulatory molecule and have acquired the expression of replicative senescence markers CD57 and/or KLRG-1, increase in the BM with age. Exhausted PD-1$^+$ T cells are also seen to increase in the BM with age. Senescent cells secrete pro-inflammatory cytokines inducing low-grade chronic inflammation. Using BM and peripheral blood samples from patients undergoing hip replacement surgery, we show that highly differentiated CD8$^+$ T cells in the BM negatively correlated with B cells, and similar correlations were seen for highly-differentiated, pro-inflammatory cytokine-producing CD8$^+$ T cells. In addition, mRNA expression of IL-15 and IFNγ negatively correlated with B cells in the BM. Peripheral Diphtheria antibody titers negatively correlated with highly-differentiated CD8$^+$CD57$^+$ T cells, and Exhausted Central Memory CD8$^+$ and CD4$^+$ T cells in the BM. Senescent p21 and KLRG-1 expressing CD8$^+$ T cells in the BM and PB, as well as ROS production in the BM, also negatively correlated with the Diphtheria Ab titer. In summary, the accumulation and maintenance of highly-differentiated, senescent, and exhausted cells in the BM may negatively effect the maintenance of other immune cell types, and therefore reduce overall immune function.

WS.A2.01.03
Strong homeostatic TCR signals induce formation of self-tolerant virtual memory CD8 T cells

A. Moudra[1], *A. Drobek*[1], *D. Mueller*[2], *M. Huranova*[1], *V. Horkova*[1], *M. Pribikova*[1], *R. Ivanek*[2,3], *S. Oberle*[4,5], *D. Zehn*[4,6], *K. D. McCoy*[7,8], *P. Draber*[1], *O. Stepanek*[1];
[1]*Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic,* [2]*Department of Biomedicine, University Hospital and University of Basel, Basel, Switzerland,* [3]*Swiss Institute of Bioinformatics, Basel, Switzerland,* [4]*Swiss Vaccine Research Institute, Epalinges, Switzerland,* [5]*Sanofi Genzyme, Baar, Switzerland,* [6]*Division of Animal Physiology and Immunology, School of Life Sciences Weihenstephan, Technical University of Munich, Freising, Germany,* [7]*Department of Clinical Research (DKF), University of Bern, Bern, Switzerland,* [8]*Department of Physiology and Pharmacology, Cumming School of Medicine, University of Calgary, Calgary, Canada.*

Virtual memory T cells are foreign antigen-inexperienced T cells that have acquired memory-like phenotype and constitute 10-20% of all peripheral CD8$^+$ T cells in mice. Their origin, biological roles, and relationship to naïve and foreign antigen-experienced memory T cells are incompletely understood. By analyzing TCR repertoires and using retrogenic monoclonal T-cell populations, we demonstrate that the virtual memory T-cell formation is a so far unappreciated cell fate decision checkpoint. We describe two molecular mechanisms driving the formation of virtual memory T cells.
First, virtual memory T cells originate exclusively from strongly self-reactive T cells. Second, the stoichiometry of the CD8 interaction with Lck regulates the size of the virtual memory T-cell compartment via modulating the self-reactivity of individual T-cells. Although virtual memory T cells descend from the highly self-reactive clones and acquire a partial memory program, they are not more potent in inducing experimental autoimmune diabetes than naïve T cells. These data underline the importance of the variable level of self-reactivity in polyclonal T cells for the generation of functional T-cell diversity.

WS.A2.01.04
Extreme memory inflation of HLACw0702 restricted CMV specific CD8+ T cells that dominate the CD8+ T cell repertoire during healthy ageing

L. Hosie[1], *A. Pachnio*[1], *J. Zuo*[1], *H. Pearce*[1], *S. Riddell*[2], *P. Moss*[1];
[1]*Institute of Immunology and Immunotherapy, Birmingham, United Kingdom,* [2]*Fred Hutchinson Cancer Research Center, Seattle, United States.*

Introduction Cytomegalovirus (CMV) elicits a strong T-cell immune response which increases during aging in a process termed 'memory-inflation'. CMV downregulates HLA-A/-B molecules on the surface of CMV-infected cells to limit presentation of viral peptides to T-cells. Comparatively, HLA-C is relatively spared and engages with inhibitory KIR receptors to reduce lysis by NK cells. **Methods** The magnitude and functional properties of CMV-specific CD8+T-cells specific for HLA-C-restricted peptides were investigated in a cohort of 53 donors aged 23-91 years. This was achieved via peptide stimulation of PBMCs followed by multi-colour flow cytometry. **Results** Three HLA-Cw*0702-restricted peptides, derived from immediate-early expressed proteins, elicited strong immune responses which increased substantially with age such that the average aggregate response represented 37% of the CD8+T-cell pool within donors >70 years of age. This aggregate reached 70.3% TNF-α$^+$ and remarkably, a single IFN-γ$^+$ response represented 70% of the total CD8+T-cells of a 91-year old donor at the most extreme. HLA-Cw*0702-restricted CD8+T-cell responses did not show features of exhaustion such as CD39 expression. Indeed they exhibited a polyfunctional Th1 cytokine profile and cytotoxic phenotype expressing high levels of dual perforin$^+$granzymeB$^+$ that became exaggerated with age. Functionally, HLA-Cw*0702-restricted PBMCs showed exceptionally high avidity for cognate peptide-HLA demonstrating early and efficient recognition of CMV-infected cells. **Conclusions** These observations indicate that HLA-C-restricted CD8+T-cells C play an important role in the control of latent CMV infection representing a novel opportunity for CD8+T-cell therapy of CMV reactivation within immunosuppressed patients. The efficacy of such a therapy is currently being investigated via TCR transgenics.

WS.A2.01.05

Age-Related Decline in Primary CD8$^+$ T Cell Responses is Associated with the Development of Senescence in a Subset of Antigenically Naive CD8$^+$ T Cells

N. L. La Gruta[1], *K. M. Quinn*[1], *A. Fox*[2], *K. L. Harland*[2], *B. E. Russ*[3], *J. Li*[3], *T. H. Nguyen*[2], *L. Loh*[2], *M. Olshansky*[3], *H. Naeem*[4], *K. Tsyganov*[4], *F. Wiede*[1], *R. Webster*[1], *C. Blyth*[1], *X. Y. Sng*[1], *T. Tiganis*[1], *D. Powell*[4], *P. C. Doherty*[2], *S. J. Turner*[3], *K. Kedzierska*[2];
[1]*Monash Biomedicine Discovery Institute and Department of Biochemistry and Molecular Biology, Monash University, Clayton, Australia,* [2]*The Doherty Institute for Infection and Immunity and Department of Microbiology and Immunology, University of Melbourne, Melbourne, Australia,* [3]*Monash Biomedicine Discovery Institute and Department of Microbiology, Monash University, Clayton, Australia,* [4]*Bioinformatics Platform, Monash University, Clayton, Australia.*

Ageing undermines primary CD8 T cell responses and this occurs, in part, due to direct effects on naïve CD8 T cells to reduce intrinsic functionality, but the precise nature of any intrinsic defect and its molecular basis remains to be defined. Ageing also causes accumulation of antigen-naïve but semi-differentiated "virtual memory" (T_{VM}) cells, recently identified in humans, but their contribution to age-related functional decline is unclear. Here, we show that T_{VM} cells become nearly completely non-proliferative in aged mice and humans, despite being highly proliferative in young individuals. In contrast, conventional naïve T cells (T_N cells) retain almost complete proliferative capacity in both aged mice and humans. Adoptive transfer experiments in mice illustrated that the proliferative dysfunction acquired by T_{VM} cells was imposed by the aged environment and could not be rescued by maintenance in a young environment. Despite previous studies to the contrary, transcriptional analyses did not implicate exhaustion in aged T_{VM} cell dysfunction. Rather, these cells exhibited a profile consistent with senescence, with increased Bcl-2 expression and phosphorylation of γ-H2AX in steady state, along with increased *Cdkn1a* (p21) expression and defective cyclin D1 accumulation after TCR stimulation. Collectively, this study marks the first description of senescence in an antigenically naïve T cell population, and highlights markedly different impacts of ageing on distinct T cell populations. Consequently, this work has implications for the targeting of distinct T cell populations in current immunotherapies.

WS.A2.01.06

Influence of aging on calcium signals and cytotoxicity in murine CD8$^+$ T cells

A. Angenendt[1], *R. Steiner*[1], *A. Knörck*[1], *G. Schwär*[1], *E. Krause*[2], *A. Lis*[1];
[1]*Biophysics, CIPMM, Saarland University, Homburg, Germany,* [2]*Physiology, CIPMM, Saarland University, Homburg, Germany.*

Cytotoxic T lymphocytes (CTLs) are key players in the adaptive immune response and several steps of the CTL killing machinery require or are modulated by Ca^{2+} itself. The major route of Ca^{2+} influx in lymphocytes is through store-operated calcium entry (SOCE). CTL function is altered *in vivo* and *in vitro* in elderly compared to adult individuals and the immune response is compromised with progressing age. To investigate, whether reduced expressions of SOCE components, stromal interaction molecule (STIM) and Orai, contribute to Ca^{2+} signal reductions in CD8$^+$ T cells from elderly mice, we performed flow cytometry, electrophysiology and molecular biology experiments with murine CD8$^+$ T cells from an adult and an elderly age group. Furthermore, we compared their killing kinetic and efficiency using a time-resolved killing assay, investigated the Ca^{2+}-dependency of the process, and quantified the expression of relevant proteins involved in cytotoxicity. We were able to link the reduced Ca^{2+} signals and Ca^{2+} release-activated Ca^{2+} currents of CD8$^+$ T cells from elderly mice to a decrease in mRNA and protein levels of STIMs and Orais. Moreover, the reduced Ca^{2+} signals of stimulated CD8$^+$ T cells from elderly mice are not due to differences in subtype distribution between both age groups, but rather in the most abundant CD8$^+$ T cell subtypes, central and effector memory. Strikingly, we found that CD8$^+$ T cells from elderly mice show an altered expression pattern of relevant proteins involved in killing machinery correlating with improved cytotoxicity but minor Ca^{2+}-dependency.

Dynamic transcriptome-proteome correlation networks contribute to human myeloid differentiation and neutrophil development

A. J. Hoogendijk[1], *M. van den Biggelaar*[1], *F. Pourfarzad*[2], *C. Aarts*[2], *A. Tool*[2], *I. Hiemstra*[2], *F. van Alphen*[1], *C. van der Zwaan*[1], *T. K. van den Berg*[2], *L. Grassi*[3], *M. Frontini*[3], *W. H. Ouwehand*[3], *A. B. Meijer*[1], *T. W. Kuijpers*[2];
[1]*Department of Plasma Proteins, Sanquin Research, Amsterdam, Netherlands,* [2]*Department of Blood Cell Research, Sanquin Research, Amsterdam, Netherlands,* [3]*Department of Haematology, University of Cambridge, Cambridge, United Kingdom.*

Neutrophils are the most abundant leukocytes in human blood and form the frontline of the innate host-response to bacterial and fungal infections. To fulfill this role, they exert a wide array of pathogen eliminating actions. During neutrophil development, transcriptional programs and protein production are induced to enable these actions.
Using mass spectrometry-based quantitative proteomics combined with previously obtained transcriptomics data, we unraveled the dynamic transcriptome and proteome changes that accompany the metamorphosis from four developmental stages in the bone marrow into a mature distinct non-dividing polymorphonuclear blood cell.
We identified 2429 transcript-protein pairs that were differentially expressed on either RNA, protein or on both levels, which were used to assemble a co-expression network comprising of 12 modules. These included transcript-protein dynamics following the classical dogma of protein levels lagging behind changes in RNA expression. In contrast, we also observed modules with discordant dynamics, e.g. increased RNA expression at the final stages of differentiation, with no changes in protein level. Importantly, the transcript-protein dynamics of most modules could directly be linked to functional aspects of neutrophil development and mature neutrophil functions; such as: modules containing decreased mitochondrial process, increased immune response signatures; or modules exhibiting high association with specific neutrophil granules.
Therefore, this comparison of proteome with transcriptomic data unveiled highly dynamic and differential interactions between RNA and protein kinetics during human neutrophil development linked to functional aspects of myeloid development and the typical end-stage blood neutrophil features including morphology and killing activities.

WS.A2.02.02

CircRNA expression is a highly regulated process during hematopoiesis and lymphocyte differentiation

B. P. Nicolet, *S. Engels, F. Aglialoro, E. van den Akker, M. von der Lindern, M. C. Wolkers;*
Sanquin Research, Amsterdam, Netherlands.

Lymphocyte differentiation during hematopoiesis is dependent on micro-RNAs and long-non-coding RNAs that - in addition to transcription factors - drive the cellular differentiation. Circular RNA (circRNA), another recently identified type of RNA, was also shown to determine vital cellular functions in many cell types. Whether and how circRNAs regulate immune cells is not yet described. Here we investigated the circRNA expression in the hematopoietic tree. Clustering based on circRNA expression recapitulated the differentiation stages in hematopoiesis. Furthermore, correlating the circular with the linear RNA expression revealed that circRNA usage is differently regulated during hematopoiesis. Interestingly, circRNA expression is significantly higher in lymphocytes than in other hematopoietic cells. Analysis of circRNA expression in naïve and memory CD4+ and CD8+ T cells revealed higher circRNA expression in naïve than in memory T cells. Further, we found that CD4+ and CD8+ maturation is marked by 100's of differentially expressed circRNA. We show here for the first time that circRNAs are differentially expressed during hematopoiesis and T cell differentiation, which points to a novel regulatory layer in lymphocyte differentiation.

WS.A2.02.03

IL-2-vs. IL-15-dependent intrathymic development of regulatory T lymphocytes

C. APERT[1], *N. McJannett*[1,2], *P. Romagnoli*[1], *J. van Meerwijk*[1];
[1]*INSERM UMR1043 Centre de Physiopathologie Toulouse Purpan, TOULOUSE, France,* [2]*Keele University, Staffordshire, United Kingdom.*

Natural regulatory T cells (nTreg) develop in the thymus and are defined by their expression of the master regulator transcription factor Foxp3 as well as by their high self-reactivity, which enables them to prevent autoimmune diseases. Peripheral nTreg are heterogeneous. The distinct Treg-subsets display different degrees of self-reactivity, express different transcription factors and chemokine-receptors, and inhibit peripheral immune-responses using distinct effector mechanisms. Among the various signals controlling Treg development in the thymus, the γ_c-cytokines IL-2 and IL-15 apparently play an important role in the survival of these cells. We investigate the roles of these two cytokines in the development of distinct nTreg subsets. By using IL-2- and IL-15-deficient mice harboring a Rag2-GFP transgene that allows discrimination between developing Tregs from peripheral mature cells that had recirculated to the thymus, we confirmed that these two cytokines play quantitatively important and non-redundant roles in the development of Tregs: Treg development is decreased in absence of one or the other cytokine and virtually abolished in absence of both. Single cell RNAseq and multicolor cytometry analysis revealed that these cytokines also have a qualitative effect on Tregs favoring development of in part distinct Treg-subsets. Currently we are assessing the TCR repertoires and immunosuppressive function of Tregs that develop in absence of either of the two cytokines. A better understanding of Treg-development will be of a great importance for targeting these cells in various diseases where they play a beneficial or deleterious role.

WS.A2.02.04

Recent thymic emigrants in neonates and adults share an antimicrobial molecular signature

M. L. Pekalski[1], *A. Rubio Garcia*[1], *A. Paterou*[1], *R. C. Ferreira*[1], *D. B. Rainbow*[1], *A. J. Cutler*[1], *J. L. Jones*[2], *J. A. Todd*[1], *L. S. Wicker*[1];
[1]*Wellcome Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [2]*Cambridge Neuroscience, University of Cambridge, Cambridge, United Kingdom.*

The neonatal immune system has to balance tolerance to commensal antigens and yet be able at this critical time to fight pathogenic infections. Importantly, owing to the large and active thymus at birth as opposed to adults, neonatal naive T compartment consist mostly of recent thymic emigrants (RTEs). However the role that recent thymic emigrants have in the early life period is still relatively unexplored. We studied 20 adult donors to achieve 80% power to detect 2-fold differences in gene expression between highly-purified naïve T cell subsets of different cellular age within each donor i.e. the youngest T cells were RTEs and the oldest were naïve T cells that have spent decades outside the thymus.
A unique gene-expression signature in RTEs was confirmed by FACS protein investigation of 389 donors *ex vivo* and in functional studies including RNA-seq and FACS analysis of activated RTEs from the blood of babies, children and adults. We also studied RTEs arising directly from the thymus post lympho-depletion. We showed that complement receptors CR1 and CR2, which are known to bind complement C3b- and C3d-decorated microbial products, are hallmarks of RTEs. These most naïve T cells also express transcripts encoding the LPS-degrading enzyme, AOAH, and TLR1. Following activation RTEs in babies and adults produce IL-8 (CXCL8), a major chemoattractant for neutrophils in bacterial defense.
In conclusion, although RTEs underpin the adaptive arm of the immune system, these cells have innate, anti-bacterial functions that could help orchestrate the balance between neonatal tolerance and microbial defence.

Characterising the maturation of T cell polarisation in preterm and term infants and in the neonatal chronic lung disease bronchopulmonary dysplasia

J. C. Lao[1], *M. A. Pang*[1], *A. Malhotra*[2], *K. Tan*[2], *F. Beker*[3], *K. Konig*[3], *C. Collins*[3], *C. Theda*[4], *O. Kamlin*[4], *P. J. Berger*[5], *A. Veldman*[1], *C. A. Nold-Petry*[5], ***M. F. Nold***[1,6,2];
[1]*Monash University, Clayton, Australia,* [2]*Monash Newborn, Clayton, Australia,* [3]*Mercy Hospital, Heidelberg, Australia,* [4]*Royal Women's Hospital, Parkville, Australia,* [5]*Hudson Institute, Clayton, Australia,* [6]*Hudson Institute, Melbourne, Australia.*

Background: Bronchopulmonary dysplasia (BPD) is a common neonatal lung disease that is underpinned by pulmonary inflammation. Despite extensive research, a dominant immune pathway that drives BPD remains elusive.
Methods: Cord and peripheral blood was collected from: i) infants born at 24-29 gestational weeks at birth, on days 1, 7 and 14, and at 36 weeks gestational age; ii) healthy term infants at birth and at 4-16 weeks of age; iii) healthy adults. Following overnight stimulation with PMA+ionomycin or vehicle, the Th1/2/17 and regulatory T cell (Treg) subsets were enumerated by flow cytometry. Results were analysed against BPD status and clinical events such as respiratory support, sepsis and medication.
Results: 51 preterm infants, 20 term infants and 5 adults were enrolled, and 258 unique samples collected. Th2 polarisation predominated in preterm and term infants up to 16 weeks of age, with up to 62% of CD4+ T cells Th2-polarised vs 2% in adults. Baseline Th1 and Th17-polarisation was low in all groups; inducibility of Th1 and Th17-polarisation developed at 16 weeks of age. The percentage of Treg was 5-fold higher in infants than in adults. The 36 preterm infants who suffered from BPD exhibited up to 36-fold increased frequencies of Th2-polarised T cells at most timepoints.
Conclusions: Our study sheds light on the maturation of the immune system in preterm and term infants. The severe chronic lung disease BPD is associated with strong Th2 polarisation, suggesting that therapies targeting the Th2 pathway may offer benefit to the tiny BPD patients.

WS.A2.02.06

CD4$^+$ T cells from human neonates and infants respond extensive against antigens of *Candida albicans* and *Aspergillus fumigatus*

K. Vogel[1], *M. Pierau*[1], *A. Arra*[1], *K. Lampe*[2], *D. Schlueter*[3,4], *C. Arens*[2], *M. C. Brunner-Weinzierl*[1];
[1]*Department of Experimental Pediatrics, Magdeburg, Germany,* [2]*Department of Otorhinolaryngology, Head and Neck Surgery, Magdeburg, Germany,* [3]*Institute of Medical Microbiology and Hygiene, Magdeburg, Germany,* [4]*Organ-specific Immune Regulation, Helmholtz Centre for Infection Research, Braunschweig, Germany.*

Fungi are widespread in nature and often colonize human body surfaces. Rarely, an invasive pathology is initiated, but the figure is on the rise. Besides immune suppressed individuals, especially neonates are most susceptible to fungus pathology. Therefore, a better understanding of antifungal responses especially in neonates and infants is essential. Here, we show that antifungal CD4 T-cell responses are initiated from birth on to monocyte-derived antigen presenting cells pulsed with *Candida albicans* or *Aspergillus fumigatus* lysates and fungal peptide pools, respectively. We found that, the neonatal responding T-cell pool constitute 20 out of 24 different TCR-V_β families whereas infant and adult pools display significantly less TCR-V_β-variability. In comparison to adults, naïve T cells from neonates and infants proliferated at a 4-5 times higher frequency in response to *C. albicans*, which was also corroborated by an immediate co-expression of multiple cytokines. Frequencies of unglycosylated IL-4 producers were similarly high at any age in response to *A. fumigatus*, implicating the activation of Th2-machinery, not biased due to developmental age differences. Frequencies of IL-17 producers were about 3 times higher among neonates compared to adults. Notable, only T cells from neonates and infants could co-express transcription factors T-bet and RORγt and eventually co-express their target genes IL-17 and IFNγ, implicating a high plasticity of T cell responses in early life. These observations clearly confirm the age-dependent characteristics of antifungal T-cell responses. In this way, our findings will contribute to optimizing antifungal therapies that were previously limited to antimycotics with severe side effects.

WS.A2.03 Immune cell aging and differentiation

WS.A2.03.01

Identification of age-related immune signatures by mass cytometry

J. Braun, *S. Schlickeiser, A. Andrzejewska, F. Papatzika, B. Kruse, S. Geissler, A. Arampatzis, A. Thiel;
Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany.*

Human biological aging is associated with functional physiological deteriorations and increasing systemic inflammation and many cellular, immunological alterations have been reported. Due to technical limitations, these reports focused mostly on specific cell populations, e.g. only T cells were assessed. However, for a systematic understanding of age-related immune signatures, all different cell subsets should be evaluated and associated with medical and functional physiological parameters. Therefore, we have performed an integrated study combining mass cytometry, multiplex ELISA and biomechanic measurements to characterize cohorts of healthy young, healthy elderly and frail elderly participants. Fresh PBMCs were analyzed by mass cytometry (37 antibodies). We applied an analysis pipeline for Automated Comprehensive Immunophenotying and Subset Enumeration (ACISE). Here, cell populations are identified by over-clustering using SPADE, followed by characterization based on user-defined cutoffs for marker positivity, and annotation according to user-specified target phenotype definitions as well as subset hierarchies (similar to conventional gating analysis). We identified not only already reported fluctuations in CD8 TEMRA, CD4 recent thymic emigrants, or non-classical monocytes, but also changes in regulatory T cells, NK cells and B cells. Some changes were exclusively and significantly observed within frail participants. Our study may represent the first comprehensive mass cytometric analysis of immune signatures including clearly separated cohorts of frail and healthy elderly. Furthermore, the applied ACISE analysis pipeline is a helpful tool for the analysis of multi-dimensional single cell data, as it allows semi-automated categorization of cell subsets into parental immune cell subsets and calculation of subset frequencies accordingly.

WS.A2.03.02

Aging affects the frequency, functions and antibody repertoire of human B-1 cells

A. M. Hernández-Vázquez[1], *N. Rodríguez-Zhurbenko*[1], *T. Quach*[2], *T. J. Jopkings*[2], *T. L. Rothstein*[3];
[1]*Center for Molecular Immunology, Havana, Cuba,* [2]*Feinstein Institute for Medical Research, New York, United States,* [3]*Center for Immunobiology of the Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, United States.*

Introduction: Aging decreases the efficiency of several immune functions, which has been associated with an increased incidence of infections, autoimmune diseases and cancer. Human naïve and memory B cells suffer significant quantitative and qualitative changes in the elderly. However, human B-1 cells, which play critical housekeeping and anti-microbial defensive roles, have not been studied. In the present work we analyzed how the frequency and function of human B-1 cells (CD20+CD27+CD43+CD38low) change with age.
Materials and Methods: The frequency of human B-1 cells was studied by flow cytometry. The capacity of these cells to produce IgM was detected by ELISPOT and their repertoire and genes related with Ig secretion were studied by single cell PCR.
Results: Our results show that the percentage of B-1 cells, but also their capacity to spontaneously secrete IgM decrease with age. Expression levels of Xbp1 and Blimp1, associated with Ab secreting phenotype, were significantly lower in elderly donors, while Pax5, characteristic of non-secreting B cells, was significantly higher. Furthermore, elderly donors showed a reduction of the antibody repertoire variability in comparison with young individuals. It was interesting to observe differences in the usage of certain VH and DH families among young and elderly individuals. We also proved that B-1 cells are involved in the secretion of antibodies against NeuGcGM3 ganglioside, a tumor associated antigen, and this specificity also decreases with age.
Conclusions: These results show changes in the frequency and function of human B-1 cells with aging, which could affect their protective and homeostatic functions.

WS.A2.03.03

T cell immunity does not age in a long-lived rodent species

M. Izraelson[1], *T. Nakonechnaya*[1,2,3], *A. Davydov*[4], *M. Dronina*[5], *D. Miskevich*[5], *I. Mamedov*[1], *L. Barbashova*[2], *M. Shugay*[1,3,6], *D. Bolotin*[1], *D. Staroverov*[1], *E. Kondratyuk*[7], *S. Lukyanov*[3], *I. Shams*[5], *O. Britanova*[1], *D. Chudakov*[1,6,4];

The T cell receptor (TCR) diversity of naïve T lymphocytes represents a precious collection of keys from which antigen-specific variants are selected, conferring protection for the host against new challenges. Here we analyzed peripheral TCR repertoires from humans, mice, and blind mole-rats (*Spalax spp.*)—long-lived, cancer-resistant rodents. We report that *Spalax* T cell diversity remains stable even for animals that reach extreme old age (15-17 years), in striking contrast to mice and humans, for whom immunosenescence is associated with the accumulation of large numbers of memory clones. This discovery reveals a distinctive strategy for T cell immunity organization that potentially underlies the extraordinary longevity of *Spalax*, and encourages a careful re-examination of the contribution of immunosenescence to life span in mammals.The work was supported by the Russian Science Foundation project № 16-15-00149 (to BOV). Mice samples preparation was supported by grant of the Ministry of Education and Science of the Russian Federation.

WS.A2.03.04

Antigen-specific immunity is inhibited in the skin of older people by p38 MAPK-driven inflammatory monocytes

E. S. Chambers[1], *M. Vukmanovic-Stejic*[1], *H. Trahair*[1], *A. Appios*[1], *V. Birault*[2], *M. Noursadeghi*[1], *N. Mabbott*[3], *M. Rustin*[4], *A. Akbar*[1];
[1]*University College London, London, United Kingdom,* [2]*The Francis Crick Institute, London, United Kingdom,* [3]*The Roslin Institute and Royal (Dick) School of Veterinary Studies, University of Edinburgh,, Edinburgh, United Kingdom,* [4]*Royal Free Hospital, London, United Kingdom.*

Decline in immunity with age is often associated with an increase in low grade chronic inflammation, termed 'inflammageing'. We have shown that there is a large proinflammatory response to a saline injection in the skin of older (>65 years) people which is not observed in the young (<40 years). Bioinformatic and immunohistochemical analysis demonstrated that the inflammatory saline response is driven by recruitment of inflammatory monocytes (CD14+CCR2+) and a p38-MAPK inflammatory gene signature. Importantly this inflammatory response to saline is negatively correlated with an antigen specific response in the skin to VZV.
In this study we investigated if pre-treatment with a small molecular oral inhibitor for p38-MAPK, Losmapimod, would improve response to VZV challenge and decrease the inflammatory response to saline in older individuals. Losmapimod reduced systemic inflammation (CRP serum levels) and significantly enhanced cutaneous responses to VZV antigen challenge in the same individuals ($p < 0.0006$). The increase in VZV clinical score post-Losmapimod treatment correlated with an increase in the number of T cells (CD4+ and CD8+) in the skin. In those individuals with increased T cell infiltrate, there was reduced inflammatory monocyte infiltration at 6 hours.
To conclude this data proposes that inflammatory monocytes significantly inhibit antigen-specific immunity in the skin of older people. Additionally, pre-treatment with the systemic p38-MAPK inhibitor Losmapimod inhibits inflammatory monocyte infiltration and restores antigen-specific immunity.

WS.A2.03.05

Screen of epigenetic inhibitors reveals two novel T helper 17 (Th17) cell regulators: BRPF1 and BRPF2

L. Chen[1], *N. Zaarour*[1], *T. Sekine*[1], *M. Sundstrom*[2], *M. Feldmann*[3], *A. Cribbs*[1], *F. McCann*[4], *P. Bowness*[1];
[1]*Botnar Research Centre, Oxford, United Kingdom,* [2]*SGC Karolinska, Solna, Sweden,* [3]*The Kennedy Institute of Rheumatology, University of Oxford, United Kingdom,* [4]*The Kennedy Institute of Rheumatology, Oxford, United Kingdom.*

Introduction: T helper 17 (Th17) lymphocytes, defined by the production of interleukin (IL)-17A, have been implicated in the pathogenesis of several common inflammatory arthritides including rheumatoid arthritis, psoriatic arthritis (PsA) and ankylosing spondylitis (AS), with anti-IL-17A antibodies effective in treating patients with PsA and AS. Oral inhibitors for such responses are however still lacking. Through the unbiased screen of epigenetic inhibitors using CD4+ T cells from AS patients, we aim to reveal novel mechanisms of epigenetic regulation in Th17 cells and identify potential therapeutic targets for Th17 pathogenicity.
Methods: A Th17 differentiation/expansion assay using CD4+ T cells from patients with AS was used to screen a library of epigenetic inhibitors. Th17% and IL-17A cytokine production were measured using flow cytometry and ELISA respectively. siRNA gene knockdown was used for target validation, RNA-seq and qPCR were used to investigate downstream pathways.
Results: The Th17 assay screen identified a novel Th17 inhibitor, OF-1. Among the targets of OF-1, BRPF1 and BRPF2, but not BRPF3, were required for Th17 responses. Knockdown of BRPF1 indirectly suppressed Th17 response through promoting the expression of Th17 negative regulators: EGR2, DUSP2 and IL-2. In contrast, BRPF2 silencing directly reduced the expression of Th17-associated genes, including RORC and IL23R.
Conclusions: We have identified OF-1, a BRPF1-3 inhibitor, as a potent and selective epigenetic suppressor for Th17 cells. BRPF1 and BRPF2 regulate Th17 response through distinct mechanisms.

WS.A2.03.06

Differentiation of human Langerhans cells from monocytes and their specific function in inducing IL-22-specific T helper cells

Y. Otsuka[1,2], *E. Watanabe*[1], *E. Shinya*[1], *H. Saeki*[2], *T. B. Geijtenbeek*[3], *H. Takahashi*[1];
[1]*Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan,* [2]*Department of Dermatology, Nippon Medical School, Tokyo, Japan,* [3]*Department of Experimental Immunology, Amsterdam Infection & Immunity Institute, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

Human mucosal tissues and skin contain two distinct types of dendritic cell (DC) subsets, epidermal Langerhans cells (LCs) and dermal DCs, which can be distinguished by the expression of C-type lectin receptors Langerin and DC-SIGN, respectively. Although peripheral blood monocytes differentiate into these distinct subsets, monocyte-derived LCs induced by co-cultured with GM-CSF, IL-4 and TGF-β1 (moLCs) co-express both Langerin and DC-SIGN, suggesting that the environmental cues remain unclear. Here we show that LC differentiation is TGF-β1-dependent and that co-factors such as IL-4 and TNF-α promote TGF-β1-dependent LC differentiation into Langerin$^+$DC-SIGN$^-$ moLCs but continuous exposure to IL-4 blocks differentiation. Steroids such as Dexamethasone (Dex) greatly enhanced TNF-α-induced moLC differentiation and blocked DC-SIGN expression. Strikingly, CD1a triggering with squalene on moLCs but not moDCs induced strong IL-22-producing CD4$^+$ helper T cell responses. As IL-22 is an important cytokine in the maintenance of skin homeostasis, these data suggest that CD1a on moLCs is involved in maintaining the immune barrier in skin.

WS.A2.04 Evolution of immune responses in health and disease

WS.A2.04.01

Hematopoietic progenitors from old humans are metabolically active but present evidence of cellular senescence and pyroptosis

T. Fali[1], *V. Fabre Mersseman*[1], *T. Yamamoto*[2], *J. Boddaert*[1,3], *D. Sauce*[1], ***V. Appay***[1,4];
[1]*INSERM CIMI, Paris, France,* [2]*National Institutes of Biomedical Innovation, Osaka, Japan,* [3]*AP-HP, Service de Gériatrie, Paris, France,* [4]*Kumamoto University, IRCMS, Kumamoto, Japan.*

The maintenance of effective immunity over time is dependent on the capacity of hematopoietic stem cells (HSC) to sustain the pool of immunocompetent mature cells. Decline of immune competence with old age may stem from HSC defects, including reduced self-renewal potential and impaired lymphopoiesis, as suggested in murine models. To get further insights into aging related alteration of hematopoiesis, we performed a comprehensive study, including phenotypic, transcriptomic and functional assessments, of blood hematopoietic progenitor cells (HPC) from elderly humans (i.e. >75 years old). In the elderly, HPC present active oxidative phosphorylation and are pressed to enter cell cycling. However, p53-p21 and p15 cell senescence pathways, associated with telomerase activity deficiency, strong telomere attrition and oxidative stress, are engaged, thus limiting cell cycling. Moreover, survival of old HPC is impacted by pyroptosis, an inflammatory form of programmed cell death. Last, telomerase activity deficiency and telomere length attrition of old HPC may be passed on progeny cells such as naïve T lymphocytes, highlighting further the poor lymphopoietic potential and capacity to induce T-cell responses of the elderly. This pre-senescent profile is characteristic of the multiple intrinsic and extrinsic factors affecting HPC in old individuals and represents a major obstacle in terms of immune reconstitution and efficacy with advanced age.

WS.A2.04.02

IMMUNOBIOGRAM a new immunological tool to personalize immunosuppressive therapy in kidney transplant recipients

M. Di Scala[1], *J. Portolés*[2], *C. Jiménez*[3], *D. Janeiro*[2], *E. González*[3], *B. Sánchez Sobrino*[2], *M. López Oliva*[3], *J. Richter*[1], *A. Ortega*[1], *J. Pascual*[4], *I. Portero*[1];
[1]*BIOHOPE Scientific SL, Madrid, Spain,* [2]*Hospital Universitario Puerta de Hierro, Nephrology Department, Madrid, Spain,* [3]*Hospital La Paz, Nephrology Department, Madrid, Spain,* [4]*Hospital del Mar, Nephrology Department and Kidney Transplantation, Barcelona, Spain.*

INTRODUCTION: Transplant rejection is one of the biggest limitations in kidney transplantation(KT). It remains essential to control the immune-mediated tissue-specific destruction using immunosuppressive drugs (IMSs) that limit immune system hyperactivation and prevent the allograft loss.
IMSs regimens are stablished based on standard clinical guidelines and empirically.

BIOHOPE is developing a blood-based Precision Medicine test for KT. It offers a personalized comparative evaluation of patient sensitivity to a panel of IMSs most commonly used. This functional pharmacodynamic and monitoring kit is named Immunobiogram (IMBG), an immunoassay based on the concept of the antibiogram.
METHODS: IMBG is a 3D-cell culture of PBMCs included in a hydrogel capable of spontaneous generation of IMSs concentration-gradient due to a passive-diffusion process. An indicator of cell-proliferation/viability reveals the capacity of IMSs-gradient to inhibit the activation cells state.
RESULTS: IMBG was evaluated in BH-pilot study performed in two major Hospitals in Spain. It included 70 patients belonging to three immunological risk-categories (low-risk, standard, high-risk patients).
The resulting profiles were used to ascertain the sensitivity of each patient to each IMSs and to establish a panel of IMSs recommendation for the clinical management. Significantly associated low-sensitivity patterns have been observed in patients who present worse clinical evolution.
CONCLUSIONS: IMBG provides an automatized method to quantitatively measure the response of a patient to IMSs that will aid clinicians in the determination of the optimal combination/posology of IMSs/immune-modulator drugs and opens the possibility to make the necessary adjustments in immunosuppressive therapy to avoid chronic rejection and reduce side-effects of IMSs.

WS.A2.04.03
Particular neutrophils mediate environment-driven onset of airway allergy through NETs release

C. Radermecker[1]*, C. Sabatel*[1]*, S. Johnston*[2]*, M. Toussaint*[1]*, F. Bureau*[1]*, T. Marichal*[1]*;*
[1]*GIGA-R, Cellular and Molecular Immunology, Sart-Tilman, Belgium,* [2]*Imperial College, London, United Kingdom.*

Environmental changes are responsible for the dramatic rise in the prevalence of allergic asthma worldwide. Decreased exposure to microbial products such as lipopolysaccharide (LPS) and respiratory viral infections represent two major risk factors for asthma, yet the mechanisms linking such conditions and host allergic susceptibility remain unclear. First, we developed two mouse models, a virus-induced asthma model and a model of asthma promoted by exposition to low LPS doses. In these models, only previously infected mice or mice exposed to low LPS doses displayed the characteristics of asthma following sensitization and challenge to house dust mite (HDM). Then, using single-cell RNA sequencing, we found that pro-allergic environments (low LPS doses and respiratory virus) induced the recruitment into the lungs of $CXCR4^{hi}CD49d^{high}LAMP\text{-}1^{high}$ neutrophils releasing neutrophil extracellular traps (NETs). The role of NETs in asthma onset was then demonstrated using three NETosis inhibitors in our two models. Infected or low LPS doses exposed mice exhibited strong decrease of all asthma features when treated with NETs inhibitors compared to non-treated mice. Finally, to address how NETs promote the development of a Th2 immune response, we analysed by flow cytometry the distinct subpopulations of lung dendritic cells (DCs) in our models. We observed, during the NETs release phase, a recruitment of monocytic-derived DCs responsible for allergic sensitization. This recruitment was abrogated when NETS were inhibited. In conclusion, our study reveals how apparently unrelated environmental risk factors commonly shape immune responses, by recruiting particular neutrophils which release NETs, to promote asthma.

WS.A2.04.04
Alpha-Gal bound to lipids, but not to proteins, is able to cross the intestinal epithelium and might thus cause delayed allergic symptoms in meat allergic patients

P. Román-Carrasco[1]*, B. Lieder*[2]*, V. Somoza*[2]*, M. Ponce*[3]*, Z. Szépfalusi*[3]*, D. Martín*[4]*, W. Hemmer*[5]*, I. Swoboda*[1]*;*
[1]*Molecular Biotechnology Section, University of Applied Sciences, Vienna, Austria,* [2]*Department of Physiological Chemistry, Faculty of Chemistry, University of Vienna, Vienna, Austria,* [3]*Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, Austria,* [4]*Departamento de Producción y Caracterización de Nuevos Alimentos. Instituto de Investigación en Ciencias de la Alimentación (CIAL), Madrid, Spain,* [5]*FAZ-Floridsdorf Allergy Center, Vienna, Austria.*

The oligosaccharide galactose-α-1,3-galactose (α-Gal), present on mammalian proteins and lipids, causes an unusual delayed allergic reaction 3 to 6 hours after ingestion of mammalian meat, in individuals with IgE antibodies against α-Gal. To better understand the delayed onset of allergic symptoms and investigate whether protein-bound or lipid-bound α-Gal is responsible for them, we analyzed the capacity of α-Gal conjugated proteins and lipids to cross the intestinal epithelium. For this, extracts of proteins and lipids from cooked beef were prepared, subjected to *in vitro* simulated digestions and added to Caco-2 cells grown on permeable inserts. The presence of α-Gal was investigated in the basolateral medium by immunoblotting, thin-layer chromatography (TLC) with immunostaining and ELISA and its allergenic activity was analyzed in a basophil activation test. After addition of beef proteins on the apical side of Caco-2 cells, α-Gal containing peptides were not detected in the basolateral medium and those peptides that crossed the Caco-2 monolayer did not activate basophils from an α-Gal allergic patient. Instead, when Caco-2 cells were incubated with lipids extracted from beef, α-Gal was detected in the basolateral medium. Furthermore, these α-Gal lipids, were able to activate the basophils of an α-Gal allergic patient in a dose-dependent manner. We thus showed that only α-Gal carried on lipids, but not on proteins is able to cross the intestinal epithelium and trigger an allergic reaction. The slower digestion process of α-Gal conjugated lipids might explain the delay in the appearance of symptoms since it takes for dietary lipids a longer time than for proteins to reach the circulation.

WS.A2.04.05
Cytofast: A workflow for flow and mass cytometry data to discover group-related immune signatures

G. Beyrend*, K. Stam, T. Höllt, R. Arens;*
Leiden University Medical Center, LEIDEN, Netherlands.

Multi-parametric flow and mass cytometry allows exceptional high-resolution exploration of the cellular composition of the immune system. A large panel of tools have been developed to analyze the high-dimensional landscape of the data generated. Among them, Cytosplore, incorporating the HSNE algorithms, is highly suitable for multi-parametric cytometry analysis. However, this software focusses on visual exploration and does not provide means to quantify group-specific cell clusters or correlations with clinical observations. Here, we introduce an R-based workflow, called CyTOFastR, for downstream analysis of Cytosplore-processed cytometry data sets. CyTOFastR is generating visual representations to identify group-related immune cell clusters and to study the correlation of any clinical variable with the immune system composition. We apply our workflow on two previously published data sets, paired and non-paired, based on the modulation of the immune system upon a specific treatment. We discovered a new macrophage subset from a previous mass cytometry study, which decreased upon allogeneic tumor-binding IgG. Thus, our bioinformatic tool offers an automated time-efficient approach for comprehensive multi-parametric cytometry analysis to reveal group-related immune signatures.

WS.A2.04.06
A novel algorithm for analysis of the evolution of B-cell receptors repertoires using high-throughput sequencing data

A. S. Obraztsova[1]*, M. Shugay*[1,2,3,4]*, D. M. Chudakov*[1,2,3,4,5]*;*
[1]*Skolkovo Institute of Science and Technology, Moscow, Russian Federation,* [2]*Institute of Bioorganic Chemistry (RAS), Moscow, Russian Federation,* [3]*Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [4]*Privolzhsky Research Medical University (PIMU), Moscow, Russian Federation,* [5]*Central European Institute of Technology (CEITEC), Praha, Czech Republic.*

One of the mechanisms that is critical for forming an efficient immune response is the affinity maturation of B-cells, a process during which somatic hypermutations (SHMs) are introduced into the Ig sequence followed by subsequent rounds of antigen-driven selection in germinal centers of lymph nodes. Recent advances in high-throughput sequencing techniques empowered a comprehensive study this phenomenon, but some technical hurdles still complicate the analysis of B-cell receptor repertoires. The present work is devoted to the solution of two problems. First, the background noise of PCR and sequencing errors that can interfere with SHM analysis can be eliminated using the molecular tagging technique and an extension of our previously published algorithm [1] to full-length Ig sequences. The second difficulty lies in the identification of SHMs that fall into the complementarity-determining region 3 (CDR3) of the Ig sequence that doesn't have any germline reference sequence. To solve the latter problem, we have developed a novel algorithm that can accurately identify and cluster CDR3 sequences that are far more similar than can be expected from random sampling of CDR3 repertoire. This approach allows us to accurately reconstruct the clonal trees of full-length Ig sequences present in the sample using the parsimony principle. The clonal lineage structure provides information about B-cell receptor repertoire evolution as well as making it possible to detect all SHMs located in CDR3. This work was supported by Russian Science Foundation (RSF) grant 14-14-00533.

Cytokines are essential regulators of immune responses and coordinate the response against pathogens. Therefore, they hold great potential as targets for new diagnostic and therapeutic strategies. IL-12p70 is a key heterodimer molecules for driving Th1 immune responses. Despite its role in combating infection we have observed highly variable IL-12p70 responses in healthy individuals, as well as in patients infected with tuberculosis (TB) and chronic hepatitis C (HCV). We hypothesize that dissecting this variance in a healthy population will provide new insights into disease pathogenesis. Following LPS stimulation of whole blood from 1,000 donors of the Milieu Interieur cohort, 28% of healthy donors failed to secrete IL-12p70, but its production was restored with IFNa co-stimulation. However, in HCV and TB patients, greater than 50% of the patients did not secrete IL-12p70 following LPS stimulation and only a subgroup of patients were able to restore IL-12p70 secretion upon co-stimulation with IFNa.

Utilizing the Milieu Interieur cohort we have further investigated the factors behind this variability. Having identified by flow cytometry that monocytes and dendritic cells are the main IL-12p70 producers in whole blood, we confirmed that cellular differences were not responsible for the variability in healthy donors. In contrast gene set enrichment analysis revealed significant IFNg response differences between the two phenotypes under LPS stimulation, and protein Quantitative Trait Loci analysis revealed a genetic association with IL-12p70 responses. These results will allow to investigate the intracellular mechanisms by blocking specific pathways and to restore them in chronically infected HCV or TB patients.

WS.A3.01.02

New protein array technology identifies rituximab treated non responder rheumatoid arthritis patients are generating a new autoantibody repertoire

*Z. Konthur[1], M. Wiemkes[2], T. Häupl[2], G. Burmester[2], **K. Skriner**[2];*
[1]Max Planck Institute of Colloids and Interfaces, Berlin, Germany, [2]Charité University Medicine, Berlin, Germany.

Background: Rituximab (RTX) has shown clinical efficacy in cancer and autoimmune diseases but up to 40 % of RTX treated rheumatoid arthritis (RA) patients are poor responders (ref:1) and the commonly used RA biomarkers (*RF/ACPA)* are poor predictors for therapy response. **Methods:** Screening of RA sera was conducted on 37.830 unique human protein marcoarrays (http://www.engine-gmbh.de) with sera taken before and 24 weeks after treatment. Autoantibody response of different immunoglobulin classes IgD, IgA, and IgG was recorded and bioinformatically evaluated. Response was determined according to DAS28 criteria. **Results:** In the cohort of 26 patients 1292 different autoantigens (IgD,IgA,IgG) were detected. Using protein array we investigated clusters of autoantigen responses that disappeared or developed during RTX treatment of RA patients. Post treatment developing responses against new autoantigens can be correlated to mRNA tissue expression data. RA autoantigenic patterns before and 6 month after RTX treatment were patient-specific. RTX reduced the repertoire of autoantibodies after 24 weeks of treatment in the tested RA patient cohort on average by 60%. RA patients which do not respond are generating on average 63% new autoantibodies. In good responders to RTX only 5,5% (+/-3%) new autoantibodies can be detected. The IgA and IgG autoantibody repertoire in the serum after 24 weeks of RTX treatment is reduced (IgA: 41%, IgG :31%) in good responders whereas it is increased (IgA: 1,3%, IgG: 24%) in non responders to RTX. **Conclusions:** Non responders to RTX change their autoantibody repertoire directed against new but patient specific antigens. **References:** 1:AnnRheumDis. 2005 Feb;64(2):246-52.

WS.A3.01.03

Imbalance of naïve and memory T cells in peripheral lymphocyte subpopulations at onset of type 1 diabetes

*A. Teniente-Serra[1], E. Pizarro[2], **C. Esteve-Cols**[1], M. Julian[2], M. Fernández[3], E. Martínez-Cáceres[1];*
[1]Germans Trias i Pujol University Hospital, Badalona, Spain, [2]Hospital de Mataró, Mataró, Spain, [3], Germans Trias i Pujol Research Institute (IGTP), Campus Can Ruti, Badalona, Spain.

Introduction: Type 1 diabetes (T1D) is an autoimmune disorder characterized by destruction of pancreatic beta cells resulting in insulin dependency. Changes in T and B cell subpopulations in peripheral blood of T1D patients have been described, but a comprehensive multiparametric flow cytometric analysis is still lacking.
Aim: To identify changes in peripheral blood T- and B- cell compartments in patients at onset of T1D.
Material and methods: CD4+ and CD8+ T cells (including naïve, central memory, effector memory and terminally differentiated effector (TEMRA), Th17 and Tregs) and B cells subsets (naïve, unswitched memory, switched memory and transitional B cells) were analyzed in peripheral blood of T1D patients at onset (n=26) and healthy donors (HD; n=40) using multiparametric flow cytometry.
Results: A decrease in the percentage of early and late effector memory CD4+ and CD8+ T cells (TCD4+: p=0.001 and p<0.001, TCD8+: p=0.046 and p<0.001), TEMRA CD4+ and CD8+ cells (p=0.003 and p=0.004, respectively) was found. In contrast, the percentage of naïve CD4+ T cells (p=0.010), and percentage and absolute counts of naïve CD8+ T cells (p<0.001 and p=0.001) were increased in peripheral blood of T1D patients compared with HD. Moreover, an increase in percentage of total B cells and transitional B cells was observed in patients compared with HD (p=0.015 and p=0.006, respectively). No changes were found either in Tregs or in Th17 subpopulations.
Conclusion: The observed changes in the percentage and/or absolute number of lymphocyte subpopulations support that effector cells migrate to the pancreas participating in the autoimmune response.

WS.A3.01.04

Glycolytic T cell metabolism drives faster disease progressionin progressive multiple sclerosis patients

***S. DE BIASI**, E. Bianchini, M. Nasi, L. Gibellini, S. Pecorini, D. Lo Tartaro, A. Simone, D. Ferraro, F. Vitetta, P. Sola, A. Cossarizza, M. Pinti;*
UNIVERSITY OF MODENA AND REGGIO EMILIA, MODENA, Italy.

Introduction. Inflammation and neurodegeneration sustain disease progression in both primary progressive (PP) and secondary progressive (SP) form of multiple sclerosis (MS). PP and SP forms present different symptoms, but the inflammatory status and the neurodegenerative process are indistinguishable. Differences in CD4 T-cell biology identify SP patients having different rates of progression, emphasizing an association between the systemic immune activation and disease progression. However, the mechanisms responsible of such impairment are still unknown. **Aim.**T cell activation is accompanied by a switch from a metabolism mainly based upon mitochondrial respiration to a metabolism where glycolytic flux is prevalent. Hence, we investigated the metabolic changes and mitochondria (mt) functionality of T cell subpopulations in 46 progressive MS patients, to clarify if PP form is part of the disease spectrum, or a distinct entity. **Results.** When compared to SP patients, T cells from PP displayed a senescent phenotype (low proliferation, increase of terminally differentiated/exhausted cells), lower mt mass, membrane potential and respiration, a more marked down-regulation of transcription factors supporting respiration. This is counterbalanced by higher mTOR activity and higher expression of glycolytic-supporting genes. Higher levels of lactate were found in plasma of PP patients. **Conclusion.**SP and PP patients displayed differences from the phenotypic and metabolic point of view. These differences, driven by deficit or abnormalities in the metabolism of immune cells, can contribute to neurodegeneration and chronic level of inflammation in PP and SP patients, determining a faster disease progression in PP.

WS.A3.01.05

Measurement of serum infliximab levels and detection of free and bound anti-infliximab antibodies in patients with rheumatoid arthritis

***C. Hermanrud**[1], M. Ryner[1], R. Pullerits[2,3], K. Hambardzumyan[4], N. Vivar Pomiano[4], P. Marits[5], I. Gjertsson[2], S. Saevarsdottir[4], A. Fogdell-Hahn[1];*
[1]Clinical Neuroimmunology, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden, [2]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [3]Department of Clinical Immunology, Sahlgrenska University Hospital, Gothenburg, Sweden, [4]Rheumatology Unit, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden, [5]Department of Clinical Immunology and Transfusion Medicine, Karolinska University Hospital, Stockholm, Sweden.

Introduction: Tumor necrosis factor-alpha (TNF-α) inhibitors are used to treat symptoms of rheumatoid arthritis (RA). Low drug levels correlate well with the presence of anti-drug antibodies (ADA) and are likely to result in a poor clinical outcome. Levels of free TNF-α inhibitor and ADA are detected with an in-house validated ELISA used in clinical routine at Karolinska University Hospital. However, false negative results can occur due to the formation of drug/ADA immune complexes and that samples with a drug level >0.2 µg/mL should not be screened for ADA with ELISA because of the assays low drug tolerance. **Methods:** Drug levels and ADA were studied with three methods; free ADA (ELISA), neutralizing ADA (bioassay, iLite) and total ADA (precipitation and acid dissociation assay, PandA). Three RA cohorts were included; SWEFOT (prospective, n=101) Karolinska University Hospital, and REALlife with patients from Karolinska University Hospital, (cross-sectional, n=272) and Sahlgrenska University Hospital (prospective, n=42). **Results:** The majority of patients (SWEFOT 46%; REALlife 70%) had suboptimal TNF-α inhibitor serum concentration (<3 µg/mL), and around 24% had an optimal drug concentration (3-7 µg/mL). As expected, low serum TNF-α inhibitor levels (<0.2 µg/mL) correlated with ADA, of which 66% were neutralizing. Moreover, PandA measured free and bound ADA reactivity in 24% of tested serum samples that had detectable TNF-α inhibitor levels (0.2-7 µg/mL). **Conclusion:** There was a clear difference in the drug level between the clinical trial cohort and the real-life situation, showing that expected ADA prevalence might need to be adjusted in a routine clinical setting.

WS.A3.01.06

Imaging flow cytometry enhances the detection of small particles and rare events enabling emerging applications in immunology and oncology

***P. Rhein**[1], A. Goergens[2], B. Giebel[3], S. Groenefeld-Krentz[4], C. Eckert[4];*
[1]Merck KGaA, Darmstadt, Germany, [2]Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Institute of Transfusion Medicine, University Hospital Essen, Essen, Germany, [4]Pediatric Oncology/Hematology, Charité-Universitätsmedizin, Berlin, Germany.

Detection of small particles and rare events by flow cytometry is often hampered by the limited amount of information that can be gathered from light scatter signals and fluorescence. Small particles like extracellular vesicles (EVs) have recently gained increased interest as they are physiologically and diagnostically relevant. The small but variable size and abundance made analysis of single EV difficult on traditional flow cytometers.For rare events detection discrimination of relevant events and artifacts is absolutely mandatory and requires complex and challenging experimental design for traditional flow cytometers. One example are circulating tumor cells (CTCs), released into the bloodstream from primary and metastatic cancers and tumor cells persisting during therapy (minimal residual disease, MRD) that have important prognostic and therapeutic implications and are valuable tools for understanding tumor biology. The ImageStream® is a multispectral imaging flow cytometer that helps to overcome these obstacles by combining the statistical power of flow cytometry with imaging content of microscopy in one system. We are now able to characterize EVs including exosomes (70 nm - 160 nm in diameter), microvesicles and apoptotioc bodies at the single EV level. Moreover, the study shows the significance of the imagery for the detection of CTCs by preventing the misclassification of EpCAM+ CD45+ events as leukocytes and the undercounting of CTC doublets as single cells. And we demonstrate the feasibility of fluorescence in situ hybridization (FISH) in flow which can contribute to significantly improve the detection and functional analysis of biological rare events.

Rapid identification and isolation of functional antigen-specific CD8⁺ T cells by staining of activated integrins

S. Dimitrov[1], *C. Gouttefangeas*[1], *L. Besedovsky*[1], *A. T. Jensen*[2], *A. Chandrand*[1], *E. Rusch*[1], *R. Businger*[1], *M. Schindler*[1], *T. Lange*[3], *J. Born*[1], *H. Rammensee*[1];
[1]*University of Tübingen, Tübingen, Germany,* [2]*University of Copenhagen, Copenhagen, Denmark,* [3]*University of Lübeck, Lübeck, Germany.*

Immediate changes in the conformation and clustering of β_2-integrins upon T-cell receptor stimulation is critical for the strong adhesion of antigen-specific T cells to their targets and the downstream execution of T-cell effector functions. Integrin activation may therefore be used for the rapid identification of functional T cells. We present a novel, simple, and sensitive flow cytometry-based assay to assess antigen-specific T cells using fluorescent intercellular adhesion molecule (ICAM)-1 multimers that specifically bind to activated β_2-integrins. The method is compatible with surface and intracellular staining; it is applicable for monitoring of a broad range of virus-, tumor- and vaccine-specific CD8⁺ T cells, and for isolating viable antigen-reacting cells. ICAM-1 binding correlates with peptide-MHC multimer binding, but, notably, it identifies the fraction of antigen-specific CD8⁺ T cells with immediate and high functional capability, i.e., expressing high levels of cytotoxic markers and cytokines. Compared to the currently available methods, staining of activated β_2-integrins presents the unique advantage of requiring activation times of only several minutes, therefore delivering functional information nearly reflecting the *in vivo* situation. Hence, the ICAM-1 assay is utmost suitable for rapid and precise monitoring of functional antigen-specific T-cell responses including for patient samples in various clinical settings.

WS.A3.02.02
Epigenetic signatures of human T helper cell subsets

A. Ntalli[1], *S. Kumar*[2], *L. Maggi*[3], *F. Annunziato*[3], *C. Zinser*[4], *M. Beckstette*[1], *L. Graca*[2], *S. Floess*[1], *J. Huehn*[1];

Naive CD4⁺ T cells are highly plastic cells that - upon activation - can differentiate into various T helper (Th) cell fates characterized by the expression of specific transcription factors and effector cytokines. Their expression can be stabilized by epigenetic mechanisms including DNA methylation. So far, our knowledge about the link between DNA methylation and T helper cell differentiation processes is fragmentary. After the identification of an epigenetic Th17 signature suitable for the characterization of murine cells, we wanted to extend this knowledge to the human epigenome by performing a whole-genome bisulfite sequencing analysis of *ex vivo* isolated human naïve T cells and selected clones of Th1, non-classic Th1 and Th17 cells. The comparison of the different methylomes allowed for the detection of differentially methylated regions (DMRs) mainly located within introns, followed by promoter regions and exons. In accordance with literature, several DMRs were identified within lineage-specific loci like *IFNG*, *TBX21*, *IL17A* and *RORC2*. Additionally, we identified novel DMRs and cloned them into CpG-free luciferase reporter plasmids to study their transcriptional activity. Luciferase reporter assays in primary human CD4⁺ T cells revealed that DMRs within *SLAMF8* and *SRFS7* mediate transcriptional activity in a methylation-dependent fashion. In addition, we performed expression studies using *ex vivo* isolated T naïve, Th1 and Th17 helper cells to identify transcription factors that participate in transcriptional regulation via the DMRs. Thereby, we might be able to define lineage-specific regulatory modules involved in human T helper cell differentiation.

WS.A3.02.03
The cold shock protein YB-1 (Y-box binding protein 1) promotes survival of CD4⁺ T-lymphocytes

S. Meltendorf[1], *S. Gieseler-Halbach*[1], *J. Handschuh*[2], *M. Pierau*[1], *A. Arra*[1], *P. R. Mertens*[3], *U. Thomas*[4], *M. C. Brunner-Weinzierl*[1];
[1]*Department of Experimental Paediatrics, Magdeburg, Germany,* [2]*Leibniz Institute for Neurobiology, Magdeburg, Germany,* [3]*Department of Nephrology and Hypertension, Diabetes and Endocrinology, Magdeburg, Germany,* [4]*Departmente of Neurochemistry and Molecular Biology, Leibniz Institute for Neurobiology, Magdeburg, Germany.*

The cold shock protein YB-1 is highly expressed in tumours, such as breast cancer, and associated with hyper proliferation and resistance against apoptosis. Enhanced YB-1 expression at the transcription and nuclear protein levels have been shown to correlate with poor prognosis and resistance to chemotherapy for tumour patients. However, the role of YB-1 in T-lymphocytes is not understood so far. Human CD4⁺ T-lymphocytes isolated from PBMCs were stimulated with anti-CD3/anti-CD28 coupled beads. YB-1-signaling was manipulated by overexpression of YB-1^{wt} using lentiviral transduction of FuGW-GFP-constructs or reduction of YB-1 expression using specific YB-1shRNA. Apoptosis measurement was carried out six to eight days after initial stimulation and analysed. Expression of pro-and anti-apoptotic molecules was monitored by flow cytometry, western blot, and real-time PCR. Transduction of GFP-YB-1^{wt} constructs and mutant variants thereof into primary human CD4⁺ T-cells yielded around 40% GFP positive cells. We observed that YB-1 overexpression enhanced survival by 60% compared to the control. Additionally, the percentage of surviving cells was increased with specific inhibitors (QVD) for apoptosis in empty vector-transduced cells but not in YB-1^{wt} overexpressing cells. Furthermore, forced reductions of YB-1 with YB-1shRNA lead to an reduced survival in T-Lymphocytes. A substantial reduction in the mRNA and protein levels of anti-apoptotic molecule Bcl-xl following YB-1 knock-down clearly indicated the impact of YB-1 in regulating the T cell apoptosis. Thus, YB-1 tightly controls and promotes survival in T-cells.

WS.A3.02.04
Tissue resident memory T cells as a progressive multifocal leukoencephalopathy quick biomarker

A. Tejeda Velarde[1], *E. Rodríguez Martín*[1], *L. Costa-Frossard*[1], *Y. Aladro*[2], *S. Sainz de la Maza*[1], *S. Medina*[1], *N. Villarrubia*[1], *E. Monreal*[1], *E. Roldán*[1], *J. Álvarez-Cermeño*[1], *L. Villar*[1];
[1]*Ramón y Cajal University Hospital, Madrid, Spain,* [2]*Getafe University Hospital, Madrid, Spain.*

Introduction: Progressive multifocal leukoencephalopathy (PML) is a serious side effect associated with immune system modifying drugs in multiple sclerosis (MS). PML is caused by the opportunistic infection by John Cunningham virus and its early diagnosis is crucial for patient's survival. Tissue resident memory T cells (T_{RM}) are important during viral infection, and they can be detected in cerebrospinal fluid (CSF) by flow cytometry in only one hour. We aimed to explore if PML patients show an increase in T_{RM} and, in addition, to explore other CD4 and CD8 T cell subsets.
Patients and methods: We included 86 MS patients: three suffered PML (PML+) and 83 did not (PML-). CSF T cell subsets were explored by flow cytometry in a FACSCanto II cytometer. Results were expressed as percentage of CD45 mononuclear cells. Mann-Whitney U test was applied for comparison between groups.
Results: PML+ showed lower CD4 (p=0.0062), naïve CD4 (p=0.0111) and central memory CD4 (p=0.0440) compared to PML-. By contrast, in PML+ we observed a higher percentage of CD8 (p=0.0086) and terminally differentiated CD8 (p=0.0219) compared to PML-. However, the most clear difference was found in T_{RM} CD8 that were considerably higher in PML+ than in PML- (Respectively, 11.57%±5.17 vs 0.46%±0.05 [mean ± standard error], p=0.0081).
Conclusions: Although these findings should be validated in a larger cohort, our data show that PML induces a significant change in CSF T cell subsets of MS patients and strongly suggest that T_{RM} detection could be a good tool for an early PML diagnosis.

Razumovsky, Saratov, Russian Federation,* [6]*Saratov State National Research University, Saratov, Russian Federation.*

Type III Secretion System (T3SS), a system of proteins known as a powerful bacterial tool for subverting host immune response by Gram-negative pathogens. T3SS components as the key virulence factors are an attractive target for both vaccine and immunological markers development. In this study, using immunoblot technique and highly pure recombinant antigens, we investigated the potential of T3SS components, namely LcrV, YopM and YopE, to serve as the markers of humoral immune response in humans multiply vaccinated with live plague vaccine LPV, an attenuated *Y. pestis* EV strain line NIIEG possessing T3SS (n = 34). Sera from healthy naïve donors (n = 17) were used as a control. We found that anti-YopE antibodies, but not anti-YopM or anti-LcrV, were highly specific for the vaccinated group ($p<0.05$). Interestingly, humoral response to both YopE and YopM was likely short-circuiting since it correlated negatively with the post immunization period ($p<0.05$). There was an inverse association between the number of LPV injections and positive responses to YopM ($p<0.05$). No analogous relationships were observed for LcrV. Thus, we have shown that T3SS components may be promising for the development of plague humoral immunity markers. This work was supported by the RFBR #18-016-00159.

WS.A3.02.06

Skin-homing human CD8+ T cells preferentially express GPI-anchored peptidase inhibitor 16 (PI16), an inhibitor of cathepsin K

N. Lupsa[1,2], *B. Érsek*[1,3], *A. Bencsik*[1], *A. Horváth*[1], *E. Lajkó*[1], *Á. Oszvald*[1], *Z. Wiener*[1], *P. Reményi*[4], *G. Mikala*[4], *T. Masszi*[4,5], *E. Buzás*[1,2], *Z. Pós*[1];
[1]*Semmelweis University, Dept. of Genetics, Cell and Immunbiology, Budapest, Hungary,* [2]*Hungarian Academy of Sciences - Semmelweis University Immunoproteogenomics Extracellular Vesicle Research Group, Budapest, Hungary,* [3]*Office for Research Groups Attached to Universities and Other Institutions of the Hungarian Academy of Sciences, Budapest, Hungary,* [4]*Department of Hematology and Stem Cell Transplantation of the St. Istvan and Saint Laszlo Hospital, Budapest, Hungary,* [5]*3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary.*

This study sought to identify novel markers of skin- and gut-homing CD8+ T cells by analyzing them in acute graft versus host disease (aGvHD), typically involving CD8+ T cell-mediated organ damage of the skin and gut.
Patients undergoing allogeneic hematopoietic stem cell transplantation were assigned to groups developing cutaneous aGVHD, gastrointestinal aGvHD, both, or none, and their sorted skin-homing (CD8+/CLA+), gut-homing (CD8+/integrinβ7+), and reference (CD8+/CLA-/integrinβ7-) T cells were compared. Microarray analysis, Q-PCR and flow cytometry disclosed increased expression of peptidase inhibitor 16 (PI16) in skin-homing CD8+ T cells. PI16 was expressed by CD8+ T cells regardless of the organ(s) affected by aGvHD, aGvHD as such, and remained associated to skin-homing T cells in healthy blood donors, too. PI16 was not observed on CLA+ leukocytes other than T cells, and was restricted to the non-naïve CD45RO+ compartment. Induction of PI16 expression was independent of vitamin D3, remained unaffected by retinoic acid, or by co-culture with human skin and intestinal organoids. PI16 was confined to the plasma membrane, appeared GPI-anchored, and became lost upon re-stimulation of circulating skin-homing T cells. Loss of PI16 occurred by rapid downregulation of PI16 transcription, not by PLC- or ACE-mediated shedding, or by recycling from the plasma membrane. Inhibitor screening and pull-down experiments confirmed that PI16 has low affinity, if any, to most skin proteases, but inhibits cathepsin-K.
These data demonstrate robust PI16 expression in skin-homing CD8+ T cells, and raise the possibility that PI16 may inhibit an inflammatory skin protease until cutaneous CD8+ T cell activation.

NSCLC patients not responding to nivolumab show lowered frequency of co-stimulatory receptor-deficient CD8 T cells

A. Kunert*, E. A. Basak, D. P. Hurkmans, Y. Klaver, M. van Brakel, A. Oostvogels, C. H. Lamers, S. Bins, S. L. Koolen, A. A. van der Veldt, S. Sleijfer, R. H. Mathijssen, J. G. Aerts, R. Debets;*
Erasmus MC Cancer Institute, Rotterdam, Netherlands.

Checkpoint inhibitors have become standard care of treatment for non-small cell lung cancer (NSCLC). As only a limited fraction of patients experience durable clinical benefit, there is an urgent need to identify patients with early progressive disease. In the current discovery study, we have analyzed peripheral blood samples of 71 NSCLC patients treated with 2nd line nivolumab prior and throughout therapy with multiplex flow cytometry enumerating 20 immune cell subsets, and assessing frequencies of T cells using over 300 combinations of markers. Best overall response was assessed according to RECIST within 90 days from start of treatment. We discovered that patients with progressive and stable disease (PD and SD) displayed on average a 2-fold decrease in numbers of CD8 T cells prior to and throughout therapy, while patients showing partial response (PR) showed levels similar to those of healthy individuals with about 560 cells/µl. Analysis of T cell subsets expressing variable numbers of co-stimulatory or co-inhibitory receptors revealed that this reduction was accompanied by an enhanced expression co-stimulatory receptors in CD8 T cells of PD patients, while in PR patients they displayed a more exhausted phenotype. Interestingly, upon treatment with nivolumab, PD patients also showed a drop in the frequency of CD4 T cells expressing PD1 and BTLA, which may represent antigen-experienced helper T cells. Our study demonstrates that numbers of CD8 T cells as well as frequencies of CD8 and CD4 T cells with defined co-signaling signatures in peripheral blood are associated with response to nivolumab in NSCLC patients.

WS.A3.03.02

Circulating CD4 senescent T cells stratify clinical responses to PD-L1/PD-1 immune checkpoint inhibitors in NSCLC

M. Zuazo[1]*, H. Arasanz*[1]*, M. Gato*[1]*, G. Fernández*[2]*, R. Vera*[2]*, G. Kochan*[1]*, D. Escors*[1,3]*;*
[1]*Navarrabiomed, Pamplona, Spain,* [2]*Complejo Hospitalario de Navarra, Pamplona, Spain,* [3]*University College London, London, United Kingdom.*

Background: PD-L1/PD-1 blockade immunotherapies are demonstrating promising clinical outcomes in different neoplasms, although response rates are low and no accurate biomarkers of response have been discovered. Senescent T cells (Tsens) accumulate with age and comprise a large pool of antigen-specific T cells. Here, the impact of PD-L1/PD-1 blockade immunotherapy on systemic Tsens was assessed. **Methods:** A prospective small-scale study was conducted in 33 non-small cell lung cancer (NSCLC) patients treated with PD-L1/PD-1 immune checkpoint inhibitors. Baseline Tsens and their dynamic changes during treatment were quantified from peripheral blood samples and correlated with clinical efficacy based on RECIST criteria. **Results:** In our cohort study, patients with Tsen baseline values below 40% (negative baseline profile accounting to 52% of patients) had an ORR of 0% and 6 weeks PFS, in contrast to the remaining patients with a 37,5% response rate. Two main dynamic patterns of responses were identified. Increase in Tsens after the first cycle of therapy was always associated to progression (pattern 1, Tsen "burst"), while decrease (pattern 2) significantly correlated with responders. Hyperprogression was found in patients with a negative baseline profile and highly significant systemic CD4 Tsen bursts. **Conclusions:** Quantification of CD4 Tsens from routine blood samples provides an accurate predictive biomarker of responses with highly significant stratification power in NSCLC. Patients with a negative Tsen baseline profile did not respond to PD-L1/PD-1 immune checkpoint inhibitors or exhibited hyperprogressive disease. Enrolment of these patients for PD-L1/PD-1 blockade monotherapy should be avoided if other therapies are available.

WS.A3.03.03

CD103 tumor Infiltrating lymphocytes as a prognostic factor in colon cancer patients

s. M. talhouni*, J. Ramage;*
Nottingham City Hospital, Nottingham, United Kingdom.

Background: The primary site of colorectal cancer can either be in the colon or the rectum. Due to anatomic continuity of the colon into the rectum, cancers affecting these organs have historically been considered equivalent. However, recent studies have shown increased mutational burden and microsatellite instability in right-sided colon tumours versus left-sided colon and rectal tumours which may affect patient survival. T cells infiltrating tumours have shown a role as prognostic biomarker in colorectal cancer. However, recently CD103 a marker for non-circulating tissue resident memory (TRM) T cells have shown a stronger correlation with survival than CD3 or CD8 T cells in ovarian, breast and lung cancer. In this study, we investigated the association between CD103 TILs and the overall survival of right-sided colon, left-sided colon, and rectal cancer patients. Immunohistochemistry staining was conducted on validated colorectal TMA sections using a monoclonal antibody to CD103, its impact in terms of survival (in months) and clinic-pathological variables was determined **Results:** CD103 TILs were present in both colon and rectal cancer patients. However, Intraepithelial CD103 was associated with better overall survival in right colon cancer patients (p=0.01) in comparison to left sided colon and rectal cancer patients (p=0.665 and 0.818, respectively). **Conclusion:** We hypothesize that increased mutational rates in the right sided colon tumours improved the prognostic role of CD103+ antigen presenting TRM cells in comparison to the left colon/rectal tumours.

Filgrastim enhances T-cell clearance by anti-thymocyte globulin exposure after unrelated cord blood transplantation

C. de Koning[1]*, J. A. Gabelich*[1]*, J. Langenhorst*[1]*, R. Admiraal*[1]*, J. Kuball*[1]*, J. J. Boelens*[2,1]*, S. Nierkens*[1]*;*
[1]*University Medical Centre Utrecht, Utrecht, Netherlands,* [2]*Wilhemina Children's Hospital, Utrecht, Netherlands.*

Residual anti-thymocyte globulin (ATG; Thymoglobulin) exposure after allogeneic hematopoietic (stem) cell transplantation (HCT) delays CD4+ T-cell immune reconstitution (CD4+ IR), subsequently increasing morbidity and mortality. This effect seems particularly present after cord blood transplantation (CBT) compared bone marrow transplantation (BMT). The reason for this is currently unknown. We investigated the effect of active-ATG exposure on CD4+ IR after BMT and CBT in 275 patients (CBT; n=155, BMT; n=120, median age: 7.8 years; range 0.16-19.2) receiving their first allogeneic HCT between Jan-2008 and Sept-2016. Multivariate log-rank tests (with correction for covariates) revealed that CD4+ IR was faster after CBT than after BMT with <10 active-ATG*day/mL (p=0.018) residual exposure. In contrast, >10 active-ATG*day/mL exposure severely impaired CD4+ IR after CBT (p<0.001), but not after BMT (p=0.74). To decipher these differences, we performed ATG-binding and -cytotoxicity experiments using CB- and BM-graft-derived T-cell subsets, B-, NK-cells, and monocytes. No differences were observed. Nevertheless, a major covariate in our cohort was Filgrastim treatment (only given after CBT). We found that Filgrastim (G-CSF) exposure highly increased neutrophil-mediated ATG-cytotoxicity, by 40-fold (0.5 vs. 20%, p=0.002), which explained the enhanced T-cell clearance after CBT. These findings imply revision of the use (and/or timing) of G-CSF in patients with residual ATG exposure.

Next-generation antigen receptor sequencing of paired diagnosis and relapse samples of B-cell acute lymphoblastic leukemia: an algorithm for Minimal Residual Disease target selection

*P. Theunissen[1], M. de Bie[1], D. van Zessen[1], V. de Haas[2], A. P. Stubbs[3], **V. H. J. van der Velden**[1];*
[1]Department of Immunology, Erasmus MC, Rotterdam, Netherlands, [2]DCOG, The Hague, Netherlands, [3]Department of Bioinformatics, Erasmus MC, Rotterdam, Netherlands.

Antigen receptor gene rearrangements are frequently applied as molecular targets for detection of minimal residual disease (MRD) in B-cell precursor acute lymphoblastic leukemia (BCP-ALL) patients. Since such targets may however be lost at relapse, appropriate selection of antigen receptor genes as MRD-PCR target is critical. Recently, next-generation sequencing (NGS) - much more sensitive and quantitative than classical PCR-heteroduplex approaches - has been introduced for identification of MRD-PCR targets. In this study, we evaluated 42 paired diagnosis-relapse samples by NGS (IGH, IGK, TRG, TRD, TRB) to design an algorithm for selection of antigen receptor gene rearrangements which are most likely to remain stable at relapse. Overall, only 393 out of 1446 (27%) clonal rearrangements were stable between diagnosis and relapse. If only index clones with a frequency >5% at diagnosis were taken into account, this number increased to 65%; including only index clones with an absolute read count >10000, indicating truly major clones, further increased the stability to 84%. Over 90% of index clones at relapse were also present as index clone at diagnosis. Together, our data provide detailed information about the stability of antigen receptor gene rearrangements, based on which we propose an algorithm for selecting stable PCR targets for MRD monitoring, which should enable successful detection of relapse in >95% of BCP-ALL patients.

Plasma-derived exosomes in head and neck squamous cell carcinoma patients as potential biomarkers of response to immune therapies

***M. Theodoraki**[1], T. Hoffmann[1], R. Ferris[2], T. Whiteside[3];*
[1]Department of Otorhinolaryngology, Head and Neck Surgery, University of Ulm, Germany, Ulm, Germany, [2]Department of Otolaryngology-Head and Neck Surgery, University of Pittsburgh, Pittsburgh, PA, USA, Pittsburgh, United States, [3]Department of Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, Pittsburgh, United States.

Background: Circulating exosomes play a key role in immune suppression and disease progression. To evaluate their role as biomarkers of response to immunotherapy, we monitored changes in the cargo of exosomes from plasma of patients with head and neck squamous cell carcinoma (HNSCC) treated with Cetuximab, Ipilimumab and IMRT. **Methods:** Patients (n=18) with advanced HNSCC enrolled in the phase I clinical trial (NCT01935921) donated plasma at baseline and during (week 5, 14) immunotherapy. Exosomes were isolated by size exclusion chromatography and were separated into T cell-derived and non-T cell-derived exosomes by immunoaffinity capture. On-bead flow cytometry was used for detection of CTLA-4, PD-L1 and CD15s (Treg marker) on exosomes. To immunocapture tumor-derived exosomes (TEX), a microarray containing 4 antibodies specific for antigens overexpressed on HNSCC was used. Results were correlated to patients' outcome. **Results:** All patients had high TEX levels at baseline with a decrease at week 5. However, in patients who recurred (n=5), TEX levels increased at week 14; in contrast, TEX levels in 13 patients responding to therapy remained low. PD-L1 levels in CD3(-) exosomes (enriched in TEX) were elevated at week 5 in patients with recurrence but significantly decreased in responders to therapy. The responders had significantly higher levels of CTLA4 in exosomes at baseline than non-responders. However, a drastic decrease of CTLA4 occurred during therapy. Levels of CD15s were elevated at week 5 only in non-responders. **Conclusions**: Exosomes in plasma of cancer patients treated with immune therapies may serve as biomarkers of early response to treatment.

Follicular dendritic cells originate from subepithelial mesenchymal cells in Peyer's patches

***A. Prados**[1], V. Koliaraki[1], G. Kollias[1,2];*
[1]BSRC Alexander Fleming, Vari, Greece, [2]National and Kapodistrian University of Athens, Athens, Greece.

Peyer's patches (PPs) are lymphoid organs that are located in the small intestine and play an important role in gut immunity. B and T lymphocytes are the main cell populations, which are segregated into different lymphoid areas, driven by the presence of two major mesenchymal populations: fibroblastic reticular cells in the T cell area and follicular dendritic cells (FDCs) in the B cell area. Our group has previously shown that Collagen VI (ColVI)-Cre mice are a useful new tool for PP FDC analysis. Here, we used multicolor fate mapping systems in combination with confocal and light sheet fluorescent microscopy, to dissect the ontogeny and dynamics of this cell population. Analysis of adult PP from ColVI-Cre Confetti mice revealed the presence of monocolored cell columns connecting subepithelial mesenchymal cells and FDC networks, pointing towards an ontogenetic relation between them. To discern the directionality of this relation, we studied PP organogenesis. At embryonic day 18.5 ColVI-Cre$^+$ cells appeared as a single cell layer underneath the epithelium. During the first week of life, these cells proliferated, migrated into the muscle layer and differentiated into FDCs. Interestingly, this migration/differentiation process was lymphotoxin β receptor (LtβR) dependent, since ColVI-Cre$^+$ cells in the LtβR$^{ColVI\text{-}CreKO}$ adult mice were restricted to a single cell layer under the epithelium. In contrast, specific deletion of Tnf receptor 1 (TnfR1) in ColVI-Cre$^+$ cells allowed their migration but blocked their differentiation into FDCs. To summarize, we demonstrate that during PP development, FDCs arise from subepithelial mesenchymal cells in a LtβR/TnfR1 dependent manner.

WS.A4.01.02

Novel branched proximity hybridization assay to quantify nanoscale protein-protein interaction

*S. Zheng[1], M. Mitterer[2], M. Reth[1], M. Cavallari[1], **J. YANG**[1];*
[1]Institute of Biology III, Freiburg, Germany, [2]Max-Planck-Institute of Immunobiology and Epigenetics, Freiburg, Germany.

Recent studies suggest that membrane proteins are pre-clustered and highly organized at nanometer (nm) distances. This cell surface nanoscale protein organization plays an essential role for receptor activation and signaling in both healthy and neoplastic cells. Duo the current technical limitation, it is still difficult to study this nanoscale protein organization. To tackle this challenge, we have developed a new branched proximity hybridization assay (bPHA). In this assay, target proteins are first bound by specific antibodies, antibody fragments (Fab, scFv, VHH) or aptamers coupled to specially designed (plus and minus) oligonucleotides. A nanoscale distance between two target proteins places the plus and the minus oligonucleotide in close vicinity. This close vicinity signal is then amplified by 400 times through a sequential hybridization processes using the branched DNA (bDNA) technique. With the new bPHA method the nanoscale protein-protein interactions on or inside cells can be measured by flow cytometry in a multiplexing, high-throughput and quantitative manner. Deploying bPHA, we reliably detected the intermixing of B cell receptor isotypes upon B cell stimulation. We were also able to measure the intracellular dynamics of Syk kinase recruitment to the BCR signaling subunit after treatment of B cells with different stimuli.

Reconstitution of T-cell synaptic ectosomes unravels vesicular CD40L density as a critical determinant in the feed forward activation of antigen presenting cells

***P. F. Céspedes-Donoso**[1], D. G. Saliba[1], S. Valvo[1], S. Balint[1], K. Korobchevskaya[1], E. Compeer[1], M. Tognolli[2], E. O´Neill[2], M. L. Dustin[1];*
[1]The Kennedy Institute of Rheumatology, University of Oxford, Oxford, United Kingdom, [2]Department of Oncology, University of Oxford, Oxford, United Kingdom.

Extracellular vesicles are important intercellular communication elements across tissues. Recently, we have described synaptic ectosomes (SE) as a specialized type of extracellular vesicle that both form in response to antigen receptor stimulation and are released into the synaptic cleft by T-cells. However, the nature and functionality of the protein cargo remain largely unknown. Here, we developed a bead supported lipid bilayer system (BSLB) linked to quantitative flow cytometry (FCM) for characterizing SE composition and test their functionality using synthetic small unilamellar vesicles (SUVs). CD4+ T-cells were stimulated in the presence of BSLBs containing ICAM-1/anti-CD3-Fab/+/- CD40/ICOSL. After dissociation of BSLB-T-cell conjugates, BSLBs and cells were analyzed by FCM to characterize the transfer dynamics of CD40L molecules, a key effect of helper T-cells. To assess functionality, we developed SUV that both have the same size, and contained equivalent densities of CD40L as SE. We observed that SE were enriched in CD40L when the bilayers contained anti-CD3-Fab and CD40. Interestingly, the synaptic transfer of CD40L was triggered at low anti-CD3 densities and then plateaued at higher anti-CD3, unlike TCR transfer, which was linear with anti-CD3 density. The density of CD40L on SE was 100-1000 fold higher than the average calculated density on the surface of T-cells. CD40L on SE appears to be the dominant form leading the feed-forward activation of APCs, as evidenced by a superior APC activation compared to equivalent soluble CD40L. WS.A4.01.04

In follicular regulatory T cells NFATc1 is essential for homing to germinal centers

***A. Koenig**[1], M. Vaeth[1], G. Müller[2], S. Klein-Hessling[1], M. Klein[3], D. Stauss[2], L. Dietz[1], T. Bopp[3], M. Lipp[2], I. Berberich[4], F. Berberich-Siebelt[1];*
[1]Institute of Pathology, Julius-Maximilians-University of Wuerzburg, 97080 Würzburg, Germany, [2]Department of Tumor Genetics and Immunogenetics, Max-Delbruck-Center for Molecular Medicine (MDC), 13092 Berlin, Germany, [3]Institute for Immunology, University Medical Center, University of Mainz, 55131 Mainz, Germany, [4]Institute for Virology and Immunobiology, University of Wuerzburg, 97080 Würzburg, Germany.

Plasma cells, secreting class-switched antibodies with high affinity, are the product of the germinal center reaction (GCR). The GCR is supported by CD4$^+$CXCR5$^+$ follicular T-helper cells (T_{FH}), and controlled by CD4$^+$CXCR5$^+$Foxp3$^+$ follicular regulatory T-cells (T_{FR}). Expression profiling revealed high expression of the 'Nuclear Factor of Activated T cells c1' (NFATc1) in follicular T cells, covering T_{FH} as well as T_{FR} cells. The ablation of *Nfatc1* in all T cells, but also in Foxp3-expressing cells only, led to an increase in the GCR. This effect was due to an impaired homing of the T_{FR} population to the B-cell follicle, because T_{FR} cells specifically failed to upregulate the homing receptor CXCR5.

In T_{FR} cells - in contrast to T_{FH} cells - 'B lymphocyte-induced maturation protein' (Blimp-1) is highly expressed in line with being a hallmark of effector regulatory T-cells. Our data indicated that Blimp-1 directly represses the expression of *Cxcr5* in Tregs. However, it supports the recruitment of NFATc1 to *Cxcr5* by protein-protein interaction, by those means cooperating with NFATc1 for transactivation of *Cxcr5*. In line, overexpressing constitutive active NFATc1 in post-thymic T cells supported CXCR5 expression on Tregs. Interestingly, the numbers in T_{FH} and germinal center B cells were so deeply reduced that a surplus in NFATc1 might even enhance the effector function of T_{FR} cells. In sum, NFATc1 is essential for overcoming Blimp-1-mediated repression of *Cxcr5* and therefore for homing of T_{FR} cells, which control the GCR, an essential part of the humoral immune response.

Ectopic lung resident germinal centres are formed during chronic house dust mite driven allergic airway disease in a T follicular helper cell dependent manner

***F. I. Uwadiae**, R. Siroya, A. Gerasimov, C. Spilsbury, C. J. Pyle, S. A. Walker, C. M. Lloyd, J. A. Harker;*
Imperial College London, London, United Kingdom.

Introduction: Allergic asthma is a disease of chronic allergen exposure, characterised by airway inflammation, airway hyperresponsiveness and allergen specific IgE. Germinal centres (GC) are anatomically distinct structures, located primarily in secondary lymphoid organs, critical for antibody generation. Lymphocyte aggregates exist in the asthmatic lung, but their formation and contribution to disease is not understood. This study aims to understand ectopic GCs during chronic allergic airway disease (AAD).
Method: To establish chronic AAD, mice were repeatedly exposed to intranasal house dust mite for up to 5 weeks.
Results: GC B cells and T follicular helper cells (Tfh) were found in the mediastinal lymph nodes (mLN) and the lungs after 3 weeks of allergen exposure. Large B cell aggregates containing GC B cells, T cells and follicular dendritic cell (FDC) networks were identified in the lungs by confocal microscopy, indicative of an active GC. Sorting mLN and lung resident B cells revealed transcripts indicative of IgG1 and IgE switch in both compartments by qPCR, while IgA transcripts were only identified in the lungs, suggesting the lungs to also provide protective antibodies. Ectopic GCs were absent in Tfh deficient mice (*$Cd4^{cre}Bcl\text{-}6^{fl/fl}$*), which additionally lacked allergen specific IgE. Despite this, *$Cd4^{cre}Bcl\text{-}6^{fl/fl}$* mice had exaggerated Th2 cell biased AAD. Mixed bone marrow chimeras revealed a regulatory role for Tfh during AAD, rather than an intrinsic role for Bcl6 in regulating Th2 cell differentiation. **Conclusions:** Lung resident GCs form during chronic AAD in a Tfh dependent manner and Tfh are important regulators of disease.

WS.A4.01.06

Antigen stimulation of lymphoid cells supports alternative pathway of T Follicular helper cell differentiation by polarizing CD45RA$^-$ CD4 T cells into Tfh cells

***R. Jeger-Madiot**[1], M. Pereira[1], C. Richetta[2], V. Quiniou[3], P. Buffet[4], D. Klatzmann[3], A. Moris[1], S. Graff-Dubois[1];*
[1]Centre d'Immunologie et des Maladies Infectieuses, Paris, France, [2]Ecole Normale Supérieure Paris Saclay, Paris, France, [3]Laboratoire Immunologie-Immunopathologie-Immunothérapie, Paris, France, [4]Institut National de la Transfusion Sanguine, Paris, France.

Lymphoid environment and antigenic stimulation synergize to generate Tfh cells that promote B cell maturation. In chronic infections, Tfh cell frequency is increased. Chronic antigen stimulation might promote Tfh cell differentiation leading to pathogenic antibodies. Understanding the pathways of Tfh differentiation and GC reaction under pathologic conditions is of particular interest to develop new therapeutic approaches. Tfh cells are not easily accessible, limiting their study in humans. Here, we provide a culture system to generate fully differentiated Tfh cells, allowing to understanding the Tfh biology. Our culture system use human splenocytes stimulated with a superantigen and suitable cytokines. We showed that induced Tfh cells present hallmarks of autologous Tfh cells, expressing Tfh markers and promoting B cell maturation. Compared with PBMC, Tfh cell differentiation is much more efficient with splenocytes in terms of quantity. This suggests that lymphoid environment promotes Tfh differentiation. Using this culture system, we demonstrated that Tfh could differentiate from CD45RA$^-$ CD4 T cells and naive T cells. We are currently performing experiments to characterize the functional properties of Tfh cells generated from naïve and repolarized CD4$^+$ T cells. To our knowledge, this is the first evidence of a CD4 T cell repolarization into Tfh cells in humans. CD4$^+$ T cell repolarization into Tfh cells might contribute to increase Tfh cell frequency during chronic inflammatory diseases where lymphoid structures are ectopically induced. Using this culture system will provide insights on Tfh cell differentiation/functions. Looking ahead, this culture system will constitute an platform to test new therapeutic approaches.

WS.A4.02 Regulation of B cell development and differentiation

WS.A4.02.01

B cell positive selection is developmentally regulated during ontogeny by the heterochronic protein Lin28b

***S. Vanhee**, S. Datta, T. Kristiansen, H. Åkerstrand, S. Lang, S. Vergani, A. Doyle, K. Olsson, S. Soneji, E. Jaensson Gyllenbäck, J. Yuan;*
Department of Molecular Hematology, Biomedical Center (BMC), Lund University, Lund, Sweden.

While all T cell maturation requires self-antigen driven positive selection, most self-reactive B cells are subject to tolerance induction mechanisms. An exception to the rule is the CD5$^+$ B-1 cell population known to be primarily of fetal and neonatal origin, generated and maintained on the basis of their self-reactivity. However, the mechanisms underlying their positive selection during early life and their subsequent developmental attenuation remains unclear.
Here, we link surface CD5 levels to BCR self-reactivity within the B-1 compartment and show that CD5 is induced at the immature B cell stage during neonatal but not adult B cell maturation coinciding with B cell positive selection. Importantly, developmental induction of CD5 relies in a dose dependent manner on the heterochronic RNA-binding protein Lin28b. Ectopic Lin28b effectively reinitiates positive selection during adult B cell maturation and increases the progeny:precursor ratio of B cell selection by two fold as shown by cellular barcoding. Finally, our results uncouple the process of B cell positive selection from the semi-invariant repertoire and phosphatidylcholine reactivity characteristic for B-1 cells. Together, our data support a model in which developmentally restricted Lin28b expression potentiates a transient wave of B cell positive selection and thereby contributes to life-long heterogeneity within the B cell pool.

WS.A4.02.02

The bHLH transcription factor TCFL5 and its soform CHA differently modulate c-MYC-dependent B cell proliferation

***I. Sánchez-Gómez**, J. Galán-Martínez, M. Maza, K. Stamatakis, N. Gironès, M. Fresno;*
Centro de Biología Molecular Severo Ochoa, Madrid, Spain.

Modern lifestyle and increased average lifespan are causing a world-wide increase in cancer rates. c-MYC basic Helix-Loop-Helix (bHLH) transcription factor is key in the genesis of several types of cancer. Deregulation of c-MYC has been frequently associated with aggressive lymphomas and adverse clinical outcome in B-cell malignancies. Trancription factor TCFL5 and its isoform CHA are also members of bHLH family. Since c-MYC and TCFL5 belong to the bHLH family they may be able to form heterodimers, thus the aim of this study is to analyze whether TCFL5/CHA interact with c-MYC and if it also regulates its functionality in a cancer environment. Our results showed a direct interaction of c-MYC and CHA by co-immunoprecipitation assays. Then, we performed gene expression studies to analyze the effect that the overexpression of CHA in presence or absence of c-MYC and found inhibition c-MYC target genes expression by CHA. In addition, TCFL5/CHA stably silenced cell lines were generated that confirmed our hypothesis about the modulatory role of TCFL5 and CHA in c-MYC mediated responses. Finally, protein expression analysis in acute lymphoblastic leukemia-like activated B cells showed differential effects of TCFL5 and CHA in cell proliferation. In summary, we found that CHA downregulates c-MYC activity and as a result it reduced cell tumorogenicity. On the contrary, TCFL5 expression was induced during B cell activation and was related to an immature stage contributing to a tumorigenic phenotype. Further studies may unravel CHA as a possible therapeutic target not only in cancer but also in leukemia.

WS.A4.02.03

PI3Kδ hyper-activation in B cells promote increased susceptibility to *S. pneumoniae* airway infection through an antibody independent mechanism

***A. Stark**[1,2], A. Chandra[1,2], R. Alam[2], K. Okkenhaug[1,2];*
[1]Division of Immunology, Department of Pathology, University of Cambridge, CB2 1QP, Cambridge, United Kingdom, [2]Babraham Institute, Cambridge, CB22 3AT, UK, Cambridge, United Kingdom.

The PI3Kδ signalling pathway is critical for normal immune cell development and function. Gain of function mutations affecting the p110δ catalytic- or p85α regulatory subunits causes Activated PI3K-delta Syndrome (APDS), a primary immunodeficiency characterised by severe recurrent respiratory infections often caused by *S. pneumoniae*.
We generated conditional knockin mouse models of PI3Kδ hyper-activation (PI3Kδ^{E1020K}) and PI3Kδ inactivation (PI3Kδ^{D910A}) to study the role of PI3Kδ signalling in the immune response to respiratory infection.
Germline and B cell, but not T cell or myeloid, restricted PI3Kδ hyper-activation increases susceptibility to *S. pneumoniae* lung infection in PI3Kδ^{E1020K} mice. Kinase-inactive PI3Kδ^{D910A} mice were not more susceptible to infection, despite lacking natural antibody against *S. pneumoniae*. Furthermore, PI3Kδ hyper-activation does not limit natural antibody levels or an antibody response to Pneumovax, a T-independent vaccine. Mice lacking mature B cells (μMT) are also protected against acute disease but fail to clear the infection, highlighting the pathological role of B cells in this model.
These data indicate that, while antibodies are important in the immune response to *S. pneumoniae*, B cells can play an antibody independent detrimental role during acute lung infection, and this effect is exacerbated by PI3Kδ hyper-activation. Indeed, we found an atypical IL-10 producing CD19$^+$B220$^-$ B cell subset which is significantly expanded in PI3Kδ^{E1020K} mice and absent in PI3Kδ^{D910A} mice. Ongoing work focusses on elucidating the mechanism whereby these cells can contribute to pathology in the early phase of *S. pneumoniae* infection.
This work is funded by grants from the MRC and Wellcome Trust.

WS.A4.02.04

Expansion of activated CXCR5$^+$ICOS$^+$Tfh cells and plasmablasts induced by seasonal influenza vaccine is impaired in anti-IL-6R treated rheumatoid arthritis patients

*A. Agua-Doce[1], V. Romao[2], J. Polido-Pereira[2], R. Barros[3], I. P. Lopes[1], M. I. Seixas[3], M. J. Saavedra[3], E. Sacadura-Leite[4], H. Rebelo-de-Andrade[5], J. E. Fonseca[2], **L. Graca**[1];*
[1]Instituto de Medicina Molecular, Lisboa, Portugal, [2]Instituto de Medicina Molecular, Rheumatology Department, Hospital Santa Maria-CHLN, Lisboa, Portugal, [3]Rheumatology Department, Hospital Santa Maria-CHLN, Lisboa, Portugal, [4]Occupational Medicine Department, Hospital Santa Maria-CHLN, Lisboa, Portugal, [5]Instituto Nacional de Saúde Doutor Ricardo Jorge, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisboa, Portugal.

Identification of a T cell subset (Tfh) with access to B cell areas and in driving the GC reaction has shed light to the unique processes of development and control of these structures. Tfh cells are essential for the generation of high affinity neutralizing antibodies elicited following vaccination, and are also involved in immune dysregulation associated with immune-mediated inflammatory diseases (IMID) and, specifically, to ectopic GC formation. Murine studies have shown that interleukin (IL)-6 is required for Tfh differentiation. However, in humans this issue has not been addressed *in vivo*. Our study takes advantage from the fact that tocilizumab (TCZ), an IL-6R-blocking monoclonal antibody (MAb), is approved for RA treatment of patients with indication for influenza vaccination. We studied prospectively a cohort of RA patients treated with TCZ (n=42) or methotrexate (MTX, n=42), as well as healthy volunteers (HD, n=53), following influenza vaccination. We found marked expansion of activated CXCR5$^+$ICOS$^+$ Tfh population at day 7 post vaccination in HD and MTX-treated patients, but this was impaired in the TCZ group. The increase in the activated CXCR5$^+$ICOS$^+$ Tfh population was mainly due to the Th1-like (CXCR3+) Tfh subpopulation. The lack of expansion of CXCR5$^+$ICOS$^+$ Tfh cells in TCZ-treated patients was due to inhibition of their proliferative ability, as demonstrated by reduced Ki67$^+$CD38$^+$. Taken together we found *in vivo* IL-6 blockade in humans hampers the emergence of activated CXCR5+ICOS+ Tfh cells following influenza vaccination, suggesting IL-6 has an important role in the generation of activated Tfh cells and protective humoral immune responses.

WS.A4.02.05

Functions of ZBTB24 in human and murine B cells

*C. Zhu[1], Y. Zhao[2], J. Liang[1], X. Gao[1], **J. Wang**[1];*
[1]Institutes of Biology and Medical Sciences, Suzhou, China, [2]Department of Pathophysiology, School of Biology and Basic Medical Sciences, Suzhou, China.

ZBTB24 has been recently identified as the causative gene in patients with Immunodeficiency, Centromeric Instability and Facial Anomalies syndrome type 2 (ICF2), a rare autosomal recessive disease. Most ICF2 patients harbor *ZBTB24* nonsense mutations, and suffer from recurrent respiratory and gastrointestinal infections due to hypogammaglobulinemia, most likely due to the lack of germinal center (GC) structure and circulating CD19$^+$CD27$^+$ memory B cells (Bmem). ZBTB24 belongs to the large ZBTB family of transcriptional repressors with members like BCL6 (ZBTB27) & ZBTB7A (LRF) playing essential roles in B-cell development/functions. ZBTB24 is highly expressed in human B-cell compartment. Knockdown of endogenous ZBTB24 hampers the cell-cycle progression in human GC-derived B lymphoma Raji cells *via* upregulating the expressions of IRF4 & PRDM1, two essential transcriptional factors invovled in GC-reactions. Moreover, ZBTB24 exerts these functions independent of BCL6 as it neither heterodimerizes with nor affects the expression/transcriptional activity of BCL6. Collectively, ZBTB24 appears to control the *in vivo* Bmem development *via* regulating the proliferation and/or terminal differentiation of human GC-B cells. Intriguingly, despite the early embryonic lethality in conventional zbtb24-deficient mice, conditional-knockout of *zbtb24* in murine B cells has no significant impact on *in-vivo* antibody responses upon immunization with T-cell-dependent antigens. Thus, functions of ZBTB24 in B cells seem to differ in mice and humans.

Stem cell based gene therapy for Recombinase deficient-SCID

***F. J. T. Staal**, K. Pike-Overzet;*
LUMC, Leiden, Netherlands.

Recombinase-activating gene (RAG) deficient SCID patients lack B and T lymphocytes due to the inability to rearrange immunoglobulin and T-cell receptor genes. The two *RAG* genes are acting as a required dimer to initiate gene recombination. Gene therapy is a valid treatment alternative for RAG-SCID patients, who lack a suitable bone marrow donor, but developing such therapy for RAG1/2 has proven challenging. Hence, we tested clinically relevant lentiviral SIN vectors with different internal promoters (UCOE, PGK, MND, and UCOE-MND) driving codon optimized versions of the *RAG1* or *RAG2* genes to ensure optimal expression. We used *Rag1-/-* or Rag2-/-mice as a preclinical model for RAG-SCID to assess the efficacy of the various vectors at low vector copy number. In parallel, the-conditioning regimen in these mice was optimized using busulfan instead of commonly used total body irridiation. We observed that B and T cell reconstitution directly correlated with RAG1 and RAG2 expression. Mice receiving low Rag1/2 expression showed poor immune reconstitution; however high Rag1/2 expression resulted in a lymphocyte reconsitution comparable to mice receiving wild type stem cells. Efficiency and safety of our clinical RAG1 lentivirus batch was assessed in Rag1-/- mice model showing that functional restoration of RAG1-deficiency can be achieved with clinically acceptable vectors. Additionally, RAG1-SCID patient CD34$^+$ cells transduced with our clinical RAG1 vector and transplanted into NSG mice led to fully restored human B and T cell development. Together with favourable safety data, these results substantiate a clinical trial for RAG1 SCID which is planned for late 2018.

Objective: In this study we investigated the compartment-specific sphingolipid modulation for the development of colitis-associated colorectal cancer (CAC) and found that sphingolipids can account for both mechanisms: inflammation-induced cancer and cancer-induced inflammation. **Design:** We performed isogenic bone marrow transplantation of inducible Sphingosine-1-phosphate (S1P) lyase knockdown mice to specifically modulate sphingolipids and associated genes and proteins in a compartment-specific way in a DSS/AOM mediated CAC model. 3-D organoid cultures were used *in vitro*. **Results:** In our CAC model, S1P lyase (SGPL1) knockdown in either tissue cells or immune cells, caused compartment-specific actions resulting in a morphologically, genetically and time-dependently distinct development of inflammation and carcinogenesis in colon: Immune cell SGPL1 knockdown (I-SGPL$^{-/-}$) augmented severe leukocyte and moreover lymphocyte infiltration of a mixed T_h1 and T_h2 phenotype, initiating strong colitis with lesions. Subsequent pathological crypt remodeling and extracellular S1P-signaling facilitated emergence of tumors characterized by PDCD4 regulation. In contrast, tissue SGPL1 knockdown (T-SGPL$^{-/-}$) provoked immediate occurrence of epithelial-driven tumors. Carcinogenesis was accompanied by an IL-12/IL-23 shift and sphingosine kinase 1, S1P receptor 2 and epidermal growth factor receptor upregulation with a consecutive development of a T_h2-driven microenvironment. Moreover, both knockdown models showed distinct regulation of lymphopenia und neutrophilia, different from the global SGPL knockout. **Conclusion:** Our results demonstrate that cell type-specific sphingolipid modulation contributes to the development of either inflammation-induced cancer or cancer-induced inflammation.

CD28 co-stimulation during antigenic recall responses of CD4$^+$Th1 cells triggers IFNg secretion in vivo

***S. Haack**[1], D. Langenhorst[1], F. Lühder[2], T. Hünig[1], N. Beyersdorf[1];*
[1]Institute for Virology and Immunobiology, Würzburg, Germany, [2]Institute for Multiple Sclerosis Research and Neuroimmunology, Göttingen, Germany.

During differentiation of naïve CD4$^+$T cells CD28-mediated co-stimulation is known to play a crucial role determining the cells' fate. The relevance of CD28 costimulatory signals for antigenic recall of CD4$^+$T cell is, however, less clear. Therefore, we first differentiated T cells from OT-II TCR-transgenic mice *in vitro* into Th1 cells and then transferred them into antigen-naive recipient mice *in vivo*. Three days after T cell transfer we challenged the recipients with OVA antigen in alum. CD28 signaling was abrogated either by Tamoxifen treatment of recipient mice after using OT-II T cells from inducible CD28 KO mice or by application of Fab fragments of the αCD28 mAb E18 inhibiting ligand binding to CD28. As read-outs we measured cytokine concentrations in the serum 6, 24 and 48 h after antigenic challenge and re-isolated the OT-II T cells ten days after transfer to determine absolute cell numbers and to detect IFNγ, IL-4, T-bet and Gata-3 expression by intracellular staining. Our results show that neither expansion nor maintenance of the Th1 phenotype was influenced by CD28-mediated co-stimulation *in vivo*. In contrast, systemic IFNγ release was greatly enhanced upon CD28 co-stimulation of the donor OT-II T cells. Inhibiting CD28-triggered cytokine release from effector/memory Th1 cells may, thus, be used in treatment of autoimmune diseases like multiple sclerosis. This study was funded by grants from the DFG (BE4080/2-1 & Hu295/12-1) and the GSLS Würzburg (GSC106/3).

Blood transcriptomic analysis shows how recall innate responses are modulated by the use of an adjuvant at priming

E. Pettini[1], *F. Santoro*[1], *D. Kazmin*[2], *A. Ciabattini*[1], *F. Fiorino*[1], *G. Gilfillan*[3], *I. Evenroed*[3], *P. Andersen*[4], *G. Pozzi*[1], *D. Medaglini*[1];
[1]*Laboratorio di Microbiologia Molecolare e Biotecnologia (LA.M.M.B.), Siena, Italy, Italy,* [2]*Emory Vaccine Center, Emory University,, Atlanta, GA, United States,* [3]*Department of Medical Genetics, Oslo University Hospital and University of Oslo, Oslo, Norway,* [4]*Department of Infectious Disease Immunology, Statens Serum Institut,, Copenhagen, Denmark.*

Transcriptomic profiling of the immune response induced by vaccine adjuvants is of critical importance for the rational design of vaccination strategies. In the present study, we investigated how the vaccine adjuvant used for priming modifies the way the immune system responds to the re-exposure to the vaccine antigen alone. mRNA sequencing was performed on blood samples collected after priming and boosting from mice primed with the vaccine antigen H56 of *Mycobacterium tuberculosis* administered alone or with the CAF01 adjuvant and boosted with the antigen alone. Gene expression analysis 2 days after priming showed that the CAF01 adjuvanted vaccine induced a stronger upregulation of the innate immunity modules compared to the unadjuvanted formulation. The immunostimulant effect of CAF01 adjuvant, used for priming, was clearly seen also one day after boosting, with activation of blood transcription modules related to innate immune response, such as monocyte and neutrophil recruitment, activation of antigen presenting cells and interferon response. The analysis of the immune response showed a higher frequency of H56-specific CD4+ T cells and germinal center B cells in draining lymph nodes and a strong H56-specific humoral response in mice primed with H56 + CAF01. Transcriptomic analysis of isolated H56-specific $CD4^+$ T cells was also conducted to profile gene expression in the mature antigen-specific helper T cell population upon vaccination. These data indicate that the adjuvant used for priming strongly re-programs the immune response that, upon boosting, results in a stronger recall of the innate response essential for shaping the downstream adaptive response.

DNGR-1 dampens neutrophil recruitment to damaged tissues, fostering disease tolerance upon infection

C. DEL FRESNO SÁNCHEZ[1], *P. Saz-Leal*[1], *M. Enamorado*[1], *S. Wculek*[1], *S. Martínez-Cano*[1], *N. Blanco-Menéndez*[1], *O. Schulz*[2], *M. Gallizioli*[3], *F. Miró*[3], *E. Cano*[4], *A. Planas*[3], *C. Reis e Sousa*[2], *D. Sancho*[1];
[1]*FUNDACION CNIC, MADRID, Spain,* [2]*The Francis Crick Institute, London, United Kingdom,* [3]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain,* [4]*Unidad Funcional De Investigación De Enfermedades Crónicas, Instituto De Salud Carlos III, Majadahonda, MADRID, Spain.*

Introduction: DNGR-1-(*Clec9a*) is a dead-cell receptor mainly expressed on type-I dendritic cells (DC1s) implicated in cross-presentation of dead cell-associated antigens to $CD8^+$ T-cells. We propose that DNGR-1 also impacts on innate immune responses.
Methods: WT mice and DNGR-1-deficient were subjected to sterile (acute necrotizing pancreatitis) and infectious (systemic *Candida albicans* infection) tissue damage models, analyzing myeloid infiltration and the tissue injury extent. Same models were addressed in anti-DNGR-1-treated WT mice or DNGR-1-deficient mice lacking adaptive immunity. To address the role of neutrophils to the magnitude of the observed pathology, mice were treated with neutrophil-depleting antibodies. The inflammatory response of DC1s to some PAMPs was analyzed after *in vitro* exposition to a ligand for DNGR-1. The implication of SHP-1 was addressed *in vitro* through a chemical inhibitor. The expression of the neutrophil chemoattractant Mip-2/CXCL2 was analyzed in sorted haematopoietic populations from *C.albicans*-infected kidneys.
Results: DNGR-1 absence or blockade led to exacerbated caerulein-induced pancreatitis. Similarly, DNGR-1-deficient settings increased pathology during *Candida* infection without affecting fungal burden, suggestive of a disease tolerance-related process. Both exacerbated responses were independent of adaptive immunity and attributable to increased neutrophilia. Ligand engagement by DNGR-1 activates SHP-1 to dampen inflammatory responses, decreasing the expression of the neutrophil chemoattractant Mip-2/CXCL2. Among the renal immune infiltrate of *Candida*-infected DNGR-1-deficient mice, DC1s were the only population overexpressing Mip-2/CXCL2.
Conclusions: Tissue damage sensing by DNGR-1 in DC1s negatively regulates Mip-2/CXCL2 expression, reducing host-damaging neutrophil infiltration. Upon infectious conditions, this immunomodulation occurs without affecting pathogen burden, suggesting that DNGR-1 could promote disease tolerance.

WS.A5.01.05

Toll-like receptor signalling induces a temporal switch from inflammatory towards a more resolving lipid profile in monocyte-derived macrophages

J. von Hegedus[1], *M. Heijink*[2], *T. Huizinga*[1], *M. Kloppenburg*[1,3], *M. Giera*[2], *R. Toes*[1], *A. Ioan-Facsinay*[1];
[1]*Department of Rheumatology, 2333 ZA, Netherlands,* [2]*Center for Proteomics and Metabolomics, 2333 ZA, Netherlands,* [3]*Department of Clinical Epidemiology, Leiden, Netherlands.*

Background: Inflammation is a tightly regulated process that usually resolves spontaneously. Dysregulation of this process can lead to chronic inflammation. Several cells and soluble mediators, including lipid mediators, regulate the course of inflammation and its resolution. Previous data suggest a temporal lipid-mediator switch from pro-inflammatory lipid mediators at the start of inflammation towards specialized pro-resolving lipid mediators (SPM) during the resolution phase of inflammation. It is, however, unclear which signals initiate secretion of SPM and the resolution process. Macrophages are key players in regulating tissue inflammation through secretion of soluble mediators , including lipid mediators.
We hypothesize that the initiation of resolution is orchestrated by macrophages in response to persistent inflammatory stimuli.
Methods: M1 polarized monocyte-derived macrophages were stimulated with LPS for different periods of time. Changes in lipid profile were measured using liquid chromatography coupled to tandem mass spectrometry. In parallel, expression of cyclooxygenase and lipoxygenases-15 was determined using qPCR. Additionally, lL-10 and TNFa ELISA's were performed on monocyte-derived macrophages that were pre-incubated with lipid mediators.
Results: Twenty-four different lipids were detected in LPS-stimulated macrophages. Cyclooxygenase-derived pro-inflammatory prostaglandins were observed in the first six hours of stimulation. Interestingly, a switch towards the 15-lipoxygenase SPM precursors 15-HETE and 17-HDHA was observed after 24h. The mRNA expression of cyclooxygenase and 15-lipoxygenase was in line with this trend. Treatment of macrophages with 17-HDHA during stimulation decreased TNFα and increased IL-10 production, indicating the anti-inflammatory properties of 17-HDHA.
Conclusion: Macrophages can initiate the resolution of inflammation in response to persistent inflammatory stimuli.

WS.A5.01.06

OX40 is required for both Th17 and Th1 effector T cell programmes

D. Gajdasik[1], *C. Willis*[1], *R. Fiancette*[1], *M. Botto*[2], *T. Vyse*[3], *G. Frankel*[2], *D. Ruano-Gallego*[2], *D. Withers*[1];
[1]*University of Birmingham, Birmingham, United Kingdom,* [2]*Imperial College London, London, United Kingdom,* [3]*King's College London, London, United Kingdom.*

Whilst it is clear that CD4 T cell responses require signals through OX40 and CD30, the cellular sources of the ligands and exactly what benefits they confer to the response have not been fully elucidated.
Our unpublished studies using an attenuated *Listeria monocytogenes*-2W1S infection model have demonstrated that IFNg production by effector T cells is highly OX40L dependent. Furthermore CD11c+ DCs are the critical cellular source of OX40L during this primary response, with OX40L expression by T cells and ILC3 redundant.
To test whether the Th17 effector response shares the OX40 requirements identified in our systemic Th1 model, we have analysed the role of OX40 in intestinal Th17 responses. Mice deficient in OX40 and CD30 show a dramatic defect in intestinal IL-17A-producing CD4 T cells upon *ex vivo* restimulation and RORgt-expressing CD4 T cells are absent from this tissue.
To further dissect the requirement for OX40 and CD30 in Th17 responses, Smart17 (IL-17A) reporters and Smart17 x OX40-/- x CD30-/- mice were infected with a novel *Citrobacter rodentium*-2W1S strain and the antigen specific response assessed. 2W1S-specific effector CD4 T cells in the intestine were substantially reduced and Citrobacter fecal counts significantly elevated. Thus, the Th17 effector programme in the intestinal lamina propria appears to also be highly OX40L dependent and ongoing experiments with conditional knockout mice are dissecting whether DC or ILC3 are key sources of OX40L.
Combined these data demonstrate the fundamental role played by OX40 in establishing functional effector CD4 T cells in both Th1 and Th17 responses.

The identification of neutrophil populations, as well as the characterization of their immunoregulatory properties, is an emerging topic under extensive investigation. In such regard, the presence of circulating CD66b$^+$ neutrophil populations, exerting either immunosuppressive or proinflammatory functions, has been described in several acute and chronic inflammatory conditions. However, due to the lack of specific markers, the precise phenotype and maturation status of these neutrophils remain unclear. Herein, we report that CD10 can be used as a marker that, within heterogeneous populations of circulating CD66b$^+$ neutrophils present in inflammatory conditions, clearly distinguishes the mature from the immature ones. Accordingly, we observed that the previously described immunosuppressive neutrophil population that appears in the circulation of granulocyte colony-stimulating factor (G-CSF)–treated donors (GDs) consists of mature CD66b$^+$ CD10$^+$ neutrophils displaying an activated phenotype. These neutrophils inhibit T cell functions via a CD18-mediated contact-dependent arginase 1 release. By contrast, we found that immature CD66b$^+$ CD10$^-$ neutrophils, also present in GDs, display an immature morphology, promote T-cell survival and functionality. Altogether, our findings uncover that in GDs, circulating mature and immature neutrophils exert opposite immunoregulatory properties. Therefore, CD10 might be used as a phenotypic marker discriminating neutrophil populations present in patients with acute or chronic inflammatory conditions, as well as facilitating their isolation, to better define their specific immunoregulatory properties. WS.A5.02.02

Tight translational control of glycolysis and fatty acid metabolism regulates the transition of CD4$^+$ T cells from quiescence to metabolic remodelling

S. Ricciardi[1], *N. Manfrini*[1], *R. Alfieri*[1], *P. Calamita*[1], *M. Crosti*[1], *R. Muller*[2], *M. Pagani*[1,3], *S. Abrignani*[1,4], *S. Biffo*[1,5];
[1]*National Institute of Molecular Genetics, Milan, Italy,* [2]*Helmholtz Institute for Pharmaceutical Research, Saarbrücken, Germany,* [3]*Department of Medical Biotechnology and Translational Medicine, Universita' degli Studi di Milano, Milan, Italy,* [4]*Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milan, Italy,* [5]*Bioscience Department, Università degli Studi di Milano, Milan, Italy.*

Upon antigen encounter via TcR, naïve cells undergo a metabolic reprogramming, which supports growth and imprints distinct functional fate, but the molecular basis for this is unclear. Integrating multiple "omics" analysis of human resting and naïve cells following activation, we discovered that T cells exert the transitional process through translational control. Naïve cells are poised at the preinitiation step of translation, accumulate untranslated mRNAs encoding for glycolysis and fatty acid synthesis factors, and present a unique metabolomic profile. Upon TcR engagement, activation of the translational machinery leads to synthesis of GLUT1 protein that steers glucose entry. Next, translation of ACC1 mRNA, via eIF4E, completes metabolic reprogramming toward an effector phenotype. Notably, inhibition of eIF4E abrogates lymphocyte metabolic activation and differentiation, defining ACC1 as a key regulatory node. Our results demonstrate that translation is the mediator of T cell metabolism and indicate translation factors as targets for novel immunotherapeutic approaches.

WS.A5.02.03

Regulatory and conventional T cell transcription factors are reciprocally controlled during *Salmonella* infection

S. Clay, *A. Bravo Blas, D. Wall, M. MacLeod, S. Milling;*
Institutue of Infection, Immunity and Inflammation, Glasgow, United Kingdom.

Peripherally induced FoxP3$^+$ Tregs (pTregs) play an important role in controlling inflammation and maintaining homeostasis at mucosal sites. pTregs differentiate from conventional T cells and can express transcription factors (TFs) including T-bet, GATA3 and RORγT, markers used to identify T helper (Th) subsets. T-bet$^+$ Tregs can selectively suppress T-bet$^+$ Th1 cells but it is unclear whether Tregs expressing other TFs selectively inhibit corresponding Th subsets. It is also unclear whether this selective regulation influences T cell polarisation. To address these questions we use a *Salmonella enterica* serotype Typhimurium (STM) strain that allows characterisation of antigen specific and total T cells in lymphoid and mucosal sites. One week after oral infection, an increased proportion of Th17 cells are found in the colon, with a reduced proportion of Tbet$^+$ Th1 cells and increase in T-bet$^+$ Tregs. Two weeks post-infection this dynamic is switched to a Th1 bias, with a reduced proportion of RORγT$^+$ Th17 cells and increase in RORγT$^+$ Tregs. This reciprocity between conventional Th cells and Tregs expressing the same TFs occurs in the colon and caecum but not in draining lymph nodes. These findings are consistent with the hypothesis that pTregs shape T cell responses by selectively suppressing Th subsets at effector sites. To test this hypothesis we adoptively transfer Tregs expressing specific TFs into Treg-depleted recipients and assess the impact on the T cell response. This will reveal whether pTregs are capable of subset-specific regulation of Th cells, highlighting their potential utility for targeted therapeutic approaches.

WS.A5.02.04

CD28 costimulation and not TCR controls the effector functions of activated CD4 T cells

B. Soskic[1], *D. A. Glinos*[1], *D. M. Sansom*[2], *G. Trynka*[1];
[1]*Wellcome Sanger Institute, Cambridge, United Kingdom,* [2]*Institute of Immunity and Transplantation, University College London, London, United Kingdom.*

T cell response is initiated following interaction with antigen presenting cells. The T cell receptor (TCR) determines the specificity of the response and the CD28 costimulatory receptor helps to ensure that activation does not occur upon recognition of self-antigens. It is widely thought that CD28 is required for activation of naive and not memory T cells. Here, we used functional genomic assays to investigate the role of costimulation via CD28 on gene expression programmes in human naive and memory T cells. We demonstrate that T-helper differentiation, cytokine and chemokine expression increase in response to CD28 intensity in both naive and memory cells. Strikingly, we observe that cell cycle and cell division are sensitive to CD28 in memory cells, but under TCR control in naive cells, in contrast to the paradigm that memory cells are CD28-independent. Using a combination of chromatin accessibility and enhancer profiling, we demonstrate that interferon response elements (IRFs) and Blimp-1 motifs are enriched in naive and memory T cells in response to TCR. In contrast, memory cells initiate AP1 transcriptional regulation only when both TCR and CD28 are engaged, implicating CD28 as an amplifier of transcriptional programmes in memory cells. Lastly, we show that CD28-sensitive genes are enriched in autoimmune disease loci, pointing towards the role of memory cells and the regulation of T cell activation through CD28 in autoimmune disease development. This study provides new insights into the impact of TCR and CD28 in the activation of human naive and memory CD4 cells.

WS.A5.02.05

The genome organizer Satb1 is required for the development of T_H17 cells through regulation of IL-2 expression

M. Köhne[1,2], *D. Sommer*[2], *J. Schulte-Schrepping*[2], *L. Schmidleithner*[1,2], *K. Klee*[2], *J. Wißfeld*[2], *L. Holsten*[2], *K. Händler*[3], *M. Geyer*[4], *T. Kuhlmann*[5], *J. Alferink*[6], *C. Wickenhauser*[7], *J. L. Schultze*[2,3], *M. Beyer*[1];
[1]*Molecular Immunology in Neurodegeneration, German Center for Neurodegenrative Diseases (DZNE), Bonn, Germany,* [2]*Life & Medical Sciences Institute (LIMES), University of Bonn, Bonn, Germany,* [3]*PRECISE, Platform for Single Cell Genomics and Epigenomics, German Center for Neurodegenrative Diseases (DZNE), Bonn, Germany,* [4]*Institute of Innate Immunity, University of Bonn, Bonn, Germany,* [5]*Institute for Neuropathology, University of Münster, Münster, Germany,* [6]*Department of Psychiatry and Psychotherapy, University of Münster, Münster, Germany,* [7]*Institute for Pathology, Martin-Luther-University, Halle, Germany.*

T cells play an important role in host defense and tissue homeostasis. T-cell dysfunction is associated with multiple diseases such as increased susceptibility to pathogen infection, inflammatory and autoimmune diseases as well as cancer formation. Therefore, it is critical to identify the common underlying mechanisms governing T-cell differentiation and establish new approaches to influence their differentiation in disease settings.
Here we describe the genome organizer Special AT-rich-binding protein 1 (Satb1) as a critical regulator of T_H17-cell development. We could show that Satb1 is highly expressed during T_H17-cell differentiation and that a loss of Satb1 prevents T_H17-cell development. Furthermore, expression of Satb1 in CD4$^+$ T cells is required for the induction of autoimmune diseases, like experimental autoimmune encephalomyelitis (EAE) and inflammatory bowel disease. The formation of complex transcription factor networks, controlled through epigenetic modifications and chromatin reorganization, is required for specific T-cell function and linage commitment. Using transcriptional and epigenetic characterization of Satb1-deficient CD4$^+$ T cells, we could show that Satb1 mediates T_H17-cell development by preventing IL-2 expression early during T_H17-cell development. Satb1-dependent IL-2 regulation influences STAT proteins, the pioneer factors for T-cell differentiation, thus affecting T_H17-cell transcription factor network formation phenocopying Ahr ligation-mediated induction of T_H17-cell differentiation. In line with this, activation of Ahr signaling in Satb1-deficient CD4$^+$ T cells could rescue T_H17-cell differentiation.
Taken together, Satb1 is critical for the differentiation of T_H17 cells through epigenetic programming early during T_H17-cell development. Thus, Satb1 may pose a novel therapeutic target for the treatment of T_H17-cell driven autoimmune diseases.

Unique metabolic requirements for T helper 2 polarization by dendritic cells

L. Pelgrom[1], *A. Sergushichev*[2], *A. J. van der Ham*[1], *B. M. Winkel*[1], *M. Yazdanbakhsh*[1], *M. N. Artyomov*[3], *B. Everts*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*ITMO University, Saint Petersburg, Russian Federation,* [3]*Washington University School of Medicine, St. Louis, United States.*

Dendritic cells (DCs) play a central role in the activation and polarization of T cell responses. We recently found that toll-like receptor signalling promotes a shift to glycolysis to support the anabolic demands of murine DC activation and effective priming of T cell responses. However, the metabolic requirements for polarization of distinct T helper cell (Th) responses by DCs, in particular Th2 responses, remain poorly defined. Based on unbiased global transcriptomic comparison of immature, Th1-, Th17- and Th2-priming human monocyte-derived DCs, we here report that suppression of genes involved in glycolysis is a key distinguishing feature of Th2-priming DCs. Consistent with these observations, in contrast to Th1- and Th17-priming DCs, Th2-priming DCs display low glycolytic rates and fail to increase glycolysis upon TLR stimulation. Importantly, blocking of glycolysis in DCs is sufficient to condition them for Th2 priming. Furthermore, based on unbiased analysis of integrated global metabolomic with transcriptomic data (CoMBI-T), we additionally identified an activated UDP-GlcNAc module in Th2-priming DCs, which points towards an important role for N- and/or O-glycosylation in Th2 priming by DCs. In line with these data, inhibition of O-linked GlcNAc transferase (OGT) impeded Th2 priming by DCs, without affecting their Th1- and Th17-priming capacity. Together, these findings suggest that DC-driven polarization of different T cell responses is dependent on the activation of distinct metabolic programs in DCs and highlights that metabolic manipulation of DCs could hold promise as a novel therapeutic approach to control immune-polarization in disease settings.

Engulfment and active shuttling of mast cell granules boosts dendritic cell functions

J. Kotrba, *J. Dudeck, J. Froebel, A. Dudeck;*
Institute for Molecular and Clinical Immunology, Otto-von-Guericke University Magdeburg, Magdeburg, Germany.

Mast cells (MCs) are known as key effector cells of type I allergic reactions but also play an important role in host defense against pathogens. Despite increasing evidence for a critical impact of MCs on the induction of adaptive immunity, the underlying mechanisms are poorly understood. We therefore aimed at monitoring MC intercellular communication with neighboring dermal dendritic cells (DCs). We studied MC behavior and communication using intravital multiphoton microscopy of Mcpt5-Cre reporter mice. Moreover, we developed a strategy to stain the intracellular secretory MC granules *in vivo* inside the intact MCs allowing for the detection of MC degranulation. To assess the activation of DCs, intravital imaging was combined with flow cytometry, sorting and *ex vivo* functional assays. Here, we demonstrate using intravital imaging, that dermal DCs engulf the intact dense core secretory granules exocytosed by MCs upon LPS-induced skin inflammation. Subsequently, the engulfed MC granules are actively shuttled to skin draining lymph nodes (LNs) and finally degraded inside DCs within the lymphoid tissue. Most importantly, DCs bearing MC-granules show an advanced early migration to skin draining LN, a highly enhanced maturation and boosted T cell priming efficiency as compared to MC granule-negative DCs. Consequently, we highlight a unique feature of peripheral MCs to impact on lymphoid tissue borne adaptive immunity over distance by modifying DC functionality via the delivery of granule-stored mediators.

WS.A5.03.02

Cross-dressing of mast cells with MHC II from dendritic cells during skin Inflammation

J. Dudeck[1], *A. Medyukhina*[2], *J. Froebel*[1], *J. Kotrba*[1], *M. Figge*[2], *A. Dudeck*[1];
[1]*Institute for Molecular and Clinical Immunology, Otto-von-Guericke University Magdeburg, Magdeburg, Germany,* [2]*Applied Systems Biology, Leibniz Institute for Natural Product Research and Infection Biology, Hans-Knöll-Institute Jena, Jena, Germany.*

Mast cells (MCs) and dendritic cells (DCs) are essential innate sentinels populating host-environment interfaces. Despite increasing evidence for a critical impact of MCs on DC functionality and the induction of adaptive immunity, the underlying mechanisms are poorly understood. Here, we studied the intercellular communication between MCs and dermal DCs during contact hypersensitivity (CHS) associated skin inflammation by means of longitudinal intravital multiphoton microscopy of MC/DC double reporter mice and extensive quantitative analysis. Further, the functional relevance of MC/DC interaction in T cell-driven CHS responses was analyzed by flow cytometry analysis and functional studies. We herein provide *in vivo* evidence that migratory DCs execute targeted cell-to-cell interactions with stationary MCs before leaving the inflamed skin to draining lymph nodes. During initial stages of skin inflammation, DCs dynamically scan MCs, whereas at a later stage, long-lasting interactions predominate. These innate-to-innate synapse-like contacts ultimately culminate in DC-to-MC molecule transfers including major histocompatibility complex class II (MHC II) proteins enabling subsequent ex vivo priming of allogeneic T cells with a specific cytokine signature. The extent of MHC II transfer to MCs correlates with their T cell priming efficiency. Importantly, preventing the cross talk by preceding DC depletion decreases MC antigen presenting capacity and T cell-driven inflammation. Consequently, we identify an innate intercellular communication arming resident MCs with key DC functions that might contribute to the acute defense potential during critical periods of migration-based DC absence.

WS.A5.03.03

CD86$^+$ antigen-presenting B cells are increased in solid cancers and induce tumor antigen-specific T cell responses

K. Wennhold[1], *M. Thelen*[1], *A. Lechner*[1], *H. Schlößer*[1,2], *M. von Bergwelt-Baildon*[3,4,5];
[1]*Center for Molecular Medicine Cologne, Cologne, Germany,* [2]*General-, Visceral- and Tumor Surgery, University Hospital Cologne, Cologne, Germany,* [3]*Department of Medicine III, University Hospital, LMU Munich, Munich, Germany,* [4]*German Cancer Consortium (DKTK), Heidelberg, Germany,* [5]*Comprehensive Cancer Center Munich (CCCM), Munich, Germany.*

B cell effector functions do not only include secretion of antibodies, but also presentation of antigen to T cells. Recently, a physiological B cell subset with strong immunostimulatory properties was described in humans. These antigen-presenting B cells (B_{ACP}) are characterized by a high expression of CD86 and downregulation of CD21. B_{ACP} are expanded following vaccination or under inflammatory conditions. We analyzed seven different tumor entities for the presence of B_{ACP} by flow cytometry and found increased percentages in lung adenocarcinomas, head and neck squamous cell carcinomas, colorectal cancer, esophageal-gastric cancers and renal cell carcinomas. Confocal microscopy demonstrated that CD86$^+$ B cells organize in tertiary lymphoid structures in the tumor microenvironment. Tumor antigen-specific B cells isolated from tumor-draining lymph nodes of cancer patients show increased percentages of B_{ACP}. Furthermore, we demonstrate a strong induction of tumor-specific T cell responses by B_{APC} using an antigen-specific fluorospot assay. Our results highlight the relevance of B_{ACP} as professional antigen-presenting cells in cancer.

WS.A5.03.04

Beta2-integrins restrict dendritic cell migratory phenotype through MRTFA/SRF signaling and a Syk-dependent epigenetic mechanism

C. Guenther[1], *M. Fusciello*[2], *M. Ilander*[1], *M. Sokolova*[3], *T. Savinko*[1], *L. Uotila*[1], *S. Yao*[4], *M. Moser*[5], *S. W. Morris*[6], *V. Cerullo*[2], *S. Tojkander*[4], *M. Vartiainen*[3], *S. C. Fagerholm*[1];

Dendritic cells (DCs) are the classic antigen presenting cells of the immune system. DCs switch from an adhesive, phagocytic phenotype to a migratory phenotype in response to stimuli such as LPS[1] but also through unknown stimuli, resulting in spontaneous migration to lymph nodes. We have found that beta2-integrins regulate the migratory phenotype of DCs and their ability to induce strong immune responses[2]. We used a beta2-integrin knock-in mouse model, which lacks the beta2-integrin-kindlin-3 interaction (TTT/AAA-beta2-integrin KI mice) and thus has non-functioning beta2-integrins, to investigate how beta2-integrins restrict DC function. Interestingly, we found that beta2-integrin KI BMDCs displayed reduced adhesion and traction force generation but increased 3D migration speed *in vitro*. We show that RhoA activation and F-actin polymerization is abolished in beta2-integrin KI DCs, which leads to a failure of MRTF-A transcription factor to localize to the cell nucleus to co-activate genes with SRF. The integrin/RhoA/MRTFA/SRF pathway regulates DC adhesion, traction force generation and expression of chemokine receptors necessary for DC migration, eg CCR7. Furthermore, KI DCs display increased Syk activation and a Syk-dependent global increase in histone methylation (H3K4me3, characteristic of active genes). Inhibiting Syk led to a reduction of KI DC 3D migration speed, whilst inhibiting histone demethylases in WT DCs induced faster 3D migration. Furthermore, utilizing a B16OVA tumor model, we show that DCs expressing dysfunctional integrins induced increased tumour rejection *in vivo*. Thus, beta2-integrin-mediated adhesion to the extracellular environment restricts DC migration and DC-mediated tumor rejection *in vivo* through MRTFA/SRF signalling and a Syk-dependent epigenetic mechanism.

WS.A5.03.05

Expanded T-cell clones are present in the synovium before the clinical onset of rheumatoid arthritis

G. Balzaretti[1], *P. L. Klarenbeek*[1], *M. E. Doorenspleet*[1], *M. J. de Hair*[1], *B. C. van Schaik*[1], *R. E. Esveldt*[1], *M. G. van de Sande*[1], *D. M. Gerlag*[2], *A. H. van Kampen*[1], *F. Baas*[3], *P. Tak*[4], *N. de Vries*[1];

Introduction: In healthy individuals with RA-specific autoantibodies the presence of expanded B-cell receptor (BCR) clones in peripheral blood (PB) accurately predicts who will develop arthritis in the short term. Following up on these observations, we investigated whether T-cell receptor beta (TCRβ) repertoire characteristics in PB and synovial tissue (ST) in this phase might also predict imminent onset of arthritis. Methods: Next-Generation Sequencing of the TCRβ repertoire was performed on 20 randomly selected individuals with elevated IgM-RF and/or ACPA levels. Ten individuals did not develop arthritis during at least 3 years of follow-up, and 10 individuals did. PB and ST samples were analysed during the *at-risk* phase and again after onset of arthritis.Results: In the *at-risk* phase the synovium is already characterized by expanded TCRβ clones, both in *at-risk* individuals that will and will not develop arthritis later. These clones persist during onset of arthritis. A higher impact of dominant TCRβ clones in synovial tissue at baseline was associated with longer time to arthritis (p=0.02). Conclusion: Expanded T-cell clones are present in the synovium in the *at-risk* phase regardless of future development of RA. They are maintained after onset of clinical disease. Combined with literature data, these observations show that T cell clones are already expanded in ST very early in disease, and suggest an overall regulatory role. Further studies are needed to characterize these clones.

Introduction: The metabolic processes that regulate the fate of distinct T lymphocyte subpopulations remain poorly defined, especially in humans.
Materials and methods: We used a systems approach to characterize the basal and activation-induced energetic requirements of naive and phenotypically-defined subsets of memory CD4+ and CD8+ T cells. To test the importance of metabolic pathways on primary responses, we used an original model of in vitro priming of epitope-specific naïve $CD8^+$ T cells. Priming was performed in the presence of different drugs affecting metabolic pathways, and the expansion and phenotype of epitope-specific $CD8^+$ T cells assessed. **Results**: Profound metabolic differences were apparent as a function of lineage and differentiation status, both at rest and in response to stimulation via the T cell receptor (TCR). Of particular note, resting naive CD4+ and CD8+ T cells were largely quiescent, but rapidly upregulated diverse energetic pathways after ligation of surface-expressed TCRs. Moreover, autophagy and the mTOR-dependent glycolytic pathway were identified as critical mediators of antigen-driven priming in the naive CD8+ T cell pool, the efficiency of which was dampened by the presence of neutral lipids and fatty acids. **Conclusions**: These observations provided a metabolic roadmap of the T cell compartment in humans and revealed potentially selective targets for novel immunotherapies <!--EndFragment-->

WS.A6.01.01

CLIP upregulation on B cells associates with multiple sclerosis onset and is governed by autoimmunity risk allele CLEC16A

L. Rijvers[1], *M. Meliefl*[1], *M. Stéphant*[1], *J. van Langelaar*[1], *R. M. van der Vuurst de Vries*[2], *A. F. Wierenga-Wolf*[1], *M. van Ham*[3], *R. Q. Hintzen*[1,2], *M. M. van Luijn*[1];
[1]*Department of Immunology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands,* [2]*Department of Neurology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands,* [3]*Department of Immunopathology, Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

C-type lectin *CLEC16A* is located next to *CIITA* at a susceptibility locus for many autoimmune diseases, including multiple sclerosis (MS). We previously reported that CLEC16A is upregulated in MS and promotes the biogenesis of HLA-II peptide-loading compartments (MIIC) in myeloid antigen-presenting cells. Since T-cell activation by B cells is an important trigger of early MS, we questioned whether key members of the HLA-II pathway in B cells are associated with disease onset in MS patients, and how *CLEC16A* is involved in this process.
Blood B cells of clinically isolated syndrome (CIS) patients who rapidly develop MS (n=16) and clinically definite MS patients (n=15) were enriched for class II-associated invariant chain peptide (CLIP)-containing HLA-DR molecules and showed reduced CD74 (invariant chain) expression. Out of 15 autoimmunity-associated genes analyzed, the expression of *CLEC16A* correlated to CLIP/HLA-DR surface ratios (r=0.78) in human BLCL. *CLEC16A* was only triggered under CLIP-stimulating conditions *in vitro*, and was mainly expressed in $CLIP^{high}$ naive B-cell populations. Lentiviral shRNA-mediated knockdown of *CLEC16A* resulted in downregulation of CLIP-containing HLA-DR molecules and upregulation of CD74 on the plasma membrane (n=8). Moreover, CLEC16A-silenced B cells showed impaired BCR-mediated antigen uptake and extensive cytoplasmic scattering of MIIC, indicating that CLEC16A is a key regulator of human B-cell antigen processing and presentation.
These data demonstrate that HLA-II machinery in B cells is dysregulated in early MS and is functionally controlled by autoimmunity-associated *CLEC16A*. The abundance of CLIP-loaded HLA-II molecules on B cells mechanistically links to their escape from peripheral tolerance checkpoints during MS onset.

WS.A6.01.02

CD55deficientpatient PBMCs respond differentially to TLR, Inflammasome and patient exosome stimulation before and after Eculizumab therapy

G. G. Kaya[1], *M. Yildirim*[1], *I. Evcili*[1], *N. Bozbeyoglu*[1], *I. C. Ayanoglu*[2], *A. Ozen*[3], *S. Sari*[4], *B. Dalgic*[4], *M. Gursel*[2], *I. Gursel*[1];
[1]*Bilkent University, Ankara, Turkey,* [2]*Middle East Technical University, Ankara, Turkey,* [3]*Marmara University, Istanbul, Turkey,* [4]*Gazi University, Ankara, Turkey.*

CD55 is a membrane bound protein whose deficiency has been recently defined as hyperactivation of complement, angiopathic thrombosis, and protein-losing enteropathy (CHAPLE syndrome). It inhibits classical and alternative complement pathways while it acts and mediates activity of leukocytes via CD97 engagement. Herein, $CD55^{-/-}$ immune cell responses in the presence of TLR and Inflammasome ligand stimulation and exosome incubation was studied. Fresh plasma and PBMCs of CHAPLE patients (N=7) before and after Eculizumab therapy (BT & AT, respectively) were obtained. PBMCs were stimulated with various ligands such as p(I:C), LPS, R848, CpG ODNs, cGAMP Nigericin and BT and AT exosomes. Responses were assessed for IL-1β, IL-8, IL-10, IP-10, IFNγ and IFNα levels from cell supernatants. Results revealed that IL-8 and IP10 levels from plasma and stimulated BT cells were higher and AT exosomes induced PBMCs to secrete elevated IL-8 levels compared to AT exosomes. The IFNγ secretions BT and AT to PMA, R848 and cGAMP showed higher levels compared to healthy cells. Moreover, AT exosomes of patients induced substantially higher IFNγ levels. IL-10 secretion in response to TLR2, 4 and 7 were found to be lower even AT but significantly increased compared to BT measurements. Furthermore, AT exosomes induced healthy PBMCs to secrete less IL-10 compared to BT exosomes. Spontaneous NETotic tendencies of patient neutrophils significantly subsided after Eculizumab therapy. Healthy or AT exosomes compared to BT exosomes induced much lesser NET formation from both healthy or AT neutrophils. Consequently, $CD55^{-/-}$ patients PBMCs regain healthy donor-like character following Eculizumab therapy.

Mice lacking functional dedicator of cytokinesis 8 (DOCK8), an immune cell-expressed guanine exchange factor for Cdc42, have recently been described as resistant in the experimental autoimmune encephalomyelitis (EAE) model of multiple sclerosis (MS). The IL-17 producing T helper 17 (Th17) cells are seen as the major mediator of central nervous system (CNS) inflammation in this model. We here investigate for the first time the role of DOCK8 in Th17 mediated CNS inflammation.
Contrary to expectation, we observed an elevation of Th17 cells (CD4+ IL17a producing cells) in two different DOCK8 mutant mouse strains in the steady state. In vitro T helper cell differentiation revealed that the elevated Th17 cell population was not based on a T cell intrinsic differentiation bias. Th17 cells remain elevated systemically during an episode of EAE but the cellular infiltration in the CNS is reduced in these mice, out of proportion to the systemic balance in Th1 and Th17 cells. DOCK8 deficient Th17 cells expressed normal Th17 cell specific CCR6 levels and migrated towards chemokine gradients in transwell assays, but adoptive transfers of Th1 and Th17 cells in EAE affected mice indicated a Th17 cell specific migration defect in the absence of functional DOCK8. Here we show for the first time a cell intrinsic mediator of migration that specifically affects the pathogenic Th17 cell subset responsible for neuroinflammation in this model further elucidating the mechanism of resistance of DOCK8 mutant mice to EAE.

WS.A6.01.04

Consequences of an IL2RA locus duplication in a very early onset inflammatory bowel disease patient

M. E. Joosse[1], *F. Charbit-Henrion*[2], *R. C. Raatgeep*[1], *D. J. Lindenbergh-Kortleve*[1], *L. M. Costes*[1], *S. Nugteren*[1], *S. Veenbergen*[1], *V. Malan*[2], *J. K. Nowak*[3], *M. Mearin*[4], *J. C. Escher*[1], *N. Cerf-Bensussan*[2], *J. N. Samsom*[1];

Rare single genetic mutations can predispose to very early onset inflammatory bowel disease (VEO-IBD). Here, we identify a *de novo* duplication of the 10p15.1 chromosomal region, including the *IL2RA* locus, in a 2-year-old patient presenting with therapy-resistant VEO-IBD that was brought into remission by subtotal colectomy. As IL-2 is important for T-cell survival and proliferation, we hypothesized that the *IL2RA* duplication results in aberrant T-cell function. Indeed, after subtotal colectomy and without medication, the patient still had an increased CD4 to CD8 ratio in peripheral blood and an increased CD25 expression on circulating effector memory, Foxp3^{+} and Foxp3^{neg} CD4^{+} T cells. Isolated patient CD4^{+} T cells were intrinsically activated as evidenced by increased STAT5 phosphorylation, proliferation and Ki67 expression. In agreement with increased CD25 surface expression, patient CD4^{+} T cells were more sensitive to low-dose IL-2 compared to healthy control cells. The colon, but not the unaffected duodenum, was infiltrated with proliferating CD3^{+} cells in the lamina propria and epithelial layer. Inflamed colonic tissue contained numerous Tbet^{+} cells and expressed high levels of *IFNG* mRNA. Crucially, inhibiting IL-2 signaling with the JAK1/3 inhibitor tofacitinib ablated IFNγ secretion and restored normal CD25 expression by CD4^{+} T cells. In conclusion, the patient's immune system exhibits constitutive activation of the CD25-phosphoSTAT5 pathway leading to hyper-proliferative CD3^{+} T cells predisposing to a T-cell driven pancolitis. These findings shed new light on the role of IL-2 in intestinal homeostasis and directs further studies to examine the functional consequences of *IL2RA* genetic variation in IBD patients.

Vall d'Hebron, Barcelona, Spain,* [6]*Pediatric Infectious Diseases and Immunodeficiencies Unit (UPIIP), Hospital Universitari Vall d'Hebron., Barcelona, Spain.*

Monoallelic loss-of-function mutations in *NFKB1* have been recently recognized as the most frequent monogenic cause of common variable immunodeficiency (CVID). The prototypic clinical phenotype of NFKB1 deficient patients included common CVID features as hypogammaglobulinemia and sinopulmonary infections plus other very diverse complications. Here we report a patient with a profound CVID phenotype and severe gastrointestinal manifestations. Using a custom panel of 323 genes causative of primary immunodeficiencies and massive parallel sequencing we identified a novel monoallelic loss-of-function mutation in *NFKB1*: a 1-bp deletion in exon 12 (c.1149delT) leading to a frameshift and a premature stop codon (p.Gly384Glu*48). Interestingly, we also found a rare missense variant in *NOD2* known to be associated to Crohn's disease (p.His352Arg). Our patient presented hypogammaglobinemia with of low number of B most of which are naïve. The most remarkably findings included a marked skewing towards a Th1 tbet+ phenotype in peripheral blood T cells and an excessive production of proinflammatory cytokines (IL-1beta, TNF-alfa and IFN-gamma). The 6-year old patient's daughter, carrier of the *NFKB1* mutation, remained clinically asymptomatic but started to show changes at cellular and molecular level. Data here presented constitutes an example this case of NFKB1 deficiency a combined immunodeficiency with a hyperinflammatory state and a glimpse of the preclinical period.

The molecular machinery that regulates the balance between self-renewal and differentiation properties of hematopoietic stem cells (HSCs) has yet to be characterized in detail. We sought to determine the role of tetratricopeptide repeat domain 7 A (Ttc7a) protein, a putative scaffold protein, in HSCs biological functions. We found that Ttc7a acts as an intrinsic regulator of the proliferative response and the self-renewal potential of murine HSCs *in vivo.* Loss of Ttc7a consistently enhanced the HSCs' competitive repopulation ability and their intrinsic capacity to replenish the hematopoietic system after serial cell transplantations, relative to wild-type cells. To gain insights into the molecular mechanisms, we performed RNAseq study on control and Ttc7a-deficient HSCs. Ttc7a-deficient cells exhibit a different transcriptomic profile for a set of genes controlling the cellular response to stress, which was associated with increased proliferation in response to chemically induced stress *in vitro*and myeloablative stress *in vivo*. Our results therefore reveal a previously unrecognized role of Ttc7a as a critical regulator of the HSCs stemness. This role is related, at least in part, to regulation of the endoplasmic reticulum stress response.

WS.B1.01 Immune checkpoints in anti-tumor therapy

WS.B1.01.01

Impact of tumor heterogeneity on response to immune checkpoint inhibition

S. Sánchez Alonso[1], *G. Setti Jeréz*[2], *M. Arroyo Correa*[1], *T. Hernandez Paredero*[2], *A. Alfranca González*[1];
[1]*Hospital Universitario de La Princesa, Madrid, Spain,* [2]*Universidad Autónoma de Madrid, Madrid, Spain.*

Lung cancer has emerged as the leading cause of death from cancer among men and women worldwide in the past decades. Several factors are involved in regulating tumor growth, and among them host immune system has an important role in modulating tumor behavior. Specially, tumor escape from immunosurveillance and its progression from a latency state are strongly affected by immune system function, which suggests the existence of heterogeneous subpopulations composed by tumor cells with different immunogenic potential. Particularly, generation of an immunosuppressive microenvironment is widely recognized to be essential in tumor escape. Thus, novel therapies focused on blockade of inhibitory checkpoints, such as anti-PD1 antibodies, are being developed to improve immune response against tumor.
We have analyzed the influence of intratumoral heterogeneity in the immune response to immunotherapy in non-small cell lung cancer (NSCLC) to identify potential conditioning factors of response to treatment. For this, we have established a syngeneic mouse model of NSCLC marked with RGB lentiviral vectors for multicolor cell tracking, to analyze clonal subpopulations in tumors treated with anti-PD1 or control antibodies. This has allowed us to track different clonal subpopulations derived from initial tumor and isolate treatment resistant subsets by cell sorting, some of which were re-inoculated to analyze the behavior of each one individually. We have studied tumor progression, host immune response and gene expression profile in individual clonal subpopulations derived from anti-PD1- and control-treated NSCLC.

WS.B1.01.02

Rational therapeutic modulation of the tumour microenvironment sensitizes cancers to immune checkpoint blockade

R. M. Zemek[1,2], *E. De Jong*[3], *W. L. Chin*[1,2], *V. Fear*[2], *C. Forbes*[2], *T. Casey*[2], *A. R. Forrest*[4], *D. O'Muiri*[4], *M. Small*[5], *A. Zaitouny*[5], *M. J. Millward*[6,1], *A. K. Nowak*[6,1,2], *T. Lassman*[7], *R. A. Lake*[8,2], *A. Bosco*[7], *W. J. Lesterhuis*[8,2];

Background: It is not well understood what molecular events contribute to an effective response to immune checkpoint blockade (ICB). Numerous combinations of drugs with ICB are currently being trialled with limited empirical preclinical evidence of efficacy. Predictive biomarkers and a rational approach to improve efficacy are therefore urgently needed.
Methods: Using inbred mouse strains inoculated bilaterally with monoclonal cancer cell lines, treatment with ICB results in a clear symmetric, yet dichotomous response, allowing us to sample entire tumours from one side and correlate findings with response, knowing the future outcome from the contralateral tumour. We used bulk RNAseq, single cell RNAseq and flow cytometry to characterise the pre-treatment tumour microenvironment of responding versus non-responding tumours. Findings were validated using publicly available RNAseq datasets of patients treated with ICB, and through in vivo pharmacologically targeting in murine cancer models.
Results: Responders had greater NK cell infiltrate and upregulation of NK associated genes. In addition, responders displayed an inflammatory gene expression signature driven by STAT1, which was corroborated in a dataset of patients with diverse cancers treated with ICB. We identified key positive and negative upstream regulators that were predicted to induce the response-associated signature. Pre-treatment of difficult-to-treat mouse tumour models, using a combination of therapeutics targeting these upstream regulators resulted in full cures when they were subsequently treated with immune checkpoint blockade.
Conclusion: We identified a pre-treatment STAT1-driven gene signature associated with response. Phenocopying this response-associated gene expression profile by rational pre-treatment of the tumour microenvironment sensitizes tumours to ICB.

Introduction: Checkpoint inhibitors and adoptive cell therapy provide promising options for treating solid cancers such as hepatitis B-related hepatocellular carcinoma but have limitations. We tested the potential to combine advantages of each approach, genetically re-programming T cells specific for viral/tumour antigens to overcome exhaustion by down-modulating the co-inhibitory receptor PD-1. **Methods:** We developed a novel lentiviral transduction protocol to achieve preferential targeting of endogenous low-frequency or TCR-redirected antigen-specific CD8 T cells for shRNA knockdown of PD-1 and tested functional consequences for anti-tumour immunity in 2D and 3D cultures. **Results:** Antigen-specific CD8 T cells transduced with LV-shPD-1 consistently had a marked reduction in PD-1 compared to those transduced with a control lentiviral vector. PD-1 could also be down-modulated on liver-resident or T cell receptor (TCR)-redirected T cells. PD-1 knockdown of human T cells rescued anti-tumour effector function and promoted killing of hepatoma cells in a 3D microdevice recapitulating the pro-inflammatory PD-L1^{hi} liver microenvironment.
However, upon repetitive stimulation, PD-1 knockdown drove T cell senescence and induction of other co-inhibitory pathways. **Conclusion:** We provide proof-of-principle that T cells with endogenous or genetically engineered specificity for HCC viral antigens can be targeted for functional genetic editing. We show that PD-1 knockdown enhances immediate tumour killing but is limited by compensatory engagement of alternative co-inhibitory and senescence programmes upon repetitive stimulation. **Grants:** EASL postdoctoral fellowship, WT Senior Investigator Award.

CD47-SIRPa checkpoint blockade involves kindlin3-dependent enhancement of CD11b/CD18-integrin affinity and cytotoxic synapse formation

P. Bouti[1], *H. Matlung*[1], *M. van Houdt*[1], *P. Verkuijlen*[1], *K. Franke*[1], *T. W. Kuijpers*[1,2], *T. K. van den Berg*[1,3];
[1]*Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands,* [2]*Academic Medical Centre, Amsterdam, Netherlands,* [3]*Department of Molecular Cell Biology and Immunology, VU medical center, Amsterdam, Netherlands.*

Recently, we established that neutrophils kill antibody-opsonized tumour cells by a novel cytotoxic process that we have termed *trogoptosis*. This previously unknown killing mechanism involves trogocytosis (from Greek *trogo*, gnaw), where fragments of target cell membrane are actively taken up by the neutrophil, thereby disrupting the target cell plasma membrane and killing the cancer cells. Trogocytosis and subsequent killing is strictly dependent on antibody-opsonization of the tumour cells, neutrophil Fcγ-receptor signalling and CD11b/CD18 integrin-dependent cytotoxic synapse formation. Furthermore, it is promoted by CD47-SIRPα checkpoint inhibition. Here, we present evidence that CD47-SIRPα interactions act by controlling the initial stage of the killing process i.e. the CD11b/CD18-dependent cytotoxic synapse formation. In particular, CD47-SIRPα interactions negatively regulated the CD11b/CD18 inside-out activation that occurred as a consequence of Fc-receptor signalling in neutrophils. Moreover, the inhibitory effect acted via the integrin-associated protein kindlin-3, as demonstrated, amongst other things, by using neutrophils from rare LAD-III patients that have mutations in FERMT3 and lack kindlin-3 expression. Collectively, these findings demonstrate that CD47-SIRPα interactions control a kindlin-3-dependent pathway of CD11b/CD18-integrin activation, and that targeting the CD47-SIRPα checkpoint primarily improves integrin activation, and therefore also the resultant cytotoxic synapse formation, trogocytosis and killing during neutrophil ADCC towards cancer cells.

WS.B1.01.05

HVEM as a new checkpoint blockade for cancer immunotherapy

P. KC[1], *S. Brunel*[1], *N. Aubert*[1], *D. Olive*[2], *G. Marodon*[1];
[1]*Sorbonne Université - Centre d'immunologie et des maladies infectieuses-Paris, UMRS 1135, Paris, France,* [2]*Aix-Marseille Universités, Inserm, CNRS, CRCM, Institut Paoli-Calmettes, Marseille, France.*

Expression of the co-inhibitory molecule Herpes Virus Entry Mediator (HVEM) has been identified in a wide range of cancers and its expression level might be inversely correlated with patient survival.
HVEM positive tumor cells could inhibit the immune response through co-inhibitory molecules BTLA or CD160, the main HVEM ligands expressed by human T lymphocytes.
To release the anti-tumor immune response, a monoclonal antibody (mAb) targeting this immune checkpoint was evaluated in NSG mice, genetically deficient for T, B and NK cells. NSG mice grafted with PBMC and PC3, a human prostate cell line expressing HVEM, showed a reduced tumor growth with anti-HVEM therapy whereas no effect was observed with another prostate cancer cell line not expressing HVEM. TILs had an increased proportion or proliferation of CD8+ T cells, suggesting that the mAb improved anti-tumor immunity. Albeit to a lesser extent, reduction in tumor growth was also observed in mice without PBMC. Depletion experiments with anti-Gr1 antibody indicated a role for myeloid cells on tumor growth. Moreover, co-culture of NSG macrophages and PC3 showed an increase in tumor mortality with the anti-HVEM.
These results suggest that the anti-HVEM mAb might directly target the tumor and recruits myeloid cells to induce cell death while at the same time, it might release local immunosuppression by preventing the inhibitory HVEM/BTLA interaction to occur. Thus, HVEM, by its dual effect on tumors and T lymphocytes, is a promising target for cancer immunotherapy.

WS.B1.01.06

Gastro-intestinal Stromal Tumors show enhanced numbers of checkpoint-negative CD8 T-cells

Y. Klaver, M. Rijnders, A. Oostvogels, R. Wijers, M. Smid, D. Grunhagen, C. Verhoef, S. Sleijfer, ***C. Lamers****, R. Debets;*
Erasmus MC Cancer Institute, Rotterdam, Netherlands.

Soft Tissue Sarcoma (STS) is a relatively rare type of cancer with over 50 different subtypes that can originate from fat, muscle, nerves, fibrous, endothelial, or deep skin tissues. To explore whether STS subtypes show differential sensitivity to immune therapies, we analyzed quantity, immune phenotype and TCR diversity of tumor infiltrating lymphocyte (TIL) as well as immunogenicity of gastrointestinal stromal tumors (GIST), leiomyosarcoma (LMS), liposarcoma (LPS), myxofibrosarcoma (MFS), and pleomorphic sarcoma (PMS). Fresh resection specimen were processed for in situ stainings and single cell flowcytometry with a focus on CD8 T-cell differentiation and surface expression of immune checkpoints. STS DNA and RNA sequencing data were processed in silico to assess mutational load, TCR diversity, frequencies of immune cells, and antigen presentation and expression of checkpoints and their corresponding ligands. GIST, MFS and PMS were observed to have relatively high numbers of CD8 TILs with highest fractions of differentiated CD8 T-cells in GIST and LPS. These CD8 TILs generally expressed the checkpoints PD-1, LAG3 and TIM3, with highest co-expression in MFS and PMS and, unexpectedly, nearly absent co-expression in GIST. Interestingly, when analyzing TCR-Vb sequences, the fractions of dominant clones were lowest in GIST and LPS. Interrogation of Next Generation Sequencing data revealed that numbers and checkpoint expression levels of CD8 TILs relate to immune evasive mechanisms, in particular with respect to intra-tumoral T-cell activation. In conclusion, STS subtypes differ in quantity and quality of CD8 TILs, making these subtypes amenable to different forms or combinations of immune therapy.

WS.B1.02.01

BAFF-R as a novel therapeutic target for Acute Lymphoblastic Leukemia

R. Parameswaran*, Y. Vicioso;*
Case western reserve university, Cleveland, United States.

Introduction: Acute Lymphoblastic Leukemia (ALL) is the most common childhood cancer. Drug resistance and relapse are two major problems in ALL. Pre-B ALL cells express B-cell activating factor receptor (BAFF-R) on their surface, which is not present on normal pre-B cells. **Results:** We observed that BAFF-R expression was maintained in drug resistant and relapse pre-B ALL cells. We used an anti-BAFF-R antibody optimized for antibody dependent cellular cytotoxicity (ADCC) to enhance NK cell mediated killing of drug resistant and relapsed ALL cells, which are difficult to treat by conventional chemotherapy. We found that anti-BAFF-R antibody enhanced NK cell mediated killing of drug resistant and relapse ALL cells *in vitro.* Early treatment with anti-BAFF-R antibody and NK cells significantly reduces disease burden in xenograft ALL models. However, in advanced disease, the efficacy of anti-BAFF-R antibody to mediate ADCC is reduced. ALL cells are known to produce TGF-beta, that causes NK cell dysfunction. We found that co-culturing ALL cells with NK cells lead to a decrease in FCγ-RIII expression on NK cells. Since FCγ-RIII is essential for ADCC, we evaluated the effect of EW-7197, a potent TGF-beta receptor I inhibitor, to enhance ADCC killing of ALL cells. We found that neutralizing TGF-beta receptor I on NK cells, using EW-7197, prevented ALL and TGF-beta-induced downregulation of FCγ-RIII expression in NK cells and improved *in vitro* and *in vivo* killing of ALL cells. **Conclusion:** Treatment with BAFF-R antibody, NK cells and EW-7197 may eradicate relapse and drug resistant pre-B ALL.

Investigation of novel immunotherapeutic targets for colorectal cancer

D. Shinko[1], *H. McGuire*[2,3], *T. Ashhurst*[3,2], *S. Clarke*[4], *S. Byrne*[5,6], *K. Charles*[1];
[1]*Discipline of Pharmacology, The University of Sydney, Sydney, Australia,* [2]*Discipline of Pathology, The University of Sydney, Sydney, Australia,* [3]*Ramaciotti facility for Systems Biology, The University of Sydney, Sydney, Australia,* [4]*Royal North Shore Hospital, Sydney, Australia,* [5]*The Westmead Institute for Medical Research, Sydney, Australia,* [6]*Discipline of Infectious Diseases and Immunology, The University of Sydney, Sydney, Australia.*

An enhanced understanding of the immune-tumour interaction has led to significant clinical benefit in the use of immunotherapy in cancer. In colorectal cancer, however, a lack of understanding of the immune cell complexity means that the correct drug targets for exploitation remain elusive. Our aim was to investigate the immune phenotype and inflammatory signalling pathways in colorectal cancer patients undergoing chemotherapy to identify novel immunotherapeutic targets. Using a 35-marker mass cytometry panel, we quantified 7 major circulating immune cell types and over 20 subtypes in 10 advanced colorectal cancer patients and 9 healthy volunteers. We found significant difference in major B cell populations and sub-populations of T cells (including regulatory T cells, central memory T helper cells and effector memory cytotoxic T cells) between the patients and the healthy volunteers. Further interrogation of B cell sub-populations are underway. We also quantified nine phosphorylated intracellular signalling markers. At baseline, results show that pP38 and pSTAT3 are significantly decreased in patients across the majority of immune cells whereas pSTAT5 is increased. Results also show that phosphorylated markers, such as pERK, can be activated following a cycle of chemotherapy and remain activated throughout the therapy. Relationships between immune profiles and clinical outcomes are currently being explored. The use of mass cytometry has allowed the investigation of the immune profile of CRC patients and potential novel immunotherapeutic targets have been identified to improve clinical outcomes.

WS.B1.02.03

IL-1R8 is a novel checkpoint regulating anti-tumor and anti-viral activity of NK cells

M. Molgora[1], *E. Bonavita*[2], *A. Ponzetta*[1], *F. Riva*[2], *M. Barbagallo*[2], *S. Jaillon*[1], *B. Popovic*[3], *G. Bernardini*[4], *E. Magrini*[2], *F. Gianni*[2], *S. Zelenay*[5], *S. Jonjic*[3], *A. Santoni*[4], *C. Garlanda*[1], *A. Mantovani*[1];
[1]*Humanitas University, Pieve Emanuele, Italy,* [2]*Humanitas Research Hospital, Rozzano, Italy,* [3]*University of Rijeka, Rijeka, Croatia,* [4]*Università di Roma "La Sapienza", Roma, Italy,* [5]*Cancer Research UK, Manchester, United Kingdom.*

IL-1R8 is an Interleukin-1 receptor family member that acts as a negative regulator of IL-1 family receptor and TLR signaling. Both murine and human NK cells express high levels of IL-1R8 but its functional role in this cell type has not been described so far. Expression analysis showed that IL-1R8 was acquired during differentiation in human and murine NK cells. IL-1R8 deficiency in the mouse was associated with enhanced NK cell maturation and activation. IL-18, which is a key regulator of NK cell activities and can be targeted by IL-1R8, was responsible for this phenotype. To assess the role of IL-1R8 in NK cells in pathology, we used models of MCA-induced lung metastasis, colon cancer-derived liver metastasis and DEN-induced hepatocellular carcinoma. The number and dimension of liver and lung metastasis and the liver disease severity were significantly reduced in *Il1r8*$^{-/-}$ mice. The depletion of NK cells in these models totally abrogated the protection observed in *Il1r8*$^{-/-}$ mice. Finally, we investigated the role of IL-1R8 in NK cell antiviral activity, in a model of MCMV infection. *Il1r8*$^{-/-}$ mice controlled the virus more efficiently in the liver and the protection was associated with enhanced NK cell degranulation and IFN-γ production. The adoptive transfer of *Il1r8*$^{-/-}$ NK cells conferred protection in both metastasis and viral infection models. IL-1R8 plays a non-redundant role in the regulation of NK cell development and effector functions by tuning IL-18-dependent activities. IL-1R8 therefore emerges as a crucial regulator of NK cell antitumoral and antiviral potential.

WS.B1.02.04

Glycan modified vesicles as a targeted and personalized vaccination strategy for the induction of anti-tumor immunity

S. K. Horrevorts*, D. A. Stolk, S. J. van Vliet, T. D. de Gruijl, A. A. van de Loosdrecht, Y. van Kooyk;*
Vu university medical center, Amsterdam, Netherlands.

Effective immunotherapies should boost existing or elicit *de novo,* tumor-specific immune responses. Challenges in vaccine development are the choice of suitable antigens and targeting of these antigens to antigen presenting cells (APCs). We developed a new personalized vaccination approach, which encompasses apoptotic vesicles derived from the patients tumor and glyan modification, to allow targeting to APCs for the induction of tumor specific T cells. Apoptotic vesicles derived from the patients tumor contain both tumor associated antigens (TAAs) and neo-antigens, making them a potent source for vaccination. For the efficient targeting of the vesicles to APCs we modified their glycocalyx, resulting in the surface expression of high mannose glycan structures. These glycans are the natural ligand of the DC specific C-type lectin receptors DC-SIGN and Langerin, expressed on skin dermal DCs (dDCs) and Langerhans cells (LCs), respectively. Using *ex vivo* skin explants as a model for intradermal vaccination in humans, we are able to specifically target apoptotic vesicles to dDCs and LCs, thereby significantly increasing vesicle uptake, resulting in an enhanced antigen presentation to $CD8^+$ T cells. In conclusion we developed a novel personalized vaccine strategy were we combine patient derived tumor vesicles with glycan modification to efficiently target (neo-) antigens to APCs, for the induction of anti-tumor immune responses.

WS.B1.02.05

Heme as a modulator of the therapeutic efficacy of an anti-cancer antibody

A. Tavares-Kanyavuz*, A. Marey-Jarossay, S. Lacroix-Desmazes, J. Dimitrov;*
SorboINSERM UMR_S 1138, Centre de Recherche des Cordeliers, 75006 Paris, France.

Introduction: Polyreactive antibodies have potential to bind to multiple structurally unrelated antigens. Some apparently monoreactive antibodies like Rituximab can acquire polyreactivity post-translationally by contact with heme. Rituximab (anti-CD20) is used for the treatment of different B-cell malignancies and among these diseases some can be accompanied by hemolysis. The main goal of this study is to characterize the effect of heme on therapeutic efficacy of anti-CD20 antibodies. Materials and Methods: We performed *in vitro* studies with human B-cell lymphoma cell lines, to characterize the polyreactivity and cytotoxicity of Rituximab after heme-exposure. Then, we evaluated the impact of heme binding on the therapeutic activity of Rituximab using a murine B-lymphoma model. Results: Rituximab acquires a large gain of reactivity after exposure to heme, while retaining its capacity to bind to its cognate antigen. Induction of polyreactivity improves therapeutic efficacy of Rituximab *in vitro* and *in vivo*. Conclusions: We documented an important role of the induced polyreactivity in the function of anti-CD20 antibodies. This phenomenon may occur in patients treated with Rituximab and could potentially have therapeutic repercussions. The induction of polyreactivity could represent a new axis for improvement of the therapeutic potential of Rituximab. The project is funded by ERC (StG-2015 CoBABATI) and Association for Cancer Research (ARC, France) grants.

WS.B1.02.06

Evaluation of a New Anti-Galectin 9 Immunotherapy Strategy in Pancreatic Cancers

A. Quilbe[1], *R. Mustapha*[1], *S. Renaud*[1], *B. Duchêne*[2], *C. De Schutter*[1], *G. Herlin*[1], *O. Moralès*[1], *I. Van Seuningen*[2], *N. Jonckheere*[2], *N. Delhem*[1];
[1]*CNRS UMR 8161, Institut de Biologie de Lille, 59021 Lille Cedex, France,* [2]*INSERM UMR837 Team 5, 59021 Lille Cedex, France.*

Background: We have previously described in an humanized mouse model of nasopharyngeal carcinoma that an anti-Galectin-9 (Gal-9) monoclonal antibody (mAb) is able to significantly limits tumor growth by specifically inhibiting the suppressive activity of human natural Tregs (Patent WO: WO2015185875). Herein, we propose to use this new specific active immunotherapy in a pancreatic cancer mouse model ($KRAS^{G12D}$), insofar as a high Treg prevalence has been described and correlated to the tumor progression of pancreatic cancer.
Methods and Results: Gal-9 expression was confirmed by immunohistochemistry on pancreas isolated from the $KRAS^{G12D}$ mouse model. This Gal-9 expression level has been correlated to the progression of pre-cancerous lesions. Furthermore, an increase of Tregs prevalence has been observed in this transgenic model at a systemic and intratumoral level. Very interestingly, we also showed that **(i)** murine Tregs expressed Gal-9 (flow cytometry, immunofluorescence and western-blot), **(ii)** anti-Gal9 mAb neutralized the immunosuppression induced by recombinant murine Gal-9 (proliferation assays) and **(iii)** anti-Gal9 mAb neutralized the suppressive activity of murine Tregs (MLR assay). Further investigations performed on four human pancreatic cancer cell lines (Capan-1, Capan-2, MIAPaCa-2, Panc-1) have also confirmed the Gal-9 expression at a genomic (RT-qPCR), proteomic (Immunofluorescence, Western-blot and flow cytometry) and secreting (ELISA) level.
Conclusion: Our preliminary results suggest that the use of an anti-Gal-9 mAb could be considered as a new anti-tumoral immunotherapy targeting Tregs in the pancreatic cancer.

WS.B1.03 Genetically engineered TCR for immunotherapy

WS.B1.03.01

Development and characterization of novel anti-GD2 target modules for retargeting of Universal CAR T cells toward GD2 expressing tumors

*N. Mitwasi[1], **A. Feldmann**[1], R. Bergmann[1], N. Berndt[1], C. Rössig[2], M. Bachmann[1,3,4];*
[1]Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany, [2]Department of Pediatric Hematology and Oncology, Münster University Hospital (UKM), Dresden, Germany, [3]Tumor Immunology, University Cancer Center (UCC) 'Carl Gustav Carus' TU Dresden, Dresden, Germany, [4]German Cancer Research Center (DKFZ), Heidelberg, Germany.

Although chimeric antigen receptor (CAR) engineered T cells demonstrated promising therapeutic effect against cancer, they are still associated with adverse side effects which could be life threatening in some cases. Therefore, in our group we have developed a switchable universal CAR T cell platform "UniCAR", which can be repeatedly switched on and off. This system consists of CAR T cells that cannot bind tumor antigens directly but instead they are redirected with a target module (TM). Such TMs are mainly composed of an epitope on one side, which is recognized by the UniCAR T cells, and on the other side a tumor antigen-binding domain. Once the TM is eliminated, the UniCAR T cells are no more activated. Disialoganglioside GD2 was shown previously to be a very promising target for several tumors such as neuroblastoma and Ewing's sarcomas. Therefore, anti-GD2 TMs were developed and evaluated regarding their functionality. They were shown to be functional in activating the UniCARs to secrete important pro-inflammatory cytokines and to kill $GD2^+$ tumor cells both in vivo and in vitro. To further characterize the anti-GD2 TM with PET imaging, it was labeled with radioactive Cu^{64}. The TM showed a specific enrichment at the site of the $GD2^+$ growing tumor, and it was mainly eliminated through the kidneys within half an hour due to its small size. Such short half-life, provide the UniCAR system with the fast safety switch in case any complications occurred in patients treated with the UniCAR T cells.

WS.B1.03.02

Functional comparison of CARs targeting CD20 with a TCR directed against a CD20 derived peptide

***T. L. A. Wachsmann**[1], L. Jahn[1], E. van Diest[2], J. Leusen[2], J. Kuball[2], J. Falkenburg[1], M. Heemskerk[1];*
[1]LUMC, Leiden, Netherlands, [2]UMC Utrecht, Utrecht, Netherlands.

With the rise of chimeric antigen receptor (CAR) T-cells, the role & potential of T-cell receptors (TCRs) targeting surface antigen derived peptides for gene transfer therapy needs to be reevaluated. While the non HLA-restricted CAR T-cells have demonstrated remarkable clinical efficacy in hematological malignancies, severe toxicity in responders and non-responsiveness in a subset of patients remain major challenges. We hypothesize that TCR transduced T-cells targeting tumor surface antigen derived peptides pose a valuable alternative to CAR T-cells by maintaining a comparable efficacy while exhibiting a more tolerable toxicity profile, alongside higher resistance to activation induced cell death and exhaustion.
Our group has previously identified a high affinity TCR targeting a CD20 derived peptide presented in the context of HLA-A2. Using a panel of human acute lymphoblastic leukemia cells with different levels of CD20 expression, we aim to functionally compare our TCR with four 4-1BB-CD3z second generation CARs differing in their CD20 recognition domain. Primary endpoints are functionality (killing capacity & cytokine profiling), resilience, proliferative capacity and maintenance of functionality after antigen challenge.
Preliminary *in vitro* studies reveal markedly elevated cytokine production alongside indications of accelerated killing kinetics in the CAR T-cells as opposed to the TCR transduced T-cells in a CD20 expression sensitive manner. However, this appears to trade off against activation induced cell death and severe impairment of proliferative capacity in response to high levels of antigen exposure in the CAR T-cells. Ultimately, our experimental framework provides a rationale for the future direction of antigen receptor design.

WS.B1.03.03

Impaired Early Downstream Signaling Blunts Antigen Sensitivity of CAR-T-cells

***V. Gudipati**[1], J. Rydzek[2], I. Perez[1], S. Königsberger[1], H. Stockinger[1], M. Hudecek[2], J. Huppa[1];*
[1]Medical University of Vienna, Vienna, Austria, [2]Universitätsklinikum Würzburg, Würzburg, Germany.

Adoptive immunotherapy employing chimeric antigen receptor (CAR)-modified T-cellshas given rise to new hope in oncology as an effective treatment regimen for advanced malignancies. While high rates of complete remission after CAR T-cell therapy can be obtained in patients with B cell malignancies, relapse may occur in significant number of patients, often owing to antigen loss variants. Rational design of CARs with optimized anti-cancer performance mandates detailed knowledge of how CARs engage tumour antigens and how antigen-engagement triggers activation. To gain a deeper insight into the mechanisms of CAR-induced activation and the development of the CAR immunological synapse, we employed total internal reflection fluorescence (TIRF) microscopy. We found the sensitivity of CAR-T-cells towards antigen is reduced by 500 times when compared to T-cell antigen receptor-mediated detection of nominal peptide/MHC complexes. While CAR-antigen binding was efficient, receptor-proximal signalling was significantly attenuated due to reduced recruitment of the tyrosine kinase ZAP70 at ligated CARs. At limiting antigen densities absence of adhesion molecule ICAM1 significantly affects CAR T-cell mediated cytotoxicity indicating that blunted CAR signalling leads to attenuated activation of the integrin LFA-1, thereby compromising cell adhesion. our findings expose fundamental limitations of current one-dimensional CAR designs that has to be overcome for personalized cancer treatment. Furthermore, our findings highlight unique strengths of live molecular imaging for preclinical CAR-development.

WS.B1.03.04

Antitumor activity by TEGs: alpha/beta T cells engineered to express a defined gamma/delta TCR in a 3D bone marrow niche model of multiple myeloma

***T. Straetemans**[1], M. Braham[2], T. Aarts-Riemens[1], J. Alblas[3], M. Minnema[4], Z. Sebestyen[1], J. Kuball[4];*
[1]Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of Orthopaedics, University Medical Center Utrecht, Utrecht, Netherlands, [3]Department of Orthopeadics, University Medical Center Utrecht, Utrecht, Netherlands, [4]Department of Hematology, University Medical Center Utrecht, Utrecht, Netherlands.

γδT cells mediate cancer immune surveillance by sensing metabolic changes of malignant cells via their γδTCR. This concept led to the development of next generation CAR T cells, so-called TEGs: αβT cells Engineered to express a defined γδTCR. A particular γ9δ2TCR, has been selected as candidate for clinical testing (TEG001). TEG001 cells showed a strong and broad recognition of hematological malignancies and are able to differentiate between healthy and leukemic stem cells. Important for the therapeutic success of immune therapy concepts such as TEGs is a better understanding of the interplay between malignant, stromal and immune cells in the tumor microenvironment. To this end a 3D model was established that allowed engraftment of primary multiple myeloma (MM) cells within a humanized bone marrow niche...TEG001 cells were engineered from both healthy donor and MM patients' T cells and added when MM growth was established. TEG001 cells, but not mock engineered T cells, migrated into the 3D structure and exerted a killing response towards the tumor cells but not towards the stromal cells. This cognate recognition was associated with the differential production of chemokines, cytokines and inhibitory molecules. Amongst others, TEG001 cells induced CCL1 secretion, but also the secretion of IL-6 and GM-CSF, reported to be involved in cytokine release syndrome. Soluble Galectin-9, the proposed ligand for inhibitory receptor TIM-3, was reduced in the supernatant. These findings demonstrate that TEGs are a promising addition to the currently available immune therapeutic strategies as they target cancer as a metabolic disease.

WS.B1.03.05

Engineering antigen-specific Natural Killer cells against the melanoma-associated antigen tyrosinase via TCR gene transfer

***A. Parlar**[1,2], C. Pamukcu[1,2], E. C. Sayitoglu[3], A. Georgoudaki[3], D. Ozkazanc[1,2], M. Aras[1,2], M. Chrobok[3,4], P. Zahedimaram[1,2], L. Ikromzoda[1,2], E. Alici[3,4], B. Erman[1,2], A. D. Duru[3], T. Sutlu[1];*
[1]Nanotechnology Research and Application Center, Sabancı University, Istanbul, Turkey, [2]Faculty of Engineering and Natural Sciences, Sabancı University, Istanbul, Turkey, [3]NSU Cell Therapy Institute, Nova Southeastern University, Florida, United States, [4]Center for Hematology and Regenerative Medicine, Karolinska Institutet, Stockholm, Sweden.

While genetic modification of cytotoxic T lymphocytes (CTLs) using T Cell Receptors (TCRs) to target intracellular antigens or using Chimeric Antigen Receptors (CARs) to target cell surface antigens are commonly investigated; for Natural Killer (NK) cells, CARs have so far been the only practical method of antigen-specific retargeting, TCR gene therapy can supply large populations of CTLs genetically modified to express a specific TCR, but the mispairing of endogenous and genetically transferred TCR subunits constitutes a bottleneck in the development of safe therapies. In order to overcome this obstacle and open the realm of intracellular antigens to targeting by NK cells, we propose to use NK cells for TCR gene therapy. Our results show that ectopic expression of the CD3δ, CD3γ, and CD3ε chains along with TCR α/β gene delivery to NK cells enables the functional expression of a TCR specific to tyrosinase-derived peptide $Tyr_{368-379}$ in complex with HLA-A2. We observed that neither the TCR α/β heterodimer, nor the CD3 subunits had the capacity to transport to the cell surface alone but could only form a stable complex when all components were present. The introduction of a functional TCR complex to NK cells enabled antigen-specific and MHC-restricted triggering of effector functions against tyrosinase expressing tumor cells both *in vitro* and *in vivo*. This strategy not only opens the realm of intracellular antigens to targeting by NK cells but also provides a definite solution for the mispairing problem observed in TCR gene therapy.

WS.B1.03.06

TCR replacement in the endogenous locus via non-viral CRISPR-Cas9-mediated knock-in

K. Schober[1], *T. Müller*[1,2], *D. H. Busch*[1,2,3];
[1]*Institute of Medical Microbiology, Immunology and Hygiene, München, Germany,* [2]*National Center for Infection Research (DZIF), Munich, Germany,* [3]*Focus Group "Clinical Cell Processing and Purification", Institute for Advanced Study, TUM, Munich, Germany.*

Recently emerged advanced genome editing tools like CRISPR/Cas9 open up new avenues for the development of next-generation cell therapies, including T cell therapy for the treatment of viral infections or cancer. Knockout of the endogenous T cell receptor (TCR) has been reported to both increase the functionality of TCR-transduced T cells and reduce the risk of Graft-versus-Host-Disease (GvHD) (Provasi et al. Nat Med 2012). Adeno-associated virus (AAV)-mediated delivery of a chimeric antigen receptor (CAR) into the CRISPR/Cas9-edited TCR locus has been achieved with high editing efficiency and revealed superior *in vivo* functionality due to physiological receptor expression regulation (Eyquem et al. Nature 2017). Recently, non-viral CRISPR/Cas9-mediated TCR replacement in the endogenous locus has been realized (Roth et al. bioRxiv 2017), but a systematic investigation of the contribution of 'lacking competition' through the endogenous TCR on the one side, and physiological transgenic TCR expression on the other side, has not been undertaken. Combining CRISPR/Cas9-mediated TCR replacement with a library of differential avidity TCRs directed against the same epitope (e.g. A2-pp65), we have set up a platform to in-depth dissect the parameters leading to superior functionality of 'replacing TCRs'. Simultaneously, we show that through-put of TCR characterization - so far the key bottleneck in TCR testing platforms - can be massively accelerated by CRISPR/Cas9-mediated re-expression. In consequence, TCR candidates for engineered T cell therapeutics can not only be assessed more quickly, but also in their physiological regulatory framework.

WS.B1.04 Antigen specificity in anti-tumor immunity

WS.B1.04.01

Towards the next generation CAR T cells with TEGs: in vivo efficacy - toxicity profile in xenografts of primary human AML disease and healthy bone marrow

I. Johanna[1], *T. Straetemans*[1], *S. Heijhuurs*[1], *T. Aarts-Riemens*[1], *H. Norell*[2], *L. Bongiovanni*[3], *A. de Bruin*[3], *Z. Sebestyen*[1], *J. Kuball*[1];
[1]*Department of Hematology and Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal,* [3]*Department of Pathobiology, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.*

γδT cells mediate cancer immune surveillance by sensing metabolic changes of malignant leukemic blasts and not their healthy counterpart via their γδT cell receptor (TCR). This concept led to the development of next generation CAR T cells, so-called TEGs: αβT cells Engineered to express a defined γδTCR. A particular γ9δ2TCR, isolated from "clone 5", has been selected as the candidate for clinical testing (TEG001). TEG001 cells showed a strong and broad recognition of hematological malignancies against both cell lines and primary AML.
In order to evaluate the biodistribution and safety profile of TEGs we developed a patient-derived xenograft (PD-X) *in vivo* model by establishing primary malignant AML blasts, which tested positive in an *in vitro* assay for recognition by TEGs, in NSG mice. In addition, healthy stem cells from human cord-blood were in parallel engrafted in a separate set of NSG mice. After engraftment, TEGs were infused and mice followed for additional 50 days. While engrafted primary AML blasts were no longer detectable in the peripheral blood at the end of the study period, all healthy hematological cellular compartments remained unharmed.
Within the limitations of humanized PD-X models, TEGs target acute myeloid leukemia but do neither interfere with engraftment of hematopoietic progenitors nor harm matured subsets of the hematopoiesis. In addition, no additional signs of off-target toxicity were observed in mice. TEGs are a promising addition to the currently available immune therapeutic strategies as they target cancer as a metabolic disorder.

WS.B1.04.02

Harnessing Pre-Existing Antiviral Immunity to Treat Solid Tumors

N. Cuburu[1], *R. Kim*[1], *S. M. Pontejo*[2], *C. D. Thompson*[1], *D. R. Lowy*[1], *J. T. Schiller*[1];
[1]*National Cancer Institute, NIH, Bethesda, United States,* [2]*National Institute of Allergy and Infectious Diseases, NIH, Bethesda, United States.*

Human cytomegalovirus is highly prevalent in humans with polyfunctional T cell responses expanding with age. We questioned whether redirecting pre-existing anti-cytomegalovirus T cells into solid tumor could arrest tumor growth, induce epitope spreading, and confer long-term anti-tumor immunity.Persistently infected mice with murine cytomegalovirus (mCMV) were challenged with TC-1 tumor cells expressing human papillomavirus (HPV) E6 and E7 oncogenes. In vivo transduction of TC-1 tumors with a viral vector expressing MCMV antigens or intratumoral injection of peptidic mCMV epitopes with a TLR3 agonist (poly I:C) caused the expansion of mCMV-specific CD4+ and CD8+ T cells. Using PanCancer Imune profiling panel (Nanostring) we show that intratumoral injection of mCMV peptide epitopes induced massive modifications of the tumor innate and adaptive immune environment. Intratumotal injection of mCMV CD8 peptide epitopes provoked the arrest of tumor growth. Intratumotal injection of mCMV CD4 peptide epitopes with poly I:C promoted induction of E7-specific CD8+ T cells. Sequential administration of CD4 and CD8 mCMV epitopes together with poly I:C was the best protocol to eradicate pre-existing tumor of 5 to 10mm diameter, and rechallenge experiments showed antitumor immunity up to 4 months after the last treatment.Our results provide a proof of concept to design "antigen-agnostic" intratumoral therapies based on pre-existing antiviral T cells. Such approach changedthe tumor immune microenvironment, induced epitope spreading, and conferred long term anti-tumor immunity. These findings prompt further evaluation in other spontaneous tumor models and provide a model to decipher the mechanisms of epitope spreading notably to investigate CD4 T cell help.

WS.B1.04.03

Ephemeral immune control of cytomegalovirus infection by T-cells recognizing a single viral epitope

F. Mbui, *L. Borkner, Z. Chaudhry, L. Cicin-Sain;*
Helmholtz Center for Infection Research (HZI), Braunschweig, Germany.

The cytotoxic T cells play an important role in the control of cytomegalovirus (CMV). T cell-based adoptive immunotherapy using antigen specific cells is explored as a treatment option for CMV disease. However, therapeutic success varies among individual recipients and the underlying reasons remain unclear and unpredictable. To understand the minimal requirements for adoptive immunotherapy of CMV disease, we generated recombinant murine CMVs expressing the immunodominant epitopes SSIEFARL or KCSRNRQYL. We infected TCR transgenic mice on a $RAG2^{-/-}$ background, recognizing only these epitopes, and followed their survival upon infection. While wild-type virus rapidly killed the mice, recombinant viruses expressing the corresponding epitope were controlled. However, the immune protection was transient, because the mice succumbed by 6-8 weeks post infection. To test if poor viral control was caused by T-cell exhaustion, we analyzed their phenotype. While we observed an accrual of exhausted T cells ($PD1^+$, $Eomes^+$) at times of death, these increases were modest. Most T cells remained PD1-negative and retained functionality in ex vivo assays. Alternatively, viral escape of immune recognition could have explained the phenomenon. Therefore, we isolated MCMV genomes from organs of infected mice at time of death and sequenced them. We identified epitope deleterious mutations in the vast majority of viral genomes, which were sufficient to prevent T-cell recognition of infected cells. Our data argue that T-cell immunotherapy against one immunodominant epitope may provide transient protection against CMV, but also drive immune escape. Therefore, our data indicate that optimal T-cell protection may require targeting multiple epitopes.

WS.B1.04.04

Autologous neo-antigen-specific T cell responses in low mutation burden colorectal cancers

J. van den Bulk, *D. Ruano, M. Visser, M. IJsselsteijn, R. van der Breggen, K. Peeters, S. van der Burg, E. Verdegaal, N. de Miranda;*
LUMC, Leiden, Netherlands.

Innovative treatment options are required to improve cure rates in advanced colorectal cancer patients. Immune checkpoint blockade therapy (anti-PD-1) was shown to be effective in colorectal cancers with high mutation burden (e.g. mismatch repair deficient) as anti-tumour reactivity is largely explained by the recognition of somatically mutated antigens (neo-antigens). No immunotherapeutic strategies are currently available for patients diagnosed with low mutation burden CRC, while they could greatly benefit from the induction of immune responses. We hypothesized that if autologous neo-antigen-reactive T cells are present in such patients, they might benefit from specific immunotherapeutic interventions that stimulate neo-antigen recognition. In order to detect neo-antigens, whole exome and RNA next-generation sequencing were performed in cancer and healthy tissues from colorectal cancer patients. Corresponding peptides were synthesized and tested for their ability to induce immune cell activation in lymphocytes isolated from the tumour tissue and from peripheral blood. Neo-antigen-specific T cell responses were identified against 5 out of 39 neo-antigens corresponding to 35 somatic mutations that were expressed in the tumour tissue from a CRC patient. In conclusion, we developed a neo-antigen screening pipeline to unlock the immunogenic potential of colorectal cancers with low mutation burden. We have detected a relatively high number of neo-antigens that are recognized by autologous T cells in a mismatch repair proficient, low mutation burden CRC patient. This finding supports the widespread evaluation of the potential to employ neo-antigen-targeted therapies to improve the treatment of colorectal cancer patients.

WS.B1.04.05

A minority of tumor associated antigen specific T-cells restricted to self-HLA alleles is of sufficient avidity to recognize overexpressed endogenously processed antigen

M. Roex[1], *L. Hageman*[1], *E. van Egmond*[1], *S. Veld*[1], *C. Hoogstraten*[1], *L. Germeroth*[2], *F. Falkenburg*[1], *I. Jedema*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Juno Therapeutics, Göttingen, Germany.*

Tumor associated antigens (TAA) are proposed as targets for graft versus leukemia effect after HLA-matched allogeneic stem cell transplantation. As TAA are self-antigens, high avidity TAA-specific T-cells are thought to be eliminated from the T-cell repertoire by thymic selection. In this study, we investigated whether TAA-specific T-cells with sufficient avidity to recognize overexpressed endogenously processed antigen in self-HLA can be found in healthy donors. T-cells directed against TAA peptides NY-eso-1-SLL/A*02:01, WT1-RMF/A*02:01, RHAMM-ILS/A*02:01, Proteinase-3-VLQ/A*02:01 and PRAME-VLD/A*02:01 were isolated from HLA-A*02:01+ donors using MHC-I-*Strep*tamers. Generated tetramer+/CD8+ T-cell clones were classified based on the minimal concentration of peptide exogenously loaded on TAP-deficient T2-cells needed for cytokine production. To analyze recognition of overexpressed endogenously processed antigen, high-potential clones were tested against HLA-A*02:01+ EBV-LCL transduced with the full corresponding TAA sequence. >800 tetramer+/CD8+ TAA-specific clones were isolated from 18 donors. T-cell receptor Vbeta-family analysis revealed a minimal number of unique clones: 14 NY-eso-1-SLL/A*02:01, 30 WT1-RMF/A*02:01, 14 RHAMM-ILS/A*02:01, 8 Proteinase-3-VLQ/A*02:01 and 14 PRAME-VLD/A*02:01 clones. The functional screening revealed 27 non-functional clones, 16 low-potential clones (activation threshold ≥10^-6M peptide) and 37 high-potential clones (activation threshold ≤10^-7M peptide). Of the high-potential clones, only 2 NY-eso-1-SLL/A*02:01, 7 WT1-RMF/A*02:01 and 5 PRAME-VLD/A*02:01 clones showed recognition of overexpressed endogenously processed antigen. These results illustrate that self-HLA restricted TAA-specific T-cells can be easily isolated from donor PBMC, but that only a minority of T-cells are capable of recognizing overexpressed endogenously processed antigen. Classification of functional TAA-specific T-cells by only high tetramer staining and peptide specificity leads to overestimation of relevant avidity.

WS.B1.04.06

Cross-reactive CD8+ T cell receptor clonotypes elicited by influenza epitope variants are drawn from a narrow repertoire distinct from non-cross-reactive receptors

P. G. Thomas*, P. Dash, P. Bradley, A. Williams, S. Duan;*
St. Jude Children's Research Hospital, Memphis, United States.

T cells specific for one peptide-MHC (pMHC) epitope can occasionally cross-react with closely related pMHC, such as those containing single amino acid mutations. What determines the extent of cross-reactivity has not been well-characterized. To define the "rules" of cross-reactivity, we chose two variants of the influenza D^bNP_{366}(ASNENMETM, NP-wt) epitope with a single residue change, (NP-T8A) and (NP-N3A), that are known to elicit cross-reactive responses to NP-wt. We analyzed the paired αβ TCR repertoire of cells recognizing these epitopes from mice infected with each of the variant viruses singly or in combination in a prime-challenge model. Each combination elicited highly variable degrees of cross-reactivity, ranging from 20% (T8A elicited cells reacting to wt epitope) to 90% (N3A-elicited cells reacting to wt epitope). Most strikingly, regardless of the magnitude of cross-reactivity, cross-reactive cells between each NP variant displayed an extremely narrow TCR repertoire diversity, often dominated by a single clonotype, while the non-cross-reactive cells had markedly higher diversity in their TCR repertoires. Importantly, many of these cross-reactive receptors did not appear to be the dominant receptors responding to the eliciting epitope (i.e. they had a higher TCRdistance). Our results indicate that cross-reactivity is mediated by a rare subset of TCRs that are not representative of the typical responses elicited by an epitope. This work has implications for tumor immunity, as it provides insight into how to avoid self-reactivity, and vaccine design, as repeated immunizations with distinct epitopes are likely to select for extremely narrow, cross-reactive repertoires.

dissecting the immune heterogeneity of neuroblastoma microenviroment in murine models to develop novel therapeutic strategies for high-risk neuroblastoma patients

V. Lucarini*, O. Melaiu, M. Vinci, M. Compagnone, G. Zicchedda, L. Cifaldi, V. Pistoia, D. Fruci;*
Ospedale Pediatrico Bambino Gesù, Rome, Italy.

Introduction The presence of tumor-infiltrating T cells (TILs) and the absence of immunosuppressive elements have been associated with favourable prognosis of high-risk neuroblastoma (NB) patients. Recently, a subset of intratumoral dendritic cells (iDC) has been found crucial for anthracycline-induced anticancer immune responses suggesting that they might be exploited to improve NB therapy. Herein, we investigated the modulation of the immune infiltrate in NB murine models treated with chemotherapeutic drugs in combination with immune checkpoint blocking antibodies. **Methods** Luciferase-expressing NB cell lines derived from spontaneous tumors arising in the TH-MYCN transgenic mice were injected subcutaneously or orthotopically in syngeneic mice. Mice bearing established tumors were sacrificed and TILs were analysed by flow cytometry. The crosstalk between immune and tumor cells was evaluated in drugs-treated NB spheroids co-cultured with tumor-infiltrating $CD45^+$ cells. **Results** Tumor microenviroment was characterized by a consistent number of $CD45^+$ immune cells, including T cells, NK cells, NKT cells, macrophages, neutrophils and iDCs. The orthotopic model showed a more aggressive phenotype than the subcutaneous model, resulting in the development of tumors with an immunosuppressive microenvironment predominantly infiltrated by macrophages, myeloid-derived suppressor cells and T regulatory cells. Treatment with anthracycline-derived drugs resulted in a reduced diameter of spheroid and an increased recruitment of TILs. *In vivo* experiments are currently underway to evaluate the TILs in tumor-bearing mice treated with anthracycline-derived drugs and immune checkpoint blocking antibodies. Overall, we provide insights for the study of a novel immunotherapeutic approach in NB.

WS.B1.05.02

Deficiency of host CD96 and PD-1 or TIGIT enhances tumor immunity without significantly compromising immune homeostasis

H. Harjunpaa[1,2], *S. J. Blake*[1], *E. Ahern*[1,2,3], *S. Allen*[1], *J. Liu*[1], *J. Yan*[1,2], *V. Lutzky*[1], *K. Takeda*[4], *A. Roman Aguilera*[1], *C. Guillerey*[1,2], *D. Mittal*[1,2], *X. Y. Li*[1], *W. C. Dougall*[1], *M. J. Smyth*[1,2], *M. W. Teng*[1,2];
[1]*QIMR Berghofer Medical Research Institute, Brisbane, Australia,* [2]*The University of Queensland, Brisbane, Australia,* [3]*Royal Brisbane and Women's Hospital, Brisbane, Australia,* [4]*Juntendo University, Tokyo, Japan.*

Multiple non-redundant immunosuppressive pathways co-exist in the tumor microenvironment and their co-targeting can increase clinical responses. Indeed, concurrent blockade of CTLA-4 and PD-1 in patients with advanced melanoma increased clinical responses over monotherapy although the frequency and severity of immune related adverse events also increased. Nevertheless, a substantial number of patients still display an innate resistance phenotype and are unresponsive to current approved immunotherapies even when utilized in combination. In this study, we generated *Pdcd1*$^{-/-}$*CD96*$^{-/-}$ and *Tigit*$^{-/-}$*CD96*$^{-/-}$ mice to investigate how loss of CD96 in combination with PD-1 or TIGIT impacts on immune homeostasis and hence the potential of inducing immune related toxicities following co-targeting of these pairs of receptors. The ability of *Pdcd1*$^{-/-}$*CD96*$^{-/-}$ and *Tigit*$^{-/-}$*CD96*$^{-/-}$ mice to suppress primary tumor growth was also assessed using the MC38 colon carcinoma and SM1WT1 BRAF-mutated melanoma tumor models. Both *Pdcd1*$^{-/-}$*CD96*$^{-/-}$ or *Tigit*$^{-/-}$*CD96*$^{-/-}$ mice displayed no overt perturbations in immune homeostasis over what was previously reported with *Pdcd1*$^{-/-}$ or *Tigit*$^{-/-}$ mice even when aged for 22 months. Interestingly, increased suppression of subcutaneous tumor growth and complete responses was seen in *Pdcd1*$^{-/-}$*CD96*$^{-/-}$ mice compared to *Pdcd1*$^{-/-}$ or *CD96*$^{-/-}$ mice depending upon the tumor model. This enhanced anti-tumor efficacy of *Pdcd1*$^{-/-}$*CD96*$^{-/-}$ mice appeared to be due to favorable changes in the ratio of $CD8^+$T cells to Tregs or $CD11b^+GR\text{-}1^{hi}$ myeloid cells in the tumor microenvironment. Co-targeting CD96 and PD-1 may increase anti-tumor immunity over targeting PD-1 alone and potentially not induce serious immune-related toxicities and thus appears a promising strategy for clinical development.

WS.B1.05.03

Stromal Protein βig-h3 Reprograms Tumor Microenvironment in Pancreatic Cancer

D. Goehrig[1], *J. Nigri*[2], *R. Samain*[3], *Z. Wu*[4], *C. Paola*[5], *G. Gabiane*[4], *X. Zhang*[4], *Y. Zhao*[4], *I. Kim*[6], *M. Chanal*[4], *R. Curto*[5], *V. Hervieu*[7], *C. de la Fouchardière*[8], *F. Novelli*[5], *P. Milani*[9], *R. Tomasini*[2], *C. Bousquet*[3], *P. Bertolino*[10], ***A. HENNINO***[10];

Pancreatic cancer is associated with an abundant stromal reaction leading to immune escape and tumor growth. This massive stroma drives the immune escape in the tumor. We identified βig-h3 stromal protein as a key actor of the immune paracrine interactions mechanism that drives pancreatic cancer. We performed studies with *p48*-Cre;*Kras*^{G12D}, *pdx1*-Cre;*Kras*^{G12D};*Ink4a/Arf*$^{fl/fl}$, *pdx1*-Cre;*Kras*^{G12D}; *p53*^{R172H} mice and tumor tissues from patients with PDA. Some transgenic mice were given injections of anti-βig-h3 depleting antibody (Ab). Tumor growth as well as modifications in the activation of local immune cells were analyzed by flow cytometry, immunohistochemistry, immunofluorescence and stiffness by atomic force microscopy.
We found that βig-h3 is highly produced by Cancer Associated Fibroblasts in the stroma of Human and mouse. This protein acts directly on tumor specific-$CD8^+$ T cells and F4/80 macrophages. Depleting βig-h3 *in vivo* reduced tumor growth by enhancing the number of activated $CD8^+$ T cell within the tumor and subsequent apoptotic tumor cells. More importantly, we found that targeting βig-h3 in established lesions increased immune-mediated tumor clearance by releasing the tissue tension and functionally reprogramming F4/80 macrophages in the tumor microenvironment. Our findings present βig-h3 as a novel immunological target in pancreatic cancer.

Retargeting T cells against leukemia by lipid-specific TCR transfer

M. Consonni[1], *C. Garavaglia*[1], *C. de Lalla*[1], *A. Bigi*[1], *A. Mancino*[1], *M. Casucci*[2], *A. Bondanza*[2], *M. Lepore*[3], *L. Mori*[3], *G. De Libero*[3], *F. Ciceri*[4], *P. Dellabona*[1], *G. Casorati*[1];
[1]San Raffaele Scientific Institute, Division of Immunology, Transplantation, and Infectious Diseases, Experimental Immunology Unit, Milano, Italy, [2]San Raffaele Scientific Institute, Division of Immunology, Transplantation, and Infectious Diseases, Innovative immunotherapies Unit, Milano, Italy, [3]Experimental Immunology, Department of Biomedicine, University Hospital, Basel, Switzerland, [4]San Raffaele Scientific Institute, Division of Regenerative medicine, Stem cells, and Gene therapy, Hematology and hematopoietic stem cell transplantation Unit, Milano, Italy.

CD1-restricted T cells specific for self-lipids could play a role in cancer immune surveillance, where self-antigens are the targets of immune responses. We showed that primary acute myelogenous (AML) and B-lymphoblastic (B-ALL) leukemia blasts express CD1c and are recognized by a group of CD1c self-reactive T cells specific for methyl-lysophosphatidic acids (mLPAs), a novel class of self-lipid antigens that accumulate in malignantcells. mLPA specific T cells can kill and control leukemia growth *in vitro*and *in vivo*. These findings point to CD1c and self-lipids as new potential targets for leukemia immunotherapy. The little polymorphism of CD1 molecules and their selective expression on mature leukocytes are indeed highly attractive for adoptive cell therapy (ACT) with such T cells in the context of stem cell transplantation for hematological malignancies. To assess the feasibility of ACT for acute leukemia with mLPA-specific T cells, we generated a library of lentiviral vectors encoding a panel of human mLPA-specific TCRs. Upon TCR transduction, either Jurkat T cells or human primary T cells were specifically retargeted against CD1c-expressing malignant targets *in vitro*, highlighting a lead mLPA-specific TCR suitable for adoptive immunotherapy. Primary T cells transduced with this TCR killed CD1c-expressing malignant targets *in vitro* and significantly delayed leukemia progression in NSG mice. Togain further insight into the efficacy and safety of mLPA-specific ACT, we generated transgenic mice expressing CD1cwith a pattern similar to the human one, which harbored functional APCs recognized by mLPA-specific T cells and selected a CD1c self-reactive peripheral T cell repertoire.

WS.B1.05.05

Chorioallantoic membrane model to study glycan dependent tumor growth and differentiation

N. M. Sahasrabudhe*, L. Cornelissen, K. Castricum, J. van der Horst, V. L. Thijssen, S. J. van Vliet;
VU University medical center, Amsterdam, Netherlands.*

Immune activation in the colon plays a major role in colorectal cancer (CRC) progression, as exemplified by the many cases of CRC that develop from inflammatory bowel diseases. We have determined that glycans present on the colorectal tumors are vital epitopes that lead to immune evasion mechanisms in late stage tumors. Macrophages are the main tumor-associated immune cells, wherein the activation status of tumor-associated macrophages (TAM) is dependent on the tumor microenvironment. We hypothesize that glycans in tumor microenvironment influence macrophage differentiation. To decipher the role of glycans in CRC, we developed mouse MC38 CRC cell line expressing tumor associated glycans using CRISPR-Cas9 genome editing. We have knocked out *COSMC* gene to increase Tn antigen (GalNAcα-1Ser/Thr) exposure. To study growth of these glycovariant tumors we used the chorioallantoic membrane (CAM) assay with fertilized chicken eggs as a model. The CAM acts as the growth surface for development of solid tumors using cancer cell lines. This method allowed us to study tumor growth characteristics in a physiological 3D model along with angiogenesis and differentiation potential of the tumor. We observed higher angiogenesis potential of the MC38 *COSMC* knockout cell lines, suggesting a role for Tn antigen. In addition, we have modified the CAM assay to include monocytes in the tumor to study glycan-dependent monocyte differentiation into TAMs. Our objective is to elucidate the specific glycan epitopes that lead to immune evasion mechanisms in tumors through immunoregulatory macrophages.

WS.B1.05.06

An NK cell-driven inflammatory switch regulated by cyclooxygenase-2 activity restricts tumor growth and predicts cancer patient outcome

E. Bonavita*, V. S. Pelly, C. Bromley, E. Flanagan, S. Sahoo, H. Leong, S. Zelenay;
CRUK Manchester Institute, Manchester, United Kingdom.*

Inflammation plays opposing roles in cancer. It can either support or restrain tumor growth depending on the composition and levels of various cellular and molecular mediators. Nevertheless, how different types of inflammatory environments are established and manipulated by a growing tumor remains unclear. Studying cancer models rendered immunogenic by tumor cell-specific ablation of the cyclooxygenase (COX)-2 pathway, we showed the necessity of natural killer (NK) cells in establishing a cancer-inhibitory microenvironment that precedes activation of conventional dendritic cell 1 (cDC1) and drives cytotoxic T cell (CTL)-dependent tumor control. NK cells were found to be equally essential for the efficacy of immunotherapy based on combinations of a COX-2 inhibitor and PD-1 blockade. In agreement, *in silico* analysis of cancer patient datasets suggested that the COX-2 pathway similarly regulates the cellular and molecular inflammatory profile across multiple human malignancies. A gene signature that combines COX-2-dependent tumor-promoting factors and NK cell-driven anti-tumor mediators discriminated cancer types with diverging immune cell composition and predicted overall patient survival and response to PD-1/PD-L1 blockade. Collectively our findings demonstrate a major role for the COX-2 pathway in determining the inflammatory nature of tumors and that monitoring its driven gene signature constitutes a powerful biomarker of cancer patient outcome.

WS.B1.06.01

Revisiting the role of type 1 conventional dendritic cells (cDC1) in cancer immunosurveillance and in responses to immunotherapies against cancer

R. Mattiuz[1], *J. Cancel*[1], *L. Pouyet*[2], *F. Romagné*[2], *N. Bendriss-Vermare*[3], *C. Caux*[3], *J. Valladeau-Guilemond*[3], *M. Dalod*[1], *K. Crozat*[1];
[1]Centre d'Immunologie de Marseille Luminy, Marseille, France, [2]MI-mAbs, Marseille, France, [3]Centre de recherche en cancérologie - Lyon, Lyon, France.

It is essential to develop new clinical strategies to reactivate the natural anti-tumoral CD8+ T cell responses, or to induce de novo protective immunity in cancer patients. Here, we aim at analyzing to what extent type 1 conventional dendritic cells (cDC1) functions can be manipulated to improve immunotherapies currently applied to cancer. cDC1 excel in tumor antigen cross-presentation, and are strong inducers of CD8+ T cell responses in many experimental settings. In human, tumor infiltrating cDC1 are associated with a good prognosis in many solid cancers. Therefore, the protective functions of cDC1 need to be described both in context of immunotherapies against cancers and during natural tumor immuno-surveillance to tumor. We have generated unique mouse models, which allow either a constitutive or a conditional depletion of all cDC1 through the body. Using these mice, we found quite unexpectedly, that cDC1 are dispensable for tumor control at the time of immunotherapy administration (ACT or checkpoint blockers) in thymoma, melanoma and colon cancer models. However, cDC1 are critical to tumor immunosurveillance in a model of breast cancer that is naturally controlled when orthotopically engrafted in mice. In this last setting, cDC1 protective functions depend on anti-tumor CD8+ T cells and their infiltration into the tumor. Although our work puts in perspective recent findings about the involvement of cDC1 in immunotherapies against cancer, it will nonetheless help in defining new ways to mobilize cDC1 functions to improve immunotherapies currently applied in clinics to patients.

WS.B1.06.02

Generation of Memory Stem T cells specific for tumor antigens and resistant to inhibitory signals by genome editing

B. C. Cianciotti[1], *A. Potenza*[1], *Z. Magnani*[1], *V. Vavassori*[2], *P. Genovese*[2], *L. Naldini*[2], *E. Ruggiero*[1], *C. Bonini*[1];
[1]Division of Immunology, Transplantation, and Infectious Diseases, Experimental Hematology Unit, Ospedale San Raffaele, Milan, Italy, [2]San Raffaele Telethon Institute for Gene Therapy (TIGET), Ospedale San Raffaele, Milan, Italy.

Introduction: Exhausted T cells infiltrating solid tumors express multiple inhibitory receptors (IRs) that are exploited by cancer cells for protection from immune attack. We recently showed that a large fraction of $CD8^+$ cells infiltrating the bone marrow of patients with acute myeloid leukemia relapsing after allogeneic transplantation co-express IRs. Here we aim to simultaneously redirect T cell specificity and permanently disrupt IRs by CRISPR/Cas9 system in long-living memory stem T cells (T_{SCM}) for adoptive cell therapy.
Methods: Primary T cells activated with anti-CD3/CD28-conjugated beads and cultured with IL7+IL15 were electroporated with Cas9/gRNA ribonucleoproteins (RNPs) targeting Tim3, LAG3, 2B4 and the TCR alpha chain constant region (TRAC) genes. The frequency of NHEJ was assessed with FACS analysis, surveyor assay and ddPCR. A lentiviral vector (LV) encoding for an NY-ESO1-specific TCR (LV-NYESO1-TCR) was used for TCR gene editing.
Results: By single genome editing we obtained up to 60-70% genetic disruption at the Tim3 locus, 80-90% at the LAG3 and 63% at 2B4 locus. TRAC gene disruption resulted 98% $CD3^{neg}$ cells, that were then efficiently (70-85%) transduced with LV-NYESO1-TCR. We then combined one IR disruption with TCR gene editing in a single protocol. We obtained an average of 47% and 69% of $Tim3^{neg}$ and $LAG3^{neg}$ NY-ESO1-TCR redirected T cells respectively. More than 90% of edited cells showed a T_{SCM} functional phenotype and proved effective and specific in killing $NY\text{-}ESO1^+$ tumor targets.
Discussion: By exploiting the plasticity and multiplexity of CRISPR/Cas9 we generated innovative tumor-specific cellular products resistant to inhibitory signals.

WS.B1.06.03
A CD3xCD19 bispecific DART®molecule induces T-cell mediated killing of CLL cells *in vitro*

A. W. J. Martens[1], *S. R. Janssen*[1], *L. Izhak*[2], *A. P. Kater*[1], *G. J. van der Windt*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*The Janssen Pharmaceutical Companies of Johnson & Johnson, Spring House, Pennsylvania, United States.*

Chronic lymphocytic leukemia (CLL) is an incurable B-cell malignancy, associated with severe T-cell dysfunction. Recently, CD3xCD19 bispecific antibodies have been successfully applied in lymphoblastic leukemia, but efficacy in CLL has not been thoroughly assessed. We investigated whether CLL cells can be targeted by CD3xCD19 bispecific DART® (also known as MGD011) therapy and if this overcomes T-cell dysfunction in CLL.
We found that MGD011 redirects healthy donor T-cells to kill CD19$^+$ lymphoma cell lines, and primary CLL cells. Clinical responses seen in current therapies are highly dependent on specific prognostic factors (unmutated IgVH, high-risk cytogenetics, and chemoresistance). However, using MGD011, killing of CLL cells could be achieved at comparable levels among these different prognostic subgroups.
Next, we assessed the responses of CLL-derived T-cells upon therapy with MGD011. When autologous CLL cells were used as targets, addition of MGD011 resulted in robust activation of both CD4$^+$ and CD8$^+$ cells, measured by CD25 upregulation, proliferation, TNFα and IFNγ production and degranulation. CLL-derived T-cells (CD4 vs CD8 vs combined) were able to kill CD19$^+$ cell lines (average specific lysis at a 1:1 E:T ratio of 85%). Killing of autologous CLL by single CD4 or CD8 cells was remarkably lower but 1:1 combination of CD4 and CD8 resulted in enhanced killing capacity (21%, 25% and 45% for single CD4, single CD8 and combined respectively).
Together, this indicates that even high-risk CLL cells can be killed using MGD011. Nevertheless, we are currently investigating means to further improve the T-cell mediated lysis of CLL cells.

WS.B1.06.04
MDM2-targeting as a new Natural Killer cell-based immunotherapy of neuroblastoma

I. Veneziani[1], *E. Ferretti*[2], *D. Fruci*[1], *L. Moretta*[3], *V. Pistoia*[3], *F. Locatelli*[1], ***L. Cifaldi***[1];
[1]*Department of Pediatric Hematology and Oncology, Bambino Gesù Children's Hospital, Rome, Italy,* [2]*Laboratory of Oncology, Giannina Gaslini Institute, Genoa, Italy,* [3]*Immunology Research Area, Bambino Gesù Children's Hospital, Rome, Italy.*

Neuroblastoma (NB) is the most common extracranial solid tumor occurring in childhood. Amplification of the MYCN oncogene is associated with poor prognosis. Down-regulation of ligands on tumor cells recognized by Natural Killer (NK) cell-activating receptors, involved in tumor cell recognition and lysis, may contribute to tumor progression and relapse. We demonstrated that MYCN expression is inversely correlated with ligands recognized by NKG2D and DNAM1-activating receptors. ULBP activating ligands are induced by p53 and c-MYC transcription factors. Of note, p53 is mutated only in 2% of NB. On the other hand, MDM2 inhibits p53 function. Both p53 and MDM2 are direct transcriptional targets of MYCN and are co-expressed at high levels in MYCN-amplified NB cells. Indeed, p53 is functionally suppressed by MDM2 in MYCN-amplified NB cells. In this study, we found that MDM2-targeting mediated by Nutlin-3a, a well-established MDM2 antagonist, enhanced *in vitro* the expression of activating ligands in NB cells, thus rendering them more susceptible to NK cell-mediated killing, and *in vivo* in NSG-mice-xenograft model. Moreover, ChIP assay revealed that p53, upon Nutlin-3a treatment, is a direct transcription factor of PVR. Taken together, these results provide the first demonstration that MYCN acts as an immunosuppressive oncogene in NB cells. The restoration of p53 function, mediated by MDM2-targeting, represents a promising molecular approach to sensitize NB cells to NK cell-mediated killing to be exploited to design a new NK cell-based immunotherapy to treat high-risk NB patients. *Grant: Italian Ministry of Health (Rome, Italy) grant GR-2011-02352151 to Loredana Cifaldi.*

WS.B1.06.05
Mutated *NPM1* as target for immunotherapy of acute myeloid leukemia

D. I. van der Lee*, R. M. Reijmers, M. W. Honders, R. S. Hagedoorn, R. M. de Jong, M. G. Kester, D. M. van der Steen, A. H. de Ru, H. M. Bijen, C. Kweekel, I. Jedema, H. Veelken, M. H. Heemskerk, P. A. van Veelen, F. J. Falkenburg, M. Griffioen;*
Leiden University Medical Center, Leiden, Netherlands.

The most frequent subtype of acute myeloid leukemia (AML) is defined by mutations in the nucleophosmin (*NPM1*) gene. Mutated *NPM1* is an attractive target for immunotherapy, since it is an essential driver gene and 4 base pair frameshift insertions occur in the same region in 30% of AML, resulting in a novel C-terminal alternative reading frame of 11 amino acids. By searching in the HLA class I ligandome of primary AML, we identified multiple peptides derived from mutated *NPM1*. For one of these peptides, i.e. HLA-A*02:01-presented CLAVEEVSL, we searched for specific T-cells in healthy individuals using peptide-MHC tetramers. Tetramer-positive CD8 T-cell clones were isolated and analyzed for reactivity against primary AML with mutated *NPM1*. From one selected clone with superior anti-tumor reactivity, we isolated the T-cell receptor (TCR) and demonstrated specific recognition and lysis of HLA-A*02:01-positive AML with mutated *NPM1 in vitro* after retroviral transfer to CD8 and CD4 T-cells. Anti-tumor efficacy of TCR-transduced CD8 and CD4 T-cells was confirmed in a mouse model engrafted with a human AML cell line expressing mutated *NPM1*. Interestingly, co-infusion of TCR-transduced CD8 and CD4 T-cells resulted in superior anti-tumor reactivity as compared to TCR-transduced CD8 T-cells alone.
These data show that mutated *NPM1*-derived peptides are presented on AML and that CLAVEEVSL is a neoantigen that can be efficiently targeted on AML with mutated *NPM1* by TCR gene transfer in a co-receptor independent fashion. Immunotherapy targeting mutated *NPM1* may therefore contribute to treatment of AML. This research was supported by the Dutch Cancer Society.

WS.B1.06.06
Enhanced immunogenicity of mitochondrial localised mutated proteins in cancer cells

G. Prota[1], *U. Gileadi*[1], *M. Rei*[1], *A. Lechuga Vieco*[2], *J. Chen*[1], *J. Rehwinkel*[1], *A. Ahmed*[3], *J. Enríquez*[2], *V. Cerundolo*[1];
[1]*MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom,* [2]*Centro Nacional de Investigaciones Cardiovasculares Carlos III (F.S.P.), Madrid, Spain,* [3]*Nuffield Department of Obstetrics and Gynaecology, University of Oxford, UK, Oxford, United Kingdom.*

The evidence that priming of tumour specific CD8+ T cells relies on cross-presentation of tumour debris by dendritic cells (DCs) is compelling. However, it remains unclear whether cellular localisation of mutated cancer proteins plays a role in the ability of CD8+ T cells to be primed by cancer cells. To address this question, we have analysed the ability of the full length NY-ESO-1 protein and ovalbumin localised either in mitochondria or cytosol to elicit *in vivo* antigen specific CD8+ T cell responses and compared direct vs cross-presentation. Our results show that cytoplasmic proteins are rapidly degraded and elicit strong direct presentation *in vitro* of processed epitopes. In contrast, mitochondrial localised proteins are significantly longer lived, due to their protection from proteasome dependent degradation, and are capable of eliciting *in vivo* significantly stronger antigen specific CD8+ T cell responses than cytosolic proteins. We showed that such enhanced response of mitochondrial localised proteins is mediated by cross-presentation events dependent on STING activation and by uptake of mitochondria by CD103+ and CD11b+ DC. Finally, we have extended these findings in humans by isolating several CD8+ T cells clones specific to defined epitopes expressed by mitochondrial localised proteins from one endometrial cancer patient with high mutational burden due to loss of function of the proof reading polymerase POLE. In conclusion, these findings demonstrate the greater immunogenicity of mitochondrial localised mutated proteins, highlighting strategies to identify highly immunogenic peptide epitopes for the development of cancer vaccination strategies.

High glycolytic tumors evade immune destruction by acidosis-dependent induction of ICER in tumor-associated macrophages

T. Bohn[1], *S. Rapp*[2], *M. Klein*[1], *S. Pektor*[3], *K. Renner*[4], *M. Kreutz*[4], *V. Popp*[5], *K. Gerlach*[5], *B. Weigmann*[5], *C. Lueckel*[6], *M. Huber*[6], *C. Becker*[7], *E. von Stebut-Borschitz*[8], *H. Schild*[1], *E. Schmitt*[1], *T. Bopp*[1];
[1]*Institute for Immunology, Mainz, Germany,* [2]*Institute for Preventive Cardiology, Mainz, Germany,* [3]*Institute for Nuclear Medicine, Mainz, Germany,* [4]*Internal Medicine III, Regensburg, Germany,* [5]*Department of Medicine 1, Erlangen, Germany,* [6]*Institute for Medical Microbiology and Hospital Hygiene, Marburg, Germany,* [7]*Dermatology, Mainz, Germany,* [8]*Dermatology, Köln, Germany.*

Aggressive types of skin cancer have become more common over the last 25 years. Immune checkpoint inhibitors have revolutionized melanoma treatment. However, only less than 40% of patients benefit from this therapy suggesting additional immune evasion mechanisms. To develop new innovative therapeutic strategies, detailed understanding of tumor- and micro milieu-specific mechanisms contributing to inefficient anti-tumor immune responses is essential. Therefore, we focused our work on identifying signaling pathways and molecules involved in melanoma formation and anti-tumor immune responses.
We explored a molecular mechanism of non-classical physicochemical communication deployed by high glycolytic tumors for immune evasion. Melanomas are transcriptionally privileged to produce energy by high-rate glycolysis resulting in tumor acidification. This tumor acidosis induced a cAMP-mediated expression of the transcriptional repressor ICER in tumor-associated macrophages (TAM), leading to functional polarization of TAM towards a non-inflammatory M2 phenotype promoting tumor growth. In contrast to that, B16 melanoma-infiltrating macrophages of *Icer*-deficient mice possess an inflammatory anti-tumor M1 phenotype which results in a spontaneous rejection of high glycolytic tumors by *Icer*-deficient mice, as well as mice with a conditional deficiency of *Icer* in macrophages.
To test the "drugability" of cAMP modulation in melanoma treatment we conducted *in vivo* experiments with therapeutic application of the Adenylate cyclase inhibitor MDL-12. Inhibition of *de novo* cAMP synthesis lead to a rejection of B16 melanomas in C57BL/6J mice.
Taken together, our findings identify an evolutionary conserved mechanism of physicochemical communication between non-lymphoid tissue and the immune system that is exploited by high glycolytic tumors for immune evasion.

WS.B2.01.02

Carcinoma-associated pancreatic stellate cells induce CD4$^+$ and CD8$^+$ T-cell exhaustion

L. Gorchs[1], *C. Fernández Moro*[2], *Q. Meng*[1], *E. Rangelova*[3,4], *H. Kaipe*[1,5];
[1]*Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden,* [2]*Department of Pathology/Cytology, Karolinska University Hospital, Stockholm, Sweden,* [3]*Department of CLINTEC, Karolinska Institutet, Stockholm, Sweden,* [4]*Pancreatic Surgery Unit, Center for Digestive Diseases, Karolinska University Hospital, Stockholm, Sweden,* [5]*Clinical Immunology and Transfusion Medicine, Karolinska University Hospital, Stockholm, Sweden.*

Carcinoma-associated pancreatic stellate cells (CAPSCs) are the major type of stromal cells in pancreatic ductal adenocarcinomas and besides their pathological release of extracellular matrix proteins they are also perceived as key contributors to immune evasion. Despite the known relevance of tumor infiltrating lymphocytes in cancers, the interactions between T-cells and CAPSCs remain largely unexplored. Here, we found that CAPSCs isolated from tumors of pancreatic cancer patients expressed higher levels of the PD-1 ligands PD-L1 and PD-L2 compared to primary skin fibroblasts from healthy donors. CAPSC strongly inhibited T-cell proliferation via both contact-dependent and independent fashions. Blocking the activity of prostaglandin E_2 (PGE_2) partially restored the proliferative capacity of both CD4$^+$ and CD8$^+$ T-cells. After stimulation, the proportion of proliferating T-cells expressing HLA-DR and the proportion of memory T-cells was decreased when CAPSCs were present compared to T-cells proliferating in the absence of CAPSC. Interestingly, proliferating T-cells had a greater expression of the immune checkpoint markers TIM-3, PD-1, CTLA-4 and LAG-3 in the presence of CAPSCs. Functional assays showed that T-cells expressing immune checkpoints produced less IFN-γ, TNF-α, and CD107a after restimulation when CAPSCs had been present. Thus, this indicates that CAPSCs induce expression of immune checkpoints on CD4$^+$ and CD8$^+$ T-cells, which contribute to a diminished immune function. This study was funded by the Swedish Cancer Society (Dnr 2017/749) and the Cancer Society in Stockholm (Dnr 171083).

WS.B2.01.03

The tumour microenvironment supports the self-renewal of tumour-promoting macrophages in colon adenoma

I. Soncin*, J. Sheng, Q. Chen, K. Karjalainen, C. Ruedl;*
Nanyang Technological University, Singapore, Singapore.

Circulating CCR2$^+$ monocytes are crucial in maintaining the adult tissue-resident F4/80^{hi}MHCII^{hi} macrophage pool in the intestinal lamina propria.
Herein, we delineated murine colonic tissue-resident F4/80^{hi} macrophages and identified a CCR2-independent F4/80^{hi}MHCII^{lo} macrophage subset as the only F4/80^{hi} subset present in the embryonic lamina propria that was gradually lost after birth and almost entirely replaced by CCR2-dependent F4/80^{hi}MHCII^{hi} macrophages in the adulthood. However, in colon adenomas F4/80^{hi}MHCII^{lo} macrophages were not only preserved but became the dominant tumour-associated macrophages within large tumours. Furthermore, by utilizing Kit$^{MerCreMer/R26}$ fate-mapping mouse model we demonstrated that in the tumour microenvironment both macrophage fractions were able to maintain their numbers mostly independent from bone marrow contribution. Indeed, they upregulated the expression of numerous genes related with cell proliferation, which may represent the driving source of *in situ* maintenance. Analyses of colon adenomas indicated that CSF1 could be a key facilitator of macrophage self-renewal.
Thus, as the intestinal environment switches from healthy to tumoural there is a corresponding shift in the renewal of tissue-resident macrophages, from bone-marrow dependency to self-maintenance through *in situ* proliferation, conferred by the local niche.
This work was supported by MOE2014-T2-1-011 and MOE2016-T2-1-012 Ministry of Education Tier2 grants to C.R.

Recent studies have established that metabolic restrains, such as glucose restriction, impair the activities of effector T cells in the tumor microenvironment. In the same context, a huge expansion of activated regulatory T cells (Tregs) in tumor tissues has been described in mice and humans, contributing to the suppression of protective anti-tumor immunity. Here we showed that Tregs advantage in the tumor milieu relies on supplemental energetic routes involving lipid metabolism.
In murine models, tumor-infiltrating Tregs displayed intracellular lipid accumulation, which was attributable to an increased rate of fatty acid (FA) synthesis. Since relative advantage in glucose-uptake may fuel FA synthesis in intratumoral Tregs, we demonstrated that both glycolytic and oxidative metabolism concurred to Tregs expansion. We corroborated our data in human tumors showing that Tregs displayed a gene signature towards glycolysis and lipid synthesis. Our data support a model in which signals from the tumor microenvironment induce a circuitry of glycolysis, FA synthesis and oxidation that confers to Tregs a preferential proliferative advantage compared to the counterpart effector T cells that rely primarily on the glycolytic pathway for their metabolic demands. The awareness of the metabolic dynamics of Treg in tumor could provide new means for cancer immunotherapy.

WS.B2.01.05

IL-18 is a key driver of immunosuppression and a therapeutic target in multiple myeloma

S. Kassem[1], *K. Nakamura*[2], *H. Avet-Loiseau*[3], *M. J. Smyth*[2], *L. Martinet*[3];
[1]*Cancer Research Center of Toulouse, TOULOUSE, France,* [2]*QIMR Berghofer, Brisbane, Australia,* [3]*Cancer Research Center of Toulouse, Toulouse, France.*

Tumor-promoting inflammation and avoiding immune destruction are hallmarks of cancer. Here, we demonstrate that the pro-inflammatory cytokine IL-18 is critically involved in these hallmarks in multiple myeloma (MM). Mice deficient for IL-18 were remarkably protected from Vk*MYC MM progression in a CD8$^+$ T cell-dependent manner. The MM-niche derived IL-18 drove generation of myeloid-derived suppressor cells (MDSCs), leading to accelerated disease progression. A global transcriptome analysis of the immune microenvironment in 73 MM patients strongly supported the negative impact of IL-18-driven MDSCs on T cell responses. Strikingly, high levels of bone marrow plasma IL-18 were associated with poor overall survival in MM patients. Furthermore, our preclinical studies suggested that IL-18 could be a potential therapeutic target in MM.
Although novel anti-myeloma agents have been developed, MM is still an incurable disease. The growth of MM cells highly depends on the bone marrow (BM), where cellular components and soluble factors cooperatively orchestrate the pro-survival and immunosuppressive microenvironment. However, the molecular and cellular mechanisms of MM-associated inflammation and immunosuppression remain poorly understood. Using Vk*MYC preclinical models, a comprehensive analysis of the transcriptional landscape of the immune microenvironment in MM patients, and BM
cytokine analyses, we demonstrate that dysregulated production of IL-18 is a key driving force for immunosuppression in the MM microenvironment and a potential therapeutic target. Our results reveal the critical role of IL-18 in the MM immunopathology, which provides insight into therapeutic strategies against MM (Nakamura et al. Cancer Cell, 2018).

Chronic lymphocytic leukemia impairs metabolic fitness in CD8 T cells

A. van Bruggen[1], *A. Martens*[1], *J. A. Fraietta*[2], *M. Levin*[3], *P. J. Siska*[4], *S. Endstra*[1], *J. C. Rathmell*[4], *J. J. Melenhorst*[2], *A. P. Kater*[1], *G. J. van der Windt*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*University of Pennsylvania, Philadelphia, United States,* [3]*Albert Schweitzer Hospital, Dordrecht, Netherlands,* [4]*Vanderbilt University Medical Center, Nashville, United States.*

In chronic lymphocytic leukemia (CLL) T cell exhaustion is acquired and impedes development of effective immunotherapeutic strategies by yet unknown mechanisms. Since cellular metabolism is tightly linked to T cell function, we hypothesized that interaction of CLL cells with T cells leads to an altered metabolic programming resulting in impaired T cell function. Here we used CLL-derived and age-matched healthy donor (HD)-derived PBMCs, and CAR-T cell infusion products derived from CLL patients to study CD8 T cell metabolism. CLL-derived CD8 T cells showed increased mitochondrial membrane potential and basal respiration, while spare respiratory capacity was reduced, indicating a lower ability to deal with enhanced energy demand. In addition, CD8 T cells in CLL had increased mitochondrial ROS, which coincided with decreased levels of PGC1a and the anti-oxidant super oxide dismutase 2. After stimulation in vitro, CLL CD8 T cells became less activated, showed decreased glucose uptake and glycolysis, and impaired mitochondrial biogenesis. In line with this, antigen experienced CD8 T cells in CLL showed no increase in mitochondrial mass compared to naïve CD8 T cells, as opposed to healthy donors. CD8 CAR-T cells from complete responders had higher mitochondrial mass compared to non-responders which correlated positively with the expansion of the CAR-T cell culture in vitro, and CAR-T cell persistence in vivo. These data indicate that metabolic fitness of CD8 T cells is impaired in CLL. Therefore, boosting T cell metabolism in CLL by enhancing mitochondrial biogenesis might improve CAR-T cell therapy and other emerging immunotherapies.

WS.B2.02 Tumor immune surveillance and evasion

WS.B2.02.01
Tumor immune evasion arises through loss of TNF sensitivity

***J. Oliaro**, C. Kearney, S. Vervoort, R. Johnstone;*
Peter MacCallum Cancer Centre, Melbourne, Australia.

Immunotherapy has revolutionized outcomes for cancer patients, but the mechanisms of resistance remain poorly defined. Here, we used a series of whole genome CRISPR-based screens performed *in vitro* and *in vivo* to identify mechanisms of tumor immune evasion from cytotoxic lymphocytes ($CD8^+$ T cells and natural killer (NK) cells). Deletion of key genes within the TNF signaling, IFN-γ signaling, and antigen presentation pathways provided protection of tumor cells from $CD8^+$ T cell-mediated killing, and blunted anti-tumor immune responses *in vivo*. Deletion of a number of genes in the TNF pathway also emerged as the key mechanism of immune evasion from primary NK cells. Remarkably, we found that tumors delete the same genes when exposed to perforin deficient $CD8^+$ T cells, demonstrating that the dominant immune evasion strategy utilized by tumor cells is acquired resistance to T cell-derived cytokine mediated anti-tumor effects. Indeed, we demonstrate that TNF-mediated bystander killing is a potent T cell effector mechanism capable of killing antigen-negative tumor cells. In addition to highlighting the importance of TNF in $CD8^+$ T and NK cell mediated killing of tumor cells, our study also provides a comprehensive picture of the roles of the TNF, IFN and antigen presentation pathways in immune-mediated tumor surveillance.

WS.B2.02.02
IL-33/ST2 signaling promotes the survival and proliferation of AML1/ETO leukemic stem cells

***P. Näf**[1], R. Radpour[1], C. Riether[1,2], A. F. Ochsenbein[1,2];*
[1]Department for BioMedical Research, Bern, Switzerland, [2]Department of Medical Oncology, Bern, Switzerland.

Interleukin (IL)-33 is an alarmin released upon cell necrosis and binds to the heterodimeric receptor ST2/IL1RaP, which is expressed on a subset of immune and epithelial cells. BCR/ABL transformation in chronic myeloid leukemia (CML) stem cells was shown to induce ST2 expression and propel malignant cell growth. However, the role of IL-33/ST2 signaling in acute myeloid leukemia (AML) is currently unknown. Gene expression analysis of human bulk and $CD34^+CD38^+$ AML samples harboring variety of translocations revealed that ST2 was particularly upregulated on AML1/ETO transformed AML cells, but not expressed on other AML subtypes and healthy hematopoietic stem cells (HSCs). We next generated an *in vivo* AML model by transfecting murine hematopoietic stem cells with an AML1/ETO lentiviral construct. AML/ETO transformed leukemic stem cells (LSCs) highly expressed ST2 and showed increased colony formation in recombinant IL-33 (rIL-33) conditioned methylcellulose-based culture assays when compared to controls. Interestingly, amongst all screened human AML1/ETO LSCs a heterogeneity in ST2 expression was observed. Molecular profiling of the LSCs revealed a negative correlation of ST2 gene expression and key genes of the Notch pathway. Blocking the Notch pathway in the $ST2^{low}$AML1/ETO LSCs using siRNA revealed that ST2 protein expression could be restored. Furthermore, siRNA induced gain of ST2 expression also restored *in vitro* colony formation capacity in the presence of rIL-33. Taken together, these data provide evidence that IL-33/ST2 signaling plays a disease promoting role in AML1/ETO transformed AML LSCs. Further investigations will focus on detailed signaling mechanisms and propose new therapeutic strategies to treat AML.

WS.B2.02.03
Characterizationof CC-chemokine Receptor 6 (CCR6) and CC-chemokine Ligand 20 (CCL20) mediated immunosurveillance in the initiation and progression of malignant melanoma

***D. Martin-Garcia**, A. H. Enk, A. S. Lonsdorf;*
Department of Dermatology, Heidelberg, Germany.

Chemokine ligand 20 (CCL20) expressed in the epidermis is a potent impetus for the recruitment of subsets of DCs, B-cells and memory T-cells expressing chemokine receptor 6 (CCR6), its exclusive receptor. CCL20 and a corresponding CCR6-expressing immune cell infiltrate have been detected in several malignancies, including melanoma. Yet, the functional contribution of the CCR6/CCL20 axis for the immune control of melanoma remains controversial. The characterization of CCR6-guided immune cell subsets and their functional contribution for the immune control of melanoma comprises the focus of this project. We evaluated the homeostatic and inducible secretion of CCL20 by different murine and human melanoma cutaneous cell lines by ELISA. Both murine (B16, Ret) and human (A375, C32) melanoma cell lines are capable of secreting CCL20 upon stimulation with pro-inflammatory cytokines in vitro. In order to determine the functional relevance of CCR6 on local tumor growth, B16 melanoma cells retrovirally transduced with a vector that constantly overexpresses CCL20 (B16-CCL20) were injected subcutaneously in C57BL/6 wt mice and congenic CCR6-knockout (CCR6ko) mice. While animals in both groups developed local tumors, we observed a significantly reduced tumor growth in CCR6ko mice. By contrast, wt and CCR6ko control groups did not display differences in tumor growth rate. Our results suggest that CCL20 interactions in the microenvironment of cutaneous melanoma may be an essential factor for local tumor growth. Preliminary experiments have pointed out a possible autocrine pathway that would affect only B16 tumor growth in CCR6ko mice, although the precise mechanisms are still being investigated.

WS.B2.02.04
Unraveling the mechanism behind aberrant CD37 expression in human B cell lymphoma

***S. Elfrink**[1], C. de Winde[1], M. van den Brand[2], E. Jansen[1], F. Doubrava-Simmer[2], S. van Deventer[1], C. Hess[3], W. Stevens[3], D. van Spronsen[3], H. van Krieken[2], C. Figdor[1], B. Scheijen[2], A. van Spriel[1];*
[1]Department of Tumor Immunology, Radboud Institute of Molecular Life Sciences, Radboudumc, Nijmegen, Netherlands, [2]Department of Pathology, Radboudumc, Nijmegen, Netherlands, [3]Department of Hematology, Radboudumc, Nijmegen, Netherlands.

Diffuse large B cell lymphoma (DLBCL) is the most common type of non-Hodgkin lymphoma and remains a clinical problem. We and others have recently shown loss of immune cell-specific tetraspanin CD37 protein in half of the DLBCL tumors, which is directly correlated with clinical outcome. Tetraspanins are membrane proteins that control cell surface organization by forming tetraspanin enriched microdomains. Hereby they are involved in cell migration, proliferation and survival, and play a role in cancer cell migration and cellular interactions. We discovered that CD37 controls signal transduction pathways that regulate the survival of B cells, and *Cd37*-deficient mice spontaneously develop lymphomas. Genomic mutation analysis of the coding sequence of the human *CD37* gene revealed a pathogenic mutation in 3/16 DLBCL tumors, resulting in aberrant expression of the protein. Other potential mechanisms of loss of CD37 expression may include alterations in the *CD37* promoter region or increased DNA methylation. Mutation analysis of the promoter region of CD37-negative tumors (n=12) did not reveal any pathogenic mutations. MspJI digestion on genomic DNA indicates increased methylation of the *CD37* promoter region in CD37-negative B cell lines compared to CD37-positive B cell lines. Preliminary results from bisulfite sequencing of the promoter region and the first intron of *CD37* show differential methylation in CD37-expressing cells versus CD37-negative cells. Taken together, the B cell tetraspanin CD37 is a novel tumor suppressor that protects against malignant transformation of B cells. This work provides important insight into the molecular mechanisms underlying CD37-deficiency in human B cell lymphoma.

WS.B2.02.05
A generic, cost-efficient high performance capillary liquid chromatography-high resolution mass spectrometry method for quality control of peptide pools

***G. Bosc-Bierne**[1], V. Armuzza[2], M. G. Weller[1], O. J. Kreuzer[2];*
[1]Federal Institute for Materials Research and Testing (BAM), Berlin, Germany, [2]peptides&elephants GmbH, Berlin, Germany.

Synthetic peptide pools are used in antigen-specific T-cell assays, which are an important part in vaccine and immunotherapeutic clinical trials. As the analytical characterization is challenging due to the similarity of the single peptides or is expensive due to isotope labeled standards, usually only a pre-characterization of the single peptides is performed. However, a regular quality control of the peptide mix would be highly desirable. Therefore, a cost-efficient high performance liquid chromatography-high resolution mass spectrometry (HPLC-HRMS) method for quality control of a model peptide pool is developed.
Peptides were synthesized using peptides&elephants proprietary libraries of individual peptides (LIPS) technology and purified by reversed-phase chromatography to >90% each. The lyophilized single peptides were combined to a model peptide pool and analyzed by reversed-phase high-performance capillary liquid chromatography coupled to an orbitrap mass spectrometer. Separation was performed on a capillary reversed phase column (2 µm, ID x L 300 µm x 150 mm) with a linear gradient of acetonitrile + 0,05 % trifluoroacetic acid. Absolute quantification was accomplished based on ultraviolet spectroscopy. Identification was obtained by high resolution mass spectrometry.
After optimizing the injection mode, the gradient elution, the temperature, the additives and sample preparation a model peptide pool was separated. The extracted ion chromatogram (XIC) was studied to confirm the exact masses as well as the total ion chromatogram (TIC) to identify possible degradation products.
By combination of capillary HPLC and HRMS a new cost-efficient quality control method could be developed for the separation and quantification of complex synthetic peptide pools.

G-MDSC derived exosomes promote the progression of colon cancer

S. WANG[1,2], *Y. WANG*[1], *J. MA*[3], *H. XU*[3];
[1]*THE AFFILIATED PEOPLE'S HOSPITAL, JIANGSU UNIVERSITY, ZHENJIANG, China,* [2]*Department of Immunology, School of Medicine, Jiangsu University, Zhenjiang, China,* [3]*Department of Immunology, School of Medicine, Jiangsu University, ZHENJIANG, China.*

Introduction: Myeloid-derived suppressor cells (MDSC) are present in most cancer patients where these cells inhibit anti-tumor immunity and enhance cancer stem cells (CSC) which are important cellular component in the cancer microenvironment. MDSC derived exosomes have been proposed to act as intercellular communicators, but the role of MDSC derived exosomes in colon cancer is unclear.
Materials and Methods: Granulocytic MDSCs were isolated by microbeads, and G-MDSC derived exosomes (GM-Exo) were purified from the cell supernatant. Phenotypic analysis of immune cells was performed by flow cytometry. Cancer cell stemness was detected by sphere formation and biomarkers. Tumor model were monitored and assessed by histopathology.
Results: GM-Exo promoted colon carcinoma CT-26 cells proliferation and migration in vitro. GM-Exo exacerbated tumor incidence and developed rapidly progressing lethal tumors mice, and enhanced the migration ability of CT-26 cells through liver metastasis model in vivo. Exosomal S100A9 enhanced tumor sphere formation and the levels of a panel of established CSC markers, which was associated with Nox/ROS/NF-κB pathway. After treatment of GM-Exo, the percentage of CD133+ or CD44+ CSC cells was increased in tumor tissue. Silencing of Rab27a halted G-MDSC exosomes release, and attenuated the ability to promote the development of transplanted tumor.
Conclusions: The results suggested that S100A9 cargo packaged into GM-Exo promoted the metastatic and tumorigenic potential of colon cancer through enhancing cancer cell stemness.

The macrophage tetraspan MS4A4A interacts with Dectin-1 and is required for macrophage-NK cell cross-talk and resistance to metastasis

I. Mattiola[1,2], *F. Tomay*[2], *M. De Pizzol*[2], *B. Savino*[2], *T. Gulic*[3], *R. Silva-Gomes*[4], *R. Carriero*[2], *D. Morone*[2], *I. N. Shalova*[5], *Y. Lee*[5], *S. K. Biswas*[5], *G. Mantovani*[6], *M. Sironi*[2], *B. Bottazzi*[2], *A. Mantovani*[2,7,8], *M. Locati*[2,3];
[1]*Department of Microbiology and Infection Immunology, Charité - University Medical Centre Berlin, Berlin, Germany,* [2]*Humanitas Clinical and Research Center, Pieve Emanuele, Italy,* [3]*Department of Medical Biotechnologies and Translational Medicine, University of Milan, Milan, Italy,* [4]*Graduate Program in Areas of Basic and Applied Biology (GABBA), Instituto de Ciências Biomédicas Abel Salazar (ICBAS), University of Porto, Porto, Portugal,* [5]*Singapore Immunology Network (SIgN), Agency for Science, Technology & Research (A-STAR), Singapore, Singapore,* [6]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy,* [7]*Humanitas University, Pieve Emanuele, Italy,* [8]*The William Harvey Research Institute, Queen Mary University of London, London, United Kingdom.*

Introduction: MS4A4A is a tetraspan-like molecule that is induced during monocyte-to-macrophage differentiation and is upregulated by M2 or M2-like signals, including IL-4, dexamethasone and tumor cell supernatants. We observed that MS4A4A is expressed by human tissue macrophages and tumor-associated macrophages in human cancers and is induced in monocytes from patients treated with methylprednisolone. However, MS4A4A function is totally unknown. **Materials:** Associating molecules of MS4A4A were identified by a split-ubiquitin assay and then confirmed by FLIM-FRET, co-immunoprecipitation and immunofluorescence. Conditional knock-out mice for MS4A4A ($Ms4a4a^{fl/fl}$ x LysM-Cre) were generated and MS4A4A contribution to macrophage functions was assessed both *in vitro* and in *in vivo* models of cancer. **Results:** MS4A4A associates with the β-glucan receptor Dectin-1 and the heterocomplex translocates to lipid rafts. MS4A4A is essential for the full activation of the Syk pathway downstream Dectin-1. The impaired Syk phosphorylation correlates with the reduced production of cytokines and reactive oxygen species by MS4A4A-lacking macrophages. MS4A4A deficiency in macrophages has no influence on primary tumor growth, but impacts on Dectin-1-driven NK-mediated resistance to metastasis. Indeed, the absence of MS4A4A on macrophages impairs NK cell cytotoxic potential leading to the uncontrolled spread of Dectin-1-dependent metastasis. **Conclusion:** We showed that MS4A4A interacts with Dectin-1 and is essential for innate responses driven by Dectin-1, including NK cell-mediated resistance to metastasis. Therefore, we demonstrated for the first time that Dectin-1 is an associating molecule of MS4A4A and that MS4A4A plays a key role in the regulation of macrophage activation.

WS.B2.03.02
Heparanase is required for dendritic cell-natural killer cell crosstalk and subsequent natural killer cell activation

A. Mayfosh, *N. Baschuk;*
Department of Biochemistry and Genetics, La Trobe Institute for Molecular Science, Melbourne, Australia.

Heparanase is a beta-D-endoglucuronidase that cleaves heparan sulphate, a major component of the extracellular matrix and basement membrane. Heparanase expression and function have been documented in some leukocyte populations, but have not been described in natural killer (NK) cells. Here we investigate the importance of heparanase in NK cell activation and function, and the impact on tumour clearance. We first observed that heparanase-knock out (Hpse-/-) mice implanted with EO771.LMB tumour cells presented more metastatic lesions in the lungs compared to WT animals, suggesting an impairment in tumour clearance. Following challenge *in vivo* with the viral RNA mimetic Poly(I:C), NK cells isolated from Hpse-/- mice displayed reduced expression of the NK cell activation markers CD69, NKG2D, CD11b and CD27, reduced interferon □ production and impaired cytotoxicity against EO771.LMB cells *in vitro*. Interestingly, direct cytokine stimulation of Hpse-/- NK cells *in vitro* was sufficient to induce NK cell activation equal to that of WT NK cells. Given that Poly(I:C) signals through DCs to stimulate NK cells *in vivo*, we assessed the ability of Hpse-/- DCs to activate WT NK cells *in vitro*. Indeed, Poly(I:C)- activated Hpse-/- DCs were unable to induce NK cell activation equal to that of WT DCs, suggesting heparanase allows for efficient DC-NK cell crosstalk and subsequent NK cell activation. This finding raises the question of how heparanase inhibitors, currently used as anti-cancer therapies, may affect immune surveillance, and uncovers a new approach to increasing immune cell-crosstalk in immunotherapies.

WS.B2.03.03
CD137 (4-1BB) costimulation counteracts TGF-β1 inhibition of antibody-dependent NK cell responses against HER2+ transformed cells

M. Cabo[1], *R. Lozano-Rodríguez*[1], *M. Ataya*[1], *M. Costa-Garcia*[2], *S. Santana*[1], *M. C. Ochoa*[3], *P. Berraondo*[3], *I. Melero*[3,4], *M. López-Botet*[1,2], *A. Muntasell*[1];
[1]*Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain,* [2]*University Pompeu Fabra (UPF), Barcelona, Spain,* [3]*Centro de Investigación Médica Aplicada (CIMA), Pamplona, Spain,* [4]*Clínica Universitaria de Navarra, Pamplona, Spain.*

NK cell recognition of antibody-coated tumor targets through CD16A triggers antibody-dependent cellular cytotoxicity and the release of IFN-γ and TNF-α. Several observations support the contribution of NK cells to the efficacy of anti-HER2 therapeutic antibodies in breast cancer (BC), and NK cell dysfunction owing to immunosuppressive factors (i.e. TGF-β1) has been related to BC progression in metastatic patients. In this context, strengthening NK cell responses by targeting activating co-receptors is envisaged as a relevant option for enhancing the therapeutic benefit of anti-HER2 mAbs. Among stimulatory co-receptors, CD137 was the TNFRSF member showing the highest induction in microarray analysis of CD16-activated human NK cells, as well as along trastuzumab-dependent NK cell activation in a HER2+ BC *in vitro* model. In this context, CD137 upregulation showed earlier kinetics, larger magnitude and sustained persistence as compared to OX40. Trastuzumab-induced CD137 expression was enhanced by TNF-α signaling through TNFRI/TNFRII, as indicated by the effect of specific blocking mAbs. Agreeing with their proficient TNF-α secretion, CD137 upregulation was greater in NK cells from individuals harboring adaptive NKG2C+ NK cell expansions as compared to those lacking this NK cell subset. Remarkably, CD137 co-stimulation in CD16-activated NK cells by the agonist mAb Urelumab reversed TGF-β1-mediated inhibition in a dose-dependent manner, restoring CD25 (IL2Rα) expression, IL2-dependent proliferation and CD16+ NK cell numbers. Overall, our data reveals CD137 as a costimulatory receptor capable of overcoming TGF-β1 immunosuppression, and provide the rationale for combinatorial strategies including CD137 agonists for broadening anti-HER2 mAb therapeutic efficacy.

B7H6, a ligand for NKp30, is regulated by BRD4 in acute myeloid leukemia cells

A. Baragaño Raneros, ***P. Díaz Bulnes****, R. M. Rodriguez, B. Suárez Álvarez, C. López Larrea;*
Traslational Immunology Laboratory, Instituto de Investigación Sanitaria del Principado de Asturias, Oviedo, Spain.

Acute myeloid leukemia (AML) is a disease with a great morphological and genetic heterogeneity making it difficult to treat. Inhibition of bromodomain and extraterminal proteins (BETs) has been proposed as new therapeutic strategy in AML, but its effect on the innate immune response is unknown. NKp30 is a key activating receptor of NK cells that promotes the recognition and lysis of AML blasts through interaction with its B7-H6 ligand. Here, we examined the effect of BETs inhibitors in the B7-H6 expression and its consequences in the immune recognition. Our results showed that B7-H6 expression is drastically reduced in AML cell lines treated with BETs inhibitors (JQ1, I-BET762) leading to a lesser recognition and lysis mediated by NK cells. Assays of chromatin immunoprecipitation revealed that BRD4, the most extensively studied member of the BETs family, directly binds to the B7-H6 promoter region regulating its expression, whilst JQ1 treatment or BRD4 gene silencing abolish that binding. BRD4 recognizes acetylated lysines in histones and recruits the P-TEFb complex (Cyclin T / CDK9) aimed to phosphorylate the RNAPII, allowing gene transcription. We observed that BRD4 binding to B7-H6 promoter is associated with an enrichment of H3 acetylation and phosphorilation of RNAPII. Inhibition of P-TEFb complex with CDK9 inhibitor (DRB) or the p300 histone acetyltransferase with CBP30 suppressed the B7-H6 expression corroborating those results. Thus, B7-H6 expression in AML cells is regulated by BRD4 protein and treatment with BETs inhibitors could damage the immune recognition mediated by NK cells allowing the tumor progression.

Identification and functional properties of mature and immature neutrophils in homeostasis, inflammation and cancer

J. B. G. Mackey[1,2], *R. Jackstadt*[2], *T. Jamieson*[2], *A. McFarlane*[2], *X. L. Raffo*[2], *D. Patel*[1], *J. Secklehner*[1,2], *J. Vuononvirta*[1], *R. Snelgrove*[1], *J. Morton*[2,3], *J. Norman*[2,3], *O. J. Sansom*[2,3], *L. M. Carlin*[1,2];

[1]*Imperial College London, London, United Kingdom,* [2]*Cancer Research UK Beatson Institute, Glasgow, United Kingdom,* [3]*University of Glasgow, Glasgow, United Kingdom.*

Neutrophils are a critical component of the innate immune response and are capable of identifying and destroying pathogens as a result of their receptor expression and effector mechanisms. During cancer, severe infection and chronic inflammation increased numbers of neutrophils are produced and released from the bone marrow into the peripheral circulation, many of which are postulated to be developmentally immature. Neutrophil maturation within the bone marrow is essential to their development of distinct granules that are crucial to neutrophil function in host defence. We have identified and developed methods that efficiently distinguish immature from mature neutrophils *in vitro* and *in vivo* that can be utilised for their direct study.
Neutrophils are thought to worsen pathology in cancer and severe infection by both direct mediator production and suppression of other leukocytes. We identified immature Ly6G^{Intermediate} and mature Ly6G^{High} neutrophils by flow cytometry, transgenic reporters and adoptive transfer experiments. We studied localisation and function of these immature populations in colony stimulating factor 3 (CSF3; G-CSF) treated mice, lipopolysaccharide treated mice, and multiple genetically-engineered mouse cancer models. In these models, neutrophil populations alter their cell surface adhesion and chemokine receptor expression, compared with mature neutrophils. Interestingly, immature neutrophils also differ in their capacity to generate reactive oxygen species production with and without stimulation. We also measured the differential capacity of these populations to suppress cytotoxic lymphoid cell activity. Overall, circulating immature neutrophils are present in models of cancer, severe infection and emergency granulopoiesis where they display different functional capacity compared to mature neutrophils.

Epithelial damage and tissue γδ T cells promote a unique tumour-protective IgE response

G. Crawford[1], *R. Castro Seoane*[1], *S. Ward*[1], *M. Hayes*[1], *M. Haniffa*[2], *D. Dunn-Walters*[3], *J. Strid*[1];

[1]*Imperial College London, London, United Kingdom,* [2]*Newcastle University, Newcastle, United Kingdom,* [3]*University of Surrey, Guildford, United Kingdom.*

IgE is an ancient and conserved immunoglobulin isotype with potent immune function. Nevertheless, the regulation of IgE responses remains enigmatic and evidence for a role of IgE in host defense is limited. We have previously described that IgE is strongly induced through the skin as part of the lymphoid stress-surveillance (LSS) response. LSS refers to the capacity of resident γδTCR$^+$ intraepithelial lymphocytes (IEL) to directly sense epithelial cell dysregulation and initiate a restorative response. Here we explore the afferent pathways leading to IgE following skin exposure to environmental xenobiotics and the role of this endogenous IgE in controlling spontaneous tumour growth. We demonstrate the development of a potent autoreactive IgE response following topical exposure to the common environmental xenobiotic and carcinogen, 7,12-Dimethylbenz(a)anthracene. Further we show how tissue γδTCR$^+$ IELs are uniquely initiating and regulating the IgE, but not IgG1, response. High-throughput antibody sequencing reveals that γδ T cells shape the IgE repertoire by supporting specific VDJ rearrangements with unique CDRH3 characteristics. This endogenous IgE response, via the FcεRI, protects against epithelial skin carcinogenesis and *FceR1a* expression in human squamous cell carcinoma correlates inversely with poor disease outcome. Thus, LSS promotes a unique IgE response, which is part of an early host defense mechanism providing protection against cancer. Our data provides experimental support for the 'toxin hypothesis', suggesting IgE as an intentional host defense mechanism against non-infectious cell-damaging environmental xenobiotics and propose a cooperative role for T and B cell immune surveillance in epithelial tissues.

Resident CD4+ T cells in secondary lymphoid organs

A. C. Kaminski[1], *O. Pabst*[1], *M. Ugur*[2];

[1]*Molecular medicine, Aachen, Germany,* [2]*Department of Microbiology and Immunology, Melbourne, Australia.*

Adaptive immunity relies on controlled lymphocyte migration and proper lymphocytes positioning. We and others established in vivo cell tracking based on photoconvertible proteins. Photoconversion enables the labelling of immune cells in situ and is thus particularly suited for studying cell egress and migration. To enable long-term tracking of photoconverted cells, we established a histone-fused photoconvertible Dendra2 protein. Retroviral overexpression of histone-fused Dendra2 and in vivo cell tracking experiments allowed us to identify a population of lymphoid node (LN) resident CD4+ T cells. In this project we analyse the molecular and functional characteristics of LN resident CD4+ T cells. We use a novel transgenic mouse with stable expression of histone-fused Dendra2 in immune cells. Naïve CD4+ T cells typically leave LNs after 8-12 hours. Recently activated T effector cells stay in LNs for approximately 3 days. We have identified another migratory pattern: resident CD4+ T cells remain in peripheral LNs for at least up to 28 days. Resident CD4+ T cells constitute 20-50% of all effector/memory CD4+ T cells, indicating a major population of effector/memory CD4+ T cells with hitherto unappreciated migratory behaviour. Our data indicate that generation of resident CD4+ T cells requires strong immune stimulation and sustained availability of antigen. Resident CD4+ T cells were maintained in a model of induced T cell receptor deficiency. This indicates that CD4+ T cells can remain resident in LN independently of continuous T cell receptor triggering. At present, we further characterise the mechanisms to generate and maintain resident CD4+ T cells.

WS.B3.01.02

Production of extracellular adenosine by CD73$^+$ dendritic cells is crucial for induction of T cell hyporesponsiveness

C. Silva-Vilches, *K. Mahnke;*
University Hospital Heidelberg, Heidelberg, Germany.

Dendritic cells (DCs) express the ecto-5'-nucleotidase CD73 that generates immunosuppressive Adenosine (Ado) by dephosphorylation of extracellular Adenosine-monophosphate. To investigate whether Ado that is produced by CD73$^+$ DCs affects induction of tolerance in contact hypersensitivity (CHS) reactions, C57BL/6 wildtype (WT) and CD73$^{-/-}$ animals were tested in a 2,4-dinitrofluorobenzene (DNFB) induced-CHS model. In this model pre-treatment with 2,4-dinitrothiocyanobenzene (DNTB) induces tolerance to DNFB. We demonstrate that treatment with DNTB induced tolerance to DNFB only in WT but not in CD73$^{-/-}$ mice. Analysis of DCs that migrated from skin to draining lymph nodes (smDCs) in WT mice revealed increased expression of CD73 after application of DNTB and a lower expression of activation markers (CD80 and CD86) compared to CD73$^{-/-}$ smDCs, accompanied by elevated concentrations of extracellular Ado within the LN tissue. Also, markers of T cell anergy, namely early growth response protein-2 (EGR2) and N-Myc downstream regulated protein-1 (NDRG1) were upregulated in LN T cells of DNTB-treated WT mice. Moreover, those T cells from WT animals exhibited less proliferation, less activation and less cytokines production than T cells from CD73$^{-/-}$ mice upon *ex vivo* re-stimulation. Similar effects were observed *in vitro*.
I.e., Ado-producing WT DCs, but not CD73$^{-/-}$ DCs rendered T cells hyporeactive, decreased their T cell costimulatory signaling and induced upregulation of EGR2 and NDRG1. Thus, these data demonstrate that expression of CD73 by DCs, which triggers elevated levels of extracellular Ado, is a crucial mechanism for the induction of anergic T cells and tolerance.

EGFR-HIF1α signaling positively regulates the development of Th9 cells

S. Roy, *Z. Rizvi, A. Awasthi;*
Translational Health Science and Technology Institute (THSTI), Faridabad, India.

Epidermal growth factor receptor (EGFR) is crucial for the proliferation and differentiation of immune cells and is important for the development of tumors. EGFR has been shown to be expressed on T cells and play a role in T cell differentiation and regulation. The role of EGFR and its ligands in IL-9-producing Th9 cells has not been identified yet. Th9 cells play a critical role in inducing anti-tumour immunity, allergic inflammation as well as in autoimmunity. To understand the transcriptional network of Th9 cells using RNASeq analysis, we identified a strong upregulation of EGFR expression in Th9 cells. We have identified that the expression of EGFR is required for the induction of IL-9 in Th9 cells, as EGFR specific inhibitor, Gefitinib, suppressed the development of Th9 cells. Further analysis of EGFR pathways in Th9 cells revealed EGFR activation upregulates hypoxia-inducible factor 1α (HIF1α) and inducible nitric oxide synthase (iNOS) in Th9 cells. The increased expression of HIF1α and iNOS increases the production of amphiregulin, an EGFR ligand in Th9 cells, which acts in a feed-forward loop further enhancing Th9 cells differentiation. Mechanistically, we have identified that HIF1α binds and transactivates iNOS and IL-9 in Th9 cells. Furthermore, inhibition of EGFR and HIF1α pathway suppressed IL-9 production in both mouse and human Th9 cells, and substantially promoted the tumor development. Our findings thus identify a critical role of EGFR-HIF1α module in the development and functions of Th9 cells which can be targeted for successful immunotherapy.

WS.B3.01.04

Post-transcriptional regulation of cytokine production in T cells by RNA binding proteins

B. Popovic[1], *F. Şalerno*[1], *S. Engels*[1], *F. van Alphen*[2], *A. Guislain*[1], *B. P. Nicolet*[1], *M. C. Wolkers*[1];
[1]*Sanquin Research/Landsteiner Laboratory, Amsterdam, Netherlands,* [2]*Sanquin Research, Amsterdam, Netherlands.*

Effective cytotoxic CD8+ T cell responses depend on the concerted production of inflammatory cytokines and cytotoxic molecules. The co-production of IFNγ, TNFα and IL-2 is a hallmark of the most potent effector cells. We recently showed that post-transcriptional regulatory mechanisms are key to fine-tune cytokine production. Both the translational rate and stabilization of cytokine mRNA was a determinant of production levels. Intriguingly, all three cytokines used private regulatory mechanisms for their production: whereas the production of TNFα almost exclusively depended on the translational rate, IL-2 primarily depended on *de novo* transcription, and mRNA stabilization was only used to amplify the production rate. IFNγ used all three regulatory mechanisms for optimal production, i.e. *de novo* transcription, translation efficiency and mRNA stabilization. Here we set out to identify which factors drive this individual regulation of cytokine mRNA, with a specific focus on regulatory RNA binding proteins (RBPs). To this end, we employed streptavidin-binding RNA aptamers containing the 3'Untranslated Region (3'UTR) of the three mRNAs to identify RBPs binding to the individual 3'UTR. Using lysates from *in vitro* expanded, resting primary human T cells, we identified differential binding of RBPs by mass spectrometry analysis to each individual cytokine 3'UTR. We currently investigate the mode of action of the identified RBPs to fine-tune cytokine production. Unraveling the post-transcriptional mechanisms that define the cytokine production in T cells should yield valuable biological insights that will help driving effector responses against pathogens and malignant cells.

Lysosome-related organelle tethering controls directionally distinct cytokine transport in T cells

B. Qu*, Y. Zhou, R. Zhao, E. C. Schwarz, R. Akbar, V. Pattu, V. Helms, H. Rieger;*
Saarland University, Homburg, Germany.

Cytokines are small proteins playing a key role in orchestrating activation and responses of immune cells. It is of markedly importance to target cytokines to the desired destination. In $CD4^+$ T cells, in particular, cytokines are delivered in two distinct modes: either exclusively to the immunological synapse (IS) (eg. IL-2) or transported multi-directionally (eg. TNFα). However, the molecular mechanisms responsible for these distinct transport patterns remain elusive. Here we show that in primary human $CD4^+$ T cells both $TNFα^+$ and $IL\text{-}2^+$ vesicles tether with lysosome-related organelles (LROs), mediated by the SNARE protein Vti1b. Only LRO-tethered but not untethered cytokine vesicles are preferentially transported to the desired secretion sites, namely LRO-tethered $IL\text{-}2^+$ to the IS and LRO-tethered $TNFα^+$ multi-directionally. LRO tethering enhances the recruitment of kinesin and dynein to $TNFα^+$ vesicles, favoring the transport to both directions along microtubules. In contrast, the recruitment of dynein but not kinesin is selectively enhanced in LRO-tethered $IL\text{-}2^+$ vesicles, promoting minus-end transport to the MTOC, which localizes at the IS. Our findings suggest that LRO tethering serves as a novel mechanism to regulate directionally distinct cytokine transport, especially in $CD4^+$ T cells.

Targeting E3 ubiquitin ligase receptor cereblon to stimulate Myc-driven metabolismin CD8+ T cells

R. Hesterberg, A. A. Akuffo, M. S. Beatty, W. E. Goodheart, M. Fernandez, J. L. Cleveland, ***P. K. Epling-Burnette****;*
Moffitt Cancer Center, Tampa, United States.

Derivatives of thalidomide known as immunomodulatory drugs (IMiD) bind to and elicit anti-cancer and immune modulating activity by binding to the E3 ubiquitin ligase substrate receptor cereblon (CRBN). While IMiDs potentiate T cell effector functions in healthy and immunosuppressed cancer patients, the physiological roles of CRBN in T cells is undefined. To understand the immunological role of CRBN in T cells, we made use of a germline *Crbn* knockout mouse ($Crbn^{-/-}$) and created OT1;$Crbn^{-/-}$ mice as well as LckCre;$Crbn^{fl/fl}$ mice. T cells derived from $Crbn^{-/-}$ mice manifest higher rates of proliferation and cytokine production and an elevated bioenergetics profile, with supraphysiological levels of polyamines secondary to enhanced glucose and amino acid transport and increased expression of metabolic enzymes including ornithine decarboxylase related to stabilization of c-Myc.
To determine if these changes occur in the presence of IMiD treatment, we examined Myc expression and metabolic rates after T cell activation and found that both IMiDs and Crbn deficiency increased and sustained the expression of the master metabolic regulator Myc. While *Crbn* deficient T cell can exacerbate graft-versus-host (GVHD) disease *in vivo*, they also endow tumor infiltrating lymphocytes with superior anti-tumor reactivity following adoptive transfer and after T cell-specific deletion of *Crbn*. Therefore, CRBN represents a druggable target that has a profound effect on sustaining the immunometabolism of CD8+ T cells.

WS.B3.02 T cell mediated immune regulation in tumors

WS.B3.02.01

HDAC7 controls $CD8^+$T cell dependent anti-tumor immunity

C. Yerinde[1,2,3], *J. Keye*[1,2], *F. Schmidt*[1,2], *B. Siegmund*[1], *R. Glauben*[1], *C. Weidinger*[1,4];
[1]*Charité - Universitätsmedizin Berlin, Medical Department, Division of Gastroenterology, Infectiology and Rheumatology, Campus Benjamin Franklin, Berlin, Germany,* [2]*Freie Universität Berlin, Department of Biology, Chemistry and Pharmacy, Berlin, Germany,* [3]*Berlin School of Integrative Oncology (BSIO) MKFZ, Berlin, Germany,* [4]*Berlin Institute of Health (BIH), Clinician Scientist Program, Berlin, Germany.*

Class II Histone deacetylases (HDAC) were shown to orchestrate T cell-dependent immune responses via the epigenetic control of genes and via the post-translational modification of cytoplasmic and nuclear proteins. However, the contribution of single HDAC family members to T cell differentiation and function remain elusive. To elucidate the role of histone deacetylase 7 (HDAC7) in T cells, we assessed the immune cell composition of $Hdac7^{flox/flox}$*Cd4-Cre* mice by mass cytometry under steady state conditions using a panel of 31 classifying-, differentiation- and activation- markers, which revealed a highly pre-activated phenotype within the $CD8^+$ T cell compartment. By using Seahorse analysis and RNA sequencing, we observed that deletion of HDAC7 reduced the cellular expansion of $CD8^+$ T cells, due to the transcriptional deregulation of metabolism- and apoptosis-regulating genes resulting in an impaired glycolytic capacity and apoptosis of $CD8^+$ T cells. Furthermore, HDAC7-deficient $CD8^+$ T cells harbored impaired production of IFNγ, which could be linked to reduced activation levels of Store-operated Calcium Entry (SOCE) signaling. Importantly, $Hdac7^{flox/fox}$*Cd4-Cre* mice formed significantly bigger tumors when injected with the syngenic lymphoma cell line EG-7, as $Hdac7^{fl/fl}$*Cd4-Cre* mice harbored significantly lower numbers of tumor-infiltrating $CD8^+$T cells in comparison to wild type littermates. Taken together our data reveal that HDAC7 might serve as a key regulator of T cell mediated anti-tumor immunity via controlling the metabolism and calcium homeostasis of $CD8^+$ T cells.

WS.B3.02.02

Deciphering the molecular pathways underlying oncogenic IL-7R signaling in T-cell acute lymphoblastic leukemia

A. Murcia Ceballos[1], *P. Fuentes Villarejo*[1], *S. González García*[1], *M. García Peydró*[1], *J. Alcain*[1], *E. García Martínez*[1], *A. A. Ferrando*[2], *M. Toribio*[1];
[1]*Centro de Biología Molecular "Severo Ochoa", Madrid, Spain,* [2]*Institute for Cancer Genetics, New York, United States.*

Introduction: Interleukin-7 plays a crucial role in normal T and B-cell development and also contributes to proliferation in acute lymphoblastic leukemia (ALL), the most common pediatric cancer. Recently, *IL7R* mutations have been described in 10% of T and B-ALL cases, and mutational activation of IL-7R was suggested to be involved in T-cell leukemogenesis. We thus sought to investigate intracellular pathways underlying oncogenic IL-7R signaling in T-ALL, with the final aim of delineating specific therapeutic strategies.
Methods: We investigated the impact of a novel gain-of-function mutation located in *IL7R* exon6 identified in T-ALL patient, by expression in cytokine-dependent and independent cell lines, and primary human early thymic precursors and T-ALL cells. Fetal thymus organotypic cultures (FTOC) allowed us to assess the step-wise oncogenic impact of mutant IL-7R in T-cell development. Moreover, biochemical approaches were performed in combination with *in vitro* cell proliferation and *in vivo* tumor progression assays of cells expressing mutant IL-7R.
Results: We show that mutant IL-7R promoted the selective expansion and accumulation of primary human pre-T cells in FTOC, and the constitutive proliferation and survival of cytokine-dependent cells *in vitro*. More importantly, it also enhanced tumor progression of cell lines and primary T-ALL cells *in vivo*. This functional impact was associated with constitutive JAK-STAT, MAPK and mTORC1 activation and c-myc expression, independently of PI3K-Akt activation. Possible pathways underlying mutant IL-7R-dependent constitutive mTORC1 activation will be discussed.
Conclusions: The identification of mTORC1 activation through an Akt-independent pathway, points to novel molecules as promising and unexplored therapeutic targets for T-ALL.

WS.B3.02.03

Epithelial signals promote local effector Foxp3$^+$ regulatory T cell accumulation in the gut

*A. Bremser[1], H. Meinicke[2], **A. Izcue**[3];*
[1]Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany, [2]Freiburg University Hospital, Freiburg, Germany, [3]Institute of Molecular Medicine, Aachen, Germany.

Tumors are often accompanied by a local accumulation of CD4$^+$ Foxp3$^+$ regulatory T cells (Treg) that can inhibit anti-tumoral responses. However, the pathways leading to local Treg accumulation and whether accumulating Treg represent a specific Treg population remain to be investigated. Using genetically modified mice we have found that cadherin switch and increased β-catenin in intestinal epithelial cells, two features associated with malignant transformation, lead to a striking increase in the frequency and numbers of the KLRG1$^+$ GATA3$^+$ Treg subset. Although KLRG1 is a ligand for E-cadherin and KLRG1 expression can reduce Treg accumulation in the gut, ablation of KLRG1 on Treg did not lead to an increase in the gut Treg populations. Rather, both E-cadherin ablation and increased β-catenin signals resulted in higher levels of interleukin-33 in epithelial cells. We found that IL-33 preferentially expands KLRG1$^+$ GATA3$^+$ Treg cells in vitro, suggesting that IL-33 could link alterations in epithelial cells with a local increase in Treg. Intestinal tumors often present reduced E-cadherin expression, enhanced β-catenin signaling and increased IL-33. Analysis of intestinal tumors from APC$^{min/+}$ mice showed that local Treg accumulation in this model was exclusively due to an increase in KLRG1$^+$ GATA3$^+$ Treg cells. Our data identify a novel axis through which epithelial cells control local Treg cell subsets, an axis which may be activated during intestinal tumorigenesis.

WS.B3.02.04

Intravital signaling visualization reveals that transient productive interactions between T regulatory cells and classical DC support cancer immune tolerance

***F. Marangoni**[1], E. Carrizosa[1], V. Mani[1], M. Thelen[2], J. Prüssmann[1], T. R. Mempel[1];*
[1]Massachusetts General Hospital - Harvard Medical School, Charlestown, United States, [2]Uniklinik Köln, Köln, Germany.

The recognition of cognate antigen within tumors is necessary for CD4$^+$Foxp3$^+$ T regulatory cells (Treg) to enforce local immunological tolerance (Bauer JCI 2014). However, how cellular interactions, tightly controlled in space and time, regulate this process *in vivo* is unknown. We visualized Treg activation using an NFAT-GFP construct whose nuclear localization reports the activation of TCR-calcineurin-NFAT signaling (Marangoni Immunity 2013). NFAT-GFP-transduced Treg were transferred in mice with red-fluorescent CD11c cells, and imaged within implanted tumors by multiphoton microscopy. We found that ~30% of polyclonal Treg, but no conventional CD4$^+$ T cells (Tconv), were activated in tumors. This was due to differences in the TCR repertoire because Treg and Tconv with an identical hemagglutinin (HA)-specific TCR were activated in HA-expressing tumors. Notably, while HA-Tconv:CD11c interactions were stable, HA-Treg:CD11c contacts were short-lived.
This was not due to characteristics intrinsic to Treg but to their capacity to progressively modulate antigen presentation by APC, because HA-Treg were capable of stable interactions early after transfer but destabilized HA-Tconv:CD11c interactions over time. We studied the meaning of Treg:CD11c interactions by inducing Treg-specific deletion of calcineurin B (CnB), which reduced tumor-associated Treg numbers, lowered the expression of ICOS and CTLA4, and delayed tumor growth. Deletion experiments identified zbtb46-dependent classical DC as the APC activating tumor-associated Treg. We thus conducted the first imaging-based investigation of Treg activation demonstrating that short-lived productive interactions with classical DC, which may be detrimental for conventional T cell function (Marangoni Immunity 2013), conversely suffice to maintain Treg numbers and immunosuppressive capacity in tumors.

WS.B3.02.05

The CD58-CD2 axis controls killing of leukemic B cells by cytotoxic T lymphocytes

***V. Zurli**[1], T. Montecchi[1], G. Wimmer[1], O. Acuto[2], C. Baldari[1], A. Kabanova[1];*
[1]University of Siena, Siena, Italy, [2]University of Oxford, Oxford, United Kingdom.

Introduction: Cytotoxic T lymphocytes (CTLs) play a key role in the immune defence against cancer. To exert their vital function, CTLs polarize and focally release lytic granules at the immune synapse formed with their targets. We previously reported that leukemic B cells can resist CTL killing by establishing dysfunctional synapses characterized by non-polarized granule release. In the current work we address the mechanisms controlling lytic granule polarization in human CTLs.
Methods: Firstly, we identified the factor responsible for the formation of dysfunctional synapses by applying comparative proteomics analysis of surface proteins to a panel of B cells, either susceptible or resistant to CTL lysis. Then we used CRISPR/Cas9 technology, functional assays, and phospho-proteomics to characterize molecules involved in the lytic granule movement in CTLs.
Results: We identified four co-stimulatory molecules highly expressed on susceptible B cells: CD58, CD30, SLAMF-1 and SLAMF-7. Among these, only CD58, through the interaction with its receptor CD2 on CTLs, was able to promote granule polarization towards the synapse. Notably, we found that CTL costimulation through CD2 was of crucial importance for B cell killing. We are currently applying a phospho-proteomics approach to elucidate the CD2 signaling network implicated in granule polarization.
Conclusions: Considering that loss of CD58 expression on B-cell tumours has been described as the mechanism of cancer progression, our results both highlight new key aspects of CTL biology and are expected to be valuable for the development of focused therapies counteracting cancer immune evasion.

Functional anti-TIGIT antibodies modulate T cell responses *in vivo*

*K. O. Dixon[1], **M. Schorer**[2], J. Nevin[1], Y. Etminan[1], Z. Amoozgar[3], T. Kondo[1], S. Kurtulus[1], N. Kassam[1], R. A. Sobel[4], D. Fukumura[3], R. K. Jain[3], A. C. Anderson[1], V. K. Kuchroo[1], N. Joller[2];*
[1]Evergrande Center for Immunologic Diseases and Ann Romney Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, United States, [2]Institute of Experimental Immunology, University of Zurich, Zurich, Switzerland, [3]Edwin L. Steele Laboratories, Department of Radiation Oncology, Massachusetts General Hospital and Harvard Medical School, Boston, United States, [4]Palo Alto Veteran's Administration Health Care, Department of Pathology, Stanford University School of Medicine,, Stanford, United States.

Introduction: The selective engagement of inhibitory receptors plays an important role in maintaining immune homeostasis and their divergent expression gives rise to a broad range of pathologies such as autoimmunity, cancer and chronic infections. Blocking antibodies directed against co-inhibitory receptors such as PD-1 and CTLA-4 showed great efficacy as anti-cancer drugs in the clinics because of their potential to restore T cell responses *in vivo*. TIGIT is a novel co-inhibitory receptor that has recently gained attention as a potential regulator of T cell exhaustion in the context of cancer as well as in ameliorating autoimmune disorders. Materials and Methods: In order to study the immune modulatory properties of TIGIT, we generated a panel of functional anti-TIGIT antibody clones using hybridoma cultures and tested them in both autoimmune and cancer models. Results: We found that the administration of the agonistic anti-TIGIT antibody ameliorated autoimmune disease severity in EAE, whereas administration of the blocking anti-TIGIT antibody in combination with anti-PD-1 blockade showed a synergic anti-tumor effect in models of colon carcinoma and glioblastoma. Conclusions: Collectively, our data demonstrates that TIGIT modulation can be used to effectively regulate T cell responses and disease outcome *in vivo* and provides further insight for the development of novel therapeutic approaches.

Loss of NIK in thymic epithelial cells leads to fatal autoimmunity through aberrant Treg development

***C. Haftmann**[1], F. Mair[1], E. Terskikh[1], M. Spalinger[2], B. P. Leung[3], A. Waisman[4], B. Becher[1];*
[1]Inst. of Experimental Immunology, Zürich, Switzerland, [2]Universitätsspital, Klinik für Gastroenterologie und Hepatologie, Zürich, Switzerland, [3]University of Southern California, Department of Physiology & Biophysics, Zürich, Switzerland, [4]Johannes Gutenberg University Mainz, Inst. for Molecular Medicine, Mainz, Germany.

Medullary thymic epithelial cells (mTECs) mediate central T cell tolerance through negative selection. mTecs are, however, also critical for the formation of peripheral tolerance by instructing the development of nTregs. Which of these two functions dominate is a matter of some debate. We have generated a mouse model in which the development and function of mTECs are compromised by conditional ablation of the NF-kB inducing kinase (NIK, encoded by *Map3k14*) restricted to the TEC compartment (mTEC-NIK). In contrast to germ-line deficient *NIK$^{-/-}$* mice, which develop largely normally and show no overt pathology, mTEK-NIK mice rapidly developed severe and fatal multi-organ autoimmunity shortly after birth, characterized by infiltration of effector T cells in various organs. The observed autoimmunity was clearly T cell mediated, as the survival of the mice could be significantly improved upon antibody mediated T cell depletion. However, whereas there was no obvious indication of augmented auto-reactivity through the loss of negative selection, Tregs, although emerging from the thymus, were dysfunctional as indicated by high-parametric single cell analysis of Treg markers and *in vivo* suppression assays. Conversely, adoptive transfer of normal Tregs prevented autoimmunity. Most strikingly, in thymic co-transplantation, Tregs primed by wildtype thymi were able to prevent autoimmune pathology by mTEC-NIK educated T cells. We thus postulate that Treg induction rather than negative selection of autoreactive T cell clones is the superior duty of mTECs in thymic T cell education. The author received a fellowship of the German Research Council (DFG).

A Timer for analyzing temporally dynamic changes in transcription during T cell differentiation in vivo

*D. Bending[1], P. Prieto Martín[1], A. Paduraru[1], C. Ducker[1], E. Marzaganov[1], M. Laviron[1], T. Crompton[2], **M. Ono**[1];*
[1]Department of Life Sciences, London, United Kingdom, [2]University College London, London, United Kingdom.

Background: Understanding the mechanisms of cellular differentiation is challenging because differentiation is initiated by signaling pathways that drive temporally dynamic processes, which are difficult to analyse in vivo. **Results**: We establish a new Tool, Timer-of-cell-kinetics-and-activity (Tocky [toki], time in Japanese). Tocky uses the Fluorescent Timer protein, which spontaneously shifts its emission spectrum from blue-to-red, in combination with computer algorithms to reveal the dynamics of differentiation in vivo. Using a transcriptional target of T cell receptor (TCR)-signaling, we establish *Nr4a3*-Tocky to follow downstream effects of TCR signaling. Using *Nr4a3*-Tocky, we determined the temporal sequence of events during regulatory T cell (Treg) differentiation, identified the major precursor population of Treg, and showed that persistent TCR signals leads to the initiation of *Foxp3* transcription and Treg generation. Interestingly, in the periphery, *Nr4a3*-Tocky showed that self-reactive T cells, which include Treg and memory-phenotype T cells, received spontaneous infrequent TCR signals. Furthermore, using the murine model of Multiple Sclerosis, myelin-specific T cells at the site of autoimmune inflammation also showed persistent TCR signalling, which *Nr4a3*-Tocky distinguished from infrequent TCR signals in self-reactive T cells. In addition, by generating *Foxp3*-Tocky, we establish that the Tocky approach can be applied to another gene as well. By analysing differentiating Treg using *Foxp3*-Tocky, we showed a progressive demethylation of the *Foxp3* gene across time, demonstrating that the active demethylation process occurred in T cells with sustained *Foxp3* transcription. **Conclusion**: Tocky is a tool for cell biologists and immunologists to address previously inaccessible questions by directly revealing dynamic processes in vivo. **Funder**: Biotechnology and Biological Sciences Research Council

A temporally dynamic Foxp3 autoregulatory transcriptional circuit controls the effector Treg programme

***D. Bending**[1], A. Paduraru[2], C. Ducker[2], P. Prieto Martin[2], T. Crompton[3], M. Ono[2];*
[1]University of Birmingham, Birmingham, United Kingdom, [2]Imperial College London, London, United Kingdom, [3]University College London, London, United Kingdom.

Foxp3$^+$ Regulatory T-cells (Treg) are negative regulators of the immune response, and upon activation, Treg can suppress the activities of other T cells as effector Treg. Whilst thymic Treg development has been extensively characterised, it remains largely unknown whether and how *Foxp3* transcription is induced and regulated in the periphery during T-cell responses. In addition, it is poorly known what controls the differentiation of Treg into effector Treg, which are Treg with enhanced expression of potent immunoregulatory molecules, such as IL-10. Here, using our state of the art *Foxp3-Timer of cell kinetics and activity* (Tocky) mice, which capture both quasi real-time and historical *Foxp3* expression, we show that both the generation of new *Foxp3* expressors and the rate of *Foxp3* transcription are dramatically increased during inflammation. These persistent dynamics of *Foxp3* transcription drive the effector-Treg programme and are dependent on a Foxp3 protein-dependent autoregulatory transcriptional circuit, which simultaneously sustains *Foxp3* transcription whilst repressing IL-2 expression. Persistent *Foxp3* transcriptional activity controls the expression of coinhibitory molecules, including CTLA-4 and effector-Treg signature genes.
Using RNA-seq, we re-classify key Treg-associated surface proteins based on their relationship to the temporal dynamics of *Foxp3* transcription. Furthermore, we show proof-of-principle for the manipulation of Foxp3$^+$ T-cell dynamics by immunotherapy: new Foxp3 flux is promoted by anti-TNFRII antibody, and high frequency *Foxp3* transcribers are targeted by anti-OX40 antibody. Collectively, our study dissects time-dependent mechanisms behind Foxp3-driven T-cell regulation and establishes the *Foxp3*-Tocky system as a tool to investigate the mechanisms behind Treg-targeting immunotherapies.

N4BP1 and TNIP1 control MHC-1 display on neuroblastoma tumors

*L. Spel[1], J. Nieuwenhuis[2], R. Haarsma[1], E. Stickel[2], O. Bleijerveld[2], M. Altelaar[3], j. Boelens[1], T. Brummelkamp[2], S. Nierkens[1], **M. Boes**[1];*
[1]UMC-Utrecht, Utrecht, Netherlands, [2]Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Utrecht University, Utrecht, Netherlands.

Neuroblastoma is the second most common tumor in children. The cause of neuroblastoma is thought to originate from derailed development of embryonic neural crest cells and is accompanied by low MHC-1 expression and suppression of the NF-κB transcription factor. Here, we addressed MHC-1 gene regulation in neuroblastoma, with ultimate goal to enhance its immunogenic potential for therapeutic T-cell targeting. Using a genome-wide CRISPR screen, we identified N4BP1 and TNIP1 as inhibitory factors of NF-κB-mediated MHC-1 expression in neuroblastoma. In support for a clinical relevance of these NF-κB-inhibiting factors, advanced stage neuroblastoma patients who express high levels of TNIP1 and N4BP1 have worse overall survival. Depletion of N4BP1 or TNIP1 indeed increased NF-κB and MHC-1 expression, and stimulated recognition by antigen-specific CD8+ T-cells. We confirmed that TNIP1 inhibits canonical NF-κB member RelA by preventing activation of the RelA/p50 NF-κB dimer. Furthermore, we show that N4BP1 inhibits both canonical and non-canonical NF-κB through binding of deubiquitinating enzyme CEZANNE, resulting in stabilization of TRAF3 and degradation of NF-κB-initiating kinase NIK. Thus, N4BP1/CEZANNE or TNIP1 are candidate immunotherapy targets in neuroblastoma tumors that should lift NF-κB suppression, and thereby trigger increased peptide/MHC1-mediated tumor reactivity to enhance therapeutic T-cell targeting.

T cell-induced tumor vulnerability discovery in anIFNg-independent genomic landscape

*D. Peeper, **D. Vredevoogd**;*
The Netherlands Cancer Institute, Amsterdam, Netherlands.

New clinical opportunities are needed to increase immunotherapy (IT) benefit. Whereas IFNγ-pathway mutations cause IT resistance, we find that IFNγ receptor-deficient tumors remain remarkably susceptible to T cell elimination. By integrating transcriptomics, proteomics and genome-wide CRISPR-Cas9 screening with clinical data, we defined the IFNγ-independent tumor landscape and uncovered a new immunotherapeutic opportunity. Ablation of TRAF2 enhanced T-cell elimination of both melanoma and lung cancer cells by redirecting TNF signaling to favor RIPK1-dependent apoptosis. TRAF2 loss greatly enhanced the therapeutic potential of pharmacological inhibition of its interaction partner cIAP. Corroborating these observations clinically, we identified recurring TRAF2 mutations that reduced T-cell sensitivity of tumor cells. Furthermore, both IT response duration and overall survival were lower for tumors that had acquired TNF pathway mutations on IT, suggesting immune-editing by TNF pressure. These results functionally annotate the tumor genome landscape of IFNγ-independent T cell cytotoxicity, and merit clinical exploration of TRAF2 for cancer immunotherapy.

WS.B3.03.06

NKG2A blockade potentiates CD8$^+$ T-cell immunity induced by cancer vaccines

***T. van Hall**[1], N. van Montfoort[1], L. Borst[1], M. J. Korrer[2], Y. Kim[2], S. Santegoets[1], M. Welters[1], P. Andre[3], S. Piersma[4], S. H. van der Burg[1];*
[1]Leiden University Medical Center, Leiden, Netherlands, [2]Vanderbilt University, Nashville, United States, [3]Innate Pharma, Marseille, France, [4]University of Washington, St Louis, United States.

Cancer vaccination has shown thus far limited clinical efficacy due to multiple suppressive factors in the tumour environment. We now demonstrate that the inhibitory receptor NKG2A constitutes an adaptive resistance mechanism during cancer vaccination by interaction with HLA-E on tumour cells. This immune receptor was preferentially found on tumour-infiltrating natural killer cells and CD8$^+$, but not CD4$^+$, T cells. Expression on CD8$^+$ T cells was found on CD103$^+$ tumour-infiltrating cells and only partly overlapped with other checkpoint receptors. Particularly high frequencies of NKG2A-expressing lymphocytes were detected in tumours with an immune-reactive profile and could be induced by therapeutic cancer vaccination. To examine if NKG2A represented an adaptive resistance mechanism during cancer vaccination, we blocked the receptor with a therapeutic antibody and performed genetic knockdown experiments for its ligand Qa-1, the conserved ortholog of HLA-E. In four mouse tumour models, the modest effect of therapeutic vaccines was greatly potentiated by disruption of the NKG2A/Qa-1 axis. NKG2A blockade operated through CD8$^+$ T cells and was even effective in a mouse model refractory to anti-PD-1 therapy. These findings indicate that NKG2A-blocking antibodies might improve clinical responses to therapeutic cancer vaccines.

PTPN22-deficient CD8 T cells resist TGFb suppression and mediate improved anti-tumour responses

*R. J. Brownlie[1], C. Garcia[2], M. Ravasz[2], D. Zehn[3], R. Zamoyska[2], **R. J. Salmond**[1];*
[1]Universty of Leeds, Leeds, United Kingdom, [2]Universty of Edinburgh, Edinburgh, United Kingdom, [3]Technical University Munich, Munich, Germany.

T cell adoptive therapy has the potential to treat human malignancies. Nonetheless, the poor immunogenicity of tumours and a strongly suppressive tumour microenvironment, characterized by high levels of inhibitory cytokines such as TGFb, limit the efficacy of this approach. We have previously shown that T cells lacking inhibitory phosphatase PTPN22 have enhanced responses to weak antigens (1), which may be of benefit in a tumour setting. We now show that PTPN22-deficient CD8+ T cells also have a substantially reduced susceptibility to TGFb inhibition. Subsequently, tumour-reactive PTPN22-/- CD8 T cells are superior in their ability to clear weakly immunogenic TGFb-secreting tumours in vivo. Mechanistically, in the absence of PTPN22, TCR-induced NFAT activation and IL-2 secretion is enhanced, which enables T cells to overcome the anti-proliferative effects of TGFb (2). Furthermore, we present data showing that PTPN22 also influences anti-tumour T cell memory.

Heterochromatin silencing of stemness during CD8⁺ T cell fate commitment

L. Pace[1,2,3], C. Goudot[4,3], E. Zueva[2,3], P. Gueguen[2,3], N. Burgdorf[2,3], J. Waterfall[5,3], J. Quivy[6,3], G. Almouzni[6,3], S. Amigorena[2,3];
[1]Italian Institute Genomic Medicine (IIGM), Turin, Italy, [2]U932, Curie Institute, Paris, France, [3]PSL Research University, Paris, France, [4]U932, Institute Curie, Paris, France, [5]U830, Curie Institute, Paris, France, [6]UMR3664, Curie Institute, Paris, France.

Following activation by antigens, naïve CD8⁺ T lymphocytes establish specific heritable gene expression programs that define the progression to long-lasting memory or to short-lived effector cells. While lineage specification in T cells is critical for protection, the impact of epigenetic silencing on T lymphocyte differentiation is still incompletely understood. Here, we explore the role of heterochromatin-mediated gene expression silencing by Suv39h1, a histone H3 lysine 9 methyltransferases that plays a critical, evolutionary conserved, role in heterochromatin structure and dynamics. We show that in murine CD8⁺ T cells activated after *Listeria monocytogenes* infection *in vivo*, Suv39h1-dependent H3K9me3 deposition controls the expression of a set of stem cell-related/memory genes. Single-cell RNA sequencing analysis reveals that the silencing in stem/memory genes selectively affects terminally differentiated effector subsets. The results also show increased proportions of CD8⁺ T cells with central memory phenotype and the de-repression of stem cell-related genes across different *Suv39h1*-defective CD8⁺ T cell sub-populations. In line with these observations, *Suv39h1*-defective CD8⁺ T cells show increased memory potential, including sustained survival and increased long-term re-programming capacity, as compared to *Suv39h1*-proficient CD8⁺ T cells. We conclude that Suv39h1 plays a critical role in marking chromatin to silence stem/memory gene expression during CD8⁺ effector T cell terminal differentiation. In doing so, Suv39h1/H3K9me3 would establish an epigenetic barrier on the stem/memory gene expression program, preventing the effector re-programing into memory cells. These results open new perspectives for the manipulation of epigenetic programming of T lymphocyte identity in the context of T cell-based immunotherapies.

TLR9 signaling mediates functional responses induced by direct ligation of ODN 2216 in CD4+CD25- effector T cells

R. K. Sharma[1], J. Sharma[1], P. Jain[2], A. Gupta[1], N. Sachdeva[1];
[1]Post Graduate Insiitute of Medical Education and Research, Chandigarh, Chandigarh, India, [2]Drexel University College of medicine, Philadelphia, Philadelphia, United States.

Oligodeoxynucleotides (ODNs) are established TLR9 ligands; however, their functional responses in CD4+ T cells are believed to be independent of TLR9 and MyD88. We have recently demonstrated activation of TLR9 signaling after ODN 2216 ligation in CD4+ effector T (Teff) cells. However, the consequences of direct ODN ligation on the immunophenotype of CD4+ Teff cells remain to be elucidated. In view of this, we looked upon the functional responses in CD4+ Teff cells after stimulation with ODN 2216 and the role of TLR9 signaling in the observed changes in cellular phenotype. Firstly, TLR9 expression in CD4+ Teff cells was regulated by downstream molecules of TLR9 signaling in a feedback controlled fashion. Next, we observed a TLR9 signaling dependent increase in proliferation of CD4+ Teff cells stimulated using ODN 2216.
Also, we observed increased synthesis of immunoregulatory molecules including TGF-β, CTLA4 and IL-10, resulting in an anti-inflammatory phenotype similar to the Th3 type of regulatory T cells. These Th3 like cells were able to suppress the proliferation of untreated Teff cells. The expression of predominant immunoregulatory cytokine, TGF-β was found to be dependent on molecules involved in TLR9 signaling in these cells, with exception of MyD88. Collectively, our results demonstrate that ODN 2216 induced functional responses in CD4+ Teff cells depend upon TLR9 signaling pathway resulting in modulation of Teff cells. Our findings thus, pave the way for future research to explore direct modulation of adaptive immune cells, using innate immune ligands, to subvert exaggerated inflammatory/autoimmune responses.

The T cell genome in 3D: how higher order chromatin structures regulate virus-specific T cell differentiation

B. E. Russ[1], *M. Olshansky*[1], *Z. He*[2], *J. Paulsen*[3], *S. Tomei*[1], *J. Li*[1], *P. Collas*[3], *C. Murre*[1], ***S. J. Turner***[1];
[1]Biomedical Discovery Institute, Clayton, Australia, [2]University of California, San Diego, San Diego, United States, [3]University of Oslo, Oslo, Norway.

Infection triggers large-scale changes in the phenotype and function of virus-specific CD8+ T cells ensuring that they acquire the necessary lineage specific functions critical for immune clearance of the pathogen. Whilst the molecular mechanisms that control these changes are becoming apparent, how they combine and contribute to regulate CD8+ T cell differentiation is still unclear. Genome wide mapping of chromatin interactions (HiC), histone PTMs (ChIP-seq) and chromatin accessibility (ATAC-seq) within immature thymocytes, naive effector and memory virus-specific CD8+ T cells demonstrated that maturation of higher order chromatin structures occurs upon differentiation of CD8+ T cells from an immature to mature state. Interestingly, the chromatin structure within naïve CD8+ T cells appear to be pre-configured in a lineage-specific way, both at the level of histone PTMs and higher order chromatin contacts. This genomic pre-configuration is then associated with targeted epigenetic maturation of lineage-specific genomic elements upon T cell activation, thus implying that the outcome of CD8+ T cell differentiation is largely pre-determined. These data have implications better understanding of the molecular events, and their regulation, that occur during the generation of effective T cell responses and establishment of immunological memory.

Deep phenotyping of colorectal cancers by high-dimensional mass cytometry reveals tumor-specific immune landscapes

N. L. de Vries[1,2], *V. van Unen*[1], *T. R. Abdelaal*[3,1], *M. E. van Herk*[1], *R. van der Breggen*[1], *A. Farina Sarasqueta*[1], *K. C. Peeters*[1], *T. Höllt*[3,1], *B. P. Lelieveldt*[3,1], *F. Koning*[1], *N. F. de Miranda*[1];
[1]Leiden University Medical Center, Leiden, Netherlands, [2]TECObiosciences GmbH, Landshut, Germany, [3]Delft University of Technology, Delft, Netherlands.

Introduction: Immune checkpoint blockade has revolutionized cancer treatment. However, clinical outcomes are highly variable as only a proportion of cancer patients benefit. As such, an in-depth understanding of the immune cell populations that participate in the process of tumorigenesis is necessary. The aim of this study is to unravel local and systemic immune profiles of colorectal cancer (CRC) using high-dimensional immunophenotyping by mass cytometry.
Materials and Methods: The expression of 36 immune cell markers was simultaneously assessed at the single-cell level by mass cytometry in tumor tissues, tumor-associated lymph nodes, adjacent normal mucosa, and peripheral blood samples from 18 CRC patients. Cytosplore and HSNE (Hierarchical Stochastic Neighbor Embedding) analyses were carried out to identify and visualize the immune composition in the tissues.
Results: We identified 218 phenotypically distinct immune subsets, including tumor-resident CD103⁺PD-1⁺ cytotoxic, helper, and gammadelta T cells, CD4⁺ICOS⁺CD27⁻ T cells, and the recently described lineage-negative CD7⁺CD127⁻CD45RO⁺CD56⁺ intermediate-innate lymphoid cells (int-ILCs), all with an activated phenotype. These cells were exclusively found in tumor tissues. Unsupervised clustering of the tissues based on the composite immune profile separated mismatch-repair (MMR)-deficient from MMR-proficient CRCs, and showed strong correlations between the presence of int-ILCs and the CD103⁺PD-1⁺ and ICOS⁺ T cell populations in MMR-deficient CRCs.
Conclusions: High-dimensional immunophenotyping of CRCs reveals tumor-specific immune signatures and points towards a coordinated adaptive and innate immune response to CRC. Previously unappreciated immune cell populations further differentiate the two main pathways of CRC tumorigenesis, and suggests a multi-targeted exploitation of their anti-tumor properties in a therapeutic setting.

ATTACK, a novel bispecific T cell-recruiting antibody with trivalent EGFR binding and monovalent CD3 binding for cancer immunotherapy

S. Harwood[1], ***S. Lykkemark***[1], *A. Ana Alvarez-Cienfuegos*[2], *N. Natalia Nuñez-Prado*[1], *M. Compte*[3], *S. Hernandez-Perez*[4], *N. Merino*[5], *J. Bonet*[6], *R. Navarro*[7], *P. M. van Bergen en Henegouwen*[8], *K. Mikkelsen*[1], *K. Mølgaard*[1], *F. Jabs*[1], *L. Sanz*[7], *F. J. Blanco*[5], *P. Roda-Navarro*[4], *L. Alvarez-Vallina*[1];
[1]Aarhus University, Aarhus, Denmark, [2]fMolecular Immunology Unit, Hospital Universitario Puerta de Hierro, Majadahonda, Spain, [3]Leadartis, Madrid, Spain, [4]Universidad Complutense de Madrid, Madrid, Spain, [5]CIC bioGUNE, Derio, Spain, [6]Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland, [7]Hospital Universitario Puerta de Hierro, Majadahonda, Spain, [8]Utrecht University, Utrecht, Netherlands.

The redirection of T cell activity using bispecific antibodies is one of the most promising cancer i mmunotherapy approaches currently in development, but it is limited by cytokine storm-related toxicities, as well as the pharmacokinetics and tumor-penetrating capabilities of current bispecific antibody formats. Here, we have engineered the ATTACK (Asymmetric Tandem Trimerbody for T cell activation and Cancer Killing), a novel T cell-recruiting bispecific antibody which combines three EGFRbinding single-domain antibodies (VHH; clone EgA1) with a single CD3-binding single-chain variable fragment (scFv; clone OKT3) in an intermediate molecular weight package. The two specificities are oriented in opposite directions in order to simultaneously engage cancer cells and T cell effectors, and
thereby promote immunological synapse formation. EgA1 ATTACK was expressed as a homogenous, nonaggregating, soluble protein by mammalian cells and demonstrated an enhanced binding to EGFR, but
not CD3, when compared to the previously characterized tandem bispecific antibody which has one EgA1VHH and one OKT3 scFv per molecule. EgA1 ATTACK induced synapse formation and early signaling
pathways downstream of TCR engagement at lower concentrations than the tandem VHH-scFv bispecific antibody. Furthermore, it demonstrated extremely potent, dose-dependent cytotoxicity when retargeting human T cells towards EGFR-expressing cells, with an efficacy over 15-fold higher than that of the tandem VHH-scFv bispecific antibody. These results suggest that the ATTACK is an ideal format for the development of the next-generation of T cell-redirecting bispecific antibodies.

WS.B4.02.01
Improving anti-CD137 immunotherapy against multiple myeloma through PD1 blockade

***A. C. Pichler**;*
Centre de Recherches en Cancérologie de Toulouse, Toulouse, France.

Multiple Myeloma (MM) is the second most common hematological malignancy in the world. MM is characterized by the development of malignant plasma cells within the bone marrow (BM). Despite new therapies, there is no cure and therefore a critical need to find new treatments. Agonist monoclonal antibodies (mAb) targeting the activation-induced costimulatory molecule CD137 (4-1BB) expressed by CD8+ T lymphocytes were recently shown to represent a promising agent against myeloma[1]. In this study, we dissected the immunological mechanisms implicated in anti-CD137 therapy in order to potentiate the anti-MM activity of this agent. Using the most relevant mouse model for MM, the Vk*MYC model, we found that anti-CD137 therapy induced CD8+ T cell activation, effector T cell expansion and anti-MM activity. However, we found that anti-CD137 mAbs was progressively accompanied with T cell dysfunctions and MM relapse. We found that anti-CD137 mAbs strongly increased the expression of immune checkpoints such as PD-1, Lag3 and Tigit that may directly account for T cell defects and myeloma outgrowth. The loss of proliferative capacity and cytokine secretion by PD1+ CD8+ T cells isolated from anti-CD137 treated mice confirmed this hypothesis. In addition, we showed that in vivo PD-1 blockade increased effector CD8+ T cells expansion induced by anti-CD137 mAb. Furthermore anti-PD1 mAb increased significantly the survival of MM bearing mice treated with anti-CD137 mAb. Altogether our data reveal that anti-CD137 promote an exhaustion program associated with PD-1 and that PD1 blockade could potentiate anti-CD137 treatment and represent a new therapeutic strategy against MM.

WS.B4.02.02
PD-1 Signals are Critical for Maintenance of Functional CD8 T Cell Memory

***S. Sarkar**[1], Y. Yuzefpolskiy[2], F. Baumann[3], K. Ernst-Bernhard[1], M. Prlic[4], P. Nghiem[2], S. Riddell[4], M. Sedensky[1], P. Morgan[1], M. C. Jensen[1], V. Kalia[1];*
[1]Seattle Children's Research Institute, Seattle, United States, [2]University of Washington School of Medicine, Seattle, United States, [3]Pennsylavania State University, University Park, United States, [4]Fred Hutchinson Cancer Research Center, Seattle, United States.

Inhibitory signaling in dysfunctional/exhausted cytotoxic T lymphocytes through the PD-1 axis is well established in diseases with chronic antigen. While PD-1 is expressed at the highest levels during priming of both acute and chronic infections, its role in long-lived antigen-independent T cell memory remains undefined. Paradoxical to its role as an inhibitory receptor, here we show that during priming and activation, PD-1 expression has minimal impact on the proliferation, size, polyfunctionality and effector program of T cells. Instead, our studies reveal an unexpected requirement of PD-1 in the maintenance of functional T cell memory, when it is expressed at significantly lower levels than recently activated or exhausted CD8 T cells. Loss of T cell-intrinsic PD-1 signals led to a striking defect in homeostatic renewal, thus resulting in a precipitous decline and near ablation of the memory pool.
Notably, in the setting of PD-1 checkpoint blockade immunotherapy for chronic viral infection, where the exhausted CTLs regained function as expected, there was significant attrition of pre-existing functional memory cells to a previously administered vaccine. Metabolically, PD-1 signals were necessary to drive the critical switch from anabolic glycolysis to fatty acid oxidation program needed for bioenergetics of quiescent memory sustenance. These studies define PD-1 as a key metabolic regulator of protective T cell immunity, and have clinical implications for pre-existing T cell memory to prior infections and vaccinations during PD-1 checkpoint-blockade immunotherapy in cancer.

WS.B4.02.03
Combination therapy with anti-PD-L1 antibody and depletion of regulatory T cells during acute viral infections results in improved virus control but lethal immunopathology

*M. Drabczik-Pluta[1], P. David[1], E. Pastille[2], T. Knuschke[2], T. Werner[1], N. Honke[3], A. M. Westendorf[2], K. S. Lang[3], U. Dittmer[1], **G. Zelinskyy**[1];*
[1]Institute for Virology, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, [2]Institute for Microbiology, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, [3]Institute of Immunology, University Hospital Essen, University of Duisburg-Essen, Essen, Germany.

Inhibitory checkpoints like PD-1/PD-L1 and regulatory T cells (Tregs) are important suppressive mechanisms preventing immunopathology by damping immune responses against acute viral infections. Recently, combination therapy blocking these inhibitory mechanisms was induced into the clinic for the treatment of tumor diseases. It was previously reported that an experimental combination therapy targeting PD-L1 and Tregs was also effective in chronic viral infections. However, whether such a therapy is efficient during an acute infection remains to be investigated. In the current study, depletion of Tregs combined with PD-L1 and Tim-3 blocking antibodies was used during acute Friend Retrovirus infection of mice, which normally develop only transient splenomegaly after infection. The combinatorial treatment resulted in a dramatic expansion of cytotoxic CD4+ and CD8+ T cells and a subsequent reduction of viral loads in infected organs. However, limited viral replication was accompanied by a rapid development of lethal gastrointestinal immunopathology. Similar results were obtained after combination therapy in influenza virus infected mice. Treated mice efficiently controlled influenza virus, nonetheless they died of immunopathology in the lung likely mediated by cytotoxic CD8+ and CD4+ T cells. Our findings demonstrate that multiple mechanisms control the T cell response against acute viral infections, even in those infections that normally cause only mild clinical symptoms. Immunopathology is the main complication in cancer patients treated with immune checkpoint blockers. Acute infections can strongly enhance the immunopathology associated with combination immunotherapy and therefore effective measures for infection prevention should be applied in cancer patient undergoing such treatments.

WS.B4.02.04
Plasticity of Tc17 cells is regulated by CTLA-4 via STAT1/3

***A. Arra**[1], H. Lingel[1], B. Kuropka[2], T. Fischer[3], C. Freund[2], M. Pierau[1], M. Brunner-Weinzierl[1];*
[1]Department of Pediatrics, Otto-von-Guericke-University, Magdeburg, Germany, [2]Leibniz-Institut für Molekulare Pharmakologie & Freie Universität, Berlin, Germany, [3]Department of Hematology and Oncology, Otto-von-Guericke-University, Magdeburg, Germany.

Blockade of CTLA-4 on $CD8^+$ T-cells is demonstrated to be of particular importance in enhancing effector functions of Tc1 cells by secretion of granzymeB and cytokines IFNγ and TNFα. Nevertheless, the role of CTLA-4 in regulating Tc17 cells, which are generally less cytotoxic in nature but are shown to exhibit strong anti-tumor activity due to their highly plastic nature to acquire Tc1 characteristics with increased persistence, is not completely understood.
B16-melanoma model was used to investigate the effects of CTLA-4 on Tc17 cell mediated control of tumor growth. CTLA-4-mediated phosphorylation of targets in Tc17 cells was analyzed using PepScan screen. ChIP-qPCR was performed to determine STATs competence in binding to IL-17 promoter.
Tc17 cells lacking CTLA-4 signaling displayed limited activation of STAT3, leading to compromised production of its target gene products such as IL-17, IL-23R and RORγt. Upon re-stimulation with IL-12, these cells displayed faster downregulation of Tc17 hallmarks and acquire Tc1 characteristics, which are known to correlate with tumor control.
Mechanistically, in primary and re-stimulated Tc17 cells, STAT3 binding to IL-17 promoter was strongly augmented by CTLA-4, associated with less binding of STAT5 and reduced relative activation of STAT1, which is known to block STAT3 activity. Consistent with these findings, inhibition of CTLA-4-induced STAT3 activity reversed enhancement of signature Tc17 gene products, rendering Tc17 cells susceptible to conversion to Tc1-like cells with enhanced cytotoxic potential.
CTLA-4 critically shapes the characteristics of Tc17 cells by regulating relative amounts of pSTAT1/3, which provides new perspectives to enhance cytotoxicity of antitumor responses.

WS.B4.02.05
De novo DNA methylation programming restrains T cell rejuvenation during immune checkpoint blockade therapy

*H. Ghoneim, A. Moustaki, H. Abdelsamed, Y. Fan, P. Thomas, E. Stewart, S. Federico, **B. A. Youngblood**;*
St Jude Children's Research Hospital, Memphis, United States.

Immune-checkpoint blockade (ICB)-mediated rejuvenation of CD8 T cell effector functions has emerged as one of the most promising frontiers for treating cancer and chronic infections. However, antigen-specific T cells that have experienced prolonged antigen exposure are often terminally differentiated, and have a limited capacity to mount an effector response during ICB treatment. Such exhaustion of effector potential is a major impediment of current T cell based immunotherapy efforts. Using in vivo mouse models of tumor and chronic viral infection, we assessed the role of *de novo* epigenetic programming in establishing ICB-refractory exhausted T cells. We observed that genetic deletion of the de novo DNA methyltransferase, Dnmt3a, in T cells at the effector stage of an immune response to chronic lymphocytic choriomeningitis virus (LCMV) infection allowed antigen-specific T cells to remain highly functional despite expressing high levels of PD-1 and having prolonged exposure to antigen. Quite strikingly, PD-1 blockade treatment of chronically infected animals resulted in massive expansion of PD-1+ Dnmt3a-deficient antigen-specific T cells. Whole-genome methylation profiling of WT and Dnmt3a-deficient LCMV-specific CD8 T cells identified *de novo* DNA methylation programs that are coupled to development of ICB-nonresponsive virus and tumor-specific T cells. Building upon these findings, we have identified de novo epigenetic programs acquired in human tumor-associated PD-1hi CD8 T cells. Collectively, these data establish Dnmt3a-mediated de novo DNA methylation programming as a key regulator in establishing ICB-refractory exhausted CD8 T cells and highlights epigenetic reprogramming of T cells as a novel approach to enhance T cell-based cancer therapies.

WS.B4.02.06

Mitochondrial morphological and functional reprogramming following CD137 (4-1BB) co-stimulation

I. Etxeberria[1], *S. Labiano*[1], *S. Garasa*[1], *E. Santamaría*[1,2], *A. Rouzaut*[1], *M. Enamorado*[3], *A. Azpilikueta*[1,4], *S. Inoges*[1], *E. Bolaños*[1,4], *M. Aznar*[1], *A. Sánchez-Paulete*[1,4], *D. Sancho*[3], *I. Melero*[1,4], *A. Teijeira*[1,4];

Centro Virtual de la Investigación Biomédica en red de Oncología., Madrid, Spain.*

CD137 (4-1BB) is a costimulatory receptor of the TNFR family expressed by T and NK lymphocytes whose function is exploitable for cancer immunotherapy. Mitochondria regulate function and survival of T lymphocytes. Herein, we show that CD137 co-stimulation provided by agonist mAb and CD137L (4-1BBL) induces mitochondria enlargement that results in enhanced mitochondrial mass and transmembrane potential in human and mouse CD8+ T cells. Such mitochondrial changes increase T-cell respiratory capacities and are critically dependent on mitochondrial fusion protein OPA-1 expression. Mass and function of mitochondria in tumor-reactive CD8 T cells from cancer-bearing mice is invigorated by agonist anti-CD137 mAb. In fact, mitochondrial mass and function are baseline depressed in CD137-deficient tumor reactive T-cells. Furthermore, tumor rejection induced by the synergistic combination of adoptive T-cell therapy and anti-CD137 antibodies is critically dependent on OPA-1 expression in transferred CD8 T cells. Moreover, stimulation of CD137 with anti-CD137 mAb in short-term cultures of human tumor-infiltrating lymphocytes leads to mitochondria enlargement and increased transmembrane potential. Collectively these data point at a critical link between mitochondrial morphology, function and enhanced anti-tumor T-cell effector activity upon CD137 co-stimulation.

Human skin-resident and functionally competent memory T cells survive myeloablation preceding allogeneic hematopoietic stem cell transplantation

J. Strobl[1], *N. Bayer*[1], *M. Mayrdorfer*[1], *B. Reininger*[1], *L. Hammerl*[1], *S. Saluzzo*[1], *P. Kalhs*[2], *W. Rabitsch*[2], *G. Hopfinger*[2], *G. Stary*[1];
[1]*Department of Dermatology, Medical University of Vienna, Vienna, Austria,* [2]*Department of Internal Medicine I, Bone Marrow Transplantation Unit, Medical University of Vienna, Vienna, Austria.*

Myeloablative conditioning and subsequent allogeneic hematopoietic stem cell transplantation (HSCT) present unique conditions in the human system to study longevity, residency and repopulation capacities of tissue T cells. Therefore, we profiled immune cell dynamics in 45 patients receiving HSCT as treatment for hematological malignancies.
Skin biopsies and peripheral blood were taken at 5 pre-defined time points (before start of treatment, day of transplantation, 2/14/52 weeks after HSCT) and analyzed using flow cytometry, tissue immunofluorescence and low-input RNA-sequencing of purified cell subsets. Additionally, skin sections of patients receiving sex-mismatched donor cells were assessed for X/Y-chimerism by fluorescence-in-situ-hybridization up to 8 years post transplantation.
Upon myeloablative treatment, recirculating immune cells were eliminated in skin and peripheral blood and resurfaced 2-14 weeks after transplantation of donor cells. Strikingly, epidermal and dermal αβ T cells expressing residency markers remained stable throughout all time points analyzed. This skin-resident subset was largely $CD4^+$, displayed proliferative potential after TCR stimulation and was competent of cytokine production. Furthermore, skin-resident T cells of the recipient constituted 35% of T cells at time of full immunological recovery (14 weeks post-transplant) and coexisted with donor T cells up to 8 years after engraftment.
Our results combine data of a unique clinical setting with in-depth cell profiling using RNA-sequencing and imaging techniques, painting a detailed picture of skin-resident cells as a model for T cell turnover in peripheral organs. Thus, we were able to identify a remarkably resistant and long-lived T cell population with implications for numerous inflammatory conditions including graft-versus-host-reaction.

WS.C1.01.02

Phenotypic, molecular and functional characterisation of pro-inflammatory IL-17+ CD8+ T (Tc17) cells in psoriatic arthritis

K. J. Steel[1], *U. Srenathan*[1], *L. E. Durham*[1], *S. Wu*[1], *M. L. Ridley*[1], *E. Chan*[2], *B. W. Kirkham*[2], *L. S. Taams*[1];
[1]*Centre for Inflammation Biology and Cancer Immunology (CIBCI), Dept Inflammation Biology, School of Immunology & Microbial Sciences, London, United Kingdom,* [2]*Department of Rheumatology, Guy's & St Thomas' Hospital, London, United Kingdom.*

Introduction: Psoriatic arthritis (PsA) is an inflammatory joint/skin disease. Genetic associations implying a role for CD8+ T-cells (*HLA-B, RUNX3)* and the IL-23/IL-17 axis (*IL12B, IL23R, TRAF3IP2)* together with the clinical efficacy of IL-17A blockade provide a strong rationale to investigate IL-17A+CD8+ (Tc17) T-cells in patients with PsA.
Methods: Mononuclear cells were isolated from peripheral blood (PB) and synovial fluid (SF) from patients with PsA. Cells were stimulated *ex vivo* before phenotypic, transcriptional and functional analysis.
Results: Tc17 frequencies were increased in the SF vs. paired PB. Phenotypically, SF Tc17 cells (predominantly TCRαβ+) expressed skin and gut tissue-homing (CLA/CD49a/β7 integrin) and Type-17 cell associated markers (CCR6/CD161). TCRβ-sequencing of SF Tc17 cells suggested a polyclonal TCR repertoire, whilst RNA-sequencing revealed a distinct synovial Tc17 transcriptomic signature compared to PB Tc17, SF Th17 or Tc1 cells. Interestingly, Tc17 cells expressed hallmarks of tissue-resident memory T-cells (T_{RM}; CD45RA-CCR7-CD103+) whilst sorted CD8+CD69+CD103+ T_{RM} SF cells were enriched for IL-17A. Functionally, SF Tc17 cells co-expressed cytolytic molecules granzyme A and B, pro-inflammatory cytokines IFN-γ, GM-CSF, TNF-α, some IL-21 and IL-22, but little anti-inflammatory IL-10.
Conclusion: We describe a novel phenotypic and molecular signature for PsA synovial Tc17 cells. We also demonstrate, to our best knowledge for the first time, the presence of IL-17A-producing T_{RM} cells in the PsA joint. Functionally, Tc17 cells exhibit cytolytic potential and express pro-inflammatory cytokines, suggesting these cells are important contributors to the pathogenesis of PsA.

WS.C1.01.03

Lymphoid neogenesis in kidneys during lupus: involvement of CXCR3-expressing T cells

R. VEBER[1], *C. LE COZ*[1], *S. LECOMTE*[1], *F. MONNEAUX*[1], *K. A. FENTON*[2], *H. DUMORTIER*[1];
[1]*Institut de Biologie Moléculaire et Cellulaire, Strasbourg, France,* [2]*Institute of Medical Biology, Tromso, Norway.*

Introduction: Tertiary Lymphoid Organs (TLOs) can be observed in pathological situations such as cancer, infections, graft rejection or autoimmune diseases but the mechanisms leading to their formation remain poorly understood. Our laboratory works on lupus, a chronic and systemic autoimmune disease leading to multiple organ failures among which severe kidney injuries. We have evidenced the presence of functional TLOs in the kidneys of the NZB/W spontaneous lupus mouse model (unpublished). The aim of the present study was to determine the early molecular and cellular mechanisms underlying renal TLO development in lupus.
Materials and methods: Young to old diseased NZB/W and age-matched healthy control BALB/c mice were compared and the leukocyte infiltrates present in their kidneys were characterized by flow cytometry, confocal microscopy and qPCR analyses.
Results: We demonstrate that TLO development takes place very early during the disease. Small kidney leukocyte infiltrates can be visualized in the absence of glomerular deposits and before the apparition of detectable circulating autoantibody levels. Among the first infiltrating cells, we found a majority of activated-memory T cells expressing the inflammatory chemokine receptor CXCR3. These T cells are likely attracted by the three CXCR3 ligands as we describe that CXCL9, 10 and 11 are produced in the glomeruli of very young NZB/W.
Conclusions: Altogether, our data suggest that TLO neogenesis takes place at a very early stage of disease development and that blocking T cell infiltration in the kidneys could impair TLO development and help preventing kidney dysfunction in lupus.

WS.C1.01.04

Intracapillary immune complexes recruit and activate slan-expressing $CD16^+$ monocytes in human lupus nephritis

F. Olaru[1], *T. Döbel*[1], *A. Lonsdorf*[1], *A. Enk*[1], *H. Gröne*[2], ***K. Schäkel***[1];
[1]*Department of Dermatology, Heidelberg, Germany,* [2]*DKFZ, Heidelberg, Germany.*

Lupus nephritis is a major cause of morbidity in patients with systemic lupus erythematosus. Among the different types of lupus nephritis intracapillary immune complex (IC) deposition and accumulation of monocytes are hallmarks of lupus nephritis class III and IV. The relevance of intracapillary ICs in terms of monocyte recruitment and activation, as well as the nature and function of these monocytes are not well understood. Monocytes are now classified based on their gradual differences in CD14 versus CD16 expression: classical $CD14^{++}CD16^-$, intermediate $CD14^+CD16^+$- and non-classical $CD14^-CD16^{++}$-monocytes. Within the population of $CD16^+$ LIN^- $HLA\text{-}DR^+$ leukocytes (non-classical $CD14^-CD16^{++}$-monocytes) our group defined the population of 6-sulfo LacNAc (slanMo) expressing cells. For the early focal form of lupus nephritis (class III) we demonstrate a selective accumulation of the proinflammatory population of 6-sulfo $LacNAc^+$ (slan) monocytes (slanMo), which locally expressed TNF-α. In flow chamber experiments, as well as in an in vivo model of IC-induced glomerulonephritis immobilized ICs induced a direct recruitment of slanMo from the microcirculation via interaction with Fc gamma receptor IIIA (CD16). Interestingly, intravenous immunoglobulins blocked CD16 and prevented cell recruitment. Engagement of immobilized IC by slanMo induced the production of neutrophil attracting chemokine CXCL2 as well as TNF-α which, in a forward feedback loop stimulated endothelial cells to produce the slanMo recruiting chemokine CX3CL1 (fractalkine). In conclusion, we observed that expression of CD16 equips slanMo with a unique capacity to orchestrate early IC-induced inflammatory responses in glomeruli and identified slanMo as a pathogenic proinflammatory cell type in lupus Nephritis.

WS.C1.01.05

Tbet provides advantage to Tregs for homing into type 1 inflammation sites in vivo

***B. AKKAYA**, M. Akkaya, A. H. Holstein, J. Al Souz, M. P. Maz, E. M. Shevach;*
NIH, Bethesda, United States.

T regulatory cells (Tregs) comprise subgroups that respond to microenvironmental cues. One of such is the Tbet$^+$ Tregs, which have adapted the master transcriptional factor of T helper 1 (Th1) cells. Although Tbet is considered as a prerequisite for restraining Th1 responses, there are still gaps in our understanding for how. To address this, we imaged Tbet$^+$ Tregs over the course of a Th1 response in live lymph node sections of a Tbet.ZsGreen-Foxp3.RFP reporter mouse during Type 1 inflammation. We showed that unlike Tbet$^-$ Tregs, majority of which resided within the T cell zone, Tbet$^+$ Tregs localized specifically to the Interfollicular zone. We then generated Tbet$^+$ iTregs from naïve OTII- Tbet.ZsGreen-Foxp3.RFP mice, adoptively transferred into C57BL/6 recipients that had been immunized in the footpad with OVA-CFA. We found higher number of OTII-ZsGreen$^+$RFP$^+$ iTregs than neutral OTII iTregs at popliteal lymph node following OVA-CFA injection, suggesting a homing advantage provided by Tbet. Furthermore, we generated bone marrow chimeras of WT-Tbet$^{-/-}$ mice and found that Treg compartment was reconstituted equally. However, we detected fewer Tbet$^{-/-}$ Tregs in the spleens of P. Chabaudi infected chimeric mice without any defect in CD44 expression and proliferation level indicating that the defect is not due to activation status but homing. Additionally, Tbet$^+$, Tbet$^-$ and Tbet$^{-/-}$ iTregs suppressed ex vivo differentiated Th1 proliferation equally, indicating that Tbet is not required for active suppression. Taken together, we propose that Tbet provides homing advantage to Tregs in vivo without potentiating their suppressive ability once the inflammation site is reached.

WS.C1.01.06

Nox2 deficiency in CD4$^+$CD25$^+$FoxP3$^+$ T cells limits angiotensin II-induced hypertension and cardiovascular remodelling

***S. Cellone Trevelin**, A. Emerson, H. Mongue-Din, P. D. Becker, C. Ortiz, L. A. Smyth, G. Sawyer, A. Ivetic, Q. Peng, R. Elgueta, R. I. Lechler, A. M. Shah, G. Lombardi;*
King's College London, London, United Kingdom.

Introduction: Nox2 is the catalytic subunit of a multi-protein complex that generates superoxide and is known to contribute to hypertension and cardiovascular remodelling induced by angiotensin II (ANGII). Recent studies showed that Nox2 has cell-specific roles in cardiomyocytes and endothelial cells but its role in T-cell subsets is poorly understood.
Methods: We generated a novel mouse line with CD4-targeted Nox2 deficiency (Nox2$^{fl/fl}$CD4Cre$^+$) and studied the response to infusion of ANGII (1.1mg/kg/day, 14 days).
Results: As compared to littermate controls (Nox2$^{fl/fl}$), Nox2$^{fl/fl}$CD4Cre$^+$ mice showed an increased proportion of CD4$^+$CD25$^+$FoxP3$^+$ Tregs in the heart and aorta at baseline and after ANGII infusion (multicolour flow cytometry). This was accompanied by a reduction in infiltrating CD4$^+$ROrγT$^+$ and CD8$^+$FoxP3$^-$ Teffs, and inhibition of AngII-induced hypertension, heart fibrosis and cardiomyocyte hypertrophy. The protection in Nox2$^{fl/fl}$CD4Cre$^+$ mice was reversed by depleting Tregs with an anti-CD25/PC61 antibody. *In vitro* studies revealed that Nox2-deficient CD4$^+$CD25$^+$Tregs suppress proliferation of CD4$^+$CD25$^-$Teffs more than WT-Tregs, and inhibits the IL-17 production stimulated by co-culture of Teffs with antigen presenting cells in the presence of anti-CD3. Nox2-deficient Tregs also had higher nuclear levels of FoxP3 and p65/NF-κB, and increased mRNA levels of CTLA-4, CD39, CD73, GITR and CD25, than WT-Tregs. In adoptive transfer experiments, Nox2-deficient Tregs were more potent at inhibiting ANGII-induced hypertension and heart fibrosis than WT-Tregs.
Conclusion: Nox2 deficiency in Tregs limits cardiovascular remodelling induced by ANGII by suppressing infilitration of Teffs. These results suggest that targeting Nox2 in Tregs might be a useful approach in cardiovascular disorders.

WS.C1.02.01

Intestinal Secretory Leukocyte Protease Inhibitor expression is increased in pediatric inflammatory bowel disease patients and is unfavorable during murine colitis

***S. Nugteren**, C. L. Menckeberg, Y. Simons-Oosterhuis, D. J. Lindenbergh-Kortleve, L. A. van Berkel, H. C. Raatgeep, L. M. Costes, L. de Ridder, J. C. Escher, J. N. Samsom;*
Erasmus Medical Center, Rotterdam, Netherlands.

Secretory Leukocyte Protease Inhibitor (SLPI) is an NF-κB inhibitor produced by epithelial cells in response to microbial signals. Previously, we have shown that knockdown of SLPI in intestinal epithelial cells elicits NF-κB activation and subsequent chemokine production, indicating that SLPI inhibits epithelial activation. Crucially, upon increased bacterial pressure at the epithelial border, as seen in mice deficient for one of the major colonic mucins, we detected increased intestinal SLPI expression. As inflammatory bowel disease (IBD) is driven by aberrant host microbial interactions, we hypothesized that intestinal SLPI expression is increased in IBD patients. Furthermore, we questioned whether intestinal SLPI is beneficial or deleterious during intestinal inflammation.
In therapy-naïve IBD patients, we observed increased SLPI mRNA and protein expression in macroscopically inflamed intestinal tissue, compared to macroscopically non-inflamed and non-IBD tissue. To investigate the role of SLPI during intestinal inflammation, murine colitis was induced using dextran sodium sulphate (DSS) in wild type (WT) and SLPI knockout (KO) mice. In WT mice we observed increased fecal SLPI excretion and increased intestinal *Slpi* transcripts during the peak of inflammation. Crucially, SLPI KO mice were less affected by DSS colitis compared to WT littermates, as evidenced by reduced weight loss and lower colonic expression of the pro-inflammatory cytokines TNFα and IL-1β. Altogether, our findings suggest that increased intestinal SLPI expression during intestinal inflammation is disadvantageous to the host. In IBD patients, high intestinal SLPI expression and consecutive reduced NF-κB-mediated epithelial activation may inhibit anti-microbial host defense leading to more severe disease.

WS.C1.02.02

ATF3 is crucial for intestinal mucosal immunity during homeostasis and stress

***D. Glal**;*
Institute of Biomedical sciences, Taipei, Taiwan.

Activating Transcription Factor 3 (ATF3) is induced by a wide-range of cellular stresses, and found to be involved in many critical human diseases including cancer, atherosclerosis, infections, cardiac hypertrophy, and hypospadias. Interestingly, a recent microarray study has also identified ATF3 up regulation in patients with active inflammatory bowel disease (IBD). Using mouse model and cell system, we have found that ATF3 is central to intestinal homeostasis at steady state and protection during inflammation. This was shown, in naïve ATF3-deficient mice, by decreased crypts numbers and colon length indicating defective cellular stemness and regeneration to maintain a healthy tissue mass. Using DSS-induced colitis, ATF3-deficient mice showed lethal disease activity characterized by a dramatic loss of epithelial architecture and crypt structure, poorness of proliferation/repair machine, and strenuous apoptosis, which has been effectively ameliorated by rectal transplantation of wild-type organoids indicating that the intestinal protective role of ATF3 is mainly occur through maintaining epithelial cell integrity. Paneth cells and stem cells form a niche to orchestrate the differentiation, proliferation, and repair in the intestine. Using electron microscopy, we have identified loss/degeneration of Paneth cell granules, which are the main source of antimicrobial peptides (AMPs), indicating malfunctioning of intestinal Paneth/Stem cell network. Impaired cell proliferation rate and wound healing, and loss of AMPs production have been found also to be consistent in ATF3-/- epithelial cell line. Collectively, our findings provide a new insight for ATF3 in terms of intestinal mucosal immunity; a favorable role that brings ATF3 to be a potential competent for further IBD-related researches.

WS.C1.02.03

The transcription factor MAF regulates homeostasis in colonic T cells

*C. Imbratta[1], M. Leblond[1], D. Velin[2], D. E. Speiser[1], **G. VERDEIL**[1];*
[1]University of Lausanne, Epalinges, Switzerland, [2]Lausanne University Hospital, Lausanne, Switzerland.

Maf encodes for a transcription factor belonging to the AP-1 family. In CD4 T helper cells (Th), it has a role in *il-4* transcriptional regulation in Th2, in Th17 cells through the regulation of *il-10* and *il-23r* expression and in Tfh cells together with the transcription factor *bcl6*. We recently demonstrated that *maf* is induced in CD4 and CD8 T cells in melanoma, leading to a "dysfunctional" state of the cells. The role of *maf* in regulatory T cells (Treg) is less clear. A subset of Treg cells expressing both Foxp3 and RORγt has been described. Present in the gut, ROR-γt+ Treg cells have an enhanced suppressive activity compared to ROR-γt- Treg cells, especially in an *in vivo* context of gut inflammation. Transcriptomic analysis of this population showed an enriched expression of *maf* in this specific Treg subset. To precise the function of *maf* in T cells *in vivo*, we studied a T-cell specific KO of *maf*. These mice developed late onset colitis correlating with the loss of ROR-γt+ Treg cells. While IL-10 expression was reduced, TNF-α and IL-17A production was increased in the colon. We found both *in vitro* and *in vivo* that Maf KO Treg cells produced less IL-10 and had impaired suppressive capacity compared to those derived from WT animals. Our data shows that MAF expression in T cells, especially ROR-γt+ Treg cells, is essential for their differentiation and to maintain their suppressive activity and thereby prevent inflammatory bowel disease by inhibiting Th1 and Th17 polarization.

WS.C1.02.04

Proinflammatory, high avidity CD4⁺ T cells with a memory-like phenotype in the human fetal intestine

N. Li[1], *V. van Unen*[1], *T. Abdelaal*[1,2], *K. Ladell*[3], *J. E. McLaren*[3], *D. A. Price*[3], *S. M. Chuva de Sousa Lopes*[1], *B. P. Lelieveldt*[1,2], *F. Koning*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Delft University of Technology, Delft, Netherlands,* [3]*Cardiff University School of Medicine, Cardiff, United Kingdom.*

The human fetus is thought to be protected from contact with environmental antigens prior to birth, yet evidence has emerged that CD45RO⁺ T cells are present in the human fetal intestine. We applied a combination of mass cytometric analysis, single-cell sequencing, and functional studies to gain comprehensive insight into the heterogeneity and functionality of the CD4⁺ T cell compartment in the human fetal intestine. Using mass cytometry, we distinguished 22 distinct CD4⁺ T cell clusters, including naïve-like, regulatory, memory-like, and CD45RO⁺CD117⁺ subsets. Single-cell RNA sequencing confirmed the presence of these distinct CD4⁺ T cell subsets and further characterized their expression profiles. Strikingly, the majority of CD4⁺ T cells were CD45RO⁺ memory-like cells, expressing high levels of CD69, CD226, CXCR3, CCR4, Ki67 and CD5. The latter two markers are indicative of cell proliferation and high T cell receptor avidity, respectively. Pathway analysis revealed a strong enrichment for transcripts associated with T cell activation and regulation of the inflammatory response to antigens. In addition, these memory-like T cells showed signs of clonal expansion and were readily stimulated to produce high levels of TNF-α and some IFN-γ. Our data therefore provide evidence for the existence of a large pool of memory-like, high avidity CD4⁺ T cells with a proinflammatory phenotype in the human fetal intestine, indicative of antigenic stimulation *in utero*.

WS.C1.02.05

The transcription factor NFATc3 promotes intestinal inflammation by suppression of regulatory T cells

K. Gerlach*, V. Popp, M. Neurath, B. Weigmann;*
Medizinische Klinik 1, Erlangen, Germany.

The transcription factor NFATc3 (Nuclear factor of activated T cells) belongs to a transcription factor family of five members. NFATc3 plays an important role in the activation and function of T cells regulating cytokine expression and cell proliferation. High numbers of NFATc3⁺ cells in the lamina propria of patients suffering from inflammatory bowel disease (IBD) point out the regulatory role of this transcription factor in mucosal inflammation and led us to investigate its function in colitis. Deficiency of NFATc3 in the oxazolone-induced colitis model suppressed induction of intestinal inflammation. Staining for Caspase3 showed less proapoptotic cells in the colon of NFATc3 KO mice whereas apoptotic cells were significantly increased. Additionally, we found a higher number of FoxP3⁺ T cells in the colon of NFATc3 KO mice suggesting that NFATc3 controls regulatory T cells. As Tregs have been shown to prevent and cure intestinal inflammation caused by the adoptive transfer of naïve T cells in immunodeficient RAG1 knockout mice, we next analysed the relation between Tregs and NFATc3 in this colitis model. Mice receiving NFATc3-deficient naïve T cells had a later onset of inflammation than mice reconstituted with wildtype T cells. Moreover, the adoptive transfer of NFATc3-deficient T cells was associated with an increased number of CD3⁺ FoxP3-expressing Tregs. In summary, the transcription factor NFATc3 crucially promotes intestinal inflammation by affecting FoxP3 expression and therefore serves as a potential target for therapy in IBD.

WS.C1.02.06

The molecular composition of IgA anti-carbamylated and anti-citrullinated protein antibodies in Rheumatoid Arthritis, point to a mucosal origin

M. A. M. van Delft[1], *M. K. Verheul*[1], *N. Levarht*[1], *L. Hafkenscheid*[1], *T. Kissel*[1], *A. Bondt*[2], *T. W. Huizinga*[2], *R. E. Toes*[2], *L. A. Trouw*[2];
[1]*Miss, Leiden, Netherlands,* [2]*Mr, Leiden, Netherlands.*

The presence of autoantibodies targeting post-translationally modified proteins, such as citrullinated (ACPA) and carbamylated (anti-CarP antibodies) proteins, are a hallmark of RA. As these autoantibody responses target homologous structures (citrulline and homo-citrulline) that differ only in one CH_2-group, the IgG ACPA- and anti-CarP- responses are partially cross-reactive in some- but not in other patients. Both responses use a broad spectrum of isotypes, including IgM, IgG and IgA. To better understand the nature of these prominent autoantibodies, we investigated the molecular composition of both ACPA and anti-CarP antibodies. Moreover, the degree of cross-reactivity of these autoantibodies was investigated. Sera of anti-CarP and/or ACPA positive RA-patients were fractionated using size exclusion chromatography and tested by ELISA for anti-CarP, ACPA and total IgA and IgG.
Inhibition studies were performed to investigate the cross-reactivity between anti-CarP and ACPA. Our results show that anti-CarP antibody, rheumatoid factor and anti-*E.Coli* IgA are predominantly present as polymeric-IgA, whereas ACPA and anti-Tetanus Toxoid IgA are mostly present as monomeric-IgA. These data are intriguingly as they indicate that the anti-CarP and ACPA IgA responses are differently regulated and potentially of different origin. About 75% of the anti-CarP IgA response cannot be inhibited by citrullinated antigens and vica versa for ACPA IgA by carbamylated antigens, indicating that these autoantibodies are directed against different antigens. To conclude; our data indicate that the anti-CarP- and ACPA-autoantibody responses are differently regulated and may have a different origin, with possibly a mucosal associated origin for anti-CarP antibodies.

WS.C1.03 Cytokine and transcription factor mediated immune regulation

WS.C1.03.01

Anti-TNF treatment leads to delayed activation, maturation and proliferation of CD4+ T cells but does not confer a global suppressive phenotype

G. A. M. Povoleri[1], *S. Lalnunhlimi*[1], *K. Steel*[1], *S. Agrawal*[1], *M. Ridley*[1], *S. Kordasti*[2], *C. Roberts*[1], *L. S. Taams*[1];
[1]*Centre for Inflammation Biology and Cancer Immunology (CIBCI), Dept of Inflammation Biology, School of Immunology & Microbial Sciences, King's College London, London, United Kingdom,* [2]*Department of Haematological Medicine, King's College London, London, United Kingdom.*

We previously demonstrated that *in vitro* treatment of human CD4+ T-cells with the TNF-blocking drug adalimumab, promotes anti-inflammatory IL-10 expression. We investigated whether this effect is accompanied by changes in cellular activation, maturation, proliferation and suppressive function.
CD4+ T-cells from healthy volunteers were cultured for up to 7 days with anti-CD3/CD28 mAb stimulation, in the absence or presence of anti-TNF. Phenotypic changes were evaluated by flow cytometry and CyTOF. Gene expression changes were evaluated using existing datasets (GSE51540). For suppression assays, cells were re-isolated and added to responder T-cells, monocytes or fibroblasts.
Culturing CD4+ T-cells with anti-TNF led to decreased activation as shown by reduced frequencies of CD25+, CD69+ and HLA-DR+ cells. CD4+ T-cells also contained significantly higher CD45RA+ and lower CD45RO+ frequencies in the presence of anti-TNF. Proliferation was reduced as indicated by lower percentage of Ki67+ cells and proliferation assays. Additionally, gene expression analysis of anti-TNF-treated IL-17 or IFNγ-producing CD4+ T-cells revealed multiple pathways associated with cell proliferation and cell cycle. Kinetics experiments suggested that anti-TNF treatment leads to delayed, rather than impaired T-cell activation. Furthermore, while anti-TNF treated CD4+ T-cells did not exhibit a significant difference in suppression of T-cell proliferation and monokine production, compared to untreated cells, they displayed hyporesponsiveness, induced the IL-10 regulated molecule CD163 on monocytes and downregulated IL-8 production by synovial fibroblasts.
We demonstrate that anti-TNF treatment resulted in delayed activation, maturation and proliferation of CD4+ T-cells, but not in acquisition of a global suppressive phenotype.

WS.C1.03.02

Vγ6+ γδ17 T cells home to the male reproductive tract and expand at puberty to keep pathogens at bay

H. Brigas*[1], *A. Wilharm*[*2], *I. Sandrock*[2], *T. Amado*[1], *T. Carvalho*[1], *A. Reinhardt*[2], *B. Silva-Santos*[1], *I. Prinz*[**2], *J. Ribot*[**1];
[1]*Instituto de Medicina Molecular João Lobo Antunes, Lisboa, Portugal,* [2]*Institute of Immunology, Hannover, Germany.*

γδ T cells populate multiple tissues where they make major contributions to local physiology. They have also been characterized in the female, but not in the male, reproductive tract. Here, we found that γδ T cells infiltrate the stromal tissue of the testis of naive C57/BL6 mice, expand at puberty and persist throughout life. Strikingly, this population of testicular γδ T cells selectively displayed a Vγ6+ repertoire and was highly enriched in IL-17 producers (γδ17). In fact, γδ T cells were the major source of IL-17, whereas ab T cells mostly provided IFN-γ in situ. γδ17 T cell homeostasis in the testis seemingly depended on IL-1a/IL-23 signals downstream of TLR4 expressed by resident myeloid populations. Interestingly, recent studies have shown that androgens shape the gut microbiome at puberty. Our data suggest that cues from the microbiota may drive the expansion of γδ17 T cells in the testis, as Germ-Free mice display a significant reduction in this population. Furthermore, we could induce an early γδ17 T cell expansion in the testis, before puberty, through adult male fecal transfer. We next hypothesized that testicular γδ17 T cells might contribute to tissue surveillance. We performed intra-testicular inoculation of Listeria monocytogenes, a commonly used model of orchitis. Our data indicate that infected TCRδ-/- and IL-17-/- mice display higher bacterial load and die within 4 days after infection, whereas WT controls survive. Altogether, our results identify a previously unappreciated resident testicular γδ17 T cell subset that plays a crucial role against local bacterial infection.

WS.C1.03.03

IL-27 increases the plasticity of differentiated Th17 cells by inducing IL-12R beta2 expression

A. Awasthi[1], *V. K. Kuchroo*[2];
[1]*Translational Health Science & Technology Institute, Faridabad, India,* [2]*Brigham and Womens Hospital, Harvard Medical School, Boston, United States.*

The role of Th17 cells in inducing tissue inflammation in autoimmune diseases is well established. IL-23-IL-23R-induced pathogenic T_H17 cells are critical in inducing tissue inflammation in experimental autoimmune encephalomyelitis (EAE), a mouse model of human multiple sclerosis. Interleukin (IL-) 27, an IL-12 family cytokine, has been shown to suppress tissue inflammation in EAE partly by inhibiting differentiation of T_H17 cells. In addition to inhibition the differentiation and functions of Th17 cells, IL-27 also found induce the differentiation of IL-10 producing type regulatory T cells (Tr1), which are found to play an essential role in inhibiting effector T cells function in EAE. Although the anti-inflammatory role of IL-27 was established, the precise mechanism by which IL-27 suppresses the effector functions of differentiated T_H17 cells is not well understood. Using the global gene profile data, we now show that IL-27-induced expression of IL-12Rβ2 plays a critical role in regulating the generation and functions of T_H17 cells in EAE. Moreover, IL-27-induced IL-12Rβ2 make differentiated Th17 cells responsive IL-12-mediated conversion into IFN-gamma producing T cells. IL-27 receptor deficiency leads to the inhibition of IL-12Rβ2 while enhancing the expression of IL-23R on Th17 cells, and therefore increases the IL-23 responsiveness of Th17 cells. Moreover, IL-27 is unable to inhibit T_H17 cells and development of experimental autoimmune encephalomyelitis (EAE) in *Il12rb2*$^{-/-}$ mice. Indeed, IL-27-induced expression of IL-12Rβ2 increased responsiveness of T_H17 cells to IL-12. This provides a novel mechanism by which IL-27 inhibits T_H17 cells by increasing their plasticity and responsiveness to immunosuppression.

WS.C1.03.04

TGF-β bioactivity in *Trichuris muris* homogenate induces FOXP3$^+$ T regulatory cells and inhibits Th1 and Th2 polarisation when activated

A. E. Ogunkanbi[1], *B. Eldakhakhny*[2], *J. L. Pennock*[1];
[1]*Institute of Infection, Immunity and Respiratory Medicine, Manchester, United Kingdom,* [2]*Faculty of Medicine , Department of Clinical Biochemistry, King Abdulaziz University,, Saudi Arabia, Saudi Arabia.*

The establishment of a long lasting chronic infection with helminths relies on their ability to modulate host protective immune responses by direct induction of host immunomodulatory molecules such as IL-10, Tregs cells and TGF-β. Immune modulation by helminths has been centred on induction of host regulatory responses. However, research evidence has shown that helminths themselves can encode TGF-β receptor ligands to modulate the immune response and enhance their survival. We addressed whether *T. muris* can encode TGF-β-like ligands to enhance their survival in the host using bioinformatics*, in vitro* and *in vivo* approaches. *In vitro*, acid treated worm homogenate activates TGF-β responsive cell lines. Acid activated worm homogenate also induces foxp3 expression in mouse T cells in a dose-dependent manner and reduces IL-13 and IFN-γ production during T cell polarisation. The induction of foxp3 was abolished by anti TGF-β antibody (1D11) and both the production of IL-13 and IFN-γ was restored upon addition of 1D11. Finally*, T. muris* homogenate can induce endogenous production of TGF-β both *in vivo* and *in vitro* and this is associated with the reduction in IFN-γ production. These data have shown that unique TGF-β activity is present in *T. muris* and supports the current paradigm that worms have evolved mechanisms to potentiate their survival. These data also complement and extend our current understanding of helminth immunoregulation and broaden the scope for potential therapeutics for regulation of intestinal inflammation.

WS.C1.03.05

Hobit identifies precursors of resident memory T cells within the peripheral tissues

L. Parga Vidal[1], *F. Behr*[1,2], *N. Kragten*[1], *T. Wesselink*[1], *R. Stark*[1,2], *K. van Gisbergen*[1,2];
[1]*Department of Hematopoiesis, Sanquin Research and Landsteiner Laboratory, AMC, University of Amsterdam, Amsterdam, Netherlands,* [2]*Department of Experimental Immunology, AMC, Amsterdam, Netherlands.*

Tissue-resident memory T (Trm) cells constitute a non-circulating memory subset that provides early protection against re-infection. It is unclear when, where and how these Trm develop from effector CD8 T cells. We have previously described that Hobit represents a Trm-specific transcription factor that is essential for their formation. To employ Hobit for the study of Trm differentiation, we generated a Hobit reporter mouse, which contains a “knock-in” of the fluorescent protein tdTomato and the diphtheria toxin (DT) receptor within the *Hobit* locus. We infected Hobit reporter mice with LCMV and analyzed virus-specific CD8 T cells for tdTomato expression by flow cytometry. Trm present in gut, kidney, liver and salivary glands nearly uniformly expressed tdTomato in contrast to circulating memory cells. Interestingly, tdTomato was already upregulated in a subset of effector cells located within these peripheral tissues, but not in lymph nodes, blood or spleen. To examine the potential of the tdTomato$^+$ effector cells to establish memory populations, we depleted them using DT injections at different time-points after infection. We observed a substantial and specific decrease in Trm after depletion of tdTomato$^+$ effector cells between day 7 and 10 after infection. Depletion at earlier time points did not have an impact on Trm formation. These findings show that Hobit$^+$ effector CD8$^+$ T cells are Trm precursors. Furthermore, we conclude that commitment of effector cells to the Trm lineage occurs in the peripheral tissues at the peak of the effector CD8 T cell response.

WS.C1.03.06

EOMES-positive CD4$^+$T cells are increased in *PTPN22* (1858T) risk allele carriers

K. Chemin[1], *D. Ramsköld*[1], *L. Diaz-Gallo*[1], *J. Herrath*[1], *M. Houtman*[1], *K. Tandre*[2], *L. Rönnblom*[2], *V. Malmström*[1];
[1]*Center for Molecular Medicine, Stockholm, Sweden,* [2]*Uppsala University, Uppsala, Sweden.*

The presence of the *PTPN22* risk allele (1858T) is associated with several autoimmune diseases including rheumatoid arthritis (RA). Despite a number of studies exploring the function of *PTPN22* in T cells, the exact impact of the *PTPN22* risk allele on T-cell function in humans is still unclear. In this study, using RNA sequencing, we show that, upon TCR-activation, naïve human CD4$^+$ T cells homozygous for the *PTPN22* risk allele overexpress a set of genes including *CFLAR* and *4-1BB*, which are important for cytotoxic T-cell differentiation. Moreover, the protein expression of the T-box transcription factor Eomesodermin (EOMES) was increased in T cells from healthy donors homozygous for the *PTPN22* risk allele and correlated with a decreased number of naïve CD4$^+$ T cells. There was no difference in the frequency of other CD4$^+$ T-cell subsets (Th1, Th17, Tfh, Treg). Finally, an accumulation of EOMES$^+$ CD4$^+$ T cells was observed in synovial fluid of RA patients with a more pronounced production of Perforin-1 in *PTPN22* risk allele carriers. Altogether, we propose a novel mechanism of action of *PTPN22* risk allele through the generation of cytotoxic CD4$^+$ T cells and identify EOMES$^+$ CD4$^+$ T cells as a relevant T-cell subset in RA pathogenesis.

WS.C1.04.01

Th17.1 cells preferentially recruit to the central nervous system to mediate early disease activity in multiple sclerosis

J. van Langelaar[1,2], *R. M. van der Vuurst de Vries*[1,2], *M. Janssen*[1,2], *A. F. Wierenga-Wolf*[1,2], *I. M. Spilt*[1,2], *T. A. Siepman*[1,2], *W. Dankers*[1], *G. M. Verjans*[1,3], *H. E. de Vries*[4], *E. Lubberts*[1], *R. Q. Hintzen*[1,2], ***M. M. van Luijn***[1,2];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*MS Center ErasMS, Rotterdam, Netherlands,* [3]*University of Veterinary Medicine, Hannover, Germany,* [4]*VU University Medical Center, Amsterdam, Netherlands.*

Multiple sclerosis (MS) is mediated by pathogenic CD4+ T cells that infiltrate the CNS to promote local inflammation and demyelination. IL-17-producing CCR6+ Th cells are the main drivers of EAE, the animal model for MS. However, the functional programs of CCR6+ Th cells are heterogeneous and differ between mice and men. Here, we assessed distinct effector populations of human Th17 cells and how their recruitment to the CNS associates with MS disease onset.
Low frequencies of CCR6$^+$CXCR3$^+$ (Th1-like Th17), and not CCR6$^+$CXCR3$^-$ (Th17) effector memory cells in the blood strongly associated with rapid diagnosis of MS. In CSF, Th1-like Th17 cells were abundant and showed increased IFN-γ/GM-CSF production compared to paired CCR6$^+$ and CCR6$^-$CD8$^+$ T cells and their blood equivalents after short-term culturing. Their local enrichment was confirmed *ex vivo* using paired MS CSF and brain single-cell suspensions. Across all pro-inflammatory Th populations analyzed in the blood, a IL-17^{low}IFN-γ^{high}GM-CSF^{high} subset termed Th17.1 (CCR6$^+$CXCR3$^+$CCR4$^{-/low}$) expressed the highest levels of VLA-4, and selectively accumulated in natalizumab-treated MS patients who remained free of acute relapses. This was not found for patients who encountered relapses. The pathogenicity of Th17.1 was further supported by their predominance in early MS CSF, enhanced transmigration across human brain endothelial monolayers *in vitro*, and increased expression of IL-23R, MDR1 and granzyme B.
These findings reveal a selective contribution of Th17.1 cells to CNS inflammation and provide a strong rationale for more refined and earlier use of T cell-directed therapy in MS patients.

4-1BB overexpression in basal keratinocytes induces the disruption of the eye´s immune privilege

E. Gonnelli[1]*, M. Kasper*[2]*, V. Kupas*[3]*, D. Bauer*[2]*, T. A. Luger*[1]*, A. Heiligenhaus*[2]*, K. Loser*[1]*;*
[1]*Department of Dermatology, Münster, Germany,* [2]*Institute of Experimental Ophtalmology at Franziskus Hospital, Münster, Germany,* [3]*MorphoSys AG, München, Germany.*

4-1BB (also called CD137 or TNFRS9) belongs to the tumor necrosis factor receptor superfamily (TNFRS), and has a crucial role as a costimulatory molecule in a variety of immune processes. The overall effect of 4-1BB/4-1BB ligand signaling is enhancing inflammatory responses. To investigate the role of 4-1BB signaling in more detail we generated a mouse model with overexpression of 4-1BB under control of the keratin-14 (K-14) promoter. Surprisingly, besides severe pruritus, K14-4-1BB tg mice spontaneously developed uveitis and anterior cataract beginning at the age of 3 weeks, which was associated with the infiltration of immune cells into the eye, finally resulting in blindness. Immunofluorescent staining as well as qPCR and FACS analysis was used to characterize the cell infiltrate, revealing that the infiltrate was mainly consisting of MHCII+F4/80+ macrophages. Moreover, by performing whole mRNA array analyses we confirmed the downregulation of genes related to tight junction formation, cell-cell interaction and transmigration that might favor the income of immune cells into the eye. Interestingly, in addition we observed the presence of markers supporting an epithelial-mesenchymal-transition (EMT) occurring in the epithelial cell layer of the anterior chamber´s lens capsule from K14-41BB tg mice strongly suggesting that the EMT might be the trigger for the infiltration of immune cells through leaky cell junctions. Together, these data indicate that 4-1BB signaling is critically involved in the development of uveitis and anterior cataract and might play an important role in disrupting the immune privilege of the eye.

Targeting CD146 can downregulate new blood vessel formation caused by VEGF-producing T cells in rat experimental autoimmune uveitis

G. Wildner*, M. Diedrichs-Möhring, S. Thurau;*
Section of Immunobiology, Department of Ophthalmology, University Hospital, LMU Munich, Munich, Germany.

Neovascularization in the retina as a consequence of inflammation is a major problem in the eye. We have recently shown that VEGF-producing autoreactive T cells in rat experimental autoimmune uveitis can also induce chorioretinal neovascularization (CNV). Here we investigate the expression of CD146, a molecule of endothelial tight junctions and a coreceptor of VEGFR-2, in the eye and the effect of antibody to CD146 on EAU and formation of CNV. To induce clinically monophasic uveitis with neovascularizations Lewis rats were immunized with S-Ag peptide PDSAg-CFA or adoptively transferred with PDSAg-specific T cells. After adoptive transfer anti-CD146 antibody was daily injected s.c. and uveitis intensity monitored clinically and histologically. To investigate the effect on CNV formation, anti-CD146 antibody was injected once into the anterior chamber of rats one day prior to onset of clinical disease and CNV formation determined histologically. Cryosections from rat eyes with EAU were stained with anti-CD31/PECAM and anti-CD146. In eyes with EAU CD146 was expressed in the choroid/choriocapillaris and CNV, also on some infiltrating T cells. Preventive systemic or intraocular treatment with anti-CD146 only marginally affected the intensity of intraocular inflammation, while a single intraocular injection of anti-CD146 prior disease onset significantly suppressed CNV formation. Anti-CD146 antibodies can prevent the pathological development of new vessels in the eye after a single intraocular injection in an EAU model, where autoreactive T cells produce VEGF and induce CNV. Targeting this molecule could be a new therapeutic option to prevent the growth of new blood vessels.

Persistence of dominant TCRâ clones in regulatory T cells derived from an autoimmune inflammatory environment

G. Mijnheer[1]*, J. Leong*[2]*, A. Boltjes*[1]*, E. Spierings*[1]*, A. Petrelli*[1]*, S. Vastert*[1]*, S. Albani*[3]*, A. Pandit*[1]*, F. van Wijk*[1]*;*
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*SingHealth and Duke-NUS Graduate Medical School, Singapore, Singapore,* [3]*SingHealth and Duke-NUS Graduate Medical Schoo, Singapore, Singapore.*

Inflammation is characterized by infiltration of multiple immune cells and expansions of antigen-specific T cells. In autoimmune diseases, inflammation is often limited to specific target tissues, but within tissues, multiple sites can be affected. An important outstanding question is whether affected sites are infiltrated with the same pathogenic T cell clones and whether these clones persist over time. In Juvenile Idiopathic Arthitis (JIA) it is relatively easy to analyze cells derived from the site of inflammation, i.e. inflamed joints. Here we performed CyToF and T cell receptor (TCR) sequencing to study immune cell composition and (hyper)expansion of inflamed joint derived T cells. The samples were taken from different joints affected at the same time, and joints that were affected multiple times during the relapsing remitting course of the disease. CyTOF analyses revealed that the composition and functional characteristics of the immune infiltrates are strikingly similar between joints within one patients. Furthermore we observed a strong overlap between dominant T cell clones (Teff and even more pronounced for Treg) in inflamed joints affected at the same time, and some of the most dominant clones could also be detected in circulation. Finally, these dominant T cell clones were found to persist over time and to expand during relapses, even after full remission of the disease. These data suggest that in autoimmune disease there is auto-antigen driven expansion of both Teff and Treg clones, that are highly persistent and are (re)circulating. Therefore these dominant clones can be interesting therapeutic targets.

WS.C1.04.05

Characterization of constitutively DC-deficient mice in autoimmune responses

C. Hilpert*, D. Voehringer;*
Department of Infectionbiology, Erlangen, Germany.

Introduction: Dendritic cells (DCs) play an important role as antigen-presenting cells for T-cells, but they can also induce T-cell tolerance and protect against autoimmunity. We recently reported the generation of constitutively DC-deficient mice (ΔDC mice) which can be used to address the specific function of DCs in vivo. These mice lack >95% of classical DCs, the majority of plasmacytoid DCs and Langerhans cells. ΔDC mice show impaired negative thymic selection, hyperimmunoglobulinemia and autoantibody production. About 40%of these mice develop severe autoimmune pathology starting at 6-8 weeks of age.
Objectives: We are investigating the cellular mechanisms which lead to inflammation and autoimmunity in ΔDC mice.
Methods and results: We observed that mice lacking DCs have reduced numbers of regulatory T-cells (Treg) in the gut. Microarray and flowcytometry analysis showed that those Treg show a higher expression level of inhibitory surface receptors. Analysis of suppressive function of Treg from ΔDC mice in in vitro assays revealed that Treg from ΔDC mice are less suppressive, but Treg from both strains suppress equally well in an adoptive transfer model of colitis with Rag-ko recipients. Using DC-deficient Rag-ko mice as recipients, we could see that Treg from both strains show impaired function. By creating mixed bone marrow chimeras where DCs lack MHC-II we observed weightloss, intestinal inflammation and an expression pattern of inhibitory molecules on Treg similar to ΔDC mice.
Conclusion: From our studies we can conclude that contact to DCs via MHC-II is required for proper Treg function and prevention of severe autoimmune inflammation.

Engineering antigen-expressing regulatory T cells to modulate adverse immune responses

D. W. Scott*, M. Abdeladhim, A. Zhang, J. H. Yoon, K. Parvathaneni, L. Kropp, Y. C. Kim, E. Mitre;*
Uniformed Services University of the Health Sciences, Bethesda, United States.

Expanded regulatory cells (Tregs) have been proposed for the treatment of adverse immune responses to biotherapeutics, autoimmunity, transplantation and allergy. To increase efficacy and specificity of Tregs, we previously engineered human and mouse T cells to express chimeric antigen receptors (CARs) by expressing either T-cell receptors (TCR) from human T-cell clones (derived from patients) or specific single chain fragments (scFv). All of those engineered specific Treg cells actively suppressed effector antibody responses *in vitro* and *in vivo* and modulated EAE. Recently, we expanded this approach to create antigen-specific cytotoxic T cells as well as Tregs expressing antigenic domains (B-cell antibody receptors or BARs). Such BARs are able to kill antigen-specific hybridomas and LPS-activated normal B cells *in vitro*. In one model, BAR Tregs expressing clotting Factor VIII (FVIII) actively and specifically suppressed an antibody response to FVIII *in vivo.* BAR Tregs expressing ovalbumin (OVA) modulated the anaphylactic response (as monitored by temperature drops) to OVA. These results provide a novel paradigm to specifically regulate harmful immune responses in patients. (Supported by grants from the NIH)

Induction of gliadin-specific immune inhibition following treatment with Tolerogenic Immune Modifying Nanoparticles (TIMP) containing-gliadin

J. R. Podojil[1,2], *T. L. Freitag*[3], *R. Pearson*[4,2], *D. Getts*[2], *L. D. Shea*[4], *S. D. Miller*[1];
[1]*Northwestern University, Chicago, United States,* [2]*COUR Pharmaceuticals Development Company, Chicago, United States,* [3]*University of Helsinki, Helsinki, Finland,* [4]*University of Michigan, Ann Arbor, United States.*

In celiac disease, tolerance to gluten proteins from cereals is lost. Toleragenic Immune Modifying Nanoparticles (TIMP) are poly(lactide-co-glycolide) that contain autoreactive protein or peptide epitopes. These nanoparticles have been shown to induce immune tolerance in numerous autoimmune conditions. The identification of gliadins as the primary epitopes in celiac disease suggest that TIMP containing gliadin may serve as a tool to induce tolerance to gliadin and potentially cure celiac disease. Here we developed gliaidn containing TIMP, referred to as TIMP-GLIA, and examined its safety and ability to induce immune tolerance in a delayed type hypersensitivity (DTH) and celiac disease animal model setting. The present data determine the safety and preclinical efficacy of TIMP-GLIA to restore gluten tolerance. *In vitro* studies demonstrated TIMP-GLIA were compatible with intravenous infusion in humans, induced a tolerogenic phenotype of human dendritic cells, and did not trigger T cell activation when incubated with PBMCs from active CD patients. In three mouse models of celiac disease, 1) a delayed-type hypersensitivity, 2) a HLA-DQ8 transgenic, and 3) an adoptive gliadin memory T cell transfer model, treatment with TIMP-GLIA resulted in antigen-specific reductions in T cell proliferation, inflammatory cytokine secretion, circulating gliadin-specific IgG/IgG2c, gluten-dependent enteropathy, and body weight loss. The results provide preclinical support for the safety and efficacy of TIMP-GLIA treatment in re-establishing peripheral immune tolerance in CD patients.

WS.C2.01.02

Inhibition of *arginase-1* expression by the transcription factor Fra-1 in macrophages exacerbates rheumatoid arthritis inflammation

N. Hannemann[1], *S. Cao*[1], *A. Schnelzer*[1], *J. Jordan*[2], *M. Eberhardt*[3], *U. Schleicher*[4], *S. Uebe*[5], *A. Ekici*[5], *J. Rech*[1], *T. Bäuerle*[2], *C. Bogdan*[4], *J. Vera*[3], *G. Schett*[1], *A. Bozec*[1];
[1]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany,* [2]*Institute of Radiology, Preclinical Imaging Platform Erlangen (PIPE) Universitätsklinikum Erlangen, Erlangen, Germany,* [3]*Department of Dermatology, Laboratory of Systems Tumor Immunology Universitätsklinikum Erlangen, Erlangen, Germany,* [4]*Friedrich-Alexander-University Erlangen-Nuremberg (FAU), Institute of Microbiology – Clinical Microbiology, Immunology and Hygiene, Universitätsklinikum Erlangen, Erlangen, Germany,* [5]*Institute of Human Genetics Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany.*

The activator protein (AP)-1 transcription factor family, especially its subfamily of FOS proteins (cFos, FosB, Fra-1 and Fra-2), are associated to the regulatory network of macrophage responses. Macrophages are central player during rheumatoid arthritis (RA). This study aims to delineate the role of Fra-1 in macrophages during the acute destructive inflammatory phase of RA. Therefore, we applied the serum-induced arthritis (K/BxN) model to Fra-1 deficient mice controlled by the Mx1 promoter (Fra-1$^{\Delta Mx}$) or the LysM promoter (Fra-1$^{\Delta LysM}$). Fra-1 mutant mice had decreased arthritis severity compared to their littermate wildtype mice. The alleviated arthritis was accompanied to increased arginase-1 (Arg1) expression and activity in the joints, suggesting that its anti-inflammatory features milder RA inflammation. Sorting of immune cell populations revealed macrophages as the major source of Arg1, which was increased in Fra-1 mutant mice. Mechanistically, chromatin immunoprecipitation (ChIP) sequencing and conventional ChIP, as well as luciferase functional reporter analysis uncovered, that Fra-1 transcriptionally inhibited Arg1 expression in macrophages. Moreover, inhibition of Arginase in Fra-1 mutant mice restored a full blunt inflammatory RA response and the supplementation of mice with L-arginine, leading to increased arginase activity in the joint, is sufficient to milder arthritis. Synovium histological sections from RA patients showed a correlation between Arg1, Fra-1 and the DAS28 score, confirming that increased Arg1 activity is of benefit also for human inflammatory joint disease. Our data show for the first time that Fra-1 is a pivot between pro- and anti-inflammatory macrophage. By inhibiting Arg1 activity, Fra-1 exacerbates RA inflammation and joint destruction.

WS.C2.01.03

OPAL1, a novel transmembrane adaptor protein regulates CXCR4 signalling

Š. Borna, *A. Drobek, J. Králová, M. Fabišik, T. Brdička;*
Institute of Molecular Genetics, Prague 4, Czech Republic.

Spatial distribution of immune cells in the body of vertebrates is essential for proper function of the immune system. Destination of each cell is defined by gradient of chemokines, composition of extracellular matrix, and expression pattern of surface receptors, of which chemokine receptors play the most critical role. We have analysed the function Outcome Predictor of Acute Leukemia 1 (OPAL1) a transmebrane adaptor protein with unknown function that is upregulated in TEL/AML1-positive childhood acute lymphoblastic leukemia and higher expression of which was suggested to be associated with favourable prognosis. Using shRNA-mediated knock downs we found that it is a negative regulator of CXCR4 signalling in immortalized murine monocyte progenitors and in human TEL/AML1-positive leukemic B cell line REH. Moreover, OPAL1 knock down in zebrafish changed the organisation of immune cells in the embryo. However, our analysis of OPAL1-deficient mice revealed rather mild phenotype, which is inconsistent with enhanced CXCR4 signalling. Moreover, both splenocytes and bone marrow cells showed normal response to CXCL12, a ligand of CXCR4. We speculated that over time these mice can compensate for the loss of OPAL1 function. In accordance with our hypotheses, bone marrow cells from inducible OPAL1 knock out mice have enhanced CXCR4 signalling upon acute OPAL1 deletion. Our studies of the molecular mechanism show that OPAL1 interacts with Nedd4 family ligases, known regulators of CXCR4 signalling, and suggest that through these interactions OPAL1 modifies CXCR4 signalling.
This study was supported by GACR project 16-07425S.

FcγR-TLR cross-talk promotes inflammation by human antigen presenting cells via IRF5-dependent gene transcription and glycolytic reprogramming

W. Hoepel[1,2], *L. T. Vogelpoel*[1,2], *I. S. Hansen*[1,2], *M. L. Kapsenberg*[1,2], *D. L. Baeten*[1,2], *B. Everts*[3,4], *J. den Dunnen*[1,2];
[1]*University of Amsterdam, Amsterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands,* [3]*University of Leiden, Leiden, Netherlands,* [4]*Leiden University Medical Center, Leiden, Netherlands.*

Antigen presenting cells (APCs) are crucial for initiation of adequate inflammatory responses, which critically depends on the cooperation of different receptors. An important recently identified route of induction of inflammation by APCs involves cross-talk between Toll-like receptors (TLRs), recognizing microbial structures or dead/damaged host cells, and low-affinity Fc gamma receptors (FcγRs), recognizing IgG immune complexes. The physiological function of this FcγR-TLR cross-talk is to provide protective immune responses against invading pathogens. However, undesired activation of FcγR-TLR cross-talk, e.g. by autoantibodies, also plays a major role in the development of chronic inflammatory disorders such as rheumatoid arthritis (RA). Since interfering with FcγR-TLR cross-talk may have great therapeutic potential, we set out to identify the responsible molecular mechanisms. Strikingly, we identified that production of pro-inflammatory cytokines by FcγR-TLR cross-talk critically depends on activation of interferon regulatory factor 5 (IRF5), which amplifies gene transcription and induces metabolic reprogramming. We show that TLRs and FcγR synergize by inducing two independent signaling pathways that ultimately converge on IRF5 activation. First, TLR stimulation resulted in phosphorylation of TBK1/IKKε, which is required for IRF5 phosphorylation and subsequent activation. Second, we identified that FcγR stimulation signals via a Syk-dependent pathway to induce IRF5 nuclear translocation for amplification of gene transcription. Additionally, FcγR stimulation strongly increases the glycolytic rate of APCs, which is also essential for the synergistic induction of inflammation by FcγR-TLR cross-talk. Taken together, these data provide new potential targets to suppress inflammation in auto-antibody associated diseases such as RA, systemic sclerosis, and systemic lupus erythematosus (SLE).

WS.C2.01.05

Transmembrane TNF signaling through TNF-RI induces SpA-like inflammation, whereas signaling through TNF-RII is crucial for new bone formation

M. van Tok[1], *D. Pots*[1], *I. Blijdorp*[1], *M. Armaka*[2], *G. Kollias*[3], *M. van de Sande*[1], *D. Baeten*[1], ***L. van Duivenvoorde***[1];
[1]*Amsterdam Rheumatology and immunology Center, Amsterdam, Netherlands,* [2]*Biomedical Sciences Research Center "Alexander Fleming", Vari, Greece,* [3]*Biomedical Sciences Research Center "Alexander Fleming",, Vari, Greece.*

Background. TNF can drive strictly distinct inflammatory pathologies depending on its expression form. We have shown that transmembrane (tm)TNF rather than soluble TNF contributes to key pathological features of spondyloarthritis (SpA), including the key hallmark pathological new bone formation. **Objective.** Delineate the cellular and molecular mechanisms by which selective tmTNF overexpression leads to SpA-like pathology. **Methods.** tmTNFtg mice (TgA86) were crossed with TNF-RI or TNF-RII knock-out mice and followed clinically for SpA development. Calvarial fibroblasts were cultured and differentiated towards osteoblasts. **Results.** SpA was observed in all tmTNF$^{+/WT}$ and tmTNF$^{+/WT}$xTNF-RII$^{-/-}$ mice but not in tmTNF$^{+/wt}$xTNF-RI$^{-/-}$ mice and confirmed by histology. Whereas this indicates that TNF-RI is required for tmTNF-induced inflammation, it was striking that 50% of the tmTNF$^{+/WT}$ versus none of the tmTNF$^{+/WT}$xTNF-RII$^{-/-}$ mice depicted clear histological signs of endochondral new bone formation. To test whether TNF-RII is involved in new bone, calvarial fibroblasts from tmTNF$^{+/WT}$, tmTNF$^{+/WT}$xTNF-RI$^{-/-}$, tmTNF$^{+/WT}$xTNF-RII$^{-/-}$ and wild type mice were differentiated with osteogenic medium with or without IL-17A. tmTNF overexpressing fibroblasts enhanced osteogenic differentiation as observed by alkaline phosphatase and alizarin red staining and increased mRNA levels of Collagen type I and ALP compared to wild type fibroblasts. This enhancement in osteogenesis was maintained in tmTNF$^{+/WT}$xTNF-RI$^{-/-}$-derived fibroblasts but abolished in tmTNF$^{+/WT}$xTNF-RII$^{-/-}$-derived fibroblasts. **Conclusion.** The SpA-like phenotype in tmTNFtg mice is crucially dependent on TNF-RI to drive inflammation, but TNF-RII signaling is required for new bone formation under inflammatory conditions.

WS.C2.01.06
Lactate, via SLC5A12, lights up inflammation in CD4+ T cells by inducing a metabolic reprogramming

***V. Pucino**, M. Certo, D. Cucchi, M. Lewis, K. Goldmann, M. Bombardieri, C. Pitzalis, C. Mauro;*
William Harvey Research Institute, Queen Mary, University of London, London, United Kingdom.

Introduction: Inflammatory-sites are characterised by the accumulation of lactate. CD4+ T-cells sense lactate, via the transporter SLC5A12, which in turn inhibits their motility and promotes their switch to the Th17 subset. We assessed whether the lactate/SLC5A12-induced-metabolic-signalling-pathway is key to the chronic inflammation and autoimmunity.
Material and methods: Mononuclear-cells were isolated from tonsil of patients undergoing tonsillectomy from peripheral blood of healthy volunteers and from peripheral blood and synovial fluid of RA-patients. SLC5A12 expression was evaluated by flow-cytometry. RNA-sequencing-analysis was performed for the expression of metabolic-genes in synovial tissues of naïve-to-treatments RA-patients. IL17 expression was assessed by RT-PCR and ELISA. Seahorse and western-blot analysis were performed for the evaluation of metabolic pathways. IL17-signalling-pathway was evaluated by western-blot.
Results: SLC5A12 is up-regulated by CD4+ but not CD8+ T-cells upon triggering of the T-cell receptor (TCR). This expression is higher in CD4+ T-cells isolated from RA synovial fluid, where lactate is more abundant, compared to peripheral RA and healthy donors CD4+ T-cells. Lactate-uptake by CD4+ T-cells through SLC5A12 causes a reprogramming of glycolysis and fatty acids metabolism that tied to migration and cytokine responses via the induction of specific signalling pathways. Antibody-mediated blockade of SLC5A12 limits lactate induced CD4+ T-cells IL-17A and restores lactate-impaired CD4+ T-cell migration by rescuing glycolysis hence leading to beneficial egression of inflammatory CD4+ T-cells from inflamed tissues. In vivo treatment with SLC5A12 blocking antibody ameliorates the clinical course of disease in a mouse model of arthritis.
Conclusions: Targeting lactate/SLC5A12-induced-metabolic-signalling-pathway may provide a novel therapeutic-strategy to reduce inflammation.

Efficient suppression of effector T cells isolated from multiple sclerosis patients by autologous, UniCAR-engrafted Tregs

***A. Kegler**[1], S. Koristka[1], C. Arndt[1], A. Feldmann[1], S. Albert[2], G. Ehninger[3,4,5], M. Bornhäuser[3,4,5], M. Schmitz[6,4,5], K. Akgün[7], T. Ziemssen[7], M. Bachmann[1,2,4];*

Introduction: In multiple sclerosis (MS) patients pathogenic, autoreactive effector T cells (Teffs) provoke demyelination and central nerve system damage. To impede those harmful immune reactions, the adoptive transfer of regulatory T cells (Tregs) emerged as a promising therapeutic strategy. Several preclinical mouse models confirm an inferior functionality of polyclonal compared to antigen-specific Treg cells. However, isolation and expansion of Tregs with a desired antigen-specificity proves to be highly time-consuming and labor-intensive. Materials and Methods: To overcome these hurdles, we armed polyclonal Tregs isolated from MS patients with a universal chimeric antigen receptor (UniCAR) construct. This innovative technology allows a site-specific redirection of cells against any desired surface structure, as cross-linkage to target cells is mediated by a separate, antigen-binding targeting module (TM). Results: Highly pure $CD4^+CD25^{high}CD127^{dim}CD45RA^+$ MS-Tregs could be genetically modified to stably express the UniCAR 4-1BB/ζ construct. UniCAR-endowed Tregs strongly expand and show phenotypic stability also upon pro-inflammatory challenge. By adding a TM in the presence of target cells, UniCAR-engrafted Tregs are antigen-specifically activated demonstrated by CD69 and LAP upregulation. Most importantly, upon TM-stimulation UniCAR-armed Tregs efficiently suppress pre-activated, patient-derived Teffs. Conclusions: Taken together, the UniCAR system holds an enormous therapeutic potential for MS, as it not only allows a site-specific and precisely regulated Treg activation but also confers strong suppressive capacity to Tregs from MS patients. Thereby, this innovate technology might broaden current treatment strategies to overcome impaired functionality of Tregs as well as resistance of pathogenic Teffs to Treg suppression reported for MS patients.

WS.C2.02.02
elucidation of pro-resolving lipid mediators in the cerebrospinal fluid: implications for multiple sclerosis pathogenesis

***G. Kooij**[1,2], V. Chiurchiù[3], G. Enzmann[4], P. Norris[2], M. Khameni[5], B. Engelhardt[4], H. E. de Vries[1], C. Serhan[2];*
[1]VUmc MS Center Amsterdam, Amsterdam Neuroscience, Amsterdam, Netherlands, [2]Harvard Medical School, Boston, United States, [3]European Center for Brain Research, Rome, Italy, [4]Theodor Kocher Institute, Bern, Switzerland, [5]Karolinska Institutet, Stockholm, Sweden.

Background and objective The acute inflammatory response is host protective and efficient resolution of inflammation is required to prevent excessive inflammation and restore tissue homeostasis. This protective process is orchestrated by specialized pro-resolving lipid mediators (SPMs) that are biosynthesized from omega-3 fatty acids. In the chronic neuro-inflammatory disease multiple sclerosis (MS), the abundant presence of pro-inflammatory cells and wide-spread microglial activation within the central nervous system (CNS) suggests that this resolution process is impaired. Consequently, the uncontrolled inflammatory response will acquire a chronic nature, leading to severe tissue damage (neurodegeneration) and disease progression. To date, fundamental insights into the regulation of CNS resolution processes and whether impairments in this system correlate with MS progression remain elusive.
Methods We used liquid chromatography-tandem mass spectrometry (LC-MS-MS)-based metabololipidomics to reveal lipid mediator signatures in the cerebrospinal fluid (CSF) of RRMS (either in relapse or remission), SPMS and PPMS patients as well as age/sex matched controls.
Results Here we provide first evidence for resolution of inflammation defects in MS as reflected by a complete absence of brain specific SPMs in the CSF in all MS cases. We also defined the source of these SPMs, their target cells in the CNS during neuro-inflammation and determined their *in vivo* efficacy in an MS mouse model.
Conclusion By using metabololipidomic profiling of human CSF, we here provide first evidence that impaired resolution pathways exists in MS and thereby highlight the potential to use SPMs as novel therapeutics as well as biomarkers for diagnosis.

Characterizing human CD20+ T cells and their role in multiple sclerosis

***M. von Essen**[1], C. Ammitzbøll[1], R. Hansen[1], O. McWilliam[1], E. Petersen[1], H. Marquart[2], F. Sellebjerg[1];*
[1]Danish Multiple Sclerosis Center, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [2]Department for Clinical Immunology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.

Introduction: Recently we found that T cells expressing CD20 showed high reactivity to central nervous system (CNS) antigens. In addition, the frequency of CD20+ T cells was increased in blood of patients with multiple sclerosis (MS), suggesting a role in the pathogenesis. In this study, we further characterized the phenotype of CD20+ T cells and their implication in MS.
Results: Analysing the expression of chemokine receptors and adhesion molecules, assumed to recruit blood T cells to the CNS, showed that the frequency of blood CD20+ T cells from patients with relapsing-remitting MS (RRMS) expressing CCR2, CCR5, CCR6, CXCR3 and a high level of CD49d was significantly increased compared to CD20- T cells. This increased CNS migration potential was substantiated by the observation that CD20+ T cells were enriched in the cerebrospinal fluid (CSF) from patients with RRMS. A role in MS pathogenesis was further supported by a positive correlation between CD20+ T cells in the CSF and demyelination measured as free myelin basic protein in the CSF as well as a positive correlation with disease severity (EDSS). Characterizing CD20+ T cells revealed a pro-inflammatory T cell producing high levels of IFN-γ, TNF-α and GM-CSF as well as granzyme A and K compared to CD20- T cells; both in the CD4 and the CD8 compartment.
Conclusions: Our data indicate that CD20+ T cells have a Th1/Tc1 phenotype and possibly cytolytic activity and that they may play a central role in the pathogenesis of MS.

Malat-1 LncRNA regulates inflammation and T cell differentiation in an animal model of multiple sclerosis

***F. Masoumi**, S. Ghorbani, F. Talebi, F. Noorbakhsh;*
Immunology Department, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.

BACKGROUND: A growing body of evidence points to the role of long noncoding RNAs (lncRNAs) in the pathogenesis of neurological diseases. Nonetheless, our knowledge of multiple sclerosis-related lncRNAs remains limited. Herein, we investigated the potential role of Malat-1 lncRNA in the context of autoimmune neuroinflammation. **METHODS:** The expression level of Malat-1 was measured in CNS tissues from EAE mice as well as stimulated splenocytes and macrophages using qPCR. To examine the role of Malat-1 in macrophages polarization, Malat-1 siRNA was transfected into primary macrophages followed by M1/M2 macrophage polarization. The expression of M1/M2 markers were then evaluated. Also, the role of the Malat-1 in T cell differentiation was investigated by transfection of CD4+ T cells with Malat-1 siRNA, followed by intracellular cytokine staining. Moreover, effect of Malat-1 downregulation on T cell proliferation was investigated using CFSE staining. **RESULTS:** Expression of Malat-1 was significantly decreased in the spinal cords of EAE mice at days 15 and 25 post disease induction. Stimulated splenocytes showed significant upregulation of Malat-1, whereas expression of Malat-1 in activated macrophages was reduced. Malat-1 downregulation enhanced macrophages polarization towards M1 phenotype. Also, Malat-1 downregulation in activated lymphocytes shifted the pattern of T cell differentiation towards Th1 and Th17 cells while differentiation towards Tregs was decreased. Besides, T cell proliferation was increased following Malat-1 downregulation. **CONCLUSION:** Our data highlight the anti-inflammatory actions of Malat-1 in the context of autoimmune neuroinflammation. Malat-1 influences differentiation of T cells and activation of macrophages, providing potential therapeutic options for controlling inflammation in MS.

WS.C2.02.05

Dimethyl fumarat limits Tc17 cell fate in autoimmunity via ROS accumulation

***C. Lückel**[1], H. Raifer[2], L. Campos Carrascosa[3], S. Moos[4], F. Kurschus[4], F. Marini[5], M. Klein[1], T. Bopp[1], Y. Chao[6], C. Zielinski[6], L. Bonetti[7], M. Grusdat[7], D. Brenner[7], B. Tackenberg[8], M. Huber[2];*
[1]Institute for Immunology, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, [2]Institute for Medical Microbiology and Hospital Hygiene, University Marburg, Marburg, Germany, [3]Laboratory of Gastroentrology and Hepatology, Erasmus MC University Medical Center, Rotterdam, Netherlands, [4]Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, [5]Institute for Medical Biostatistics, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany, [6]Institute forMedical Microbiology, Immunology and Hygiene, Technical University of Munich, Munich, Germany, [7]Department of Infection and Immunity, Experimental and Molecular Immunology, Luxembourg, Luxembourg, [8]Center of Neuroimmunology, University of Marburg, Marburg, Germany.

Introduction: Dimethyl fumarate (DMF) is approved for treatment of relapsing remitting multiple sclerosis (RRMS), a chronic inflammatory disease of the central nervous system (CNS) that is mediated by autoreactive T cells. The enrichment of IL-17-producing $CD8^+$ T (Tc17) cells in cerebrospinal fluid of MS patients and the co-pathogenic function during EAE point to their contribution to CNS autoimmunity in men and mice. So far, a direct impact of DMF on $CD8^+$ T cells is unknown.
Material and Methods: Analysis of human and murine Tc17 cells and quantification of ROS levels were determined by flow cytometry. To examine changes on transcriptome, RNA-Seq and bioinformatical analysis (GSEA, PCA) were performed. Chromatin immunoprecipitation and Western Blot were conducted to evaluate histone modifications.
Results: We revealed that DMF upregulated reactive oxygen species (ROS) in Tc17 and Th17 cells by glutathione depletion, leading to IL-17 suppression preferentially in Tc17 cells. Accordingly, IL-17 production of $CD8^+$ but not of $CD4^+$ T cells was reduced in DMF-treated MS patients and DMF abrogated Tc17 cell pathogenicity in a mouse model. Accumulated ROS shifted Tc17 cells towards cytotoxic T lymphocyte signature by enhancing PI3K-AKT and STAT5 pathways along with altered histone modifications at the *Il17* locus. AKT deactivated FOXO1 leading to the upregulation of T-bet, which in turn suppressed IL-17. In line, T-bet-deficiency, inhibition of HDACs, PI3K-AKT or STAT5 prevented DMF-mediated suppression of Tc17 cells.
Conclusions: Our data provide mechanistic insights into selective modulation of Tc17 cell fate by upregulated ROS and IL-2 signaling with relevance for IL-17-driven pathologies.

The TH17-associated cytokine interleukin-26 regulates central nervous system barrier function

***B. Broux**[1], E. Peelen[2], E. Gowing[2], S. Zandee[2], M. Charabati[2], M. Lécuyer[3], L. Hachehouche[2], L. Bourbonnière[2], C. Pittet[2], S. Larouche[2], J. I. Alvarez[4], A. Bouthillier[5], R. Moumdjian[5], P. Duquette[2], N. Arbour[2], A. Prat[2];*
[1]Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium, [2]CRCHUM, Montreal, Canada, [3]University Medical Centre, Goettingen, Germany, [4]University of Pennsylvania, Philadelphia, United States, [5]CHUM, Montreal, Canada.

In multiple sclerosis (MS), demyelinated lesions are caused by an inflammatory response in the central nervous system (CNS). Pathogenic T helper (T_H)17 $CD4^+$ T lymphocytes are involved in the development of these lesions. Two cytokines expressed by these cells, namely IL17 and IL22, have been shown to disrupt blood brain barrier (BBB) integrity, an important early event in MS lesion formation. Here, we report that IL26 expression is induced in human $CD4^+$ T lymphocytes by T_H17-inducing cytokines and is significantly upregulated in the blood and cerebrospinal fluid of MS patients. In addition, $CD4^+IL26^+$ T lymphocytes are found in perivascular immune infiltrates in MS brain lesions and the two receptor chains for IL26, IL10R2 and IL20R1 are detected on BBB endothelial cells (ECs) *in vitro* and *in situ*. Unexpectedly, we found that IL26 promotes tightness and reduces permeability of BBB-ECs *in vitro* and *in vivo*. Finally, treatment of mice with experimental autoimmune encephalomyelitis (EAE; an animal model of MS) with IL26 reduces disease severity and pro-inflammatory lymphocyte infiltration into the CNS. Our study demonstrates that although IL26 is largely a T_H17-associated cytokine, it promotes BBB integrity *in vitro* and *in vivo,* and using it as a therapy induces amelioration of neuroinflammation.

Cholesterol metabolism drives the function of regulatory B cells

***J. Bibby**, A. Cope, E. Perucha;*
King's College London, London, United Kingdom.

Across a life cycle, immune cells transition between vastly different metabolic profiles. This differing reliance on specific metabolic pathways dictates fundamental cellular processes, such as activation and functional output. However, despite its critical importance to immune homeostasis – as patients with mutations in the cholesterol biosynthesis pathway (CBP) enzyme mevalonate kinase, present with autoinflammatory disease – lipid metabolism has been relatively understudied.
Here were describe a central role for the CBP in regulatory B cell function. Initial observations showed that inhibition of the CBP specifically blocks the expression of IL-10 in primary human B cells. Fitting with this observation, perturbation of the pathway renders B cells unable to suppress CD4 T cell responses. Mechanistically, the CBP is shown to regulate IL-10 induction through its driving of protein isoprenylation. This is achieved through the CBP metabolic intermediate geranylgeranyl diphosphate, which, through catalytic addition of this isoprenoid group, regulates the localisation of signalling proteins. This isoprenylation event is shown to be critical in permitting signalling through the TLR9-PI3K-Akt-GSK3 pathway in human B cells, which is necessary for IL-10 expression. Finally, RNA sequencing analysis revealed that protein isoprenylation drives the expression of known transcription factors that regulate IL-10 expression.
These data uncover a novel and central role for cholesterol metabolism in human regulatory B cells. The production of geranylgeranyl diphosphate by the CBP is shown to specifically orchestrate the expression of the effector cytokine IL-10, whilst simultaneously leaving inflammatory cytokine production unperturbed.

WS.C2.03.02

Neutrophil activation and altered coagulation in a rat model for autoimmune hemolytic anemia

***L. Del Vasto Nunez**[1], G. van Mierlo[1], I. Jongerius[1], B. M. Luken[1], N. Juffermans[2], S. Zeerleder[1,2];*
[1]Sanquin Research, Amsterdam, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands.

Autoantibodies against red blood cells (RBCs) in autoimmune hemolytic anemia (AIHA) may lead to complement activation and intravascular hemolysis with subsequent release of toxic cell-free heme. AIHA patients with intravascular hemolysis and complement activation have a higher risk of thrombosis. Complement C5a and heme trigger activation of neutrophils and, as shown recently, neutrophil activation and formation of Neutrophil extracellular traps (NETs) are closely linked to thrombosis. We recently found decreased neutrophil activation in AIHA patients after complement inhibitor treatment. We therefore hypothesized that complement-mediated neutrophil activation and the formation of pro-thrombotic NETs occur in AIHA and contribute to hypercoagulability. We aimed to design a xenograft transfusion model in rats to induce antibody-initiated complement activation and intravascular hemolysis mimicking the pathophysiology of AIHA and study the role of neutrophils in the pathogenesis of thrombosis. Male Wistar rats were subjected to a transfusion with human RBCs followed by multiple blood draws. Markers for complement and neutrophil activation and signs of hypercoagulability were determined at each time point. Transfused rats exhibited increased plasma C4b/c, elastase and nucleosome levels compared to control rats. Next, heme oxygenase 1 (HO-1) mRNA expression was higher in neutrophils from transfused rats than in those from control animals. Transfusion resulted in elevated thrombin generation and plasma thrombin-antithrombin complexes in animals administered human RBCs versus control group. These data suggest that our rat model of AIHA is suitable to induce complement-mediated intravascular hemolysis and the subsequent activation of neutrophils to study the pathogenesis of hemolysis-associated thrombosis.

WS.C2.03.03

JMJD3/UTX histone H3K27 demethylases regulate metabolic and inflammatory Th17 cell function in ankylosing spondylitis

A. P. Cribbs[1], *M. Philpott*[1], *R. K. Prinjha*[2], *P. Wordsworth*[1], *P. Bowness*[1], *M. Feldmann*[3], *U. Oppermann*[1];
[1]*Botnar Research Centre, Oxford, United Kingdom,* [2]*Epinova Discovery Performance Unit, GSK, Stevenage, United Kingdom,* [3]*Kennedy institute of Rheumatology, Oxford, United Kingdom.*

Introduction: T helper 17 (Th17) cells are CD4+ effector T cells that play an instrumental role in driving pro-inflammation IL-17 production in several autoimmune conditions, such as ankylosing spondylitis (AS).
Aim: Our aim is to identify epigenetic pathways and mechanisms that inhibit Th17 pro-inflammatory cell function. To this end, we use chemical and shRNA knockdown tools to study "readers, writers and erasers of the histone code" that regulate gene transcription.
Results: A focused epigenetic compound screen, comprising 60+ selective epigenetic inhibitors, identified Jumonji-type histone demethylases as playing a fundamental role in regulating Th17 cell inflammatory function. Specifically, using flow cytometry, we showed that inhibition of the JMJD3/UTX demethylases leads to suppression of IL-17 cytokine levels. Transcriptomic analysis revealed a pronounced upregulation of the ATF4 family of transcription factors. We also observed reduced proliferation, which was driven by the ATF4 metabolic stress response, in both healthy donors and patients with AS. Chemical inhibitors of JMJD3/UTX demethylases were overtly impactful on the cellular biochemistry of Th17 differentiated T-cells, with prominent effects on differentiation-related changes in glucose utilization, anabolic processes, and remarkable changes in amino acid and TCA cycle metabolism. Using ChIP-seq and ATAC-seq, we found that this phenotype was driven through global increases in the repressive H3K27me3 histone mark.
Conclusion: We show that inhibition of JMJD3/UTX histone demethylases in Th17 cells leads to an ATF4 metabolic stress response, induction of cellular anergy and a reduction in pro-inflammatory function. Therefore, JMJD3/UTX inhibition may be a tractable therapeutic target in autoimmunity.

WS.C2.03.04

Immunoglobulin A activated myeloid cells induce pathological osteoclast activation in rheumatoid arthritis patients

M. M. J. van Gool*, A. C. Breedveld, R. E. Mebius, M. van Egmond;*
VU University Medical Center, Amsterdam, Netherlands.

Immunoglobulin A (IgA) is crucial for maintaining homeostasis at mucosal sites. However, it is becoming clear that excessive activation of myeloid cells by IgA via FcαRI leads to severe inflammation and tissue damage. Recently, our lab has shown that neutrophils get activated by IgA rheumatoid factor (RF) present in the serum and synovial fluid of rheumatoid arthritis (RA) patients. Since IgA RF is correlated with severe bone erosions in RA patients, we hypothesize that IgA contributes to the pathology of RA. Here we show that cellular functions and cytokine release by IgA activated neutrophils and monocytes results in a specific and profound pro-inflammatory response. Only IgA induces migration of neutrophils, followed by monocytes. Moreover, the release of TNF-α by both cells, IL-6 for monocytes and IL-8 for neutrophils was only seen after IgA activation. To determine the effect of IgA activated cells on osteoclast activation, we performed a bone resorption assay in which osteoclasts were cultured in the presence of supernatant of IgA or IgG activated neutrophils and monocytes. Bone resorption was significantly increased when osteoclasts were cultured in the presence of supernatant of IgA activated cells compared to IgG. This suggests that myeloid cells activated by IgA autoantibody complexes play a role in inducing joint damage in RA patients, hereby increasing disease severity. Moreover, we discovered that differentiated osteoclasts also express FcαRI in contrast to Fcγ receptors, therefore osteoclasts can be directly activated by IgA complexes. Blocking FcαRI may represent a novel therapeutic strategy for the treatment of RA.

WS.C2.03.05

Anti-Ly9 (CD229) antibody treatment reduces marginal zone B cell numbers and salivary gland inflammation in a mouse model of Sjögren's Syndrome

J. Puñet-Ortiz*, M. Sáez Moya, M. Cuenca, A. Lázaro, J. Boix Nebot, P. Engel;*
Universitat de Barcelona, Barcelona, Spain.

Sjögren's Syndrome (SS) is one of the most common chronic autoimmune rheumatic diseases. Characterized by hyper B-cell activation, lymphocyte cell infiltration and tissue damage of exocrine glands, it can also present life-threating extraglandular affectations, such as respiratory/hepatic dysfunction, chronic infections and marginal zone B-cell lymphoma. Several biologic agents have been tested in SS but none has shown significant efficacy. Here we report the effects of antibodies against Ly9 (CD229), which is a cell surface molecule that belongs to the SLAM family of immunomodulatory receptors, using NODH2^{h4} female mice as a model of SS-like disease. Female mice were treated with anti-Ly9 antibody or isotype control at week 24, when all mice present SS-related autoantibodies, salivary gland infiltrates and marginal zone (MZ) B cell pool enlargement. Plasma was collected before and after treatment, and quantified by ELISA and immunofluorescence. B and T lymphocyte subsets from lymphoid tissues and salivary glands were analyzed by flow cytometry. Salivary glands were also studied in paraffin-embedded sections. Autoantibody levels (anti-ANA, anti-Ro, anti-dsDNA and RF) were decreased or impeded to increase over time after anti-Ly9 treatment. Moreover, this treatment induced the depletion of key lymphocyte subsets involved in SS pathology such as MZ and germinal center B cells in the spleen, draining lymph nodes and salivary glands. Importantly, mice receiving anti-Ly9 mAb showed a reduction of the infiltrate within salivary glands (isotype control: 0.61 mm^2 versus anti-Ly9: 0.15 mm^2). These data indicate that Ly9 is a potential therapeutic target for the treatment of SS.

Dysregulated expression of RasGRP1 in T cells leads to autoimmunity

T. Douma[1], *D. Simeonov*[2], *D. Myers*[2], *M. Baars*[1], *G. Mijnheer*[3], *F. van Wijk*[3], *A. Marson*[2], *J. Roose*[2], ***Y. Vercoulen***[1];
[1]*Center for Molecular Medicine, UMC Utrecht, Utrecht, Netherlands,* [2]*UCSF, San Francisco, United States,* [3]*Laboratory Translational Immunology, UMC Utrecht, Utrecht, Netherlands.*

Introduction: RasGRP1 is a Ras guanine nucleotide exchange factor (GEF), and an essential regulator of lymphocyte receptor signaling. Aberrant expression of RasGRP1 results in defective positive thymocyte selection in mice. Furthermore, recent case reports describe RasGRP1 deficient patients that suffer from recurrent infections and autoimmunity. It is unknown how RasGRP1 levels are regulated and how aberrant expression contributes to autoimmunity.
Results: Increased expression of RasGRP1 directly results in increased Ras-MAPK signaling in lymphocytes. We detected antinuclear antibodies in the serum of rasgrp1$^{+/-}$ and rasgrp1$^{-/-}$ C57/B6 mice, suggesting that loss of RasGRP1 expression is causal for autoimmunity. In patients with juvenile idiopathic arthritis we detected decreased levels of rasgrp1 in CD4$^+$ T cells isolated from synovial fluid, compared to peripheral blood. Next, we analyzed H3K27 acetylation profiles and identified 2 enhancer regions of the RasGRP1 gene, active in CD4$^+$ T cells, with single nucleotide polymorphisms for autoimmune disease. Chip-seq analysis shows binding of T cell lineage transcription factors FOXP3, Tbet, GATA3 to the enhancer region. CRISPR-Cas9 editing of the enhancer resulted in decreased RasGRP1 protein expression levels.
Conclusions: We identified an enhancer region upstream of rasgrp1 that is required for regulation of rasgrp1 expression, and SNPs in this region are associated with autoimmunity. Furthermore, our data reveal that decreased expression of RasGRP1 results in autoimmunity in mice, and that rasgrp1 expression is decreased in T cells in the synovial fluid of patients with juvenile idiopathic arthritis. Together, we show that proper regulation of RasGRP1 expression is essential to prevent inflammatory disease.

Functional reprogramming of regulatory T cells in the absence of Foxp3

L. M. Charbonnier[1], *Y. Cui*[1], *D. Lopez*[2], *J. J. Bleesing*[3], *M. I. Garcia-Lloret*[4], *K. Chen*[5], *A. Ozen*[6], *M. O. Li*[7], *T. A. Chatila*[1];
[1]*Boston Children's Hospital and Harvard Medical School, Boston, United States,* [2]*University of California, Los Angeles, United States,* [3]*Cincinnati Children's Hospital Medical Center, Cincinnati, United States,* [4]*David Geffen School of Medicine at the University of California Los Angeles, Los Angeles, United States,* [5]*University of Utah School of Medicine, Salt Lake City, United States,* [6]*Marmara University Faculty of Medicine, Istanbul, Turkey,* [7]*Memorial Sloan Kettering Cancer Center, New York, United States.*

Foxp3-deficient regulatory T (T_{reg}) cells lack suppressor function and manifest a T effector (T_{eff}) cell-like phenotype. We demonstrate that Foxp3 deficiency dysregulates mTORC2 signaling and gives rise to augmented aerobic glycolysis and oxidative phosphorylation. Mutant T_{reg} cell-specific deletion of the mTORC2 adaptor gene *Rictor* or expression of a *Foxo1* transgene improved regulatory function and ameliorated disease. Rictor deficiency reestablished a subset of T_{reg} cell genetic circuits and suppressed the T_{eff} cell-like metabolic program. Treatment of mutant T_{reg} cells of patients with FOXP3 deficiency with mTOR inhibitors similarly antagonized their T_{eff} cell-like program and restored suppressive function. Thus, regulatory function can be reestablished in Foxp3-deficient T_{reg} cells by targeting their metabolic pathways, providing opportunities to restore tolerance in T_{reg} cell disorders.

WS.C2.04.02

Immune response profiling reveals signaling networks mediating TNF-blocker function and predictors of therapeutic responses in spondyloarthritis patients

S. Menegatti[1], *V. Rouilly*[2,3], *E. Latis*[1], *H. Yahia*[1], *E. Mascia*[1], *C. Leloup*[1], *D. Duffy*[2,4], *A. Urrutia*[5], *E. Achouri*[6], *L. Quintana-Murci*[7], *M. Albert*[2,5,4], *C. Miceli*[1,8,9], *M. Dougados*[9,8], *E. Bianchi*[1,9], *L. Rogge*[1,9];
[1]*Institut Pasteur, Immunoregulation Unit, Department of Immunology, Paris, France,* [2]*Institut Pasteur, Center for Translational Research, Paris, France,* [3]*DATACTIX, Paris, France,* [4]*Institut Pasteur, Laboratory of Dendritic Cell Immunobiology, Department of Immunology, Paris, France,* [5]*Genentech Inc, Department of Cancer Immunology, San Francisco, United States,* [6]*Institut Pasteur, Center of Bioinformatics, Biostatistics and Integrative Biology, Paris, France,* [7]*Institut Pasteur, Human Evolutionary Genetics, Department of Genomes & Genetics, Paris, France,* [8]*Paris Descartes University, Rheumatology Department, Cochin Hospital, AP-HP, Paris, France,* [9]*Unité Mixte de Recherche, Institut Pasteur/AP-HP Hôpital Cochin, Paris, France.*

Anti-TNF therapy has revolutionized treatment of several chronic inflammatory diseases. However, its impact on the immune system is incompletely understood and predicting therapeutic responses remains a major challenge since TNF-blockers are effective only in a subpopulation of patients.
We have used whole-blood, syringe-based assays performing ex vivo stimulation (TruCulture assays) to define the impact of anti-TNF therapy on immune responses to microbial challenges and stimuli targeting specific immune pathways in spondyloarthritis patients, and to identify immunological correlates predicting therapeutic responses.
We found that anti-TNF therapy induces specific changes in immune responses of patients to various stimuli. These changes can be measured in stimulated, but not resting immune cells and are detectable already after a single injection of anti-TNF. Quantitative set analysis for gene expression (QuSAGE) of the stimulation cultures revealed that the gene modules most affected by anti-TNF therapy are NFkB-transcription factors and target genes, suggesting that TNF-blockers primarily act by breaking TNF- and IL-1-dependent feed-forward loop of NF-kB activation. We also tested if induced immune responses correlate with therapeutic responses. Using machine-learning algorithms, we found that expression of several molecules regulating key steps of leucocyte migration and invasiveness was significantly higher in patients responding to anti-TNF therapy following LPS-stimulation, while expression of cytotoxic and T-cell genes was higher in non-responders. The random forest model that we trained and validated using 13 selected biomarkers has a predictive power of 83%. We propose that immune response profiling of patients before therapy is a powerful new strategy to help guiding clinical decisions.

Targeting NF-κB signalling in B cells: a potential new treatment modality for antibody mediated autoimmune diseases

J. P. van Hamburg[1], *P. Tuijnenburg*[2], *B. Helder*[1], *L. van Keep*[1], *K. Wesenhagen*[1], *P. Kucharzewka*[3], *M. H. Jansen*[2], *A. Al-Soudi*[i], *P. L. Klarenbeek*[1], *H. Olsson*[3], *N. de Vries*[1], *T. W. Kuijpers*[2], *S. W. Tas*[1];
[1]*Amsterdam Rheumatology & immunology Center | Department of Experimental Immunology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands,* [2]*Department of Experimental Immunology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands,* [3]*Respiratory, Inflammation and Autoimmunity IMED Biotech Unit, AstraZeneca, Gothenburg, Sweden.*

B cells play a key role in the pathogenesis of autoimmune diseases such as ANCA-associated vasculitis (AAV). NF-κB signalling can be activated by various B cell receptors, including the B cell antigen receptor, CD40, BAFFR and TLRs, and is crucially involved in B cell responses. In this study, we examined whether targeting of NF-κB signalling by novel pharmacological inhibitors of NF-κB inducing kinase (NIK; non-canonical NF-κB pathway) and IKKβ (canonical NF-κB pathway) is effective in blocking B cell responses. In B cells of AAV patients and healthy donors, targeting of NIK and IKKβ effectively inhibited non-canonical or canonical NF-κB signalling, respectively. In a B cell stimulation assay, NIK and IKKβ inhibition significantly reduced T cell-dependent (anti-IgM+anti-CD40+IL-21) and T cell-independent (CpG+IL-2) B cell proliferation, plasmablast differentiation ($CD27^{++}/CD38^{+}$), and antibody production. The effects of NIK inhibition appeared to be B cell-specific as T cell proliferation was largely unaffected. These data demonstrate that inhibition of NF-κB signalling in B cells results in the modulation of various B cell responses. Ongoing studies will indicate whether targeting of NF-κB signalling in B cells may be an effective novel treatment modality for AAV and other autoantibody-mediated autoimmune diseases.

WS.C2.04.04

Suppression of autoreactive T and B lymphocytes by selective therapy in humanized murine SCID model of systemic lupus erythematosus

S. Bradyanova[1], *N. Mihaylova*[1], *P. Chipinski*[1], *E. Ivanova-Todorova*[2], *D. Kyurkchiev*[2], *M. Herbáth*[3], *J. Prechl*[3], ***A. I. Tchorbanov***[1];

Introduction: Self-specific B and T cells play a main role in pathogenesis of Systemic lupus erythematosus (SLE) and are a logical target for selective therapy. The complement receptor type 1 (CR1) on human B-lymphocytes has suppressive activity and engagement of this receptor inhibits B cell activation. The protein Annexin A1 (Anx A1), is a modulator of the immune system and abnormal expression was found on activated B and T cells during human autoimmunity. We hypothesize that it may be possible to down-modulate the activity of autoreactive T and B cells from SLE patients in humanized SCID mouse model by treating them with a neutralizing antibody against Anx A1 or by protein engineered molecules, which co-crosslink the BCR and CR1. Materials and Methods: Protein chimeric molecules construction, Immunodeficient SCID mice transfer with human PBMC from SLE patients, ELISA for dsDNA antibodies and cytokines, flow cytometry for apoptosis and activation markers, ELISpot and MTT assays, protein array. Results: Reconstituted SCID mice showed presence of several auto-antibodies, as well as immunoglobulin deposition in the renal glomeruli. Treatment of the transferred SCID mice either with DNA-like chimera and anti-Anx A1 antibody prevented appearance of anti-DNA antibodies and proteinuria, while the PBS-injected animals had high levels after the transfer. The treatment reduced the levels of disease-associated cytokines also. Conclusions: It is possible to down-regulate the activity of pathogenic human T and B cells in humanized SLE-SCID mouse model of SLE by targeting Anx A1 or CR1 with a specific monoclonal antibody or chimeric molecule.

WS.C2.04.05

Interleukin-6 Receptor inhibition, as first-line b-DMARD, affects B cell subpopulations distribution through epigenetic modifications in Rheumatoid Arthritis patients.

C. Di Mario, *B. Tolusso, S. Alivernini, A. Fedele, L. Petricca, M. Gigante, G. Ferraccioli, E. Gremese;*
Fondazione Policlinico Universitario A. Gemelli - Catholic University of the Sacred Heart - Division of Rheumatology, Rome, Italy.

Introduction. B cell maturation is controlled by microRNA-155(miR-155)/PU.1 axis influenced by IL-6 stimulation. The aim of the study was to investigate the effect of IL-6R inhibition on the epigenetic signature of B cells(miR-155/PU.1 axis) in Rheumatoid Arthritis(RA). Methods.Twenty-nine RA starting IL-6R inhibitor were enrolled. At study entry and after 3-6-12-18months follow-up peripheral blood(PB)-derived $CD19^{+}$cells were isolated by magnetic microbeads(Miltenyi) and miR-155 and PU.1 endogenous expression was determined by RT-PCR. Moreover, B cells subpopulations were assessed through FACS analysis (IgD/CD27classification). IL-6 plasma levels was assessed by ELISA. ACR/EULAR criteria were used to assess the response rate to treatment. PB-derived $CD19^{+}$cells of healthy individuals(HC) were used as comparison. Results.At study entry, RA showed higher percentage of $IgD^{-}/CD27^{-}CD19^{+}$cells($p<0.05$) and $IgD^{+}/CD27^{+}CD19^{+}$cells($p<0.05$) than HC. Moreover, $IgD^{-}/CD27^{-}CD19^{+}$cells percentage directly correlated with Disease Activity Score($p=0.04$) and IL-6 plasma levels($p=0.06$). Stratifying patients based on remission achievement, RA who achieved DAS remission under IL-6R inhibition showed a significant decreased of $IgD^{-}/CD27^{-}CD19^{+}$cells percentage compared to not responding patients($p<0.05$), reaching $IgD^{-}/CD27^{-}CD19^{+}$cells percentage comparable to HC($p>0.05$). At baseline, PB-derived $CD19^{+}$cells of RA showed significantly higher endogenous expression of miR-155($p=0.04$) than HC. Moreover, RT-PCR showed that IL-6R inhibition significantly represses endogenous miR-155 expression in PB-derived RA $CD19^{+}$cells after 3 months($p<0.05$) restoring PU.1 expression in PB-derived $CD19^{+}$cells after 6 months($p<0.05$) only in RA achieving disease remission. Conclusions.IL-6R inhibitor acts restoring $CD19^{+}$cells homeostasis through epigenetic modulation in RA repressing endogenous expression of miR-155 in PB-derived $CD19^{+}$cells and restoring PU.1 expression mirrored by the decrease of $IgD^{-}/CD27^{-}CD19^{+}$cells rate in RA achieving disease remission.

WS.C2.04.06

Co-engaging CD47 and CD19 with a bispecific antibody impairs B cell proliferation induced by B-cell receptor cross-linking

E. Hatterer[1], *L. Barba*[1], *N. Noraz*[2], *B. Daubeuf*[1], *J. Aubry-Lachainaye*[3], *B. van der Weid*[1], *F. Richard*[1], *W. Ferlin*[1], *M. Kosco-Vilbois*[1], *V. Buatois*[1], *L. Shang*[1];
[1]*NovImmune SA, Geneva, Switzerland,* [2]*INSERM, Lyon, France,* [3]*Flow cytometry core facility, Geneva, Switzerland.*

Introduction: A CD47xCD19 bispecific antibody (BsAb) is being developed for the treatment of B cell malignancies. We investigated if B cell receptor (BCR) signalling, a key pathway targeted in auto-immune diseases and B cell malignancies, is altered in the presence of the BsAb. Materials and Methods: Using flow cytometry-based assays, we investigated whether co-ligation of CD19xCD47 could inhibit BCR-crosslinking-induced B cell proliferation and alter cell surface dynamics of BCR/CD19. Western blot and gene array were used to investigate the downstream signaling pathways. Results: We confirmed the role of CD19 in regulating BCR-signaling by showing that bivalent targeting of CD19 with a monoclonal antibody (mAb) inhibited BCR-induced cell proliferation. In contrast, monovalent engagement of CD19 failed to abrogate B cell proliferation. Interestingly, the CD47xCD19 BsAb inhibited B cell proliferation more potently than the CD19 mAb. The inhibitory effect of the BsAb was not attributable to CD47 binding alone as the anti-CD47 mAb had no effect on B cell proliferation. Co-engaging CD19xCD47 prevented CD19 clustering and its migration to the BCR. The CD19 mAb showed no impact on either CD19 clustering or its migration to the BCR. The reduced CD19 migration to the BCR resulted in a decreased CD19 phosphorylation upon BCR cross-linking. Gene array analysis confirmed that the BsAb and the anti-CD19 mAb employed different mechanisms in controlling B cell activation. Conclusions: These data suggest that the BsAb may provide therapeutic benefit in settings of autoimmunity and B cell malignancies by dampening BCR-stimulated B cell proliferation.

WS.C3.01.01
Improved risk stratification of pretransplant donor-specific antibodies with epitope analyses

***E. G. Kamburova**, on behalf of the PROCARE consortium, H. G. Otten;*
University Medical Center Utrecht, Utrecht, Netherlands.

The presence of pretransplant donor-specific anti-HLA antibodies (DSA) is associated with increased risk of kidney graft failure. HLA antibody detection by single-antigen bead assay (SAB) is much more sensitive than by complement-dependent crossmatches (CDC-XM). Here, we studied the impact of SAB-detected DSA on graft survival for all CDC-XM negative kidney transplants performed between 1995 and 2006 in the Netherlands. The impact was most pronounced in the 3237 deceased-donor transplantations: transplantations positive for SAB detected DSA (N=430/3237) had a 16% worse 10-year graft survival than those without DSA. Due to the lack of second-field donor HLA typing, donor-specificity of the SAB-detected antibodies was initially determined at serological (split) level. The SAB assay however allows for second-field definition of antibody-specificity. Using the HLA-epitope registry (http://www.epregistry.com.br) the most likely epitope-specificity of the detected antibodies was defined. NMDP-HLA-haplotype frequencies were used to determine the most likely second-field HLA types of all recipients and donors.
Combination of these tools enabled the determination of donor anti-HLA-epitope specific antibodies (DESA). Pretransplant DESA-positive deceased-donor transplantations (N=312/3237) had a 20% poorer 10-year graft survival than those without DESA. A higher number of DESA led to an even worse graft survival: transplantations with more than 2 DESA (N=236) had a 25% poorer graft survival compared to transplantations without DESA. We conclude that even without the exact knowledge of both the HLA-epitope specificity of the SAB-detected antibodies and the mismatched donor HLA-epitopes, the number of pretransplant DESA might be a better parameter to stratify risk than the presence of serologically-defined DSA.

WS.C3.01.02
Detection of alloantibodies against NK cell antigens after transplantation

***T. Langer Jacobus**, R. E. Schmidt, C. S. Falk, E. Jäckel, F. W. Vondran, C. Ferreira de Figueiredo, R. Jacobs;*
MHH, Hannover, Germany.

Introduction: Chronic antibody-mediated rejection (ABMR) is known to play a key role in graft survival, dysfunction or rejection and is still a major obstacle in transplantation success. Recent studies have shown the importance of non-HLA antigens in the formation of donor-specific antibodies (DSA) in graft rejection. Initial experiments revealed the presence of allospecific antibodies against antigens encoded in the donor NK cell gene complex (NKC) and leukocyte receptor gene complex (LRC) in 23% of the sera of liver and kidney recipients (n=92). This prompted us to further investigate the frequency and relevance of alloantibody formation against donor NK cell receptors in graft recipients after solid organ transplantation.
Materials and Methods: Recombinant proteins for the predicted most relevant antigens were produced and coupled to differentially coloured-multiplex beads which were used to screen patient sera for the presence of antibodies on a FACSCanto II flow cytometer.
Results: This screening strategy revealed antigen-allospecific antibodies against various NKC- and LRC-encoded receptors such as KIR2DL2, KIR2DS1, LILRB3 in 5 to 17% of liver, lung and kidney recipients.
Conclusions: The data indicate a high degree of potential mismatch in NK cell diversity between donor and recipient in the case of solid organ transplantation. Further analyses will be performed in order to evaluate the functional consequences and clinical relevance of these antibodies in transplantation.

WS.C3.01.03
HLA Class I Haplotype Diversity Is Consistent with Selection for Frequent Existing Haplotypes

***Y. Louzoun**[1], I. Alter[1], M. Maiers[2], L. Gragert[3];*
[1]Bar Ilan, Ramat Gan, Israel, [2]CIMBTR, Minneapolis, United States, [3]Tulane University, New Orleans, United States.

The major histocompatibility complex (MHC) contains the most polymorphic genetic system in humans, the human leukocyte antigen (HLA) genes of the adaptive immune system. High allelic diversity in HLA is argued to be maintained by balancing selection, such as negative frequency-dependent selection or heterozygote advantage. Selective pressure against immune escape by pathogens can maintain appreciable frequencies of many different HLA alleles.
The selection pressures operating on combinations of HLA alleles across loci, or haplotypes, have not been extensively evaluated since the high HLA polymorphism necessitates very large sample sizes, which have not been available until recently. We aimed to evaluate the effect of selection operating at the HLA haplotype level by analyzing 5 locus haplotype frequencies derived from over six million individuals genotyped by the NMDP registry.
In contrast with alleles, HLA haplotype diversity patterns suggest purifying selection, as certain HLA allele combinations co-occur in high linkage disequilibrium. Linkage disequilibrium is positive (D'>0) among frequent haplotypes and negative (D'<0) among rare haplotypes. Fitting the haplotype frequency distribution to several population dynamics models, we found that the best fit was obtained when significant positive frequency-dependent selection (FDS) was incorporated. Finally, the Ewens-Watterson test of homozygosity showed excess homozygosity for 5-locus haplotypes within 23 US populations studied.
Haplotype diversity is most consistent with purifying selection for HLA Class I, and was not inferred for HLA Class II. We discuss our empirical results in the context of evolutionary theory, exploring potential mechanisms of selection that maintain high linkage disequilibrium in MHC haplotype blocks.

WS.C3.01.04
High numbers of donor-specific IL-21 producing cells predict rejection after kidney transplantation

***N. M. van Besouw**[1], L. Yan[1,2], R. de Kuiper[1], M. Klepper[1], D. Reijerkerk[1], D. L. Roelen[3], F. H. Claas[3], M. C. Clahsen-van Groningen[1], D. A. Hesselink[1], C. C. Baan[1];*
[1]Erasmus MC, Rotterdam, Netherlands, [2]Trans West China Hospital, Chengdu, China, [3]LUMC, Leiden, Netherlands.

Introduction: Both IFN-γ and IL-21 support induction and expansion of highly-reactive cytotoxic $CD8^+$ T-cells. In addition, IL-21 is a key cytokine for differentiation of alloantigen activated naïve and memory B-cells into antibody-producing plasma cells. We questioned whether the donor-specific IFN-γ and IL-21 producing cells (pc) frequency can predict kidney transplant rejection.
Methods: PBMC samples from 47 patients obtained at 6 months after kidney transplantation of whom 14 patients developed a late rejection (>6 months). In addition, pre-transplantation samples of 38 patients of whom 17 patients had an early rejection (<3 months). The frequency of donor-reactive circulating IFN-γ and IL-21 pc was determined by Elispot assay.
Results: Remarkably, no relation was found between donor-specific IFN-γ pc frequency and rejection in both groups. However, significantly higher donor-specific IL-21 pc numbers were found in patients who developed rejection compared to those without rejection in both the late (p=0.020) and early (p=0.024) rejection group. ROC-curve analysis of donor-specific IL-21 pc frequencies distinguished the development of rejection from non-rejection with a specificity of 88% and 80% in the late and early rejection group, and a sensitivity of 50% and 73%, respectively. Patients with low IL-21 pc frequencies had a significantly increased rejection free survival rate in both the late (p=0.0008) and early rejection group (p=0.0005) compared to those with high frequencies.
Conclusion: The frequency of donor-specific IL-21 producing cells is linked to an increased risk of rejection, giving it the potential to be a new biomarker in predicting rejection in different phases of transplantation.

Acute graft-versus-host disease (aGVHD) is a severe complication after allogeneic hematopoietic cell transplantation (allo-HCT). Opportunistic infections, especially during the period of neutropenia, are frequently occurring in allo-HCT patients and demand antibiotic intervention to prevent bacteremia and sepsis. However antibiotics lead to a loss of microfloral diversity which is connected to a higher incidence of aGVHD. Antibacterial therapies that eliminate invading bacteria without impacting the diversity of the microflora are therefore highly desirable. A potential solution offer anti-bacterial antibodies that target pathogens ultimately leading to elimination by innate immune cells.
We investigated the potency of active and passive immunization against the polysaccharide Poly-N-acetylglucosamine (PNAG) that is expressed on numerous pathogens in a mouse model of aGVHD. Anti-PNAG antibody treatment in the early phase after allo-HCT reduced aGVHD-related mortality and histopathological aGVHD severity. The treatment did not disturb the intestinal microbial composition as determined by 16S rDNA sequencing. Mechanistically we could show that neutrophils were recruited more abundantly to the intestinal tract following anti-PNAG treatment but exhibited a reduced activation profile as determined by their myeloperoxidase activity. Vaccination against PNAG prior to allo-HCT induced high antibody titers in mice that were detectable throughout the early phase of GVHD and significantly reduced GVHD-related mortality.
In summary, antibody-treatment-based and vaccination-based anti-PNAG immunization strategies open a new strategy to interfere with aGVHD without affecting microbial diversity.

WS.C3.01.06

Motifs of peptides binding in HLA-DP and their relation with T-cell epitope groups relevant in stem cell transplantation

P. Van Balen[1], *M. G. Kester*[1], *W. De Klerk*[1], *P. Crivello*[2], *A. H. De Ru*[1], *M. Van de Meent*[1], *I. Jedema*[1], *M. H. Heemskerk*[1], *K. Fleischhauer*[2], *J. H. Falkenburg*[1], *P. A. Van Veelen*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Institute for Experimental Cellular Therapy, Essen, Germany.*

Introduction Permissiveness of HLA-DP mismatches in allogeneic stem cell transplantations is based on categorisation of HLA-DP alleles into T-cell epitope (TCE) groups. TCE1 and TCE2 are clearly defined, but TCE3 represents a relatively heterogeneous group. To investigate whether characterization of peptides binding in HLA-DP can be of use to re-define TCE groups, we analyzed the peptidome of 11 HLA-DP molecules. **Methods** To investigate peptides presented in HLA-DP encoded by DPB1*09:01, 10:01, 17:01 (TCE1), DPB1*03:01, 14:01 (TCE2) and DPB1*01:01, 02:01, 04:01, 04:02, 05:01, 13:01 (TCE3), HLA-DPB1 typed EBV-LCL were expanded. HLA-DP immunoaffinity chromatography using anti-HLA-DP B7.21 antibody was performed, followed by analysis of eluted peptides using mass spectrometry and subsequent alignment and clustering using Gibbs sampling to obtain motifs of peptides binding in different HLA-DP molecules.
Results All alleles from TCE1 had a similar KAL motif at P1, P6 and P9, reflecting their structural similarity in the relevant hypervariable regions. This motif was shared also by DPB1*14:01 from TCE2, while the motif for HLA-DPB1*03:01 was different (RAS). TCE3 alleles could be classified into two main groups: those with a totally different FFV motif at P1, P6 and P9 (DPB1*02:01, 04:01, 04:02 with high structural similarity), and those with a motif more similar to TCE1 in P1, but different in P6 and P9 (KXX), (DPB1*01:01, 05:01 and 13:01). **Conclusion** The current categorization into TCE groups may need to be adjusted based on these results, especially with regard to potentially permissive or non-permissive mismatches within HLA-DP alleles in TCE group 3.

WS.C3.02 T regulatory cells derived and other cellular therapies in transplantation

WS.C3.02.01

Development of a novel protocol to produce massive amounts of autologous thymus-derived Treg cells (thyTreg) to be employed as cellular therapy in transplanted children. A new paradigm in the treatment of immunological diseases

E. Bernaldo de Quirós[1], *V. Pérez*[1], *M. Clemente*[2], *J. Gil-Jaurena*[3], *M. Fernández-Santos*[4], *S. Suárez*[4], *V. Plasencia*[4], *A. Acosta*[4], *M. Camino*[5], *N. Gil*[5], *E. Panadero*[5], *C. Medrano*[5], *M. Pion*[1], *R. Correa-Rocha*[1];
[1]*Laboratory of Immune-regulation, Gregorio Marañón Health Research Institute, Madrid, Spain,* [2]*Cell Culture Unit, Gregorio Marañón Health Research Institute, Madrid, Spain,* [3]*Pediatric Cardiac Surgery Unit, Gregorio Marañón Hospital, Madrid, Spain,* [4]*Good Manufacturing Practice (GMP) Facility, Gregorio Marañón Health Research Institute, Madrid, Spain,* [5]*Pediatric Cardiology Unit, Gregorio Marañón Hospital, Madrid, Spain.*

Introduction: Immune allograft rejection remains the main obstacle to successful transplants. Although transfer of regulatory T cells (Treg) has acquired growing interest in achieving indefinite graft survival, Treg isolated from peripheral blood showed several limitations. Therefore, we explored the use of thymic tissue as an alternative source of Treg for use as cellular immunotherapy.
Materials and methods: We have developed a novel GMP-compatible protocol to obtain Treg from thymuses routinely discarded during pediatric cardiac surgery. Quality and safety of the thyTreg product manufactured in the GMP facility have been confirmed. After receiving the approval from the Spanish Drug Agency (AEMPS), we will initiate the first clinical trial worldwide (phase I/IIa) to evaluate the safety and feasibility of employing autologous thyTreg in children undergoing heart transplantation.
Results: The thyTreg product obtained with our protocol showed very high purity (>90% of CD25+Foxp3+ cells), viability of >85% and very high suppressive capacity. Importantly, the number of thyTreg recovered from one thymus reached values of more than $13x10^9$ cells, enough to prepare more than 1500 doses of thyTreg. A single dose of autologous thyTreg will be infused back to the patient after transplantation and the other doses will be cryopreserved for potential future reinfusions.
Conclusions: Massive amounts of pure, highly suppressive Thy-Treg obtained with our novel GMP-compatible protocol are suitable for use as cellular immunotherapy to prevent rejection in heart-transplanted children. The clinical use of these thyTreg could increase the graft survival in transplanted patients, and may revolutionize the treatment of other immunological diseases.

Effective Treg therapy of lethal acute graft-versus-host disease

C. Riegel[1], *T. Böld*[1], *E. Huber*[2], *P. Hoffmann*[1,3], *M. Edinger*[1,3];
[1]*University Hospital Regensburg, Regensburg, Germany,* [2]*University Regensburg, Regensburg, Germany,* [3]*Regensburg Center for Interventional Immunology (RCI), University Regensburg, Regensburg, Germany.*

Allogeneic stem cell transplantation (SCT) is the treatment of choice for many hematologic diseases, carrying the inherent risk of acute graft-versus-host disease (aGVHD) that is caused by alloreactive donor T cells and mainly targets the gastrointestinal (GI) tract, skin and liver. We previously showed that co-transplantation of donor $CD4^+CD25^+$ regulatory T cells (Treg) prevents lethal aGVHD even in complete MHC-mismatched SCT models, a strategy already confirmed in first clinical trials. Here, we examined the efficacy of donor Treg to treat established aGVHD. We isolated and *in vitro* expanded $CD4^+CD25^+CD62L^+$ Treg for 14d from BALB/c donors that multiplied up to 80-fold and upregulated GI-tract homing receptors *in vitro*. Upon transfer into CB6F1 mice with established aGVHD (d11 post SCT) they rescued >65% of recipients from otherwise lethal aGVHD and still 30% if administered in very late disease stages (d32 post SCT). Initially, therapeutically administered Treg (taTreg) migrated predominantly into the gastrointestinal tract. Here, they reduced the influx of neutrophils and conventional T cells into the colon and diminished their proliferation and secretion of pro-inflammatory cytokines. taTreg persisted long-term, maintained their phenotype and Foxp3 expression in GVHD and non-GVHD target organs and still represented 5-25% of the local Treg population by d100 post SCT. They promoted tissue regeneration in the GI tract, as indicated by the reappearance of Paneth cells, and blocked further lymphoid tissue destruction thereby fostering immune reconstitution. Summarized, our results demonstrate that donor Treg transfer seems effective for the treatment of severe aGVHD. *Supported by DFG.*

WS.C3.02.03

Re-directing Treg specificity toward allograft transplants to sustainably prevent rejection

R. Alhamawi[1,2]*, C. Dempsey*[1]*, R. Albugami*[1]*, S. Lee*[1]*, N. D. Jones*[1]*;*
[1]*Institute of immunology and immunotherapy, Birmingham, United Kingdom,* [2]*Medical laboratory technology department, Madinah, Saudi Arabia.*

Foxp3$^+$ regulatory T cells (Tregs) are cells with a potent immunosuppressive capacity that may be used as a cellular therapy to suppress autoimmunity and transplant rejection. It has been suggested that redirecting the specificity of Tregs to alloantigen might increase their potency to suppress rejection compared to polyclonal cells. With this in mind, we have optimised a protocol to expand mouse Tregs *in vitro* using anti-CD3/CD28 beads in the presence IL-2 and TGFβ to facilitate genetic manipulation. This protocol allowed a significant 4-6 fold expansion of Tregs with limited contamination with conventional T cells. In an assay of non-specific suppression where both conventional T cells (Tcons) and Tregs were activated by anti-CD3/anti-CD28 mAbs, expanded Tregs were found to suppress the conventional T cell response at least as well as freshly isolated Tregs. Importantly, the expanded Tregs proved to be amenable to retroviral-transduction with a plasmid carrying T cell receptor (TCR) α and β chains that confer reactivity to the MHC class I alloantigen H2K^b. Analysis of transduced Tregs revealed that 85%±5% expressed the alloreactive TCR following transduction. Finally, the TCR gene-engineered Tregs were tested for their ability to suppress an allogeneic CD4$^+$ and CD8$^+$ T cell response *in vitro*. We found that the TCR engineered Tregs suppressed alloreactive T cell responses with increased potency compared to expanded mock-transduced Tregs *in vitro*. Taken together these data suggest that indeed re-directing Tregs to transplant antigens may improve the efficacy of these cells when used as a cellular therapy to prevent transplant rejection.

WS.C3.02.04

Extracellular adenosine reversibly inhibits the activation of human regulatory T cells and negatively influences the achievement of the operational tolerance in liver transplantation

A. Baroja-Mazo[1]*, B. Revilla-Nuin*[1]*, L. Martínez-Alarcón*[1]*, J. Herrero*[2]*, A. El-Tayeb*[3]*, C. Müller*[3]*, P. Aparicio*[4]*, P. Pelegrín*[1]*, J. Pons*[1]*;*
[1]*Biomedical Research Institute of Murcia (IMIB-Arrixaca), EL PALMAR- MURCIA, Spain,* [2]*Clínica Universidad de Navarra, Pamplona, Spain,* [3]*Pharma Center Bonn, Bonn, Germany,* [4]*University of Murcia, MURCIA, Spain.*

The possibility of stimulating or inducing a state of operational tolerance in transplantation is gaining strength. In murine models, a differential role of extracellular adenosine (eADO) for regulatory (Tregs) and effector (Teffs) T cells has been proposed: inhibiting Teffs activity and inducing Tregs. The aim of the present study was to analyze the action of extracellular nucleotides in human T cells, and moreover, examine the influence of CD39 and CD73 ectonucleotidases and subsequent adenosine signaling through adenosine 2 receptor (A_2R) in the induction of clinical tolerance after liver transplantation. The action of extracellular nucleotides in human T cells was analyzed by *in vitro* experiments with isolated T cells. Additionally, 17 liver transplant (LT) patients were enrolled in an immunosuppression withdrawal trial, and the differences in the CD39-CD73-A_2R axis were compared between tolerant and non-tolerant patients. In contrast to the murine model, the activation of human Tregs was inhibited in a similar rate to Teffs in the presence of eADO although this inhibition was reversible. Moreover, the relative expression of the enzyme responsible for the irreversible degradation of ADO, adenosine deaminase (*ADA*), was much higher in tolerant patients with respect to the non-tolerant group along the immunosuppression withdrawal process. Our data support the idea that extracellular ADO signaling and its degradation by ADA may play a role in the complex system of regulation of liver transplantation tolerance. In addition, we show the capacity of *ADA* expression to differentiate the operational tolerance state at the first steps of the immunosuppression withdrawal process.

WS.C3.02.05

Targeting recipient antigen presenting cells with sialic acid- modified alloantigen to promote transplantation tolerance

M. Sen[1]*, K. Ratnasothy*[2]*, M. Ambrosini*[3]*, D. Guiliano*[1]*, Y. van Kooyk*[3]*, G. Lombardi*[2]*, L. A. Smyth*[1,2]*;*
[1]*School of Health, Sport and Bioscience, University of East London, London, United Kingdom,* [2]*MRC Centre for Transplantation, King's College London, London, United Kingdom,* [3]*Department of Molecular Cell Biology and Immunology, VU University Medical Centre, Amsterdam, Netherlands.*

Sialic acid-binding immunoglobulin-like lectins (siglec) are inhibitory receptors expressed on dendritic cells (DCs) that bind to sialic acid ligands. These receptors have previously been targeted to murine DCs to induce antigen-specific tolerance in an autoimmune mouse model. To date, it has not been established whether targeting these receptors can induce transplantation tolerance; therefore our aim was to target siglec-expressing recipient DCs with sialic acid- modified donor alloantigen MHC class I K^d peptide (sia-alloantigen) to promote organ transplant survival.
Siglec expression on bone marrow-derived DCs (BMDCs) and binding of FITC- conjugated sia- alloantigen was confirmed by flow cytometry. Following sia- alloantigen treatment, targeted BMDCs had a reduced capacity to induce antigen specific CD4$^+$ T cell proliferation and effector cytokine production. In addition, co-culturing antigen specific CD4$^+$ T cells with sia- alloantigen treated BMDCs, led to a 3-fold percentage increase in CD4$^+$FOXP3$^+$ regulatory T cells (Tregs).
Flow cytometry analysis suggests that sia- alloantigen binds to DCs *in vitro* and *in vivo*. Targeting sia- alloantigen to DCs in B6.RAG-2$^{-/-}$ recipient mice reconstituted with T cells, led to significant skin graft prolongation. To assess which DC subset was involved, B6.BATF3 $^{-/-}$ mice, which lack the CD8α$^+$ and CD103$^+$ DC subsets were compared with B6 mice. Skin transplant prolongation, reduced alloantibody production and an increased proportion of Tregs were observed only in B6.BATF3 $^{-/-}$ mice after treatment with sia- alloantigen.
In conclusion, targeting siglecs on recipient CD8α negative DCs with sia- alloantigen may represent a novel DC targeting regimen to regulate allorecognition.

WS.C3.02.06

Third party virus-specific T-cells for treatment of viral reactivations in immune compromised patients and risks of allo-HLA cross-reactivity

W. Huisman[1,2]*, D. A. Leboux*[2]*, L. Hageman*[2]*, D. Amsen*[1]*, F. J. Falkenburg*[2]*, I. Jedema*[2]*;*
[1]*SANQUIN, Amsterdam, Netherlands,* [2]*LUMC, Leiden, Netherlands.*

Adoptive transfer of partially HLA-matched virus-specific T-cells from healthy third party donors is a potential strategy to temporarily provide anti-viral immunity to immune-compromised patients. However, these T-cells harbor the risk of mediating allo-HLA cross-reactivity. To assess the magnitude of this risk, we examined the occurrence and diversity of allo-HLA cross-reactivity mediated by T-cell populations targeting different proteins from cytomegalovirus (CMV), Epstein-Bar virus (EBV) and adeno virus (AdV) using an allogeneic EBV-LCL panel covering 116 different HLA molecules and secretion of IFNγ as read-out. Allo-HLA cross-reactivity patterns were confirmed using K562 cells expressing single HLA molecules upon retroviral transduction. A significant proportion of HLA-A*01/A*02/B*07/B*08-restricted virus-specific T-cell populations (n=170) isolated from 27 healthy donors (30% of the CMV, 46% of the EBV and 36% of the AdV-specific T-cell populations tested) exerted allo-HLA cross-reactivity against one or more allogeneic EBV-LCLs in this analysis. However, for some specificities (e.g. HLA-A*02:01-restricted EBV-LMP2-FLY) the allo-HLA cross-reactivity was limited (n=1/11), whereas for other specificities (e.g. HLA-B*08:01-restricted EBV-BZLF1-RAK) almost all tested populations (n=9/13) showed profound allo-HLA cross-reactivity. Separate analysis of subcultures, sorted on TCR-Vβ usage from the bulk single specificity T-cell population, revealed several specific allo-HLA cross-reactivity patterns. Furthermore, recurrent patterns of allo-HLA cross-reactivity were observed for virus-specific T-cell cultures expressing the same TCR-Vβ family that were isolated from different donors. These data indicate that allo-HLA cross-reactivity by third party virus-specific T-cells can be a serious problem and that the magnitude and diversity may be associated with the level of T-cell receptor oligoclonality within a certain T-cell population.

PD-1 regulates the expression of HELIOS in self-reactive CD8$^+$ and CD4$^-$CD8$^-$T cells

N. Rodriguez Rodriguez[1,2]*, S. A. Apostolidis*[3]*, E. Montes Servin*[4]*, O. Arrieta*[4]*, G. C. Tsokos*[3]*, F. Rosetti*[1]*, J. C. Crispin*[1]*;*
[1]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico,* [2]*Instituto de Investigaciones Biomedicas, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico,* [3]*Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States,* [4]*Instituto Nacional de Cancerologia, Mexico City, Mexico.*

Self-reactive CD8$^+$ lymphocytes that recognize cognate antigen in peripheral tissues become inactivated, downregulate CD8, and express PD-1, becoming PD-1$^+$ double negative (DN, CD4$^-$CD8$^-$TCR-αβ$^+$) T cells, a population of lymphocytes increased in autoimmunity. However, whether PD-1 plays a role in DN T cells is unknown.
Transfer of PD-1-deficient OT-I CD8$^+$ T cells into mice that express ovalbumin as self-antigen resulted in an increased expansion of DN T cells with an elevated production of pro-inflammatory cytokines (e.g. IFN-γ), a result that was also observed under steady state conditions in *Pdcd1*-deficient mice.
Further analyses revealed that HELIOS (*Ikzf2*), a transcription factor important for immune tolerance, was specifically expressed by DN cells upon self-antigen encounter. Absence of PD-1 or PD-L1, as well as blockade of PD-1 during early self-antigen encounter, abrogated the upregulation of HELIOS, suggesting that signaling via PD-1 is necessary for HELIOS induction *in vivo*. *In vitro* experiments confirmed that presence of PD-L1 during T cell activation enabled a stable induction of HELIOS, and demonstrated that PD-1-mediated PI3K/AKT inhibition promotes its expression.
In patients with non-small cell lung carcinoma that received pembrolizumab, anti-PD-1 administration significantly reduced the frequency of HELIOS$^+$ DN T cells together with a reciprocal elevation of Ki-67$^+$ DN T cells.
RNA-sequence and shRNA studies proved that HELIOS is a central hub that regulates several transcriptional effects downstream of PD-1 signaling required to curb T cell activation.
In conclusion, by promoting HELIOS expression, which regulates the PD-1-imposed transcriptional program, PD-1 restrains the expansion of self-reactive CD8 and DN lymphocytes.

WS.C4.01.02

Immunotherapy with apitopes® blocks the immune response to thyroid stimulating hormone receptor in HLA-DR transgenic mice

E. Schurgers[1], *F. La Greca*[1], *D. C. Wraith*[1], *K. F. Martin*[2], *L. Jansson*[1];
[1]*Apitope International NV, Diepenbeek, Belgium,* [2]*Apitope Technology (Bristol) ltd, Chepstow, United Kingdom.*

Graves' disease is an endocrine, autoimmune disorder mediated by autoreactive T and B lymphocytes responding to the thyroid-stimulating hormone receptor (TSHR). Stimulatory anti-TSHR antibodies activate thyroid cells, resulting in typical Graves' hyperthyroidism. Although current treatment options are effective in initially eliminating the hyperthyroidism, they are not able to interrupt the autoimmune processes in Graves' disease. Long-term eradication of hyperthyroidism in Graves' disease patients could be achieved by antigen-specific immunotherapy as the formation of anti-TSHR antibodies is T cell dependent.
We designed a peptide-based antigen-specific immunotherapy to specifically re-establish immune tolerance to TSHR through the development of antigen-processing-independent epitopes (apitopes®). Combining MHC binding assays with immunization and tolerance induction experiments in human leukocyte antigen HLA-DRB1*0301 transgenic (DR3tg) mice, TSHR immune dominant peptides were identified. The combination of these TSHR-derived peptides induced T cell tolerance towards TSHR in DR3tg mice. In addition, a challenge model was created in DR3tg mice using an adenovirus expressing the extracellular domain of TSHR. In this animal model, a mixture of two immunodominant apitopes® was sufficient to suppress the anti-TSHR antibody production by more than 90%. Thus, selected peptides efficiently regulate the anti-TSHR T and B cell responses, specifically the generation of anti-TSHR antibodies, in DR3tg mice. Furthermore, selected peptides were assessed for their antigenicity using PBMC samples from Graves' disease patients, demonstrating the identification of relevant human T cell epitopes. These results demonstrate that antigen-specific immunotherapy with apitopes® from TSHR is a suitable approach, and is currently undergoing clinical trials, for the treatment of Graves' disease.

Pathogenic antibody development and blister formation due to impaired peripheral tolerance

S. Haeberle[1], *X. Wei*[1], *K. Bieber*[2], *S. Goletz*[2], *E. Schmidt*[2], *R. Ludwig*[2], *A. Enk*[1], *E. Hadaschik*[3,1];
[1]*Department of Dermatology, Heidelberg, Germany,* [2]*Department of Dermatology, Lübeck, Germany,* [3]*Department of Dermatology, Essen, Germany.*

Missing functional regulatory T-cells (Treg) lead to development of severe autoimmune inflammation. Scurfy mice have a mutation in foxp3 and thereby no functional Tregs. Scurfies show severe skin inflammation with Th1/Th2 prone immune response and high titers of autoantibodies against skin proteins. We wanted to analyze if autoimmune blistering diseases (AIBD) develop in the absence of Treg. We screened scurfy sera and found elevated levels of autoantibodies against different AIBD-related autoantigens. Histological examination of scurfy skin, showed the presence of subepidermal blisters. Together with deposition of autoantibodies in the skin, we demonstrate that scurfies develop the phenotype of AIBD. We generated hybridomas, to isolate monoclonal autoantibodies (mAb) from scurfies. Mass spectrometry analysis revealed BP230 as the autoantigen of one of these mAb (20B12). We confirmed the antigen by immunofluorescence, westernblot and ELISA. Furthermore, we proved pathogenicity by injection of 20B12 into neonatal mice which led to subepidermal blister formation in 70% of mice. To investigate the interaction between autoreactive CD4+ T-cells from Scurfies and B-cells, CD4+ T-cells from scurfy and WT mice were transferred into *nu/nu* mice. Transfer of autoreactive scurfy CD4+ T-cells into *nu/nu* mice, resulted in autoantibody production and subepidermal blister formation similar to scurfy. In summary, we show that impaired peripheral tolerance leads to an AIBD phenotype with pathogenic autoantibody production and blister formation in scurfy mice. Furthermore the injection of anti-BP230 autoantibody was sufficient to induce blister formation, therefore BP230 should be considered as a relevant target autoantigen in AIBD. Funded by SFB/TR156.

WS.C4.01.04

APRIL induces a novel subset of IgA$^+$ regulatory B cells that suppress inflammation through the expression of IL-10 and PD-L1

C. M. Fehres[1,2], *N. O. Van Uden*[1,2], *N. G. Yeremenko*[1,2], *L. Fernandez*[3], *G. Franco Salinas*[1], *L. M. Van Duivenvoorde*[1,2], *B. Huard*[4], *J. Morel*[5], *H. Spits*[2], *M. Hahne*[3], *D. L. Baeten*[1,2];
[1]*Department of Clinical Immunology and Rheumatology, Academic Medical Center, Amsterdam, Netherlands,* [2]*Department of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands,* [3]*Institut de Genetique Moleculaire de Montpellier, Centre National de la Recherche Scientifique, Universite de Montpellier, Montpellier, France,* [4]*Institute for Advanced Biosciences , University Grenoble Alpes , INSERM U1209, Grenoble, France,* [5]*Department of Rheumatology, CHU de Montpellier, Montpellier University, Montpellier, France.*

Regulatory B cells (Bregs) are immunosuppressive cells that modulate immune responses through multiple mechanisms, such as the production of IL-10 and the skewing of T cell differentiation in favor of a regulatory phenotype. However, the signals required for the differentiation and activation of these cells remain still poorly understood. As we have previously found that APRIL promoted IL-10 production in human B cells, we hypothesized that APRIL, but not BAFF, may be involved in the induction and/or activation of IL-10 producing Bregs that suppress inflammatory responses *in vitro* and *in vivo*. CD19$^+$IgD$^+$CD27$^-$ naïve B cells were cultured in the presence of IL-21+TGF-β, IL-21+APRIL or IL-21+BAFF to induce class switch recombination to IgA.
Regulatory B cell functions and phenotypes were assessed on the class switched IgA B cells. Here, we describe that APRIL promotes the differentiation of naïve human B cells to IL-10-producing IgA$^+$ B cells. These APRIL-induced IgA$^+$ B cells display a Breg phenotype and inhibit T cell and macrophage responses *in vitro* through expression of IL-10 and PD-L1. Moreover, APRIL-induced IL-10 producing Bregs suppress inflammation *in vivo* in experimental autoimmune encephalitis (EAE) and contact hypersensitivity (CHS) models. Finally, we showed a strong correlation between APRIL and IL-10 in the inflamed synovial tissue of inflammatory arthritis patients. In conclusion, we have identified a novel subset of regulatory B cells within the IgA$^+$ B cell population that suppresses inflammation *in vitro* and *in vivo*, which indicate the potential relevance of this subset of B cells for immune homeostasis and immunopathology.

Molecular Mechanisms of T cell Tolerance Induction

S. T. H. Ng, *S. Bevington, P. Cockerill, D. C. Wraith;*
University of Birmingham, Birmingham, United Kingdom.

Escalating peptide immunotherapy is effective in treating experimental autoimmune encephalomyelitis (EAE) in mice and multiple sclerosis in humans. EAE can be prevented and treated by subcutaneous administration of the peptide MBP Ac1-9[4Y] in H-2^u mice. This protection from disease is dependent on IL-10 secreting Foxp3- cells. This project aims to look at the transcription, epigenetic and signalling profiles of CD4+ T cells as a result of peptide immunotherapy. Tg4 mice were treated with either peptide or vehicle control. mRNA-seq, DNAse I-seq and phospho-protein array analysis were carried out on CD4+ T cells isolated from the spleen. The results show that peptide immunotherapy induces Tr1-like cells with a tolerogenic transcription profile. DNAse I-seq results show an epigenetic landscape that is permissive to the expression of tolerogenic genes such as IL10. On the other hand, the down-regulation of inflammatory genes such as IL2 and TNFa is not explained by epigenetic changes. The phosphorylation status of downstream proteins of the TCR suggests that TCR signalling is impeded in Tr1-like cells explaining the limited expression of inflammatory genes.The data indicate that both epigenetic programming and modifications in signalling are important in generating Tr1-like cells. As peptide immunotherapy has been shown to be clinically relevant, it would be imperative to look for drug targets to further improve the efficacy and longevity of the treatment.

Macrophages treated with exosome-delivered miRNA-150 release immune suppressive exosome-like nanovesicles bearing antigen/MHC complex

K. Nazimek[1,2], *B. Nowak*[1], *M. Wasik*[1], *W. Ptak*[1], *P. W. Askenase*[2], *K. Bryniarski*[1,2];
[1]*Department of Immunology, Jagiellonian University Medical College, Krakow, Poland,* [2]*Section of Allergy and Clinical Immunology, Yale University School of Medicine, New Haven, United States.*

Introduction. T cell-derived, miRNA-150-carrying exosomes suppress mouse contact (CHS) and delayed-type (DTH) hypersensitivity reactions [J Allergy Clin Immunol 2013;132:170-81]. miRNA-150-carrying exosomes were shown to target antigen-presenting macrophages finally suppressing CHS effector cells [Immunology 2015;146:23-32]. Current studies aimed at determining the mechanism of immune suppression mediated by macrophages treated with exosome-miRNA-150.
Methodology. Wild type, OT-II or miRNA-150 KO mouse peritoneal macrophages were treated with T cell-exosomes and standardly cultured for 48 hours in serum-free medium. Resulting supernatant was filtered down to 0.22micrometers and ultracentrifuged at 100.000g for 70 minutes. Pelleted nanovesicles were used for treatment of adoptively transferred DTH effector T cells or analyzed cytometrically. OT-II macrophage-derived exosome-like nanovesicles were pre-incubated with anti-ovalbumin-323 antibodies. Ovalbumin-induced DTH effector T cells of OT-II mice were pre-incubated with ovalbumin-323 peptide.
Results. MHC class II-positive exosome-nanovesicles from culture of miRNA-150-pulsed macrophages of wild type, OT-II or miRNA-150 KO mice suppressed adoptively transferred effector T cells, and this inhibitory effect was enhanced by pre-incubation of pelleted nanovesicles with ovalbumin-323-specific antibodies and blocked by pre-incubation of effector T cells with ovalbumin-323 peptide.
Conclusions. Macrophages release suppressive exosome-like nanovesicles only after treatment with T cell-exosome-carried miRNA-150. As miRNA-150-pulsed macrophage-derived exosome-like nanovesicles express MHC class II and bind antigen-specific antibodies, we concluded that they display antigen/MHC complex. These exosome-like nanovesicles finally target effector T cells to suppress DTH immune response and this effect depends on the interaction of antigen/MHC complex expressed on macrophage-derived exosome-like nanovesicles with antigen-specific TCR of effector T cells.

WS.C4.02.01

IL-21 sustains asthmatic and colitogenic CD4$^+$ T cell effector responses by promoting apoptosis of FoxP3$^+$ regulatory T cells

***L. Tortola**, H. Pawelski, S. S. Sonar, M. Kopf;*
ETH Zurich - Institute of Molecular Health Sciences, Zurich, Switzerland.

IL-21 is a key player of adaptive immunity with well-established roles in B cell- and cytotoxic T cell responses. IL-21 has also been implicated in the generation of effector CD4$^+$ T cells such as Th17 cells and inhibition of regulatory T cells (Tregs), but the mechanism and functional relevance of these findings remain controversial. We show here that IL-21 production by conventional Th2 cells drives allergic airway inflammation by intrinsic inhibition of FoxP3$^+$ Treg expansion. Mice lacking IL-21R displayed profoundly reduced generation of Th2 cells along with increased Tregs. In mixed bone marrow chimeras, we demonstrate that IL-21 promotes Th2 differentiation indirectly via inhibition of Tregs. Depleting the inflated Treg population in *Il21r*$^{-/-}$ mice restored Th2 generation and lung eosinophilia. Furthermore, IL-21 inhibited Treg generation in a model of Th1/17-driven colitis. Using elaborate competitive transfers of *Il21r*$^{+/+}$ and *Il21r*$^{-/-}$ CD4$^+$ cells into lymphopenic hosts, we show that IL-21 directly inhibited expansion rather than differentiation of Tregs, but was dispensable for development of Th1/Th17 effectors. Notably, we show that IL-21 sensitizes activated Tregs to caspase-dependent apoptosis by interfering with the expression of Bcl-2 family genes.
Collectively, our data demonstrates that IL-21 promotes apoptotic death of FoxP3$^+$ Treg cell intrinsically and thereby indirectly sustains generation of Th1, Th17 and Th2 cells and related effector responses, with profound implications in inflammatory pathologies. Blockade of IL-21 or IL-21R may be considered for regulatory T cell-based therapies of autoimmunity and allergy.

WS.C4.02.02

IL-10 signaling in CD11c$^+$ myeloid cells prevents gluten-dependent intraepithelial CD4$^+$ cytotoxic T lymphocyte infiltration and epithelial damage in the small intestine

***L. M. M. Costes**[1], D. J. Lindenbergh-Kortleve[1], L. A. van Berkel[1], S. Veenbergen[1], N. Papazian[1], Y. Simons-Oosterhuis[1], J. J. Karrich[2], R. M. Hoogenboezem[2], B. E. Clausen[3], T. Cupedo[2], J. N. Samsom[1];*
[1]Laboratory of Pediatrics, div. Gastroenterology and Nutrition, Erasmus Medical Center, Rotterdam, Netherlands, [2]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands, [3]Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany.

Celiac disease (CeD) is a chronic small intestinal inflammatory disease occurring consequently to a breach of tolerance to gluten. In mice, IL-10 producing Tr1-like cells maintain gluten tolerance. Moreover, IL-10 preserves intestinal homeostasis by regulating CD11c$^+$ myeloid cells. Therefore, we hypothesized that disrupting IL-10 regulation of CD11c$^+$ myeloid cells would trigger a small intestinal inflammatory response to gluten.
Indeed, when reared on a gluten-containing diet, *Itgax*^{cre}*Il10ra*$^{fl/fl}$ mice lacking IL-10 receptor alpha on CD11c$^+$ myeloid cells developed CeD-like small intestinal inflammation. In particular, *Itgax*^{cre}*Il10ra*$^{fl/fl}$ mice displayed increased frequencies of small intestinal cytotoxic CD4^{pos}CD8αα^{pos} IEL (CD4 CTL) expressing high *Ifng*, a key player in CeD. CD4 CTL were negative for Ki67, suggesting that conversion of CD4$^+$ T-cells into CD4 CTL rather than expansion of an existing CD4 CTL pool caused increased frequency. Crucially, this was associated with epithelial stress involving increased epithelial MHCII expression and crypt hyperplasia and was gluten-dependent as both CD4 CTL frequency increase and epithelial stress were abolished in *Itgax*^{cre}*Il10ra*$^{fl/fl}$ mice reared on a gluten free diet. Small intestinal CD103$^+$CD11b$^-$ and CD103$^-$CD11b$^+$ dendritic cells and F4/80$^+$ macrophages preferentially took up orally-administered fluorescently-labeled gluten and had the highest number of significantly changed genes in an RNA sequencing analysis comparing small intestinal myeloid subsets of *Itgax*^{cre}*Il10ra*$^{fl/fl}$ mice and littermates. This suggests that IL-10 regulation of these myeloid populations prevents gluten-dependent conversion of small intestinal CD4 CTL and associated epithelial stress.
Altogether, our data indicate that disrupting IL-10 regulation of CD11c$^+$ myeloid cells causes gluten-dependent small intestinal inflammation with CeD features .

WS.C4.02.03

An autocrine TNFa - TNFR2 loop promotes epigenetic effects inducing human Treg stability *in vitro*

*P. C. Urbano, H. J. Koenen, I. Joosten, **X. He**;*
Radboudumc, Nijmegen, Netherlands.

A crucial issue for Treg-based immunotherapy is to maintain a bona fide Treg phenotype as well as suppressive function during and after *ex vivo* expansion. Several strategies have been applied to harness Treg lineage stability, including the addition of the mTOR inhibitor rapamycin to Treg cultures and the use of CD28-superagonist mAb. A TNFR2 agonist antibody was recently shown to favor homogenous expansion of Treg *in vitro*. Combined stimulation with rapamycin and TNFR2-agonist mAb enhanced hypo-methylation of the *FOXP3* gene, and thus promoting Treg stability. To further explore the underlying mechanisms of rapamycin and TNFR2-agonist mediated Treg stability, we here stimulated FACS-sorted human Treg with a CD28-superagonist mAb in the presence of rapamycin and TNFR2-agonist mAb. Phenotypic analysis of stimulated Treg revealed an autocrine loop of TNFα-TNFR2 underlying the maintenance of Treg stability *in vitro*. Addition of rapamycin to CD28-superagonist stimulated Treg led to a high expression of TNFR2, the main TNFR expressed on Treg, and additional stimulation with a TNFR2-agonist enhanced the production of TNFα.
Moreover, our data showed that the expression of histone methyltransferase EZH2, a crucial epigenetic modulator for potent Treg suppressor function, was enhanced upon stimulation with CD28-superagonist. Interestingly, rapamycin seemed to downregulate CD28-superagonist induced EZH2 expression, which could be rescued by the additional addition of TNFR2-agonist antibody. This process appeared TNFα dependent manner, since depletion of TNFα using Etanercept inhibited EZH2 expression. To summarize, we propose that an autocrine TNFα - TNFR2 loop plays an important role in endorsing Treg stability.

WS.C4.02.04

Interleukin-34 contributes to Tregs suppressive function and inhibits allogeneics responses

***A. FREUCHET**, S. BEZIE, C. USAL, V. DAGUIN, C. GUILLONNEAU, I. ANEGON;*
CRTI INSERM UMR 1064, Nantes, France.

Identify new specific and powerful mediators of immune tolerance is important. IL-34 is a cytokine that binds to CSF-1R, CD138 and PTPz and is involved in differentiation and survival of macrophages, as well as in suppression of certain immune responses. We showed that IL-34 is expressed by rodent and human Foxp3$^+$CD8$^+$/ CD4$^+$ Tregs. Additionally, the overexpression of IL-34 induces long-term allograft tolerance in a rat model through M2-macrophages differentiation as well as CD8$^+$/CD4$^+$ Tregs induction.
To further understand the function of IL-34 in immune responses, we generated IL-34-deficient rats thanks to CRISPR/Cas9 technology. These rats showed a decrease of CD8$^+$ and CD8$^+$CD45RC^{hi} T cells in the spleen and CD8$^+$ and CD8$^+$Foxp3$^+$ T cells in the blood compared to WT animals. The suppressive function of IL-34 deficient CD8$^+$CD45RC^{low} Tregs was not affected *in vitro* nor *in vivo* (wasting disease model in *Il2rg*$^{-/-}$ rats injected with T cells). However, IL-34-deficient CD4$^+$CD25$^+$CD127^{low} Tregs were not able to control the wasting disease, suggesting that IL-34 is essential for their suppressive function.
Finally, to analyze the potential of IL-34 in human allogeneics immune responses, we used a GVHD model in NSG mice injected with human PBMC. Treatment with IL-34 and rapamycin at suboptimal dose reduced the GVHD incidence vs. rapamycin or IL-34 alone (median survival: 39, 28 and 14 respectively; n=4-8). The role of Tregs in this model is under investigation.
Altogether, our data demonstrate the implication of IL-34 in CD4$^+$ Tregs function and the relevance of this cytokine as a regulatory cytokine in GVHD.

WS.C4.02.05

Repairing Foxp3 mutations in scurfy T cells restores regulatory T cell function

***l. jeker**, m. kornete;*
Department of Biomedicine and Transplantation Immunology & Nephrology, Basel, Switzerland.

Adoptive cell transfer is a powerful approach to treat various diseases including infectious diseases and certain blood cancers. Emerging genome engineering tools enable direct genetic manipulation of primary immune cells. This opens new therapeutic opportunities for monogenic T cell diseases. We recently reported an efficient protocol for CRISPR-mediated T cell editing. Here, we report the successful correction of two different pathogenic *Foxp3* mutations in primary murine T cells. Both repairing the cause of the scurfy syndrome, a 2bp insertion in *Foxp3,* and repairing the clinically relevant Foxp3^{K276X} mutation restored Foxp3 expression in primary T cells *in vitro*. Ex vivo gene-repaired T cells adoptively transferred to lymphodeficient mice survive and expand *in vivo*. We show that the gene-corrected cells are viable, express high levels of Foxp3, CD25 and other regulatory T cell (Treg) markers and are responsive to IL-2 treatment upon adoptive transfer *in vivo*. Importantly, repaired Treg cells prevent the development of dermatitis illustrating regained suppressive capacity *in vivo*. These results suggest that gene therapy of T cells might constitute an alternative to gene therapy in hematopoietic stem cells.

WS.C4.02.06

Epigenetic editing converts naive and memory CD4+ T cells into FOXP3 expressing regulatory T cells

C. Kressler[1], *D. Hamo*[1], *G. Gasparoni*[2], *J. Walter*[2], *A. Hamann*[1], *J. K. Polansky*[1];
[1]*German Rheumatism Research Center, Berlin, Germany,* [2]*Universität des Saarlandes, Saarbrücken, Germany.*

Regulatory T cells (Tregs) harbor a huge therapeutic potential as their immuno-suppressive function may counteract errant immune responses. The key to the stable epigenetic imprinting of Treg activity is a genetic element called Treg specific demethylated region (TSDR) in the *FOXP3* gene which is selectively demethylated in stable thymic-derived Tregs and hence, assures sustained expression of the Treg master transcription factor FOXP3. However, whether selective activation of the TSDR alone is sufficient to drive FOXP3 expression and possibly induce a Treg phenotype in primary conventional T cells, is so far unclear. We applied "epigenetic editing" to achieve a targeted demethylation of the TSDR using a fusion of the catalytically inactivated Cas9 (dCas) protein and the catalytic domain of the Ten-eleven translocation 1 (TET1) enzyme. Transient transfection of primary human naive and effector memory CD4+ T cells with a plasmid coding this construct and guide RNAs targeting the CpG motifs of the TSDR induced FOXP3 expression in a proportion of these cells. Resulting FOXP3+ cells were completely and selectively demethylated in all CpGs of the TSDR. Epigenetically edited T cell clones after extensive in vitro expansion maintained TSDR demethylation in the absence of the epigenetic editor, indicating that the induced TSDR demethylation is stable. Furthermore edited T cell clones displayed suppressive capacity in an in vitro suppression assay. Our results show that epigenetic editing is feasible in primary human T cells and that modification of only one element is sufficient for stable FOXP3 induction even in memory T helper cells.

FcγRIIA/CD32A-expressing platelets determine the severity of experimental anaphylaxis

F. Jönsson[1], *H. Beutier*[1], *B. Hechler*[2], *O. Godon*[1], *Y. Wang*[1], *C. M. Gillis*[1], *L. de Chaisemartin*[3], *A. Gouel-Chéron*[3], *S. Magnenat*[2], *L. Macdonald*[4], *A. Murphy*[4], *S. Chollet-Martin*[3], *D. Longrois*[3], *C. Gachet*[2], *P. Bruhns*[1], *NASA consortium;*
[1]*Institut Pasteur/Inserm, Paris, France,* [2]*EFS Grand Est/Inserm, Strasbourg, France,* [3]*Hôpital Bichat (AP-HP)/Inserm, Paris, France,* [4]*Regeneron Pharmaceuticals, New York, United States.*

Platelets are key regulators of vascular integrity; however, their role in anaphylaxis, a life-threatening systemic allergic reaction characterized by the loss of vascular integrity and vascular leakage, remains unknown. Anaphylaxis is a consequence of inappropriate cellular responses triggered by antibodies to generally inoffensive antigens, resulting in a massive mediator release and rapidly occurring organ dysfunction. Human platelets express receptors for IgG antibodies and can release potent mediators, yet their contribution to anaphylaxis has not been previously addressed in mouse models, probably because mice do not express IgG receptors on platelets.
We investigated whether platelets contribute to IgG anaphylaxis in human IgG receptor expressing mouse models and a cohort of patients suffering from drug-induced anaphylaxis. We found that platelet counts dropped immediately and dramatically at anaphylaxis induction, only when they expressed the human IgG receptor FcγRIIA/CD32A. Platelet depletion attenuated anaphylaxis whereas thrombocythemia drastically worsened its severity. FcγRIIA-expressing platelets were directly activated by IgG immune complexes *in vivo* and were sufficient to restore susceptibility to anaphylaxis in resistant mice. Serotonin released by activated platelets contributed to anaphylaxis severity. Data from a cohort of patients suffering from drug-induced anaphylaxis indicated that platelet activation was associated with anaphylaxis severity and that anaphylaxis occurrence was accompanied by a reduction in circulating platelet numbers.
Our findings identify platelets as critical novel players in IgG anaphylaxis and provide a rationale for the design of platelet-targeting strategies to attenuate the severity of anaphylactic reactions.

In susceptible individuals otherwise innocuous environmental proteins such as allergens trigger the release of the type 2 promoting cytokine IL-33 that activates type 2 innate lymphoid cells (ILC2). Yet, the knowledge of how such allergens are sensed at mucosal surfaces is limited. We here identify the formyl-peptide receptor 2 (FPR2) and its endogenous ligand, the acute phase protein serum amyloid A1 (SAA1), as major drivers of house dust mite (HDM)-induced IL-33 release *in vitro* and *in vivo*. Mechanistically, this involved the dissociation of biologically inert SAA1 oligomers into monomers that induce epithelial IL-33 release. In mice, local inhibition of FPR2 in the lungs or *Saa1/2* deficiency abrogated HDM-induced airway hyperresponsiveness, IgE synthesis, bronchoalveolar lavage (BAL) eosinophilia, concomitant with reductions in Th2 cytokines, IL-13$^+$ ILC2s, and BAL IL-33 levels in allergen-exposed mice. This was dependent on SAA1 recognition of the cytosolic fatty acid binding protein (FABP) Der p 13 contained in HDM extract. Importantly our findings in mice translate to human allergic diseases. The FABP sensing pathway is upregulated in respiratory epithelial cells from chronic rhinosinusitis (CRS) patients resulting in increased IL-33 secretion associated with enhanced SAA1 monomer formation and FPR2 signaling. Taken together, we here report a novel mechanism of allergenicity which involves SAA1-facilitated allergen recognition via FPR2 leading to aberrant IL-33 release and type 2 responses. This novel paradigm allows for a new view on SAA1 as a potent driver of type 2 allergic immune responses at mucosal surfaces. Supported by the Austrian Science Fund FWF, NIH and ATS.

CD300c receptor co-stimulates IgE-mediated basophils activation and its expression is increased in cow´s milk allergic children

O. Zenarruzabeitia Belaustegi[1], *J. Vitallé*[1], *I. Terrén*[1], *A. Orrantia*[1], *I. Astigarraga*[1,2,3], *L. Dopazo*[1,2], *C. González*[4,3], *C. Tutau*[2], *L. Santos-Díez*[1,2], *P. Gamboa*[2], *A. Bilbao*[1,2], *F. Borrego*[1,5,6];
[1]*BioCruces Health Research Institute, Barakaldo, Spain,* [2]*Cruces University Hospital, Barakaldo, Spain,* [3]*University of the Basque Country, Leioa, Spain,* [4]*Basurto University Hospital, Bilbao, Spain,* [5]*Ikerbasque, Basque Foundation for Science, Bilbao, Spain,* [6]*Basque Center for Transfusion and Human Tissues, Galdakao, Spain.*

Basophils express high-affinity IgE receptors (FcεRI), which play an essential role in allergic diseases. To design new immunomodulatory therapies, it is important to characterize cell surface receptors that modulate IgE-mediated basophil activation threshold. We have analyzed the expression of CD300 receptors on human basophils and their implication in IgE-mediated basophil activation processes. Blood samples from healthy and allergic pediatric patients were collected. Peripheral blood mononuclear cells were obtained by density centrifugation, and phenotypical and functional studies were performed by flow cytometry. We demonstrate that basophils express the activating receptor CD300c, which is up-regulated in response to IL-3. CD300c works as a co-stimulatory molecule during IgE-mediated basophil activation, as shown by a significant increase in degranulation and cytokine production when basophils are activated through CD300c compared with the activation through the IgE/FcεRI axis alone. Co-ligation of FcεRI and CD300c increased intracellular calcium mobilization and phosphorylation of signalling intermediates evoked only by FcεRI ligation. Furthermore, we have observed that the expression of CD300c in allergic children is significantly increased compared to healthy controls, and that the intensity of expression correlates with the severity of the hypersensitivity symptoms. We conclude that CD300c could be considered a biomarker and therapeutic target in IgE-mediated allergic diseases as it seems to be involved in the modulation of IgE-mediated basophils activation.

C5a receptor 1 activation on vacuolated eosinophils drives maladaptive immunity in experimental allergic asthma

A. V. Wiese[1], *K. M. Quell*[1], *F. Ender*[1], *T. Vollbrandt*[1], *P. König*[2], ***Y. Laumonnier***[1], *J. Köhl*[1];
[1]*ISEF, Lübeck, Germany,* [2]*Institute for Anatomy, Lübeck, Germany.*

The anaphylatoxin C5a plays an important role in the development of maladaptive Th2/Th17 immunity in experimental allergic asthma through the activation of C5a Receptor-1 (C5aR1). Here, we characterized a pulmonary highly vacuolated SiglecF$^+$CD11c$^+$ eosinophilic population (vEOS) that was localized in the lung, acted as an antigen-presenting cell that translocated to the mediastinal lymph nodes (mLN) and triggered T cell proliferation *in vitro*, as well as allergic asthma *in vivo*. EOS express high levels of C5aR1. Thus, we determined C5aR1 expression in vEOS, and its contribution to vEOS-driven allergic asthma using different adoptive transfer and allergen-induced allergic asthma models. We observed that C5aR1 is highly expressed in vEOS upon ovalbumin (OVA)-induced allergic asthma. In addition, vEOS expressed C5 and C5aR1 intracellularly. Interestingly, in *C5ar1*$^{-/-}$ mice, the recruitment of vEOS to mLN was significantly reduced and the upregulation of CD86 abrogated. Further, in co-cultures with OVA-TCR-transgenic T cells, the Th17 response induced by vEOS was increased in the absence of C5aR1.

Finally, transfer of house-dust-mite-pulsed *C5ar1*$^{-/-}$ vEOS into WT recipient mice resulted in low airway hyperresponsiveness (AHR) associated with a mixed Th1/Th2 response. Collectively, our data demonstrate that vEOS exert strong antigen-presenting properties, which are controlled by the C5a-C5aR1 axis. They activate T cells *in vitro* and *in vivo* to proliferate and differentiate into Th1 and Th2 effector cells. Such T cell activation is associated with the development of AHR, which is also controlled by activation of the C5a-C5aR1 axis. Thus, vEOS serve as additional antigen-presenting cells in experimental allergic asthma.

WS.C5.01.05
Single cell RNA-Seq identifies an exquisite pathogenic Th2 cell gene signature and pinpoints cellular metabolism as a major distinguishing factor

J. M. Coquet;
Karolinska Institutet, Solna, Sweden.

T helper cells are critical to the development of asthma. In particular, Th2 cells are the main protagonists in asthma, although other T helper cells subsets are known to participate and also regulate asthma severity. Although decades of research have elucidated a number of factors regulating T helper cell differentiation, gene expression profiles of T helper cells typically come from arrays of bulk cell populations from *in vitro*-differentiated cells. We performed single cell RNA-Sequencing on T helper cells from the airways of mice administered house dust mite antigens, in an attempt to obtain pure transcriptional profiles of T helper cell subsets, in particular the pathogenic Th2 cell population. Our results indeed clearly depict populations of Th2, Treg and Th1 cells. In addition, we characterize a population of type I IFN-responding cells and a population of activated T helper cells, expressing mRNA for ribosomal proteins. Th2 cells indeed expressed *Gata3, Il4, Il5 and Il13* as expected, but were also highly enriched for the expression of approximately 100 other genes, many of whose functions are not typically associated with Th2 cells. Pathway analysis identified metabolic processes as the major point of difference between Th2 cells and other T helper cells in the airways, in particular, those relating to fatty acid oxidation and synthesis. Taken together, our data shows that Th2 cells differ substantially from other T helper cells in a mouse model of asthma, with cellular metabolism being a major point of difference. Work characterizing human Th2 cells is ongoing.

Notch signaling in CD4^{+} T cells supports lymph node egress of Th2 cells in allergic airway inflammation

I. Tindemans[1], *A. KleinJan*[1], *M. J. de Bruijn*[1], *M. Lukkes*[1], *A. van den Branden*[1], *W. F. van Ijcken*[1], *D. Amsen*[2], *R. Stadhouders*[1], *R. W. Hendriks*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Sanquin, Amsterdam, Netherlands.*

Background: Allergic asthma is characterized by a T helper-2 (Th2) response to inhaled allergens. Previous experiments showed that Notch signaling controls Th2 differentiation through direct induction of Gata3. However, the role of Notch signaling during Th2-mediated allergic airway inflammation (AAI) *in vivo* is currently unclear.
Methods: We used a house-dust mite (HDM)-driven model to investigate the capacity of Notch1 and Notch2-deficient T cells to induce AAI. The role of Notch signaling *in vitro* and *in vivo* was studied using Notch-deficient ovalbumin-specific T cells. We performed transcriptome analysis of T cells to identify genes that are controlled by Notch signaling in the context of AAI.
Results: In the HDM-treated groups, WT animals developed AAI, but conditional Notch1/Notch2 double KO animals failed to develop eosinophilic inflammation, and Th2 cytokines or serum IgE were not induced. When conditional Notch KO mice which concomitantly expressed a CD2-Gata3 transgene were treated with HDM, only a partial enhancement of Th2 inflammation was observed. Surprisingly, we found that Notch signaling is not required for the induction of Th2 cell differentiation. However, during the allergen challenge phase Notch-deficient T cells did not cause AAI, as they accumulated in draining lymph nodes and did not efficiently migrate to the lung. Transcriptome comparisons of Notch-deficient and WT Th2 cells from lymph nodes revealed 692 differentially expressed genes, including genes involved in cell migration and adhesion.
Conclusion: Notch signaling in T cells is crucial during Th2-mediated AAI in a HDM-driven asthma model, likely by mediating lymph node egress of Th2 cells.

Selective elimination of allergen-specific B lymphocytes with chimeric protein-engineered molecules

N. R. Ralchev[1], *N. Mihaylova*[1], *N. Kerekov*[1], *A. Tchorbanov*[1,2];
[1]*Laboratory of Experimental Immunology, Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria,* [2]*National Institute of Immunology, Sofia, Bulgaria.*

Introduction: Der p1 is allergenic molecule of Dermatophagoides pteronyssinus (Dpt) which causes house dust mite (HDM) allergy. The pathological Der p1-specific B cells produce allergen-specific IgE antibodies that mediate most of the hypersensitivity allergic reactions. It may be possible to influence Der p1- specific B cells in mouse model of HDM allergy by administration of chimeric molecule, containing a monoclonal antibody against the inhibitory B-cell receptor FcγRIIb coupled to a B and a T cell epitope-carrying peptides from the Der p1 allergen. Co-crosslinking of the immunoglobulin receptors and FcγRIIb by this molecule is expected to deliver strong suppressive signal selectively silencing these B cells and the subsequent allergic response. Materials and Methods: protein engineering, FACS, animal model, immunohistochemistry, histology. Results: A protein engineered chimeric molecule has been constructed, which binds Der p 1 specific B-cells via their BCR and suppresses selectively the production of anti - Der p 1 antibodies via FcγRIIb. The synthetic peptide Der p1 p52-71 and an anti-FcγRIIb monoclonal antibody were used for the construction of Der p1 chimera. The functional effects of engineered antibodies were analyzed *in vitro*. An animal model of HDM allergy has been developed. Significant inhibition of allergen-specific proliferation and reduction of DerP1 - IgE antibody production were observed after treatment of splenocytes from sick mice with DerP1-peptide chimera. Conclusions: The present study explores a different approach for preventing pathological allergen-specific IgE antibody production. Our data show that the allergic immune response can be silenced by specific targeting the pathological B cells.

WS.C5.02.02
Sulfated Non-Anticoagulant Heparin (S-NACH) blocks allergen induced asthma manifestations in mice by modulating the IL-4/STAT6/GATA-3 pathway harboring a therapeutic potential for allergic asthma

M. A. Ghonim[1], *J. Wang*[1], *S. Ibba*[1], *K. Pyakurel*[1], *H. Luu*[1], *I. Benslimane*[1], *S. Mousa*[2], *H. Boulares*[1];

Background: The efficacy of heparins and Low-MW-heparins (LMWH) against human asthma has been known for decades. However, the clinical utility of these compounds has been hampered by their anti-coagulant properties. Much effort has been made to harness the anti-inflammatory of LMWH but so far none have gone to be used as therapy for asthma. Sulfated-Non-Anticoagulant Heparin (S-NACH) is an ultra-LMWH with no systemic anticoagulant effects. The present study explored the potential of S-NACH in blocking allergic asthma. ***Methods***: Acute and chronic ovalbumin-based mouse models of asthma, splenocytes, and a lung epithelial cell line were used. Mice were challenged to aerosolized ovalbumin. Mice were administered S-NACH or saline 30 min after each ovalbumin challenge. ***Results***: S-NACH administration in mice promoted a robust reduction in airway eosinophilia, mucus production and airway hyperresponsiveness even after chronic repeated challenges with ovalbumin. Such effects were linked to a suppression of the Th2 cytokines IL-4/IL-5/IL-13/GM-CSF and ovalbumin-specific IgE without any effect on IFN-γ. S-NACH also reduced lung fibrosis in chronically ovalbumin-exposed mice. These protective effects of S-NACH may be attributed to modulation of the IL-4/JAK signal transduction pathway through an inhibition of STAT6 and a subsequent inhibition of GATA-3 and inducible NO synthase expression. S-NACH treatment also reduced the basal expression of the two isoforms of arginase Arg1 and Arg2 in lung epithelial cells. ***Conclusions***: our results demonstrate that S-NACH may represent an opportunity to take advantage of the well-known anti-asthma properties of heparins and LMWH while bypassing the risk of bleeding complications.

WS.C5.02.03
Targeting PDE3 Abrogates the Hallmarks of Asthma in Asthma Models

A. KleinJan[1], *J. Beute*[1], *K. Ganesh*[1], *V. Bos*[1], *M. Lukkes*[1], *M. v. Nimwegen*[1], *S. Hockman*[2], *V. Manganiello*[2], *R. Hendriks*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*NIH, Bethesda, United States.*

Objective: Case reports related to status asthmaticus showed that enoximone, which is a smooth muscle relaxant that inhibits PDE3, is beneficial and lifesaving. Off label use of enoximone has steroid sparing properties. From PDE3 inhibition it is not known that it has anti-inflammatory effects. Here, we investigated the pathophysiological role and disease modifying effects of PDE3 in acute and chronic house dust mite (HDM)-driven asthma mouse models. Methods: Bronchial hyperreactivity (BHR) and allergic airway inflammation (AAI) and airway remodeling was investigated by Buxco, histology and flowcytometry in chronic HDM-driven asthma models. The pathophysiological role was studied by intervention of PDE3 by transgenic mice lacking PDE3 or wild type mice treated with the PDE3 inhibitor enoximone when AAI was already established. Mucosal barrier function was investigated by measuring albumin leakage and the presence of albumin in lung tissue. Results: Mice lacking PDE3 or treated with the PDE3 inhibitor enoximone showed reduced BHR; reduced AAI as measured by BAL eosinophilia and Th2-cell cytokine profile and showed improved mucosal barrier function when compared to wild type control mice in the HDM-driven asthma models. Having established HDM driven AAI, reduced BHR, reduced smooth muscle mass and reduced mucus hypersecretion depict the role of enoximone in abrogating airway remodelling. In addition, diminished inflammatory cells and epithelial mast cells depicted its broader anti-inflammatory effects of PDE3 inhibition when intervention with enoximone or placebo starts after already established HDM driven AAI. Conclusion: Taken together this study prove the pathophysiological role of PDE3 in asthma models

WS.C5.02.04

Neutrophils negatively regulate T_H2 inflammation in allergic airways disease by limiting G-CSF driven monocytosis and ILC2 cytokine production

***D. F. Patel**, T. Peiro, J. Vuononvirta, S. Akthar, S. A. Walker, L. G. Gregory, C. M. Lloyd, R. J. Snelgrove;*
Imperial College London, London, United Kingdom.

Neutrophils are critical components of the body's anti-microbial response, yet an over-exuberant neutrophilic inflammation has traditionally been implicated in the pathology of chronic diseases. Increasingly, however, it is recognized that neutrophils are not just indiscriminate killers but are able to elegantly and specifically shape many facets of the elicited immune response. Largely circumstantial evidence has suggested a prominent role for neutrophils in the pathophysiology of severe asthma, but their precise contribution to disease progression is poorly understood. In a house dust mite model (HDM) of allergic airways disease (AAD), we demonstrate that neutrophil depletion unexpectedly resulted in exacerbated T_H2 inflammation, with increased numbers of T_H2 $CD4^+$ T-cells and type 2 innate lymphoid cells (ILC2s) and elevated levels of allergen-specific IgE and IgG1 antibodies. This augmented T_H2 inflammation in neutrophil depleted mice was preceded by an early increase in levels of ILC2-derived IL-5 and IL-13 and numbers of monocyte-derived dendritic cells (MoDCs) and ensuing antigen presentation. Central to the exacerbated T_H2 inflammation in neutrophil-depleted mice was a striking increase in G-CSF levels, which drove an expansion on monocyte progenitors in the bone marrow and T_H2 cytokine production by ILC2s in the airways. In conclusion, we demonstrate that neutrophil depletion during AAD results in profound perturbations in the G-CSF axis and an ensuing monocyte and ILC2 driven exacerbation in T_H2 inflammation. These studies reveal a novel role for neutrophils in negatively regulating monocyte and ILC2 function and highlight potential complexities of targeting neutrophils in animal models and within the clinic.

WS.C5.02.05

NOD/SCID-mice engrafted with human allergen-specific $CD4^+$ T cells develop allergic airway responses without signs of GvHD

***C. Vizzardelli**[1], F. Zimmann[1], M. Gindl[1], B. Nagl[1], C. Kitzmüller[1], U. Vollmann[1], S. Tangermann[2], L. Kenner[2,3,4], B. Bohle[1];*
[1]Center of Pathophysiology, Infectiology and Immunology, Medical University Vienna, Vienna, Austria, [2]Unit of Laboratory Animal Pathology, University of Veterinary Medicine Vienna, Vienna, Austria, [3]Department of Experimental and Laboratory Animal Pathology, Medical University of Vienna, Vienna, Austria, [4]Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria.

Introduction: We have successfully employed non-obese diabetic severe-combined-immunodeficient $\gamma c^{-/-}$ (NSG) mice engrafted with PBMC from allergic patients as *in vivo* model of respiratory allergy. Allergic airway inflammation in this model is mainly mediated by allergen-specific $CD4^+$ T-cells. As their frequency in PBMC of allergic individuals is very low and $CD8^+$ T-cells may trigger graft-versus-host-disease (GvHD) we sought to improve this model by employing T-cell lines (TCL) enriched for allergen-specific $CD4^+$ T-cells.
Methods: Betv1-specific TCL were established from birch pollen-allergic patients. The ratio of CD4/CD8 T-cells was analysed by flow cytometry. Allergen-reactivity was confirmed in proliferation assays. T-cell-specificities were identified with overlapping synthetic 12-mer peptides. Allergen-induced cytokine responses were assessed with qPCR. Betv1-specific TCL plus autologous antigen-presenting cells were injected intraperitoneally. After 17 days engraftment was assessed by flow cytometry. Airway hyperresponsiveness (AHR) and bronchial inflammation were analyzed after intranasal challenges with allergen or PBS.
Results: After injection of TCL harbouring $CD4^+$ T-cells reactive with various epitopes of Betv1, $CD4^+$ T-cells were detected in cell suspensions of lungs and spleens. $CD8^+$ T-cells did not expand *in vivo*. Mice challenged with allergen showed significantly higher AHR and larger numbers of eosinophils, neutrophils and basophils in bronchoalveolar fluids than those challenged with PBS. Lung histology revealed peribronchial inflammation in mice challenged with allergen. No perivascular inflammation indicative of GvHD was observed.
Conclusion: NSG-mice engrafted with allergen-specific $CD4^+$ TCL develop allergic airway responses without GvHD. This improved *in vivo* model may be useful in the assessment of novel therapeutic allergy vaccines targeting allergen-specific T-lymphocytes.

WS.C5.02.06

Induction of *in vitro* cross-tolerance in birch pollen-allergic patients with associated food allergies by use of tolerogenic dendritic cells

***P. V. Rostan**[1], E. Graulich[1], V. K. Raker[1], A. Wangorsch[2], S. Scheurer[2], K. Steinbrink[1];*
[1]Department of Dermatology, Division for Experimental and Translational Research, University Medical Center, Mainz, Germany, [2]Paul-Ehrlich-Institut, Molecular Allergology, Langen, Germany.

Birch-pollen allergy is one of the most prevalent allergic diseases in Northern Europe. Among birch-pollen allergic patients approximately 70% experience secondary food allergy e.g. to hazelnuts, carrots, apples or others. Increasing evidence has shown that this oral allergy syndrome (OAS) is mediated by both, IgE and T cell cross-reactivity to proteins of the pathogen related protein family 10 (PR-10) which are homologous to the major birch pollen allergen Bet v 1.0101 (e.g. Cor a 1.0401 (hazelnut)). In previous studies, we found that human tolerogenic interleukin-10-modulated dendritic cells (IL10-DC) induce anergic regulatory T cells (iTregs) exhibiting a high suppressive capacity. Therefore, we investigate the potential of IL10-DC to induce allergen-specific and cross-reactive iTregs *in vitro* in allergic patients with proven birch pollen and cross-reactive hazelnut allergies. Stimulation with Bet-v-1-loaded mature DC led to pronounced Bet-v-1-specific effector T cell proliferation whereas Bet-v-1-pulsed IL10-DC induced hypoproliferative T cells, indicating the generation of Bet-v-1-specific iTregs. However, restimulation of Bet-v-1-specific iTregs with syngeneic Bet-v-1- or Cor-a-1-loaded mDC resulted in a significantly increased or similar T cell proliferation, respectively, compared to Bet-v-1-specific effector T cells. In further experiments, we want to characterize the induced iTreg populations and explore their suppressive capacity by use of *in vitro* and *in vivo* suppressor assays. The goal of our study is the development of novel therapeutic approaches for type I allergies, including (food) cross-allergies, using tolerogenic IL-10-modulated DC for tolerance induction.
This study is financially supported by the German Research Foundation (DFG).

hIPSC-derived dendritic cells identify IRF5 as a crucial regulator that exacerbates inflammatory cytokine production during Influenza A virus infection

***J. L. Forbester**[1,2], M. Clement[1], A. Yeung[2], P. Sabberwal[1], M. Marsden[1], G. Dougan[3,2], I. Humphreys[1,2];*
[1]School of Medicine, Cardiff, United Kingdom, [2]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [3]University of Cambridge, Cambridge, United Kingdom.

IRF5 is a transcription factor expressed by myeloid cells, which plays important roles in Toll-like receptor (TLR), IFN and virus-induced signalling pathways. Human induced pluripotent stem cell (hIPSC)-derived cellular systems provide an exciting potential route towards the analysis of human cell function in a genetically defined environment, and may help elucidate complex mechanisms underlying host-pathogen interactions.
Here, we use iPSC technology to define the role of IRF5 in human myeloid cells in response to Influenza A virus (IAV). We differentiate healthy control hIPSCs, and hIPSCs with biallelic mutations in *IRF5*, generated using CRISPR/Cas9 technology, into iPS-Dendritic Cells (iPS-DCs). iPS-DCs expressed markers of $CD141^+$ myeloid DCs, and iPS-DCs generated from *IRF5*-/- iPSCs produce significantly less IL-6 in response to IAV infection, and also after stimulation with various TLR ligands. To confirm this phenotype was not due to off-target effects, we used TALEN engineering to integrate a functional copy of IRF5 back into the *IRF5*-/- iPSC line. The IL-6 response to IAV in iPS-DCs derived from $IRF5^{Comp}$ iPSCs was restored. To examine the role of IRF5 during *in vivo* infection, we challenged *Irf5*-/- mice with IAV. *Irf5*-/- mice experienced reduced pathology after IAV challenge. Despite having no impact on virus replication, *Irf5*-/- mice exhibited ameliorated pathology which was associated with reduced inflammatory cytokine production in the lung.
Therefore, we demonstrate in both human and murine model systems that IRF5 acts as a regulator for myeloid cell inflammatory cytokine production during IAV infection, and drives immune-mediated viral pathogenesis.

WS.C6.01.02

SOCS1 and SOCS3 target IRF7 degradation to suppress TLR7- mediated type I interferon production of human plasmacytoid dendritic cells

***C. Yu**[1], W. Peng[1], M. Schlee[2], W. Barchet[2], A. M. Eis-Hübinger[3], W. Kolanus[4], M. Geyer[5], S. Schmitt[5], F. Steinhagen[6], J. Oldenburg[7], N. Novak[1];*
[1]Department of Dermatology and Allergy, Bonn, Germany, [2]Institute of Clinical Chemistry and Pharmacology, Bonn, Germany, [3]Institute of Virology, Bonn, Germany, [4]Department of Molecular Immune and Cell Biology, Life and Medical Sciences (LIMES) Institute, Bonn, Germany, [5]Institute of Structural Biology, Bonn, Germany, [6]6Department of Anesthesiology and Intensive Care Medicine, Bonn, Germany, [7]Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany.

Introduction: Type I interferon (IFN) production of plasmacytoid dendritic cells (pDCs) triggered by toll-like receptor (TLR) activation is essential for antiviral responses and autoimmune reactions. The mechanism how SOCS proteins regulate TLR7-mediated type I IFN production in pDCs was largely unknown. Therefore, we aimed to investigate the role of SOCSs in TLR7- type I IFN pathway in pDCs.
Materials and Methods: The regulation of TLR7-signaling and type I IFN production by SOCS1/3 in fresh human pDCs and pDC cell line were evaluated. HEK 293 cells overexpressing SOCS1/3 as well as their mutants were conducted for signaling investigation.
Results: TLR7 activation induced the expression of SOCS1 and SOCS3 in human pDCs, SOCS1 and SOCS3 intensely dampened TLR7-mediated type I IFN production through targeting interferon regulatory factor (IRF) 7, a pivotal transcription factor of the TLR7 pathway. Further study revealed SOCS1 and SOCS3 bound IRF7 through the SH2 domain to promote its proteasomal degradation by lysine 48-linked polyubiquitination.
Conclusion: Our results demonstrate that SOCS1/3-mediated ubiquitination and degradation of IRF7 directly regulates TLR7 signaling and type I IFN production in pDCs. This mechanism might be targeted by therapeutic approaches to either enhance type I IFN production in antiviral treatment or decrease type I IFN production in the treatment of autoimmune diseases (The paper based on the study was recently accepted by the Journal of Immunology).

The dialogue between mast cells and B lymphocytes may precipitate atherosclerosis complications

A. Loste[1,2], *K. Guedj*[3], *M. Clement*[3], *S. Delbosc*[3], *M. Morvan*[3], *G. Even*[3], *A. Gaston*[3], *M. Arock*[4], *A. Eggel*[5], *J. B. Michel*[3], *G. Caligiuri*[3,6], *A. Nicoletti*[3,2], *M. Le Borgne*[3,2];
[1]*INSERM U1148, Paris, France,* [2]*Université Paris Diderot, Université Sorbonne Paris Cité, Paris, France,* [3]*INSERM U1148 "Laboratory for Vascular Translational Science", Paris, France,* [4]*CNRS U8147 "Laboratoire de biotechnologies et pharmacologie génétique appliquée", Cachan, France,* [5]*Institute of Immunology, University of Bern, Bern, Switzerland,* [6]*Assistance Publique Hôpitaux de Paris, Hôpital Bichat, Paris, France.*

Atherosclerosis leads to cardiovascular events such as myocardial infarction or stroke. The immune effectors that are recruited to the atheromatous arteries are suspected to accelerate atherosclerosis complications. Notably, mast cells (MCs) and germinal center (GC) B cells accumulate in atheromatous arteries. Also, serum IgE levels are associated with the severity of arterial diseases. We hypothesize that the MC-B cell-IgE axis could form a local amplification loop that could precipitate the evolution of atherosclerotic lesions.
To test this hypothesis, we compared paired blood and arterial samples from patients with arteries displaying complicated atheroma (ACA) or having healthy arteries (HA).
We observed that (1) the IgE levels were higher in arteries from ACA than from HA, (2) the GC B cells and plasma cells of ACA were absent from the paired patient blood, and (3) the ACA GC stained positive for IgE. These results suggest that B cells differentiate into IgE-producing cells, locally, in diseased arteries. In addition, ACA MCs are activated, covered by IgE, and located in the vicinity of GC. MCs could therefore be activated by locally produced IgE and could also interact with B cells. Importantly, IgE-antigen complexes present only in conditioned medium from ACA induced the release of IL-4 by human MCs. IL-4 is a cytokine required for B cell class switching toward IgE.
Altogether, our results identify a local loop wherein IgE would trigger the production of IL-4 by MCs, which in turn would promote the IgE-class switching of maturating GC B cells.

A role for DPP4 in T cell-mediated vascular inflammation and Atherosclerosis

J. Zhong[1], *L. Duan*[1], *C. Xia*[1], *J. Varghese*[2], *G. Mihai*[3], *X. Rao*[1], *S. Rajagopalan*[1];
[1]*Case Western Reserve University, Cleveland, United States,* [2]*Ohio State University, Columbus, United States,* [3]*Harvard Medical School, Boston, United States.*

Dipeptidyl peptidase IV (DPP4), an ubiquitously expressed peptidase, plays an important role in regulating postprandial blood glucose by degrading incretin hormones such as GLP-1 and GIP. In this study, we provided evidence showing that hematopoietic cell derived DPP4 regulates vascular inflammation and atherosclerosis development by controlling T cell migration. T cells isolated from human peripheral blood, especially CD4+ T cells express high levels of DPP4. The expression of DPP4 on circulating CD4+ T cells was significantly increased in patients with atherosclerosis and positively correlated with plasma levels of non-HDL cholesterol and triglyceride. Hematopoietic deficiency of DPP4 protected *Ldlr*$^{-/-}$ mice from high fat diet-induced atherosclerosis progression, accompanied by a reduced T cell infiltration in aortic plaque. Chimeric mice with *Dpp4*$^{-/-}$ bone marrows showed an improved response to oral glucose challenge and a much less expression of DPP4 in aorta, suggesting bone marrow derived cells are an important source for DPP4 within the circulation and the aorta. Transwell assay showed migrated T cells had higher expression of DPP4 compared to unmigrated T cells. Both *in-vitro* and *in-vivo* migration assays suggest *Dpp4*$^{-/-}$ T cells had a reduced migratory ability. By using enzymatic DPP4 inhibitor, linagliptin, we found both enzymatic and non-enzymatic actions of DPP4 are involved in the regulation of T cell migration. Taken together, our results suggest that the expression of DPP4 on hematopoietic cells promotes vascular inflammation and atherosclerotic progression by regulating T cell migration. **Acknowledgement** This work was supported by grants from AAI (CIIF-8745), AHA (17GRNT33670485), and Boehringer Ingelheim (IIS2015-10485).

V-type immunoglobulin domain-containing suppressor of T-cell activation (VISTA) is a negative checkpoint regulator (NCR) involved in inhibition of T cell-mediated immunity. Expression changes of other NCRs (PD-1, PD-L1/L2, CTLA-4) during inflammation of the central nervous system (CNS) were previously demonstrated, but VISTA expression in the CNS has not yet been explored. Here, we report that in the human and mouse CNS, VISTA is most abundantly expressed by microglia, and to lower levels by endothelial cells. Upon TLR stimulation, VISTA expression was reduced in primary neonatal mouse and adult rhesus macaque microglia *in vitro*. In mice, microglial *VISTA* expression was reduced after lipopolysaccharide (LPS) injection, during experimental autoimmune encephalomyelitis (EAE), and in the accelerated aging *Ercc1*$^{\Delta/-}$ mouse model. After LPS injection, decreased *VISTA* expression in mouse microglia was accompanied by decreased acetylation of lysine residue 27 in histone 3 in both its promoter and enhancer region. ATAC-sequencing indicated a potential regulation of *VISTA* expression by Pu.1 and Mafb, two transcription factors crucial for microglia function. Finally, our data suggested that VISTA expression was decreased in microglia in multiple sclerosis lesion tissue, whereas it was increased in Alzheimer's disease patients. We are currently analysing VISTA expression in different types of MS lesions in detail. This study is the first to demonstrate that in the CNS, VISTA is expressed by microglia, and that VISTA is differentially expressed in CNS pathologies.

WS.C6.01.06

CLEC12A regulates neutrophil functioning in Rheumatoid arthritis

L. Whitehead[1], *P. Morvay*[1], *P. Redelinghuys*[1], *I. Dambuza*[1], *S. Ansboro*[1], *A. J. Roelofs*[1], *D. M. Reid*[1], *J. A. Willment*[1], *C. De Bari*[1], *I. B. McInnes*[2], *G. D. Brown*[1];
[1]*Institute of Medical Sciences, Aberdeen, United Kingdom,* [2]*Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom.*

Rheumatoid arthritis (RA) is a complex autoimmune disease characterised by progressive joint deformity and systemic co-morbidities. Myeloid cells such as neutrophils can be found in abundance in the synovial fluid of patients and RA animal models where they release neutrophil extracellular traps (NETs), reactive-oxygen species (ROS) and other inflammatory mediators aiding the progression of joint destruction. CLEC12A (or MICL, Myeloid inhibitory C-type lectin), an inhibitory receptor expressed on myeloid cells, has previously been linked to the control of joint sterile inflammation through recognition of monosodium urate microcrystals (MSU). In a murine model of RA, *Clec12a* knock-out (KO) mice exhibit increased joint inflammation, bone erosion and an amplified influx of neutrophils into the synovium. Adoptive transfer of *Clec12a* KO neutrophils into wild-type (WT) mice can transiently recapitulate the KO mice inflammatory defect. Functionally, *Clec12a* KO neutrophils release increased ROS and NETs in response to stimulation *in vitro*. Inhibition of NETosis *in vivo,* via treatment with BB-CL-Amidine, reduced joint inflammation in *Clec12a* KO mice. While we did not find any association of polymorphisms in *CLEC12A* with disease, a subset of RA patients presented with autoantibodies against CLEC12A in their serum. Importantly, administration of anti-CLEC12A antibodies to WT mice induces the same exacerbation of inflammation seen in the KO mice. Together these data suggest a novel mechanism whereby autoantibodies may interfere with an inhibitory pathway regulating neutrophil responses in the initiation of RA.

WS.C6.02 New mediators in inflammation and its resolution

WS.C6.02.01

PPAR-γ modulates macrophage response to lipopolysaccharide and glucocorticoids

M. Heming[1], *S. Gran*[1], *S. Jauch*[1], *L. Fischer-Riepe*[1], *A. Russo*[1], *L. Klotz*[2], *S. Hermann*[3], *M. Schaefers*[3], *J. Roth*[1], ***K. Barczyk-Kahlert***[1];
[1]*Institute of immunology, University of Muenster, Muenster, Germany,* [2]*Department of Neurology, University Hospital Muenster, Muenster, Germany,* [3]*European Institute for Molecular Imaging, University of Muenster, Muenster, Germany.*

We could previously show that treatment of monocytes with glucocorticoids (GC) does not cause a global suppression of monocytic effector functions, but rather induces differentiation of a specific anti-inflammatory phenotype. However, a relationship between GC treatment and PPAR-γ expression in macrophages has not been investigated so far. We established ER-Hoxb8-immortalized bone marrow-derived macrophages from *Pparg*$^{fl/fl}$ (WT) and *LysM-Cre Pparg*$^{fl/fl}$ (PPAR-γ KO) mice in this study. The ER-Hoxb8 system allows the generation of a homogeneous and well-defined population of resting macrophages. We could show that the loss of PPAR-γ resulted in delayed kinetic of differentiation of monocytes into macrophages and could also demonstrate that CD38 expression in macrophages depends on PPAR-γ. As expected, PPAR-γ KO macrophages displayed an increased pro-inflammatory phenotype upon long-term LPS stimulation and showed impaired phagocytosis compared to WT cells. GC treatment of macrophages led to the upregulation of PPAR-γ expression. However, there were no differences in GC-induced suppression of cytokines between both cell types. Intriguingly, GC treatment resulted in an increased *in vitro* migration only in PPAR-γ KO macrophages. Performing *in vivo* cell tracking in a cutaneous granuloma mouse model, we could confirm that PPAR-γ KO, but not WT, macrophages treated with GC showed increased recruitment to the site of inflammation. In conclusion, we could demonstrate that PPAR-γ exerts anti-inflammatory activities and shapes macrophage functions. Moreover, we identified a molecular link between GC and PPAR-γ and could show for the first time that PPAR-γ modulates GC-induced migration in macrophages.

WS.C6.02.02
Anti-inflammatory microRNA-146a protects mice from diet-induced metabolic disease

M. C. Runtsch[1,2], *M. Nelson*[2], *R. M. O'Connell*[2];
[1]*Trinity College, Dublin, Ireland,* [2]*University of Utah, Salt Lake City, Utah, United States.*

Identifying regulatory mechanisms that influence inflammation in metabolic tissues, including adipose and liver, are critical to developing treatments for metabolic diseases such as obesity and diabetes. Here, we investigated the protective role of microRNA-146a (miR-146a) during diet-induced obesity (DIO). This microRNA has been shown to be reduced in obese and type 2 diabetic patients and to regulate inflammation in other contexts. Results revealed that miR-146a-/- mice fed a high-fat diet (HFD) have increased weight gain and adiposity, exaggerated adipocyte hypertrophy, liver steatosis, and diabetes compared to WT controls. Pro-inflammatory gene expression, NFκB activation, and crown-like structure accumulation increased in adipose tissue in the absence of miR-146a, indicating that this microRNA regulates inflammation in metabolic tissues. miR-146a was highly expressed in the stromal vascular fraction (SVF) of adipose tissue, suggesting a role for this microRNA in adipose immune cells. *Ex vivo* RNA-sequencing of adipose tissue macrophages (ATMs) further demonstrated a requirement for miR-146a in regulating not only inflammatory pathways, but also cellular metabolism during obesity, a role which has not been previously identified. We determined that miR-146a regulates inflammation and cellular respiration in macrophages through its mRNA target *Traf6*. Altogether, these data demonstrate important functions for miR-146a in preventing obesity and metabolic disease by regulating immunometabolic pathways within macrophages.
Training for this project was funded by an NIH T32 in Metabolism and Diabetes, awarded to M.R.

WS.C6.02.03
IFNb is a novel effector cytokine in resolving inflammation

A. Ariel[1], *S. K. Satyanarayanan*[1], *S. Soboh*[1], *S. Butenko*[1], *J. Saadi*[1], *A. Kassis*[1], *N. Peled*[1], *N. Sher*[2], *S. Schif-Zuck*[1];
[1]*University of Haifa, Haifa, Israel,* [2]*The Tauber Bioinformatics Research Center, University of Haifa, Haifa, Israel.*

The engulfment of apoptotic leukocytes (efferocytosis) by macrophages during the resolution of inflammation is essential for tissue homeostasis and results in macrophage reprogramming/immune-silencing. However, a distinct subset of resolution phase macrophages loss their phagocytic potential, and hence were termed satiated macrophages. Here, we show using an unbiased RNA-Seq analysis that satiated macrophages express a distinct IFNβ-related signature. Unexpectedly, we found peritoneal IFNβ levels peaked during the onset as well as the resolution phase of peritonitis. Consequently, we determined IFNβ limited the onset of neutrophilic inflammation by enhancing PMN apoptosis. Moreover, IFNβ enhanced macrophage efferocytosis and reprogramming to a pro-resolving phenotype. These findings indicate for the first time that IFNβ is a key effector cytokine in resolving inflammation.

WS.C6.02.04
CXCL9(74-103) reduces neutrophil recruitment and joint inflammation in experimental arthritis

D. Boff[3], ***H. Crijns***[2], *R. Janssens*[2], *V. Vanheule*[2], *G. B. Menezes*[3], *S. Macari*[4], *T. A. Silva*[4], *F. A. Amaral*[1], *P. Proost*[2];
[1]*Instituto de Ciencias Biologicas, UFMG, Belo Horizonte, Brazil,* [2]*Rega Institute, KU Leuven, Leuven, Belgium,* [3]*Centro de Biologia Gastrointestinal, UFMG, Belo Horizonte, Brazil,* [4]*Faculdade de Odontologia, UFMG, Belo Horizonte, Brazil.*

The effect of the C-terminal CXCL9-derived peptide, CXCL9(74-103), on joint inflammation was investigated in a murine model of antigen-induced arthritis (AIA) in male C57BL/6J mice. Simultaneous intravenous injection of CXCL9(74-103) with a tibiofemoral challenge with methylated bovine serum albumin (mBSA) as antigen in mice immunized with mBSA, resulted in a reduced accumulation of leukocytes, mainly neutrophils, in the synovial cavity. Periarticular tissue levels of the neutrophil-attractant chemokines (CXCL1, CXCL2 and CXCL6) and interleukin (IL)-6 were decreased in mice treated with CXCL9(74-103) compared to non-treated AIA mice. In addition, joint and cartilage damage were substantially reduced upon CXCL9(74-103) treatment. CXCL9(74-103) competes with CXCL6 and CCL3 for binding to glycosaminoglycans *in vitro*. Confocal microscopy allowed to visualize rapid binding of CXCL9(74-103) to blood vessels in joints. Delayed (up to 6 hours) treatment with CXCL9(74-103) still reduced neutrophil accumulation in the joint, but did not affect chemokine and IL-6 concentrations. Further delay of treatment failed to affect cell recruitment and chemokine and cytokine levels. Taken together, we show that a chemokine-derived peptide controlled the massive accumulation of neutrophils in the joint of AIA mice through inhibition of the interaction between chemokines and glycosaminoglycans and diminished tissue damage. This research was supported by KU Leuven, the Hercules Foundation, CNPq Brazil and FWO Vlaanderen. H.C. holds a SB PhD fellowship of the FWO Vlaanderen, Belgium.

WS.C6.02.05
Inhibition of neutrophil extravasation with a CXCL9-derived glycosaminoglycan-binding peptide

P. Proost[1], *V. Vanheule*[1], *A. Mortier*[1], *H. Crijns*[1], *D. Boff*[2], *R. Janssens*[1], *S. Struyf*[1], *F. A. Amaral*[2], *M. M. Teixeira*[2];
[1]*KU Leuven, Rega Institute, Leuven, Belgium,* [2]*UFMG, Belo Horizonte, Brazil.*

Chemokines are presented on the endothelium and immobilized in the tissue at the site of inflammation through binding to glycosaminoglycans (GAGs). This interaction ensures high local concentrations of the produced chemokines, prevents their diffusion and inhibits proteolytic degradation. Subsequently, chemokines interact with their G protein-coupled receptor(s) (GPCRs), which results in adhesion of leukocytes and extravasation through the endothelium. The binding of chemokines to GAGs has been proven indispensable for chemokine activity in vivo. We discovered that the COOH-terminal tail of CXCL9 has potent GAG-binding properties. In addition, synthetic CXCL9-derived peptides competed with active chemokines for GAG binding in an ELISA-like heparin binding assay and inhibited the in vivo recruitment of neutrophils towards the major human neutrophil attractant IL-8 or CXCL8 injected in the peritoneum or the knee cavity of mice. Reducing the length of the CXCL9 peptide, especially when one of the GAG-binding motifs was deleted, gradually decreased the capacity to compete with CXCL8 for GAG binding. Using intravital microscopy, we showed that the CXCL9 peptide coats the endothelial cell surface of blood vessels in vivo thereby inhibiting CXCL8-induced neutrophil adhesion in the murine cremaster muscle model. Intravenous application of the CXCL9-derived peptide resulted in inhibition of MSU crystal-induced neutrophil migration to the knee cavity in a mouse model of gout. In conclusion, we identified an alternative approach for inhibitors of chemokine - GPCR interactions to target the chemokine system to reduce inflammation.

WS.C6.02.06
Mechanisms by which lung surfactant protein SP-A amplifies IL-4-mediated effects on alveolar macrophages

C. Casals[1,2], *B. García-Fojedo*[2,1], *C. Montero-Fernández*[1,2], *C. Stamme*[3,4], *C. M. Minutti*[2,5];
[1]*Complutense University of Madrid, Madrid, Spain,* [2]*Biochemical Center of Respiratory Diseases (CIBERES), Madrid, Spain,* [3]*Leibniz Center for Medicine and Biosciences, Borstel, Germany,* [4]*University of Lübeck, Lübeck, Germany,* [5]*The Francis Crick Institute, London, United Kingdom.*

The phenotype of alveolar macrophages (aMϕs) is determined in part by the alveolar environment. We recently reported that aMϕs switch their phenotype by integrating IL-4 and lung-specific signals that lead to activation of tissue repair programs. Surfactant protein SP-A is a lung factor that amplifies IL-4Rα-dependent activation and proliferation of aMϕs via myosin18A receptor (Myo18A). However, the mechanism by which SP-A and IL-4 synergistically enhance activation and proliferation of aMϕs remains elusive.
Here we show that SP-A activated PI3K through binding to Myo18A receptor; accordingly, blocking PI3K activity or Myo18A receptor abrogated SP-A´s effects on IL-4 signaling. SP-A-dependent activation of PI3K and subsequent phosphorylation of its downstream effectors Akt, TSC-mTORC1, GSK3β, and PKCζ amplified IL-4-mediated aMϕ proliferation and/or alternative activation. On the one hand, SP-A sustained the PI3K-Akt-mTORC1 signaling pathway triggered by IL-4. Both alternative activation and proliferation of aMϕs induced by SP-A+IL-4 are inhibited by Akt inhibitor VIII, torin1 (mTORC1/mTORC2 inhibitor), and rapamycin (mTORC1 specific inhibitor). Our results also indicate that SP-A increased Akt-dependent phosphorylation of GSK3β, which abrogates its role in inhibiting proliferation. On the other hand, the SP-A/Myo18A/PI3K/PKCζ axis was involved in enhancing IL-4-dependent STAT6 activation and arginase activity. PKCζ inhibition by PKCζ pseudosubstrate was able to reduce IL-4+SP-A-driven p-STAT6 and alternative activation, but not proliferation.
In conclusion, SP-A activates PI3K-dependent coordinated signaling pathways that amplify IL-4 actions in cell proliferation and acquisition of effector functions.
This study was supported by Spanish Ministry of Economy and Competitiveness (SAF2015-65307-R) and Institute of Health Carlos III (CIBERES CB06/06/0002).

WS.C6.03 Immune cells in tissue fibrosis

WS.C6.03.01
Plasmacytoid dendritic cells promote lung and skin fibrosis

R. R. Singh, *S. Kafaja, A. Divekar, R. Saggar, F. Abtin, D. Khanna, D. Furst, I. Valera;*
David Geffen School of Medicine, UCLA, Los Angeles, United States.

Fibrosis is the end-result of most inflammatory conditions, but its pathogenesis remains unclear. Here, we investigated the role of plasmacytoid dendritic cells (pDC) in the pathogenesis of systemic fibrosis using the bleomycin-induced skin and lung fibrosis model and clinical samples from patients with systemic sclerosis (SSc). We demonstrate that in animals and humans with systemic fibrosis, pDCs are unaffected or reduced systemically (spleen/peripheral blood) but they increase in the affected organs (lungs/skin/bronchoalveolar lavage). Depletion of pDCs in animals ameliorated bleomycin-induced lung and skin lung fibrosis, and reduced infiltration with B-cells, T-cells, and natural killer T-cells in the affected organs but not in spleen. pDC-depleted bleomycin-injected mice also had a reduced expression of genes and proteins involved in chemotaxis, dendritic cell differentiation, inflammation, and fibrosis in the lungs as compared to controls. In resonance with animal findings, the frequency of pDCs in the lungs of patients with SSc correlated with the severity of lung disease, and with the frequency of $CD4^+$ and $IL\text{-}4^+$ T-cells in the lung. Finally, treatment with a tyrosine kinase inhibitor imatinib that has been reported to reduce and/or prevent deterioration of skin and lung fibrosis profoundly reduced pDCs in lungs but not in peripheral blood of patients with systemic sclerosis. These observations suggest a role of pDCs in the pathogenesis of systemic fibrosis and identify the increased trafficking of pDCs to the affected organs as a potential therapeutic target in fibrotic diseases.

WS.C6.03.02
S100A8/A9 promotes parenchymal damage and renal fibrosis in obstructive nephropathy

***A. Tammaro**;*
AMC, Amsterdam, Netherlands.

Despite advances in our understanding of the mechanisms underlying progression of chronic kidney disease and the development of fibrosis, only limited efficacious therapies exist. The calcium binding protein S100A8/A9, is a damage-associated molecular pattern which can activate TLR4 or RAGE. Activation of these receptors is involved in the progression of renal fibrosis, however the role of S100A8/A9 herein remains unknown. Therefore, we analysed S100A8/A9 expression in patients and mice with obstructive nephropathy and subjected wild-type and S100A9 KO mice, lacking the heterodimer S100A8/A9, to Unilateral Ureteral Obstruction (UUO). We found profound S100A8/A9 expression in granulocytes that infiltrated human and murine kidney, and enhanced renal expression over time following UUO. S100A9 KO mice were protected from UUO-induced renal fibrosis, independently of leukocyte infiltration and inflammation.
Loss of S100A8/A9 protected tubular epithelial cells from UUO-induced apoptosis and critical epithelial-mesenchymal transition steps. In vitro studies revealed S100A8/A9 as a novel mediator of epithelial cell injury, through loss of cell polarity, cell cycle arrest and subsequent cell death. In conclusion, we demonstrate that S100A8/A9 mediates renal damage and fibrosis presumably through loss of tubular epithelial cell contacts and irreversible damage. Suppression of S100A8/A9 could be a therapeutic strategy to halt renal fibrosis in patients with chronic kidney disease.

WS.C6.03.03
CXCL4 drives inflammation and fibrosis on monocyte-derived dendritic cells through transcriptional and epigenetic imprinting

***S. C. Silva-Cardoso**[1], W. Tao[1], C. Angiolilli[1], A. Lopes[1], C. Bekker[1], J. van Laar[1], E. Hack[1], R. de Boer[2], M. Boes[1], A. Pandit[1], T. Radstake[1];*
[1]University Medical Center, Utrecht, Utrecht, Netherlands, [2]Theoretical Biology group, University Utrecht, Utrecht, Netherlands.

Accumulation of extracellular matrix (ECM) or fibrosis is one of the hallmarks that characterizes the pathogenesis of systemic sclerosis (SSc), together with immune dysregulation and small vessel vasculopathy. CXCL4 (Chemokine CXC motif ligand 4) levels are increased in SSc patients and correlated with skin and lung fibrosis. We and others shown that CXCL4 modulates phenotype and function of immune cells, however how CXCL4 modulates immune cell responses remains unclear. Here we investigated the impact of CXCL4 exposure on the transcriptome and DNA methylation during monocyte-derived dendritic cells (moDCs) differentiation and stimulation with polyI:C. Integration of high-throughput data reveals that CXCL4 drives to dramatic changes on the transcriptome and DNA methylation. This is reflected in the dysregulation of metabolic pathways, HIF-1 signaling, innate and adaptive immune pathways. Also, CXCL4 potentiates a novel function to moDCs, namely the production of ECM molecules, such as fibronectin (FN1) and TGFβ1. CXCL4 exposure results in epigenetic imprinting during moDC differentiation and gene regulatory network analysis reveal that CXCL4 dysregulates key transcriptional regulators. In conclusion, we show that CXCL4 besides driving to dramatic changes on moDC phenotype and function, this chemokine is the first endogenous ligand that leads to innate immune training. Interestingly, we found for the first time the direct implication of CXCL4 on the production of ECM by moDCs, thereby underscoring the role of CXCL4 in inflammatory and fibrotic conditions such as SSc. Supported by: Portuguese FCT No.SFRH/BD/89643/2012 (SCSC); China Scholarship Council (CSC) No.201606300050 (WT); ERC starting grant (CIRCUMVENT) and Arthritis foundation grant (TRDJR)

WS.C6.03.04
Liver sinusoidal endothelial cells trigger CD8 T cell mediated liver failure and herald liver regeneration

***M. Luedemann**[1], A. Goroi[2], L. A. D'Alessandro[2], S. Donakonda[1], U. Klingmueller[2], P. A. Knolle[1];*
[1]Institute of Molecular Immunology and Experimental Oncology, Technical University of Munich, Munich, Germany, [2]German Cancer Research Center, Heidelberg, Germany.

Introduction: Liver-sinusoidal-endothelial-cells (LSECs) have unique immune features that enable them to coordinate local hepatic immune responses. Recently, we showed that LSECs trigger fulminant viral hepatitis through antigen cross-presentation to CD8 T cells leading to perforin-dependent LSEC-killing. This results in perfusion-deficits causing liver-failure. Here, we address whether LSECs also contribute to liver regeneration by HGF-expression. **Material and Methods:** Primary cell cultures of LSEC were established to investigate HGF-expression, proteomics/secretomics of *in vitro* stimulated LSECs for determination of their pro-regenerative potential, *in vitro* LSEC cross-presentation to T cells and its contribution to HGF production. **Results:** Exposing LSECs to dying hepatocytes, extracellular ATP, or other P2X7 receptor-ligands failed to induce HGF-production excluding a sentinel role for local cell death promoting liver regeneration. However, LSECs produced HGF after IL-6 cluster-signalling in a dose-dependent fashion. Since IL-6 cluster-signalling is induced in LSECs upon mutual activation during cross-presentation to CD8 T cells, HGF levels were also increased after LSEC-activation of CD8 T cells. LSEC Proteome/secretome analysis revealed that upon IL-6 cluster-signalling pro-HGF levels decreased and levels of matured HGF increased, consistent with increased enzymatic activity upon IL-6 cluster-signalling of e.g. urokinase, to convert inactive pro-HGF into bioactive matured HGF. **Conclusion:** We discovered a pivotal role for LSEC in triggering T cell-mediated liver damage but also promoting liver regeneration through production of bioactive HGF. Generation of bioactive HGF by LSECs in response to local T cell activation may act in a pre-emptive fashion to kickstart liver regeneration already at the time of impending immune-mediated liver damage.

WS.C6.03.05
NLRP3- A key in the mediation of colitis into colitis-associated colorectal cancer

***A. P. Perera**, R. Eri;*
Shool of Health Sciences, Launceston, Australia.

Ulcerative colitis is a known risk for development of colorectal cancer but the exact mechanism of how chronic inflammation induce cancer has not been established. Many studies have indicated a role for NLRP3 inflammasome in colitis and tumorigenesis but the results have been controversial due to different chemical models of colitis induction and altered microbiota. To address the inconclusive role of NLRP3 we have designed the first murine model deficient in NLRP3 in a spontaneous chronic colitis mouse model Winnie (*Muc2* mutant). Extensive studies done in Winnie has proven it to be arguably the best available murine model to study ulcerative colitis and its pathogenesis. Our results show colon tumorigenesis in Winnie x NLRP3$^{-/-}$ with high burden of colonic polyps starting at 12 weeks. NLRP3$^{-/-}$x Winnie mice have significantly shorter colons, and a higher ratio of colon weight to length indicating the severity of colitis. Histological examination NLRP3$^{-/-}$x Winnie colon revealed differentiated adenocarcinoma with high-grade dysplasia and hyperplasia regions. Extracted RNA from colonic segments was used for analysis of colorectal cancer biomarker gene expression using PCR micro array. Colon organ culture supernatants were assayed via Bio-Plex for proinflammatory cytokines. Flow cytometry was done to immunophenotype T cells, B cells, neutrophils and natural killer cells in *WinniexNlrp3*$^{-/-}$. We analysed NLRP3$^{-/-}$x Winnie faecal metabolomics and characterized the faecal microbiota with 16S rRNA to identify specific microbial signature of colitis associated colon cancer. Our results describes the role of NLRP3 inflammasome in colorectal cancer leading to the development of novel therapeutic tools.

WS.C6.03.06
The IgE-FcεR1 axis strongly promotes epithelial hyperplasia and inflammation-driven skin carcinogenesis

***M. Hayes**, S. Ward, L. Wang, R. Castro Seoane, G. Crawford, J. Strid;*
Imperial College, London, United Kingdom.

The skin is a potent site for induction of type 2 immunity and IgE. Previous work has shown that accumulation of IgE effector cells in the skin is a consistent hallmark of skin perturbation and inflammation. Little is however known about the physiological role of IgE-carrying cells in the skin. Here, we examine the role of IgE and IgE effector cells in skin inflammation and epithelial carcinogenesis driven by chronic inflammation. We show that the inflammation-driven outgrowth of skin tumours is highly dependent on IgE and FcεRI^{+} effector cells. Mice lacking IgE or FcεRI developed significantly fewer and smaller tumours in a two-stage chemical carcinogenesis model. During the 'tumour-promoting' skin inflammation, high numbers of IgE-carrying basophils and mast cells accumulated in the skin whereas basophils selectively also infiltrated the tumours. Skin basophils were more immune active than mast cells and expressed high levels of IL-4, IL-6, IL-13, histamine and prostaglandins. The production of type 2 cytokines, as well as release of histamine was critically dependent on IgE and FcεRI. Further *in vivo* and *in vitro* analysis demonstrated that basophils, in an IgE-dependent manner, induced keratinocyte activation, proliferation and differentiation. Similar results were found when primary keratinocytes were cultured with histamine alone, suggesting that the keratinocyte response was mainly induced via engagement of histamine receptors. Collectively, this work demonstrate that IgE effector cells, predominantly basophils, exacerbate skin inflammation, induce epidermal hyperplasia and play a key role in promoting inflammation-driven carcinogenesis.

WS.D1.01.01
Transcription factor c-Maf is required for the control of Th17 cell responses by intestinal regulatory T cells

***H. Hussein**, S. Denanglaire, Y. Ajouaou, O. Leo, F. Andris;*
Laboratory of Immunobiology, Gosselies, Belgium.

Intestinal Tregs selectively inhibit immune responses directed against commensal microorganisms and allow responses against pathogens, thereby maintaining intestinal homeostasis and avoiding chronic inflammation. Recent observations suggest that tissue-resident Tregs are a specialized subset of Tregs whose phenotype and function are strongly influenced by their environment. In contrast to most splenic Tregs, intestinal Tregs express high levels of c-Maf, a bZIP transcription factor involved in the differentiation and function of multiple helper T cell subsets.
Ablation of c-Maf in Tregs results in the development of spontaneous colitis, characterized by a rectal prolapse, increased Th17-associated cytokine expression and expansion of Th17 cells in the intestine. The increased Treg percentage suggests that the spontaneous colitis is a consequence of an altered Treg function rather than a quantitative defect. RORγt$^+$ Tregs are induced in the intestine by the microbiota. Their colocalization with Th17 cells and high IL-10 expression levels makes them particularly apt at controlling Th17 responses. Our results show the loss of RORγt$^+$ Tregs in the intestine of c-Maf deficient mice, suggesting a selective role for c-Maf in the differentiation of this subset. Current investigations aim to decipher the signaling pathways leading to c-Maf expression in gut-associated Tregs and identify genes controlled by c-Maf. We hope that our study will contribute to a better understanding of tissue resident Treg origin and function both in health and disease.
This work is supported by a Fund for Research Training in Industry and Agriculture fellowship from the Fund for Scientific Research.

WS.D1.01.02
Induction of intestinal Th22 cells by segmented filamentous bacteria

***U. Roy**[1], E. Galvez[1], A. Gronow[1], M. Basic[2], A. Bleich[2], S. Huber[3], T. Strowig[1];*
[1]Helmholtz Centre for Infection Research, Braunschweig, Germany, [2]Medical University Hannover, Hannover, Germany, [3]University Hospital Hamburg-Eppendorf, Hamburg, Germany.

Heterogeneous effector CD4+ T cells play an important role in modulating inflammation via their ability to produce distinct cytokines. Recently, Th22 cells have been identified as an important contributor of protection against enteropathogenic infection. While commensals inducing intestinal Th1, Th17 and Treg cells have been identified and extensively studied, microbiota-induced Th22 cells have not been reported yet.
To assess the influence of microbiota composition to shape anti-bacterial IL-22 production, we utilized cytokine knock-in reporter mice (IL-22BFP x IL-17AGFP) colonized with different SPF and non-SPF communities as well as colonization with segmented filamentous bacteria (SFB). Early after enteric *Salmonella* Typhimurium (*S.* Tm) infection CD4+ T cells are detected that are able to secrete *in vivo* IL-22, alone or together with IL-17A and we show that their abundance is modulated by microbiota composition. We demonstrate that SFB colonization is sufficient to induce Th22 cells and that they share a similar TCR V_β14 enrichment than Th17 cells. Comparison of gene expression in IL-17A and IL-22 producing CD4+ T cells revealed significant differences between Th17 cells present in the steady state in the terminal ileum as well as Th22 and Th17 cells present during *S.* Tm infection, such as the expression of IFN_γ and IL-17F. In addition, we provide evidence that Th22 cells develop independent of IL-17 production using IL-17 fate mapping mice.
Together, our study identifies that SFB induces Th22 cells and that they differ from Th17 cells in their development and during infections in their gene expression profiles.

WS.D1.01.03
Microbiota sensing by a Mincle-Syk axis in dendritic cells promotes intestinal immune barrier via the steady-state regulation of IL-17 and IL-22

*M. Martínez-López[1], S. Iborra[1], A. Mastrangelo[1], R. Conde-Garrosa[1], C. Danne[2], D. M. Reid[3], G. D. Brown[3], D. Bernardo[4], S. Leibundgut-Landmann[5], **D. Sancho**[1];*
[1]CNIC, Madrid, Spain, [2]Kennedy Institute for Rheumatology, Oxford, United Kingdom, [3]University of Aberdeen, Aberdeen, United Kingdom, [4]Hospital Universitario de la Princesa, Madrid, Spain, [5]University of Zurich, Zurich, Switzerland.

Maintenance of the intestinal barrier function keeps homeostatic host-microbiota relationship and depends on the cytokines IL-17 and IL-22. Production of these cytokines by type 17 T-helper (Th17) cells and group 3 innate lymphoid cells (ILC3) is influenced by the gut microbiota in steady state. However, the host pathways that sense commensal microbiota to trigger these immune responses need further exploring. Here, we show that a Syk kinase-coupled signaling pathway in dendritic cells (DCs) is critical for commensal-dependent production of intestinal IL-17 and IL-22. We identify Mincle as a Syk-coupled receptor that detects mucosal-resident commensals and triggers IL-6 and IL-23p19 expression, cytokines that regulate intestinal Th17 and ILC3 function. Absence of Mincle or Syk in DCs impairs antimicrobial peptide and IgA production at the intestinal epithelium. Thus, sensing of commensals by Mincle and Syk in DCs reinforces intestinal immune barrier and limits systemic microbial translocation, promoting host-microbiota mutualism.

WS.D1.01.04
Control of RORγt$^+$ regulatory T cell differentiation and intestinal immune homeostasis is dependent on the transcription factor c-Maf

***C. Neumann**[1,2], J. Blume[3,4], A. Vasanthakumar[3,4], A. Beller[1], U. Roy[5], Y. Liao[6,7], F. Heinrich[1], C. Stehle[1], G. A. Heinz[1], P. Maschmeyer[1], T. Sidwell[3,4], Y. Hu[6,7], D. Amsen[8], C. Romagnani[1], H. Chang[1], A. Kruglov[1], M. Mashreghi[1], W. Shi[6,7], T. Strowig[5], S. Rutz[9], A. Kallies[3,4], A. Scheffold[1,2];*

Foxp3$^+$ regulatory T (Treg) cells are essential for immunological tolerance and homeostasis. In peripheral tissues, Treg cells acquire enhanced suppressive functions and co-opt distinct transcriptional modules, allowing context and tissue-dependent immune regulation. Here we show that the transcription factor c-Maf was highly expressed by effector Treg cells and controlled their IL-10 production. In the intestine, c-Maf was required for the differentiation of RORγt$^+$ microbiota-dependent Treg cells, and restricted their production of inflammatory cytokines. Molecular profiling revealed that c-Maf regulated expression of key genes of the transcriptional signature of intestinal Treg cells, including *Rorc* and *Il10*. Consequently, Treg cell-specific loss of c-Maf resulted in a selective deregulation of intestinal Th17 responses, which protected mice from acute colon inflammation. In addition, Treg cell-specific c-Maf-deficiency reduced the diversity and altered the composition of the intestinal microbiota. Importantly, colonization of wild-type germ-free mice with reprogrammed microbiota from Treg-specific c-Maf-deficient mice similarly skewed the balance of RORγt$^+$ Treg/Th17 cells and increased colitis resistance, demonstrating that c-Maf-dependent Treg cells controlled host-microbial symbiosis through an interdependent regulatory loop. Thus, our study identifies a key role of c-Maf in preserving the identity and function of intestinal Treg cells, essential for the control of intestinal immune homeostasis and inflammation.

WS.D1.01.05
IL-17 receptor signaling in intestinal secretory progenitor cells regulates epithelial cells regeneration

***P. Kumar**, M. Beaupre, K. Chang, A. Banerjee, T. Chu, H. Huang, X. Lin, S. Khalid, P. Joshi, A. Bialowska, V. Yang;*
Stony Brook University, Stony Brook, United States.

Introduction IL-17A, derived from Th17 cells, plays an important role in intestinal host defense. However, the interaction and potential molecular synergies between IL-17A and epithelial cell lineages, intestinal stem cells (ISCs), and progenitors of the intestine remain unclear. Materials and Methods *Il17ra$^{fl/fl}$;Villin-cre* and *Il17ra$^{fl/fl}$;Atoh1-cre* mice were generated. A Dextran Sulfate Sodium (DSS)-mediated epithelial injury model was used. RT-PCR, immunofluorescence, and primary organoid cultures were used to study impact of IL-17A signaling on specific cell types. Results Our data show that knockout of IL-17RA from the entire intestinal epithelia in *Il17ra$^{fl/fl}$;Villin-cre* mice are more susceptible to DSS-induced colitis. We found a defect in secretory goblet cell number in DSS-administered *Il17ra$^{fl/fl}$;villin-cre* mice. Atonal homolog 1 (Atoh1) is a transcription factor required for intestinal secretory including goblet cell differentiation. Our preliminary data show a more severe DSS-induced colitis in *Il17ra$^{fl/fl}$;Atoh1-cre* mice, suggesting secretory progenitor or mature secretory epithelium-specific IL-17RA signaling regulates epithelial cell regeneration. UEA-1 and alcian blue stained colon tissues revealed reduced goblet cell number in *Il17ra$^{fl/fl}$;Atoh1-cre$^+$* mice. Next, we found reduced Sox9 expression as well as reduced Ki67$^+$ stained cells in the colon of *Il17ra$^{fl/fl}$;Atoh1-cre$^+$* mice. Furthermore, we show that IL-17A does not regulate mature goblet cell-specific functions. These data indicate a stem cell-specific defect. Based on this observation, organoids from *Il17ra$^{fl/fl}$;Atoh1-cre* mice were continuously stimulated with IL-17A. Continuous IL-17A stimulation lead to reduced organoid budding/morphogenesis, further confirming a IL-17A-mediated role in Atoh1-dependent epithelial cell regeneration. Conclusion Our data show a novel role of IL-17A in regulating Atoh1-dependent epithelial cell regeneration.

Anti-commensal IgG augments intestinal inflammation in ulcerative colitis via IL-1 beta-dependent type 17 immunity

T. Castro-Dopico[1], *T. W. Dennison*[1], *J. R. Ferdinand*[1], *R. Mathews*[1], *D. Clift*[2], *B. Stewart*[1], *C. Jing*[1], *K. Strongili*[3], *E. Monk*[1], *K. Saeb-Parsy*[4], *C. E. Bryant*[5], *M. Parkes*[3], *M. Clatworthy*[1];
[1]*Molecular Immunity Unit, Department of Medicine, University of Cambridge, Cambridge, United Kingdom,* [2]*MRC Laboratory of Molecular Biology, Cambridge, United Kingdom,* [3]*Division of Gastroenterology, Cambridge Universities NHS Foundation Trust, Cambridge, United Kingdom,* [4]*Department of Surgery, University of Cambridge, Cambridge, United Kingdom,* [5]*Department of Veterinary Medicine, University of Cambridge, Cambridge, United Kingdom.*

Inflammatory bowel disease (IBD) is a chronic relapsing condition with two major subtypes, Crohn's disease (CD) and ulcerative colitis (UC), both driven by aberrant immune responses to commensals. One of the strongest genetic associations in UC is with *FCGR2A*, the gene encoding an activating Fcγ receptor. FcγRs mediate the cellular effector functions of IgG. The UC-associated FcγRIIA-R131 variant is protective and reduces affinity for IgG. Since IgA is the dominant mucosal antibody, the role of IgG and FcγRs in IBD pathogenesis has been largely overlooked. Here we sought to investigate anti-commensal IgG responses in patients with UC and to determine the mechanism by which local IgG-FcγR engagement might contribute to intestinal inflammation in UC and murine models of dextran sodium sulfate (DSS)-induced colitis. We observed a significant increase in IgG-bound commensals and activated FcγR signalling pathways in UC patients and DSS-inflamed colon. The genes most robustly correlated with *FCGR2A* expression were *IL1B* and *CXCL8*, with hierarchical clustering confirming *IL1B* as the gene most closely associated with *FCGR2A*. Intestinal macrophages were the principle source of IL-1β and *ex vivo* stimulation with IgG immune complexes induced ROS-dependent IL-1β production mediated by activation of the NLRP3 inflammasome. *In vivo* manipulation of the macrophage FcγR activating/inhibitory ratio in mice determined IL-1β and Th17 cell induction. Finally, IL-1β blockade in mice with a high FcγR A/I ratio reduced IL-17 and IL-22-producing T cells and the severity of colitis. Our data reveal that commensal-specific IgG contributes to intestinal inflammation via FcγR-dependent, IL-1β-mediated Th17 activation.

The microbiota protects against respiratory infection via GM-CSF signaling

T. B. Clarke*, R. L. Brown, R. P. Sequeira;*
Imperial College London, London, United Kingdom.

The microbiota promotes resistance to respiratory infection, but the mechanistic basis for this is poorly defined. Here, we identify members of the microbiota that protect against respiratory infection by the major human pathogens *Streptococcus pneumoniae* and *Klebsiella pneumoniae*. We show that the microbiota enhances respiratory defenses via granulocyte-macrophage colony-stimulating factor (GM-CSF) signaling, which stimulates pathogen killing and clearance by alveolar macrophages through extracellular signal regulated kinase signaling. Increased pulmonary GM-CSF production in response to infection is primed by the microbiota through interleukin-17A. By combining models of commensal colonization in antibiotic-treated and germ-free mice, using cultured commensals from the Actinobacteria, Bacteroidetes, Firmicutes, and Proteobacteria phyla, we found that potent Nod-like receptor-stimulating bacteria in the upper airway (*Staphylococcus aureus* and *Staphylococcus epidermidis*) and intestinal microbiota (*Lactobacillus reuteri, Enterococcus faecalis*, *Lactobacillus crispatus* and *Clostridium orbiscindens*) promote resistance to lung infection through Nod2 and GM-CSF. Our data reveal the identity, location, and properties of bacteria within the microbiota that regulate lung immunity, and delineate the host signaling axis they activate to protect against respiratory infection.

WS.D1.02.02
Hypercholesterolemia affects macrophage metabolism and function

J. Baardman[1], *M. van Weeghel*[1], *S. Verberk*[2], *K. H. Prange*[1], *M. P. de Winther*[1], ***J. Van den Bossche***[2];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*VU University Medical Center, Amsterdam, Netherlands.*

Metabolic reprogramming has emerged a crucial regulator of immune cell activation but how systemic metabolism influences immune cell metabolism and function remain to be investigated. Here we demonstrate that blood leukocytes from familial hypercholesterolemia (FH) patients show reduced expression of genes related to oxidative phosphorylation. To investigate the effect of dyslipidemia on immune cell metabolism, we performed in-depth transcriptional, metabolic and functional characterization of macrophages isolated from hypercholesterolemic mice. Systemicmetabolic changes in such mice translate into altered cellular macrophage metabolism and attenuates inflammatory macrophage responses. Apart from diminished maximal mitochondrial respiration, LPS-mediated induction of the pentose phosphate pathway (PPP) was reduced. Our observation that suppression of the PPP diminished LPS-induced cytokine secretion supports the notion that this pathway is a key feature of inflammatory macrophage responses. Overall, this study reveals that systemic and cellular metabolism are strongly interconnected and together dictate macrophage phenotype and function.

The T lymphocytes repertoire is divided into two major lineages, αβ and γδ T cells, that are defined by their T cell receptor (TCR) gene-segment usage. The MHC-like molecule MR1 presents Vitamin-B derivatives to mucosal-associated invariant T cells (MAIT). Using MR1 tetramers, we characterized a population of MR1-restricted human γδ T cells that included phenotypically diverse Vγ8-Vδ1, Vγ9-Vδ1 and Vγ8-Vδ3 subsets, all of which exhibited MR1 autoreactivity, independent on the nature of the bound ligand. The crystal structure of a γδTCR-MR1-antigen complex showed the γδTCR docked in a highly unusual manner that starkly contrasted all other TCR complex structures. The γδTCR bound under the MR1 antigen-binding cleft. Contacts were mediated largely by the TCR δ-chain and more surprisingly by the α3-domain of MR1. Our findings reshape our understanding of TCR recognition determinants and γδ T cells.

WS.D1.02.04
RNA helicase DDX3 is a potent inducer of type I interferon and adaptive immunity

M. Stunnenberg*, S. I. Gringhuis, T. B. Geijtenbeek;*
Academic Medical Center, Amsterdam, Netherlands.

Strong innate and adaptive immune responses are paramount to prevent infection. We have recently identified the RNA helicase human DEAD-box polypeptide 3 (DDX3) as a powerful pattern recognition receptor (PRR) to HIV-1 in dendritic cells (DCs). Here, we have investigated the capacity of DDX3 to induce potent innate and adaptive immune responses upon triggering with synthetic HIV-1-derived RNA ligands. DDX3 recognizes abortive HIV-1 RNA that is generated during HIV-1 transcription and encodes for the first 58-nucleotides of trans-activating protein Tat. Stimulation of DDX3 in DCs with synthetic abortive HIV-1 RNA induced IFNβ as well as IFN-stimulated genes such as TRIM5α and MxA. The type I IFN responses were functional as they strongly inhibited the replication capacity of HIV-1 in DCs. We next investigated whether DDX3 triggering with abortive RNAs also induce adaptive immune responses. DC treatment with abortive RNAs induced DC maturation and pro-inflammatory cytokine responses. Moreover, DCs stimulated with abortive RNAs that were co-cultured with peripheral blood lymphocytes enhanced CD4+ and CD8+ T cell proliferation, thus supporting a role for DDX3 in inducing adaptive immunity. Comparison between putative viral ligands for DDX3 and other RIG-I-like receptors (RLRs) identified the abortive RNAs as the most potent triggers of immune responses. Abortive RNAs can be used as novel adjuvants for vaccine design and immunotherapy studies, since subsequent triggering of DDX3 evokes strong and functional antiviral immune responses. Thus, we have identified DDX3 as pattern recognition receptor of the RIG-I-like family by sensing HIV-1 and other viruses. Aidsfonds grant number P-9906.

WS.D1.02.05
Recruitment of DC-SIGN$^+$ monocyte-derived dendritic cells in the skin for antigen delivery and adaptive immunity

S. T. Schetters*, L. J. Kruijssen, M. H. Crommentuijn, J. den Haan, Y. van Kooyk;*
VU University Medical Center, Amsterdam, Netherlands.

Delivery of antigenic compounds to dendritic cells remains key to vaccination efficacy against tumors and pathogens. We have investigated the C-type lectin, DC-SIGN, as a target on dendritic cells to efficiently deliver antigens for the initiation of protective adaptive immune responses. Here, we show that subcutaneous injection of the adjuvant MF59 attracts mDC-SIGN$^+$ antigen presenting cells to the skin for antigen delivery. We identify the time-dependent influx of neutrophils and monocytes, including MoDCs, to the skin. Next, targeting mDC-SIGN$^+$ skin-infiltrating cells with ovalbumin-coupled anti-mDC-SIGN antibody with adjuvant induces multifunctional antigen-specific CD8$^+$ T cells, as well as antigen-specific antibody responses. Interestingly, when the vaccine is administered directly with the adjuvant, cytotoxic CD8$^+$ T cell responses are preferred, whereas antibody production is boosted when the vaccine is delivered 24 hours after adjuvant vaccine site preconditioning. Hence, we demonstrate a unique approach to facilitate optimal antigen delivery and adaptive immunity shaped by a time-dependent sequence of vaccination events.

WS.D1.02.06

Enhanced trained immunity by targeting SHIP-1 in myeloid cells

P. Saz-Leal[1], *C. del Fresno*[1], *P. Brandi*[1], *S. Martínez-Cano*[1], *O. M. Dungan*[2], *J. D. Chisholm*[2], *W. G. Kerr*[2,3,4], *D. Sancho*[1];
[1]*Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain,* [2]*Department of Chemistry, Syracuse University, Syracuse, NY 13210, United States,* [3]*Department of Microbiology and Immunology, State University of New York (SUNY) Upstate Medical University, Syracuse, NY 13210, United States,* [4]*Pediatrics Department, SUNY Upstate Medical University, Syracuse, NY 13210, United States.*

Introduction: β-glucan-induced trained immunity in myeloid cells leads to long-term protection against secondary infections through activation of the Dectin-1/PI3K (Phosphoinositide 3-kinase) pathway. While previous studies have addressed the characterization of this phenomenon, strategies to boost trained immunity deserve further investigation. SHIP-1 is a hematopoietic-restricted inositol poly-phosphatase that limits PI3K activity and associates with Dectin-1. Thus, we wondered whether targeting SHIP-1 could modulate Dectin-1-mediated training.
Methods: Bone marrow-derived macrophages (BMDMs) from WT and LysM-*Cre*-SHIP-1 (LysMΔ*SHIP-1*) mice were subjected to a β-glucan-induced trained immunity *in vitro* model. Receptor expression, cytokine production, pathway activation and metabolic status were analyzed. *In vivo,* both WT and LysMΔSHIP-1 mice were trained with β-glucan or *Candida albicans* and either challenged with LPS to evaluate cytokine production or lethally infected with *C. albicans* to monitor protection. We also tested the effect of the SHIP-1 inhibitor 3AC (SHIPi) in our *in vitro* and *in vivo* models and in human peripheral blood mononuclear cells (PBMCs).
Results: β-glucan-trained SHIP-1-deficient macrophages enhanced TNFα production to a secondary LPS challenge, correlating with increased phosphorylation of Akt, targets of mTOR and elevated glycolytic metabolism. This enhanced training in SHIP-1-deficient macrophages relied on epigenetic modifications. Trained LysMΔ*SHIP-1* mice showed increased TNFα production upon LPS challenge *in vivo* and better protection against reinfection with *C. albicans*. Pharmacological inhibition of SHIP-1 enhanced trained immunity against *Candida* infection, in mouse macrophages and human peripheral blood mononuclear cells.
Conclusions: Our data establish a proof of concept for trained immunity improvement and a strategy to achieve it by targeting SHIP-1.

Intestinal dysbiosis driven by dietary trp deprivation limits myelin-reactive T cell responses in a murine multiple sclerosis model

J. K. Sonner[1], *M. Keil*[1], *M. Falk-Paulsen*[2], *R. Bharti*[2], *N. Mishra*[2], *M. Kramer*[1], *K. Deumelandt*[1], *L. Wolf*[1], *I. Oezen*[1], *T. V. Lanz*[1], *I. Brandao*[3], *F. Wanke*[4], *Y. Tang*[4], *J. G. Okun*[5], *F. Kurschus*[4], *C. Reinhardt*[3], *W. Wick*[5,1], *P. Rosenstiel*[2], *M. Platten*[6,1];
[1]*German Cancer Research Center, Heidelberg, Germany,* [2]*Institute of Clinical Molecular Biology, Kiel, Germany,* [3]*University Hospital Mainz, Mainz, Germany,* [4]*Institute of Molecular Medicine, Mainz, Germany,* [5]*University Hospital Heidelberg, Heidelberg, Germany,* [6]*University Hospital Mannheim, Mannheim, Germany.*

Multiple sclerosis (MS), the most common neurological disorder among young adults, is thought to be mainly driven by auto-reactive T cells that infiltrate the central nervous system (CNS). Recent data from preclinical studies suggest that dietary components profoundly affect self-reactive T cell responses even in remote organs such as the CNS. The essential amino acid tryptophan (trp) and its metabolites have been identified as important modulators of local and systemic immune responses. While previous studies focused on trp as a source for endogenous aryl hydrocarbon receptor (AHR) ligands, we addressed the question whether dietary trp deprivation itself regulates myelin-reactive T cell responses using the murine experimental autoimmune encephalomyelitis (EAE) model.
In this study we demonstrate that omission of protein, but also selectively trp from the diet protected from CNS autoimmunity. Dietary trp depletion did not prevent priming of myelin oligodendrocyte glycoprotein-reactive T cells, yet, attenuated encephalitogenicity of circulating T cells and prevented their infiltration into the CNS. Protection from EAE induction was independent of the host's ability to sense trp via the stress kinase general control non-derepressible 2 (GCN2), but was critically dependent on the presence of the gut microbiome. Dietary trp deprivation caused mild, but evident intestinal inflammation, and, as revealed by 16S rDNA sequencing, induced substantial dysbiosis of the gut microbiome composition.
In summary, our data provide an important insight into the regulation of autoimmunity by dietary constituents and subsequent perturbations of gut microbiome homeostasis.

WS.D1.03.02

Gut dysbiosis induces dendritic-cell traffic from colon to pancreatic lymph node: implications for activation of islet-reactive T cells in type 1 diabetes

R. Toivonen[1], *S. Silojärvi*[1], *S. Pöysti*[1], *E. Yatkin*[2], *A. Takeda*[1], *M. Miyasaka*[3,1], *A. Hänninen*[1,4];
[1]*University of Turku, Turku, Finland,* [2]*University of Turku Central Animal Laboratory, Turku, Finland,* [3]*Osaka University, Osaka, Japan,* [4]*Turku University Central Hospital, Turku, Finland.*

Studies in humans and mice suggest an important role for gut microbiota in the development of autoimmune type 1 diabetes (T1D). However, the exact mechanisms by which microbiota and gut immune system influence the development of T1D remain elusive. Using KikGR-reporter mice, we investigated the possible connection between the gut and pancreatic lymph nodes (PaLN) and the effects of dysbiosis on the traffic and activation of dendritic cells (DC) and T cells. We observed significant migration of dendritic cells (DC) from colon into colon-draining mesenteric lymph nodes (coMLN) but not to PaLN. A mild infection with *Citrobacter rodentium* allowed the same DC populations to appear also in PaLN, indicating that dysbiosis activates a route from colon to PaLN. *C. rodentium* also upregulated IFNγ production by T cells. Migrated DC expressed XCR1, CD11b and CD103, typical for gut-derived and cross-presenting DC. Furthermore, in NOD mice *C. rodentium* accelerated insulitis and upregulated TLR2, TLR4 and CXCL10 expression by islet cells. Our results are in evidence for a direct, dysbiosis-activated route for DC and soluble material from the gut to the PaLN via lymphatics. This route may be the missing link between dysbiosis and its potential effects on T1D.

WS.D1.03.03

Imaging mass cytometry reveals the microanatomical location of B cell subsets in human gut associated lymphoid tissue

T. Tull[1], *K. Todd*[2], *N. Petrov*[2], *R. Ellis*[2], *S. Heck*[2], *M. Bemark*[3], *J. Spencer*[1];
[1]*King's College London, London, United Kingdom,* [2]*Biomedical Research Centre, Guy's and St. Thomas' NHS Trust, London, United Kingdom,* [3]*Mucosal Immunobiology and Vaccine Center, University of Gothenburg, Gothenburg, Sweden.*

Human gut-associated lymphoid tissue (GALT) is important for host immune defence and for maintenance of homeostatic equilibrium throughout the gastrointestinal tract that is rich in antigens from the microbiota. Here we describe the use of imaging mass cytometry to delineate the microanatomical location of B cell subsets within GALT. Frozen sections from 3 human appendixes were stained simultaneously with 13 metal tagged antibodies and ablated using a Fluidigm Hyperion™ imaging mass cytometer. Pixels were extracted from the image and clustered using Cytobank™ software to identify B cell subsets that were re-plotted onto the original image. Marginal Zone B cells in GALT (CD27+IgM+IgD+) were localized on the mucosal aspect of the germinal centre co-aligned with their CD27-IgD+IgM+CD45RB+ precursor population and sparse naïve B cells. Class switched memory B cells formed a separate zone from the marginal zone B cells on the periphery of the lymphoid tissue extending around the T cell zone and up to the follicle associated epithelium (FAE). These data show that marginal zone B cells are present in the gut as in the spleen and that they are microanatomically separate from class switched memory B cells. IgM only B cells coaligned with both marginal zone and memory B cells consistent with data showing that they can be part of both populations. B cells in the FAE and cells expressing FcRL4 at the epithelial boundary were not of a single phenotype. This study demonstrates the power of imaging mass cytometry for accurate tissue mapping.

WS.D1.03.04

De novo fatty acid synthesis during mycobacterial infection is a prerequisite for the function of highly proliferative T cells, but not for dendritic cells or macrophages

L. Berod[1], *P. Stueve*[1], *L. Minarrieta*[1], *C. Hölscher*[2], *T. Sparwasser*[1];
[1]*Twincore, Hannover, Germany,* [2]*Forschungszentrum, Borstel, Germany.*

Mycobacterium tuberculosis (Mtb) is thought to interfere with macrophage lipid metabolism to ensure its persistence. In dendritic cells (DCs), fatty acid synthesis (FAS) has been suggested to permit optimal cytokine production and antigen presentation. We therefore determined the role of fatty acid metabolism in myeloid cells and T cells during BCG or Mtb infection, using genetic models allowing cell-specific deletion of acetyl-CoA carboxylase (ACC)1 and 2 in DCs, macrophages or T cells. Our results demonstrate that FAS is induced in DCs and macrophages upon BCG infection. However, absence of ACC1 or ACC2 did not influence the ability of DCs and macrophages to cope with infection. In contrast, mice with a deletion of ACC1 specifically in T cells fail to generate efficient Th1 responses and succumb early to Mtb infection. In summary, ACC1-dependent FAS is a crucial mechanism in T cells, but not DCs or macrophages, to fight mycobacterial infection.

WS.D1.03.05

Cutting and pasting in the immunoproteome of infected cells

*C. van Els[1], J. van Gaans-van den Brink[1], J. Liepe[2], H. Meiring[3], M. Mishto[4], A. Platteel[5], M. Poelen[1], **A. Sijts**[5];*
[1]Centre for Infectious Disease Control, National Institute for Public Health and the Environment, Bilthoven, Netherlands, [2]MPI for Biophysical Chemistry, Göttingen, Germany, [3]Intravacc, Bilthoven, Netherlands, [4]King's College London, London, United Kingdom, [5]Utrecht University, Utrecht, Netherlands.

Proteasomes play an important role in intracellular protein degradation. Peptide products resulting from proteasome-mediated proteolysis, may enter the MHC class I antigen processing pathway for display on the cell surface. This allows $CD8^+$ T cells to detect and react to intracellular aberrancies, such as infections. Recently, it was discovered that an unexpected large fraction of peptides, presented by cell surface MHC class I molecules on human cells, are spliced (hybrid) peptides generated by **P**roteasome-**C**atalyzed ligation of peptides / '**P**eptide **S**plicing' (**PCPS**). To examine whether spliced peptides are a target of $CD8^+$ T cells responding to infection, i) we have developed an *in silico* reverse immunology-based approach to identify proteasome-generated spliced epitopes within protein sequences. Applying this strategy to a murine *Listeria monocytogenes* infection model, we identified two novel spliced epitopes within one of the secreted bacterial proteins that were recognized by $CD8^+$ T cells of *L. monocytogenes*-infected mice. ii) in parallel, we have applied an immunoproteomics workflow to reveal the spliced compared to linear immunopeptidome presented by MHC class I molecules of Measles Virus infected cells. Mass spectrometry analysis of peptide fractions eluted from affinity-purified MHC class I molecules identified approximately 8000 MHC class I ligands in total, amongst which diverse linear as well as spliced MeV peptide sequences. Taken together, these studies demonstrate that PCPS expands the $CD8^+$ T cell response against intracellular pathogens by exposing spliced epitopes on the cell surface.

WS.D1.03.06

Functional bias of effector memory CD8 T cells underlies the pathogenesis of Hepatitis E Virus in the elderly

***J. Gouilly**[1], F. Abravanel[1,2], E. Bahraoui[1], N. Jabrane-Ferrat[1], J. Izopet[1,2], H. El Costa[1,2];*
[1]Centre de Physiopathologie Toulouse Purpan, Toulouse, France, [2]Laboratoire de Virologie, IFB, CHU Toulouse, Toulouse, France.

The occurrence of severe clinical symptoms upon Hepatitis E virus genotype 3 (HEV-3) infection increases with aging. While the infection is clinically silent in young adults, HEV-3 is often associated with acute icteric hepatitis and liver damage in senior people. Why some elderly patients develop symptomatic hepatitis E infection while others remain asymptomatic is yet to be defined. Herein, we aimed at elucidating the mechanisms underlying age-related pathogenesis of HEV-3 by assessing phenotypic and functional plasticity of CD8 T cells during symptomatic *versus* asymptomatic infection in patients aged 60 and over. Among CD8 T subsets, effector memory cells (EM) were involved in the outcome of HEV-3 infection. Symptomatic patients were characterized by an increased proportion of highly activated EM CD8 T cells expressing HLA-DR and CD38 along with PD-1, TIM-3 and LAG-3. This activation status was associated with loss of polyfunctional cytokine type-1 production and partial commitment of EM compartment to type-2 cells producing IL-4. By contrast, EM CD8 T cells from asymptomatic patients were endowed with moderate activation and efficient secretory function. In conclusion, excessive activation associated with qualitative and quantitative defects in cytokine production within the EM CD8 T cell compartment underlie the clinical complications of HEV-3 infection in the elderly.

Non-apoptotic TRAIL function modulates NK cell activity during viral infection

*L. Cardoso Alves, M. D. Berger, N. Kirschke, C. Lauer, N. Corazza, **P. Krebs**;*
University of Bern, Bern, Switzerland.

The role of death receptor signaling for pathogen control and infection-associated pathogenesis is multifaceted and controversial. Here, we show that during viral infection, tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) modulates NK cell activity independently of its pro-apoptotic function. In mice infected with lymphocytic choriomeningitis virus (LCMV), *Trail*-deficiency led to improved specific $CD8^+$ T cell responses, resulting in faster pathogen clearance and reduced liver pathology. Depletion experiments indicated that this effect was mediated by NK cells. Mechanistically, TRAIL restricts NK1.1-triggered IFNg production by NK cells. In addition, TRAIL expressed by immune cells positively and dose-dependently modulates IL-15 signaling-induced granzyme B production in NK cells, leading to enhanced NK cell-mediated T cell killing. TRAIL also regulates the signaling downstream of IL-15 receptor in human NK cells.
The function of TRAIL on immune cells was so far confined to the induction of apoptosis on target cells. Our study reveals a hitherto unappreciated immunoregulatory role of TRAIL signaling on NK cells for the granzyme B-dependent elimination of antiviral T cells.

The interaction between natural killer (NK) cell inhibitory receptors and their cognate ligands constitutes a key mechanism by which healthy tissues are protected from NK cell-mediated lysis. However, self-ligand recognition remains poorly understood within the prototypical NKR-P1 receptor family. Here, we report the structure of the inhibitory NKR-P1B receptor bound to its cognate host ligand, C-type lectin-related-b (Clr-b). NKR-P1B and Clr-b interacted via a head-to-head docking mode through an interface that included a large array of polar interactions. NKR-P1B:Clr-b recognition was extremely sensitive to mutations at the heterodimeric interface, the majority of which severely impacted both Clr-b binding and NKR-P1B receptor function, in line with the low affinity of the interaction. Within the structure, two NKR-P1B:Clr-b complexes were cross-linked by a novel NKR-P1B homodimer, the disruption of which abrogated Clr-b recognition. Altogether, these data provide an insight intoa fundamental missing-self recognition system and suggests an avidity-based mechanism underpins NKR-P1B receptor function.

CD16A activation of NK cells primes memory-like cytotoxicity against cancer cells

***J. Pahl**[1,2], J. Koch[3], J. Götz[2], A. Arnold[2], U. Reusch[3], T. Gantke[3], E. Rajkovic[3], M. Treder[3], A. Cerwenka[1,2];*
[1]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany, [2]German Cancer Research Center, Heidelberg, Germany, [3]Affimed GmbH, Heidelberg, Germany.

CD16A/FcγRIIIa is a potent cytotoxicity receptor on human NK cells, which can be exploited by therapeutic antibodies to target and eliminate cancer cells by NK cells. So far, the effects of CD16A-mediated activation on NK cell effector functions beyond classical antibody-dependent cytotoxicity have remained poorly elucidated. Here, we investigated how tumor-reactive therapeutic antibodies such as bispecific AFM13 (CD30/CD16A) or anti-CD20 rituximab modulate the functionality of NK cells and their subsequent responsiveness to cytokines and tumor cells. Our results reveal that CD16A engagement by therapeutic antibodies greatly enhanced IL-2 and IL-15-driven NK cell proliferation and expansion. This effect involved up-regulation of CD25 (IL-2Rα) and CD132 (γ_c) on NK cells, resulting in increased sensitivity to low-dose IL-2 or to IL-15. CD16A engagement initially induced NK cell cytotoxicity, while one day later NK cell reactivity was reduced, which could be recovered by subsequent re-culture with IL-2 or IL-15. Remarkably, after re-culture, CD16A-experienced NK cells exerted more vigorous IFN-γ production upon re-stimulation with tumor cells or cytokines. Importantly, CD16A-experienced NK cells exerted increased cytotoxicity towards different tumor targets, mainly through the activating NK cell receptor NKG2D. Our findings uncover a novel role for CD16A in priming enhanced NK cell responses to re-stimulation by cytokines and tumor cells, indicative of a memory-like functionality. Altogether, a treatment combination of CD16A-engaging antibodies with IL-2 or IL-15 may boost NK cell anti-tumor activity in patients by expanding tumor-reactive NK cells and enhancing NK cell reactivity even upon repeated tumor encounters.

WS.D2.01.04

Dynamic changes in intrathymic ILC populations during neonatal development

***R. Jones**, G. Anderson, D. R. Withers;*
University of Birmingham, Birmingham, United Kingdom.

Introduction: Members of the innate lymphoid cell (ILC) family have been implicated in the development of thymic microenvironments and the recovery of this architecture after damage. Despite this, a robust characterisation of the ILC populations present in thymus is lacking and identification of ILCs amongst developing thymocytes is technically challenging given the close phenotypic similarities of ILC and T cells. Objective: To better understand the ILC compartment of the thymus. Methods: We have utilised multiple in vivo models to robustly characterise this population, including the fate mapping of Id2 expression and the use of Id2 reporter mice. Results: Our data demonstrate that ILCs are most prominent immediately after birth, but were rapidly diluted as the T cell development programme is increased. As observed in the embryonic thymus, $CCR6^+NKp46^-$ lymphoid tissue inducer cells were the main ILC3 population present, but numbers of these cells swiftly declined in the neonate and these cells were barely detectable in adult thymus.

This loss of ILC3 helps establish GATA-3^{+} ILC2 as the dominant ILC population in the thymus, with numbers of these cells gradually increasing during neonatal development. Interestingly, ILC2 were located in the medulla and in neonatal mice lacking ILC3 were able to provide RANK-L; suggesting potential competition between ILC populations for niches within the thymus. Conclusions: Collectively, these data reveal a developmental switch in the ILC populations of the thymus, with ILC3 contributing to establishing the thymic microenvironment in the embryo, but after birth ILC2 are the dominant ILC population.

WS.D2.01.05
Innate lymphoid cell reconstitution post lethal irradiation and bone marrow transplant

R. ALBUGAMI, *R. Alhamawi, C. Dempsey, C. Willis, D. Withers, N. Jones;*
Institute of Biomedical Research, BIRMINGHAM, United Kingdom.

Innate lymphoid cells (ILCs) are a family of immune cells which can be subdivided into group 1, group 2 and group 3 ILCs according to the expression of signature transcription factors and cytokines. They share the same morphology as B and T lymphocytes; however, they lack rearranged antigen receptors. Data from human and mouse studies suggest that ILCs can influence the development and severity of graft-versus-host disease (GVHD), a common complication of allogeneic bone-marrow transplantation (BMT). Therefore, determining the kinetics of reconstitution and phenotype of ILCs post-BMT is a crucial first step to manipulating these cells for therapeutic benefit. Following lethal irradiation of CD45.2+BALB/c recipients and adoptive transfer of CD45.1+C57BL/6 T cell depleted bone marrow, we found that recipient ILCs initially survived in non-lymphoid tissues post-irradiation but were slowly lost with time. Interestingly, despite full reconstitution of other immune cells by 60 days post-BMT, donor-derived ILCs remained severely depleted 11.8%, 17.7%, 11.6% of WT controls in small intestine, spleen and mLN, respectively (n=4).
In stark contrast, when performing BMT from BALB/c to CD45.1+ C57BL/6, donor-derived ILCs were found to fully reconstitute in all tissues (small intestine=202.9%, spleen=151.6% and mLN=235.9% compared to WT controls (n=4). These data suggest that ILCs can reconstitute all non-lymphoid and lymphoid compartments following BMT however this may be dependent on a number of factors. We will discuss the potential role of the environment (microbiota - immune system interactions), strains and sex differences of BMT recipients all of which are currently being investigated by the laboratory.

Killer cell Immunoglobulin-like receptor 3DL1 polymorphism defines distinct hierarchies of antigen recognition

J. P. Vivian[1], *P. Saunders*[2], *P. Pymm*[1], *J. Rossjohn*[1], *A. Brooks*[2];
[1]*Monash University, Clayton, Australia,* [2]*Department of Microbiology and Immunology, Peter Doherty Institute for Infection and Immunity, The University of Melbourne., Melbourne, Australia.*

The interaction between killer cell Immunoglobulin-like Receptor 3DL1 (KIR3DL1) and HLA-class I molecules has been linked to NK cell control of viral infections and malignancy. However due to the vast polymorphism of the genes encoding both its HLA-I ligands and the receptor itself, a mechanistic understanding of how these receptor/ligand interactions impact disease outcomes remains unclear. KIR3DL1 tetramers representative of the two main inhibitory KIR3DL1 lineages (-*005 and -*015) together with an interlineage recombinant (*001) were screened for reactivity against a comprehensive panel of HLA-I molecules. This revealed distinct hierarchies of preferred HLA-I ligands for each KIR3DL1 allotype, with KIR3DL1*005 recognising a wider array of HLA-I ligands than either the KIR3DL1*015 or -*001. These differences in binding were also reflected in functional assays utilising NK cell clones expressing specific KIR3DL1 allotypes. Intriguingly, while the polymorphic differences between KIR3DL1*001, *005 and *015 were remote from the KIR3DL1-HLA-I interface, the structures of the three KIR3DL1-HLA-I complexes showed that the broader specificity of KIR3DL1*005 correlated with an altered juxtapositioning of the D1-D2 domains and increased mobility within the ligand binding site, conferring a greater tolerance for disparate ligands. Collectively, we provide a molecular basis underpinning the impact of KIR3DL1 polymorphism on HLA-I recognition that has important implications for haematopoietic transplantation. WS.D2.02.01
Hobit specifically identifies ILC1 throughout peripheral tissues

R. L. R. Taggenbrock[1], *N. A. Kragten*[1], *F. M. Behr*[1,2], *L. Parga Vidal*[1], *T. H. Wesselink*[1], *R. Stark*[1,2], *G. Gasteiger*[3], *K. P. van Gisbergen*[1,2];
[1]*Sanquin research and Landsteiner laboratory, Amsterdam, Netherlands,* [2]*Department of Experimental Immunology AMC, Amsterdam, Netherlands,* [3]*Institute of Systems Immunology, University of Würzburg, Würzburg, Germany.*

Innate lymphoid cells (ILCs) form populations of lymphocytes involved in the regulation of inflammation, tissue repair, and immune homeostasis. These ILCs are present in mucosal barrier tissues such as the lamina propria and epithelium of the small intestine, the lungs and the salivary glands. Different subsets of ILCs have been recognized including ILC1, ILC2 and ILC3 that contribute to immune responses through the production of different sets of cytokines. The lack of ILC-specific tools has hampered the study of ILC development. Previously, we have shown that the transcription factor Homologue of Blimp-1 in T-cells (Hobit) regulates the maintenance of ILC1s, but not of conventional NK cells in the murine liver. We now have developed Hobit Reporter mice, containing a “knock in” of the fluorescent protein tdTomato and CRE recombinase in the Hobit locus that allows us to specifically address the differentiation of ILC1. We analyzed tdTomato expression in ILC subsets of the Hobit reporter mice and found high levels of Hobit expression in ILC1s in several peripheral organs including liver, small intestine and salivary gland. In contrast, conventional NK cells, ILC2 and ILC3 in these organs did not express Hobit. Using Hobit Cre x Rosa26 (floxed STOP) YFP lineage tracer mice, YFP expression was found in tdTomato+ ILC1, but not in tdTomato- NK cells, ILC2 and ILC3, suggesting that ILC1 do not contribute to the differentiation of other ILC lineages. We conclude that Hobit identifies ILC1 as terminally differentiated cells that are maintained as an independent population in the periphery.

WS.D2.02.02
Human IL-17-producing type 2 innate lymphoid cells are important regulators of neutrophilia in cystic fibrosis

K. Golebski, X. R. Ros, M. Nagasawa, B. A. Heesters, C. M. van Drunen, W. J. Fokkens, H. Spits, ***S. M. Bal****;*
Academic Medical Center, Amsterdam, Netherlands.

Innate lymphoid cells (ILCs) are crucial in the immune surveillance at mucosal sites. They coordinate early eradication of pathogens and contribute to tissue healing and remodelling, features that are dysfunctional in patients with cystic fibrosis (CF). ILCs have been implicated in CF, but the mechanisms by which they contribute to CF-immunopathology remain ill-defined.
Here we compared the ILC distribution and cytokine production in nasal polyps (NP) from CF and chronic rhinosinusitis patients and performed in vitro cultures with and without NP epithelial cells to study the mechanism behind ILC activation in CF inflammation. Finally, transcriptome analysis was performed on ILC2s cultured under conditions that induced different cytokine production profiles.
NP from CF patients were enriched with IL-17-producing ILCs. Unexpectedly, this was a result of group 2 ILCs (ILC2s) transdifferentiating from IL-5-producing into IL-17-secreting cells in response to epithelial derived IL-1β, IL-23 and TGF-β. These cytokines were elevated in NP from CF patients and induced upon infection with *Staphylococcus aureus* or *Pseudomonas aeruginosa*. IL-17-producing ILC2s induced IL-8 secretion by epithelial cells and their presence correlated with NP neutrophilia. IL-17-producing ILC2s expressed the transcription factor RORγt and could be identified by surface expression of CCR4 and CCR6. Finally, we show that this conversion of ILC2s could be abrogated by IL-4 or vitamin D3. Our data support a model in which ILC2s undergo transdifferentiation in response to local cytokines and show that limiting ILC plasticity is a potential target to ameliorate CF inflammation.

WS.D2.02.03
ILC migration between barriers sites and draining lymphoid tissue

E. Dutton[1], *C. Willis*[1], *A. Camelo*[2], *M. Sleeman*[3], *G. Carlesso*[4], *R. Herbst*[5], *A. Humbles*[2], *D. Withers*[1];
[1]*University of Birmingham, Birmingham, United Kingdom,* [2]*MedImmune, Cambridge, United Kingdom,* [3]*Regeneron, Tarrytown, United States,* [4]*MedImmune, Gaitherburg, United States,* [5]*MedImmune, Gaithersburg, United States.*

Parabiosis studies argue that most ILCs permanently reside within mucosal tissues. The extent to which ILCs are resident within lymphoid tissues is unclear and we hypothesised that ILC migration between skin and peripheral lymph nodes would be enhanced under conditions of local inflammation. Photoconversion of the brachial LN (bLN) of Kaede transgenic mice demonstrated that the ILC compartment of bLNs was not fixed and whilst ILC are far less migratory than T cells, lymph nodes contain both resident and migratory ILC populations. Analysis of CCR7$^{-/-}$Kaede mice indicated that ILC entry into tissue was CCR7-dependent, whilst analysis of contralateral LNs demonstrated minimal recirculation of these cells through lymph nodes. To determine whether ILCs migrate into peripheral LNs from the skin, photoconversion of the ear was used to assess the migration of ILCs between the ear and draining auricular LN (auLN). Under steady state there was little evidence of ILC migration to the auLN or into the labelled area of skin. However, under conditions of MC903-induced atopic dermatitis (AD), ILC migration to the draining lymph node was evident, although local proliferation alongside traffic from the circulation likely accounted for much of the increase in ILC number within the reactive lymph node. Interestingly, AD induced ILC migration into the inflamed tissue and using CCR6$^{-/-}$ Kaede mice we showed that this migration was CCR6-dependent. Thus the ILC populations in peripheral lymph nodes are not fixed and changes in these populations, in part through migration, may contribute to shaping adaptive immunity at barrier sites.

WS.D2.02.04

The chemokine receptor CCR8 regulates effector functions of group 2 innate lymphoid cells

***L. Knipfer**, A. Schulz-Kuhnt, M. Kindermann, T. Primbs, D. Vöhringer, M. Neurath, I. Atreya, S. Wirtz;*
University Clinic Erlangen, Erlangen, Germany.

In recent years, group 2 innate lymphoid cells (ILC2s) were revealed to possess an indispensable role during helminthic infections as well as acute and chronic airway inflammatory diseases. While their immunoregulatory capacity is known to be largely mediated by the production of type 2 cytokines, the factors and mechanisms involved in migration and tissue tropism of ILC2s are poorly understood. Given that our initial data showed that the type 2 immune response-associated chemokine receptor CCR8 is within the ILC subsets specifically expressed in both human and mouse ILC2s at the mRNA and protein level, we analyzed the role of CCR8 in the well characterized *Nippostrongylus brasiliensis* infection model. We found that CCR8$^{-/-}$ mice displayed substantially diminished lung ILC2 counts at day 9 post infection, which was accompanied by decreased amounts of key type 2 effector cytokines, especially IL-9. Moreover, these mice showed significantly less eosinophilia and were overall impaired in their capacity to expel adult worms from their intestines. However, migration assays and lightsheet microscopy analysis with wildtype and CCR8$^{-/-}$ ILC2s clearly indicated that ILC2s did not migrate towards CCR8 ligands in vitro and in vivo. By contrast, in vitro stimulation experiments with the CCR8 ligand CCL1 and specific CCR8 inhibitors identified CCR8-signalling as an important factor regulating the growth and effector cytokine production of mouse and human ILC2s. These data add to our understanding of ILC2 biology and may also support the further development of clinical approaches, as CCR8 is a promising target for monoclonal antibody therapy of asthma.

Molecular definition of group 1 innate lymphoid cells in the mouse uterus

***I. Filipovic**[1,2,3], L. Chiossone[4], P. Vacca[5], R. S. Hamilton[1], J. Doisne[6], A. Sharkey[7], C. Mingari[8], L. Moretta[9], F. Colucci[1,2];*
[1]Centre for Trophoblast Research, University of Cambridge, Cambridge, United Kingdom, [2]Department of Obstetrics and Gynaecology, University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, [3]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, United Kingdom, [4]G. Gaslini Institute, Genoa, Italy, [5]Department of Experimental Medicine (DIMES), University of Genoa,, Genoa, Italy, [6]Department of Immunology, Pasteur Institute, Paris, France, [7]Department of Pathology, University of Cambridge, Cambridge, United Kingdom, [8]Department of Experimental Medicine (DIMES), University of Genoa, Genoa, Italy, [9]Department of Immunology, IRCCS Bambino Gesù Children's Hospital, Rome, Italy.

Determining the function of uterine lymphocytes is challenging because of the rapidly changing nature of the organ in response to sex hormones and, during pregnancy, to the invading fetal trophoblast cells. Here we provide the first genome-wide transcriptome atlas of mouse uterine group 1 innate lymphoid cells (g1 ILCs) at mid-gestation. The subset composition of g1 ILCs fluctuates throughout reproductive life, with Eomes^{-ve}CD49a^{+} cells dominating before puberty and specifically expanding in second pregnancies, when the expression of CXCR6, a marker associated with memory NK cells, is upregulated. Tissue-resident Eomes^{+}CD49a^{+} NK cells (trNK), which resemble human uterine NK cells, are most abundant during early pregnancy, and showcase gene signatures of responsiveness to TGF-β and IL-1, and connections with trophoblast, epithelial, endothelial and smooth muscle cells, leucocytes, as well as extracellular matrix. Tissue-resident NK cells express genes involved in aerobic glycolysis, lipid metabolism, iron transport, protein ubiquitination, and recognition of microbial molecular patterns. Conventional NK cells expand late in gestation and may engage in crosstalk with trNK cells involving IL-18 and IFN-γ. These results identify trNK cells as the cellular hub of uterine g1 ILCs at mid-gestation and mark Eomes-veCD49a+CXCR6+ g1 ILCs as potential memory cells of pregnancy. This work is supported by grants from the Wellcome Trust and Centre for Trophoblast Research.

WS.D2.02.06

NCR+ ILC3 maintain larger STAT4 reservoir via T-BET to regulate type 1 features upon IL-23 stimulation in mice.

*Y. Mikami[1], G. Scarno[2], B. Zitti[3], H. Shih[1], Y. Kanno[1], A. Santoni[2], J. J. O'Shea[1], **G. Sciume**[2];*
[1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, United States, [2]Sapienza, University of Rome, Rome, Italy, [3]HERM, Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Type 3 innate lymphoid cells (ILC3) represent a heterogeneous group of cells producing interleukin(IL)-22 and/or IL-17, and involved in regulation of gut barrier homeostasis and inflammation. Cytokines activating the Janus kinases (Jaks) and members of the signal transducer and activator of transcription (STAT) pathway are key players in lymphoid development, differentiation and activation. In this context, we have previously dissected the role of STAT5 in regulation of ILC homeostasis in mice and revealed that ILC3 expressing natural cytotoxicity receptors (NCR+ ILC3) are particularly sensitive to deprivation of STAT5 signals. Here, by using mouse models in combination with genomic and transcriptomic approaches, we defined at the molecular level, initial events of NCR+ ILC3 activation and the contribution of STAT4 in the acquisition of type 1 features, downstream of IL-23 stimulation. In particular, we observed high basal expression of STAT4 in NCR+ ILC3, dependent on T-BET, which contributes to enhance production of IFN-γ. Altogether, our findings shed light on a feed-forward mechanism involving STAT4 and T-BET that modulates the outcome of IL-23 signaling in ILC3.

WS.D3.01 Novel vaccine approches to intracellular pathogens

WS.D3.01.01

Targeted delivery of BCG vaccine to the DEC-205 receptor improves protective efficacy against *Mycobacterium tuberculosis*

***C. Counoupas**[1], R. Pinto[1], L. Baker[2], G. Ngalingam[1], A. Nisa[1], W. Britton[1], J. Triccas[2];*
[1]Centenary Institute, Sydney, Australia, [2]University of Sydney, Sydney, Australia.

Tuberculosis (TB) remains a major cause of mortality and morbidity worldwide, with 1.7 million deaths annually and a third of the world infected with the latent form of the disease. The currently available vaccine, *M. bovis* BCG, is only partially effective against TB, and new strategies are required to control the global epidemic. We hypothesised that BCG may interact sub-optimally with dendritic cells (DCs), the cell type pivotal in shaping the adaptive immune response to infectious agents. Thus strengthening this interaction could improve BCG protective efficacy. In order to do this, we engineered BCG to express the single-chain variable fragment (ScFv) recognising the C-type lectin receptor DEC205 (BCG:DEC), which is expressed predominantly on migratory DCs. An increased functional ability of BCG:DEC to interact with DEC205-expressing cell lines and bone morrow derived DCs was observed; interestingly, the increased interaction resulted in an augmented secretion of inflammatory cytokines and chemokines by BMDCs. Given the high levels of expression of DEC205 in the skin of mice, we tested the protective efficacy of BCG:DEC after subcutaneous vaccination. We found that BCG:DEC conferred greater protection than BCG 4 weeks after aerosol challenge with virulent *M. tuberculosis,* and its efficacy lasted up to 20 weeks post infection, even when BCG protection had waned. Our results indicate that targeting DCs by modifying BCG is an effective strategy to improve protection against TB.

WS.D3.01.02

HLA-E restricted human CD8^{+} T-cells: a novel human T-cell subset with unique properties which impact vaccination strategies against tuberculosis

***S. A. Joosten**, K. E. van Meijgaarden, T. Prezzemolo, A. M. Drittij, K. L. Franken, C. K. Dingenouts, P. Ruibal, T. H. Ottenhoff;*
Leiden University Medical Center, Leiden, Netherlands.

Mycobacterium tuberculosis (Mtb) infection remains a major global threat, and better vaccines are urgently required. BCG induces only limited protection and novel vaccination strategies are thought to be crucial to eliminate tuberculosis (TB). HLA-E presented antigens are interesting targets for vaccination given HLA-Es' essentially monomorphic nature. HLA-E is a member of the HLA class Ib family and can present both self-peptides as well as peptides derived from intracellular pathogens. The precise phenotype and functional capacity of these cells remains poorly characterized. We have developed a new protocol combining HLA-E tetramer with intracellular staining for cytokines, transcription factors and cytotoxic molecules to characterize these cells in depth. Moreover, we have assessed the capacity of these HLA-E restricted T-cells to control intracellular Mtb outgrowth and the mechanism employed. The *ex vivo* frequency of Mtb peptide/ HLA-E-TM^{+} CD8^{+} T-cells was significantly increased in the circulation of TB patients, which are even further increased in those with concomitant HIV. HLA-E restricted CD8^{+} T-cells from TB patients produced more IL-13 than cells from controls or subjects with latent tuberculosis infection (LTBI). Compared to total CD8^{+} T-cells, HLA-E restricted cells produced more IFNγ, IL-4, IL-10, and granulysin but less granzyme-A. Moreover, compared to "classical" Mtb-specific HLA-A2 restricted CD8^{+} T-cells, HLA-E restricted CD8^{+} T-cells produced less TNFα and perforin, but more IL-4. Moreover, HLA-E restricted T-cells could inhibit intracellular growth of Mtb. Thus HLA-E restricted-Mtb specific cells represent a unique new human T-cell subset and are a novel target for vaccination against infectious diseases.

WS.D3.01.03

During experimental tuberculosis, interleukin-27R regulates protection and limits the expansion of multifunctional T cells by inhibiting interleukin-17A

K. Ritter[1], *J. Behrends*[2], *A. Hölscher*[1], *J. Volz*[1], *I. Rosenkrands*[3], *H. Erdmann*[1], *C. Hölscher*[1];
[1]*Infection Immunology, Research Center Borstel, Borstel, Germany,* [2]*Fluorescence Cytometry Core Unit, Research Center Borstel, Borstel, Germany,* [3]*Department of Infectious Disease Immunology, Statens Serum Institut, Copenhagen, Denmark.*

After infection with *Mycobacterium tuberculosis* (Mtb), mice lacking the IL-27R exhibit lower bacterial burdens but develop immunopathological sequelae in comparison to wildtype mice. This phenotype correlates with an enhanced recruitment of antigen-specific $CCR6^+$ $CD4^+$ T cells and an increased frequency of IL-17A-producing $CD4^+$ T cells. By comparing the outcome of Mtb-infection in C57BL/6, IL-27R-deficient and IL-27R/IL-17A-double deficient mice, we observed that in the absence of IL-27R both the increased protection and elevated immunopathology is supported by IL-17A. Whereas IL-17A does neither impact the development of Tr1 cells nor the expression of PD1 and KLRG1 on T cells in IL-27R-deficient mice during infection, it significantly regulates the presence of multifunctional T-cells, co-expressing IFN-γ, IL-2 and TNF, and highly stratified granulomas in the lungs. In addition, IL-17A supports *Cxcl9*, *Cxcl10* and *Cxcl13* expression in lungs of infected IL-27R-deficient mice. Taken together, IL-17A contributes to protection in Mtb-infected IL-27R-deficient mice probably through a chemokine-mediated recruitment and strategic positioning of multifunctional T cells in granulomas. Although IL-27 also prevents IL-17A-mediated immunopathology, a timely inhibition of IL-27R-mediated signaling during vaccination or host-directed therapy of tuberculosis might increase a coordinated protective effect of IL-17A without detrimental consequences.

WS.D3.01.04

Human *Plasmodium falciparum* infection induces a predictable and persistent distortion in transcriptomic landscapes across T cell subsets

T. S. Watkins[1,2,3], *F. Amante*[2], *S. Turner*[2], *S. Darko*[4], *A. Ransier*[4], *D. L. Doolan*[1,2], *D. C. Douek*[4], *J. S. McCarthy*[2,3], *J. J. Miles*[1,2,3];
[1]*AITHM, James Cook University, Cairns, Australia,* [2]*QIMR Berghofer, Brisbane, Australia,* [3]*University of Queensland, Brisbane, Australia,* [4]*VRC, NIH, Bethesda, United States.*

Malaria infection still remains one of the world's most formidable issues across both health and economical systems. Despite the best intervention strategies over 200 million people are infected annually, and mortality rates exceed 400,000 deaths per year. To develop effective therapeutics and vaccines a better understanding of fundamental human immunology is required. This is particularly true of the contribution of T cells to malaria defence. Research to date comes from field samples which can sometimes be difficult to interpret due to confounding factors including multiple exposures. As such, the underlying immune correlates of an efficient response remain unknown. To investigate the role of T cells in disease we used a human model of blood stage *Plasmodium falciparum* infection involving the Medicines for Malaria Venture (MMV).
We performed high-dimensional phenotyping and T cell receptor (TCR) sequencing of T cell subsets before infection, during infection and during convalescence. *Plasmodium falciparum* infection resulted in marked phenotypic 'scaring' across all T cell subsets and persisted during convalescence. We identified gene modules that correlated with parasitaemia, revealing a possible continua between individuals at risk of disease and 'elite controllers'. Remodelling of the TCR repertoire could also be correlated with transcriptomic changes, and gene expression and TCR repertoire metrics could serve as novel proxies of disease burden and assist in identifying pathways for immunotherapies or vaccine activation. Indeed, characterizing the T cell biology of elite controllers opens the possibility of inducing this phenotype for the purposes of rational vaccine design and therapeutic intervention.

WS.D3.01.05

BCG-induced trained innate immunity during controlled human malaria infection

J. Walk[1], *C. de Bree*[1], *W. Graumans*[1], *R. Siebelink-Stoter*[1], *G. van Gemert*[1], *M. van de Vegte-Bolmer*[1], *K. Teelen*[1], *C. C. Hermsen*[1], *R. J. Arts*[1], *M. C. Behet*[1], *S. J. Moorlag*[1], *A. Yang*[1], *R. van Crevel*[1], *P. Aaby*[2], *Q. de Mast*[1], *A. J. van der Ven*[1], *C. Stabell Benn*[2], *M. Netea*[1], *R. W. Sauerwein*[1];
[1]*Radboud university medical center, Nijmegen, Netherlands,* [2]*Statens Serum Institut, Copenhagen, Denmark.*

Recent evidence suggests that certain vaccines, including Bacillus-Calmette Guérin (BCG), can induce changes in the innate immune system with non-specific memory characteristics, termed 'trained immunity'. We performed a randomized, controlled clinical trial in twenty healthy male and female volunteers to evaluate the induction of immunity and protective efficacy of BCG vaccination against a controlled human malaria infection (CHMI) five weeks after vaccination. BCG vaccinated volunteers had earlier and more severe clinical symptoms, and showed a heterologous, memory-like monocyte and (innate) lymphocyte re-activation that correlated with reduced parasitemia. These findings demonstrate for the first time that BCG vaccination induces trained immunity with functional activity against an unrelated, clinically relevant, human pathogen *in vivo*. It forms a strong impetus to further explore its potential in the clinical development of a rational malaria vaccine strategy.

WS.D3.01.06

Evaluation of multi-epitope peptides derived from different *Leishmania* proteins as potential vaccine candidates against human Leishmaniasis

S. Hamrouni[1], *K. Aoun*[1], *A. Kidar*[2], *R. Chamakh Ayari*[1], *E. Petitdidier*[3], *J. Lemesre*[3], *R. Bras Gonçalves*[3], *A. Meddeb Garnaoui*[1];
[1]*Institut Pasteur, Tunis, Belvédère, Tunisia,* [2]*Hôpital régional, Gafsa, Tunisia,* [3]*Institut de Recherche pour le Développement, Montpellier, France.*

IFN-γ-producing-Th1 cells are required for *Leishmania* parasite control. Healing is correlated with resistance to reinfection, suggesting that vaccination is feasible. To date no vaccine is available.
To identify peptide vaccine candidates against human leishmaniasis, we evaluated the immunogenicity of multi-epitope peptides in individuals with healed cutaneous leishmaniasis due to *Leishmania major*.
PSA (Promastigote Surface Antigen), LmlRAB (*L. major* large RAB GTPase) and H2B (Histone), reported to be immunogenic in humans, mice and dogs, were screened *in silico* for T cell epitopes able to bind to frequent HLA class-I and -II alleles. Selected peptides were synthesized, pooled and used to screen peripheral blood mononuclear cells from subjects cured of cutaneous Leishmaniasis. Healthy subjects were used as control group. IFN-γ and IL-10 production was evaluated by ELISA. Phenotypes of cytokines producing T cells were analyzed by flow cytometry.
We showed that some peptide pools were able to elicit significant IFN-γ levels in cured but not in healthy individuals. No IL-10 production was detected.
A significant increase in the percentage of IFN-γ-producing CD4+ T cells and polyfunctional CD4+T cells producing IFN-γ, TNF-α and IL-2 was detected in response to peptide pools.
A significant increase of the percentage of CD4+CD45RO+CCR7+central memory T cells was also observed.
In conclusion, we demonstrated that multi-epitope peptides derived from different *Leishmania* proteins were able to induce IFN-γ and polyfunctional CD4+T cells, both associated with protection against *Leishmania* infection, suggesting that they may be exploited as vaccine candidates.

WS.D3.02 Novel vaccine approaches for viruses

WS.D3.02.01

Deciphering the complexity of vaccine-induced immunity with omics technologies: innate immune responses differ between priming and boosting immunization

J. L. Palgen[1,2], *N. Tchitchek*[1,2], *J. Elhmouzi-Younes*[1,2], *S. Delandre*[1,2], *I. Namet*[1,2], *N. Huot*[2,3], *P. Rosenbaum*[1,2], *N. Dereuddre-Bosquet*[1,2], *F. Martinon*[1,2], *A. Cosma*[1,2], *M. Müller-Trutwin*[2,3], *Y. Lévy*[2,4], *R. Le Grand*[1,2], *A. S. Beignon*[1,2];

A better understanding of vaccine-induced innate responses and their impact on immune memory is critical to more efficiently design long-term protective vaccines, but the immune system complexity admittedly makes it challenging. To take up this challenge, omics technologies are promising since they allow multiparametric and multiscale measurements.
Here, we used mass cytometry and DNA micro-arrays to longitudinally study blood innate cells (granulocytes, monocytes, DC and NK cells) during prime-boost vaccination of cynomolgus macaques with the Modified Vaccinia virus Ankara (MVA) attenuated vaccine. We developed new analyses pipelines to explore those datasets and assess the magnitude, quality and dynamics of immune responses after each immunization.
Innate myeloid and lymphoid cells numbers were similarly early, transiently and strongly impacted after each immunization. However, at a deeper resolution, several subphenotypes were differently enriched/attrited between each immunization. The key features of prime-boost differences, identified using multivariate analyses, include the differential expression of CD11b, CD66, CD45 and CD32 on neutrophils; CCR5, CXCR4, CD45 and CD16 on cDCs; CD32, CD11a, CD14 and CD45 on monocytes; and CD16, CCR5, CD69 and CD107a on NK cells. More strikingly, before the boost, the subphenotype composition of innate cells differed from baseline with the upregulation of those activation/maturation markers, strongly suggesting that the innate immune system is imprinted after the prime.
This work indicates that, similarly to adaptive responses, innate responses differ after each vaccine encounter. This revisits vaccine-induced innate responses and open new perspectives with the involvement of innate training/memory.

WS.D3.02.02

Identification of vaccine responding T-cells using TCR repertoire sequencing data

Introduction: High-throughput sequencing allows for deep profiling of TCR repertoires, however our ability to extract clinically relevant information from this data is limited. We develop approaches to identify clonotypes participating in immune response from both longitudinal repertoire data and single snapshot of repertoire.
Methods: We collected PBMCs, CD4+, CD8+ T-cells at 5 timepoints before and after yellow fever immunization of 3 pairs of twins. We sequenced TCR repertoires from all samples on illumina HiSeq.
Results: Using a novel statistical approach, we identified 500-1500 clones expanded at the peak of the response (day 15) in each individual, occupying up to 5% and 8% of CD4+ and CD8+ repertoires. We validated these clonotypes by an IFN-gamma secretion assay, MHC-multimer staining and sorting of activated T-cell subpopulations. We found little sequence overlap even between YF-reactive repertoires of identical twins, but lots of YF-reactive TCR sequences in different donors were homologous. We also developed an algorithm to identify clusters of unlikely similar TCR clonotypes in single repertoire samples. Such clusters were almost absent before immunization and very abundant at the peak of the response, where they mostly consisted of YF-specific sequences (40%-75%). We also found such clusters (immune response signatures) in published immunotherapy and autoimmune repertoire sequencing data.
Conclusions: T-cell response to YF-vaccine is strong and almost unique even in identical twins. Highly homologous sequences in antigen-specific repertoires allow us to build an algorithm to identify clusters of similar clonotypes participating in an active immune response in single repertoire samples.

Mucosal vaccine mediates cross-protection by immune training

P. Brandi[1], *L. Conejero*[2,1], *F. Cueto*[1], *S. Martinez-Cano*[1], *P. Saz-Leal*[1], *M. Enamorado*[1], *J. Amores-Iniesta*[1], *J. Subiza*[2], *D. Sancho*[1];

Respiratory tract infections by viruses and bacteria are a leading cause of morbidity worldwide. MV130 is a mucosal vaccine that consists of whole inactivated bacteria that are common pathogens in the human respiratory tract. Previous data show that administration of MV130 reduces the frequency and severity of infectious episodes in patients with recurrent respiratory tract infections, including episodes of virus-induced wheezing in children, a significant risk factor for asthma in later life. However, the mechanisms by which MV130 provides protection against these episodes are still poorly understood. We hypothesized that the mechanism of action of MV130 may rely on trained immunity, a process by which innate immune cells challenged with certain stimuli undergo long-lasting changes that result in improved response to second related or unrelated challenge. We found that pretreatment of mouse bone-marrow derived macrophages with MV130 led to increased glycolysis resulting in lactate production maintained along several days of culture and increased TNF production following LPS challenge one week later, which are hallmarks of immune training. Moreover, pretreatment of mice with MV130 protected against an unrelated fungal systemic infection by *Candida albicans*. We further explored the potential cross-protection to viral infections and found that pretreatment with MV130 one week before infection with either vaccinia or influenza virus reduced morbidity and mortality. In summary, our data suggest that the mucosal vaccine MV130 confers cross-protection to fungal or viral infections by immune training.

WS.D3.02.04

Liver-resident memory CD8 T cells develop during chronic viral infection, have reduced effector functions but can be reactivated to clear persistent viral infection of hepatocytes

M. Bosch, *K. Manske, S. Donakonda, D. Wohlleber, P. A. Knolle, N. Kallin;*
Institute of Molecular Immunology, Munich, Germany.

Introduction: Hepatic tissue-resident memory (T_{RM}) cells are found after acute and self-limited viral infections. It is unclear whether liver-T_{RM} are also found during chronic infections. iMATEs (intrahepatic-myeloid-cell-aggregates-associated-with-T-cell-expansion) that serve as hubs for T cell-expansion to promote T-cell immunity. We characterized the impact of chronic-infection and iMATE-induction for liver-T_{RM} function and viral infection-control.
Methods:Infection with liver-targeting adenoviruses encoding ovalbumin under CMV-promoter (Ad-CMV-GOL) or hepatocyte-specific TTR-promoter (Ad-TTR-GOL) caused acute self-limited or persistent liver-infection, respectively. 100 CD45-1$^+$ Ovalbumin-specific OT-I CD8 T-cells were transferred to follow antigen-specific T-cells after infection. TLR9-ligand was injected for iMATE-induction and T-cell expansion, increased T-cell functionality and infection-control were determined by flow-cytometry and *in vivo* bioluminescence-measurement.
Results: CXCR6$^+$ liver-T_{RM} developed after self-limited Ad-CMV-GOL but also after chronic Ad-TTR-GOL liver infection and were not clonally deleted. Compared to self-limited infection, no CX_3CR1-expressing antigen-specific hepatic T cells were detected during chronic Ad-TTR-GOL-infection. At 90d after chronic Ad-TTR-GOL infection, liver-T_{RM} showed severely impaired cytotoxic-capacity and cytokine-production, thus revealing functional adaption to persistent infection. RNA-sequencing of liver-T_{RM} from acute-self-limited compared to chronic-infection and bioinformatics-analysis revealed novel molecular markers to identify exhausted liver-T_{RM} and found a single exhaustion-specific transcription factor. Importantly, iMATE-induction led to increased effector function of hepatic virus-specific T-cells and control of persistent infection.
Conclusions: Exhausted liver-T_{RM} are formed during chronic viral-infection and are identified using novel biomarkers. iMATE induction overcomes liver-T_{RM} dysfunction to control chronic infection. Thus, our results provide novel markers for immunomonitoring of patients with chronic viral hepatitis and demonstrate functional plasticity of exhausted liver-T_{RM} local hepatic stimulation within iMATEs.

WS.D3.02.05

Harnessing T-helper (Th) cell responses induced by licensed vaccines for HIV vaccine development

H. Elsayed[1,2], *G. Nabi*[3], *W. J. Mckinstry*[4], *M. Tenbusch*[1], *V. Temchura*[1], *K. Überla*[1];
[1]*University Hospital Erlangen, Institute of Clinical and Molecular Virology, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany,* [2]*National Research Center, Genetic Engineering and Biotechnology Division, Department of Microbial Biotechnology, Giza, Egypt,* [3]*Department of Molecular and Medical Virology, Ruhr-University Bochum, Bochum, Germany,* [4]*CSIRO Materials Science and Engineering, Parkville, Victoria, Australia.*

Strong T-helper responses could significantly improve antibody-based effector mechanisms induced by HIV vaccines. We recently reported that Gag-specific Th responses induced by gene-based vaccines improved the quality of the Env-specific antibody in mice after booster immunizations with virus-like particle (VLP) containing Gag and Env via intrastructural help (ISH). We now show, that immunization with pICLC-adjuvanted Gag protein also induced T helper cell responses sufficient to provide ISH and to significantly enhance Env-specific IgG2a levels after VLP booster immunizations. We therefore evaluated whether T helper cells induced by the licensed Tetanol®pur or HBVAXPro vaccines could be harnessed to improve the HIV-1 Env-specific antibody response. To this end, we generated HIV-VLPs incorporating Th epitopes for tetanus-toxoid (TT) or HBsAg (HB) within Gag. After immunizing Tetanol®pur-primed mice with VLPs containing the TT-Gag, Env-specific IgG1 antibody levels increased up to 100-fold compared to non-primed mice. The avidity of the HIV-Env antibodies was also higher. HBVAXPro-primed mice boosted with VLPs containing HB-Gag showed an approximately 10-fold increase in Env-specific IgG1 levels. Priming mice with DNA vaccines encoding TT, HBsAg or Gag predominantly improved Env-specific IgG2a responses after booster immunization with epitope-matched VLPs. However, if VLPs lacked matched epitopes, the priming immunization had no effect on the HIV-1 Env-specific antibody response. Thus, harnessing T helper cells induced by licensed vaccine to provide intrastructural help for HIV Env-specific B cells is an interesting strategy to enhance overall levels of HIV Env antibodies, to modulate their IgG subtype ratio, and to increase their avidity.

WS.D3.02.06

Design of TLR2 ligand-synthetic long peptide conjugates for therapeutic vaccination of chronic HBV patients

Y. Dou[1], ***D. T. S. Jansen***[1], *A. van den Bosch*[1], *R. A. de Man*[1], *N. van Montfoort*[1], *G. G. Zom*[2], *W. Krebber*[2], *C. J. Melief*[2], *A. M. Woltman*[1], *S. I. Buschow*[1];
[1]*Department of Gastroenterology and Hepatology, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands,* [2]*ISA Pharmaceuticals BV, Leiden, Netherlands.*

Synthetic long peptide (SLP) vaccination is a promising new treatment strategy for patients with a chronic hepatitis B virus (HBV) infection. Previously, we have shown that a prototype HBV-core protein derived SLP is capable of boosting CD4+ and CD8+ T cell responses in patients *ex vivo*. These T cell responses were further enhanced by adjuvants like TLR 2 ligands. For optimal effect of a therapeutic vaccine adjuvants can be conjugated to the SLP to ensure uptake by the same cell and thus presentation of SLP-contained epitopes by matured dendritic cells (DC) only. Here, we investigated the efficacy of TLR2-ligand conjugated SLPs of different lengths and by different conjugation strategies. Engineered HBV-specific CD8+ T cells were used to analyze the cross-presentation of conjugates by *in vitro*-generated and naturally-occurring DC subsets. Results indicated better T cell responses were induced by a shorter (16 amino acids) SLP conjugate compared to longer (26 and 37 amino acids) conjugates indicating size may hamper cross presentation.

Longer SLPs however, are preferred, as inclusion of multiple CD4 and CD8 epitopes is required to ensure population-wide and long-lasting responses. To reduce size effect, we designed a conjugate in which a cathepsin-sensitive linker was placed between the TLR2 ligand and the long SLP, to facilitate endosomal release. We found this linker improved cross presentation, affected SLP intracellular processing and overall more effectively triggered patients' T cell responses *ex vivo*. These results provide an import step forward in the design of a therapeutic SLP-based vaccine to cure chronic HBV.

Introduction: Cerebral malaria (CM) is a severe complication of *Plasmodium* infection and can be studied experimentally in *Plasmodium berghei* ANKA (PbA)-infected C57BL/6 wildtype (WT) mice that develop experimental CM (ECM). PbA-infected interferon (IFN) alpha receptor knock out (*Ifnar1*$^{-/-}$) mice are protected from ECM. We characterized the composition and activity of splenic T cells between ECM-susceptible WT mice and ECM-protected mice and analysed whether these cells have different functional properties.
Material and Methods: C57BL/6 WT and *Ifnar1*$^{-/-}$ mice were infected with PbA. 6 days post infection (dpi) splenocytes were analysed by flow cytometry, cytokine/chemokine levels were determined in supernatants of splenocyte cultures with enzyme-linked immunosorbent assay (ELISA) and with intracellular FACS.
Results: ECM-positive WT mice contained on dpi 6 CD8$^+$ T cells in the brain while presenting decreased numbers of splenic CD8$^+$ T effector cells and memory cells. PbA-infected ECM-protected ko mice lacked T cell infiltration in their brains but presented higher numbers of splenic CD8$^+$ effector T cells and CD4$^+$ effector memory T cells. Whereas IFN-γ levels were comparable in splenocyte cultures of both mouse groups, WT mice contained less CCL5 in their spleens upon infection than protected mice. T cells of all PbA-groups produced more granzyme B and CCL5 than naïve controls.
Conclusions: CD8$^+$ T cells and memory cells were generally retained in the spleen of PbA-infected ECM-protected mice and might miss an egress signal migrating to the brain.

WS.D4.01.02

A distinct subset of human CD56$^+$ cells present at baseline in HbAS-SCT-children is associated with a lower parasite density during an episode of clinical malaria

C. Loiseau[1,2], *O. K. Doumbo*[3], *B. Traore*[3], *J. L. Brady*[1,2], *C. Proietti*[2], *P. D. Crompton*[4], *D. L. Doolan*[1,2];
[1]*Australian Institute of Tropical Health and Medecine, Cairns, Australia,* [2]*James Cook University, Cairns, Australia,* [3]*University of Sciences, Technique, and Technology of Bamako, Bamako, Mali,* [4]*National Institutes of Health, Rockville, United States.*

Despite mounting substantial immune response, humans fail to control *Plasmodium* spp. infection. However, some people display better immune responses and parasite control; among them are individuals presenting the sickle-cell trait phenotype which corresponds to the heterozygous state of haemoglobin A and S (HbAS-SCT). Here, we compared the immune profiles of HbAA- and HbAS-SCT-Malian children from a malaria-endemic area, to define immunological differences that could potentially explain the relative protection observed in HbAS-SCT-patients.
Blood samples were obtained from HbAS-SCT- and HbAA-children at their uninfected baseline and during their first febrile malaria episode of the ensuing malaria season. PBMCs were isolated, activated and multicolor flow cytometry analysis were performed. Functional assays were performed on PBMCs from healthy donors.
At baseline, the frequency of CD56$^+$ cells was increased in HbAS-SCT-children *(P<0.05)*; and was inversely correlated with parasite density *(r=-0.76, P<0.05)*. The CD38^{high} subset in CD56$^+$ cells was reduced in HbAS-SCT-children *(P<0.01)*; and was correlated with parasite density *(r=-0.90, P<0.01)*. Thus, the increased frequency of the CD56$^+$ cells in CD3$^-$ lymphocytes of HbAS-SCT-children appeared to be due to their CD38$^{low/med}$ subset. This subset of NK cells was inversely correlated with parasite density *(r=-0.86, P<0.05),* characterized by an increased expression of HLA-DR and CD45RO (*P<0.001*) and a 15-fold increased production of IFN-γ compared to the CD38^{high} subset.
The CD38$^{low/med}$ subset represents a novel population of CD56$^+$ cells identified at baseline in HbAS-SCT-children and is potentially associated with enhanced parasite control. The HLA-DR$^+$CD45RO$^+$CD38$^{low/med}$ CD56$^+$CD3$^-$ cells may represent a potential predictive signature of immunity to malaria.

WS.D4.01.03

Transcription factor T-bet plays a complex role in B cell mediated immune response against *Plasmodium* infection

M. Akkaya, *P. W. Sheehan, C. K. Cimperman, B. P. Theall, M. Pena, S. K. Pierce;*
National Institutes of Health, Rockville, United States.

Malaria is a global health concern which affects over 200 million individuals worldwide. Although immune system rapidly responds to *Plasmodium* infection with specific antibodies, natural antibodies fail to establish long term protection, often leading to repetitive infections and chronicity. Recent studies showed that in chronic malaria setting both B cells and T cells induce T-bet transcription factor expression. Yet it is not completely understood whether this is a host defense strategy or a result of disease pathogenesis. Here using transgenic mouse models, we show that deficiency of T-bet reduces survival of mice upon infection with *Plasmodium chabaudi*, suggesting a protective role. Similarly, using Tbet-zsgreen transgenic mice we showed that conditions specific to *P.chabaudi* infection drive T-bet expression in multiple B cell subsets in a time dependent fashion. However, no such induction is shown when mice are immunized with protein antigens adjuvanted with Alum. On the other hand, bone marrow chimeric animals reconstituted with equal amounts of congenically labeled WT and T-bet KO bone marrow cells showed that for most B cell subsets the lack of T-bet does not affect WT and KO cell ratio upon *Plasmodium* infection indicating that T-bet may not be equally crucial for all B cell responses to infection. However in vitro stimulation of WT and T-bet KO B cells with Anti-IgM plus IFN-gamma reveals that expression of several B cell markers depend at least in part on the presence of T-bet. These findings suggest a complex role of T-bet in the development of humoral responses.

WS.D4.01.04

Within host-adaptation of *Bordetella pertussis* under vaccine immune pressure

E. van Schuppen[1,2], *A. Zeddeman*[3,1,2], *K. E. Kok*[3], *M. van Gent*[3], *K. J. Heuvelman*[3], *M. J. Bart*[3], *H. G. van der Heide*[3], *F. J. van Opzeeland*[1,2], *S. van Selm*[1,2], *M. I. de Jonge*[1,2], *R. de Groot*[1,2], *F. R. Mooi*[3,1,2], *D. A. Diavatopoulos*[1,2];
[1]*Section Pediatric Infectious Diseases, Laboratory of Medical Immunology, Radboud Institute for Molecular Life Sciences, Radboudumc, Nijmegen, Netherlands,* [2]*Radboud Center for Infectious Diseases, Radboudumc, Nijmegen, Netherlands,* [3]*Centre for Infectious Diseases Research, Diagnostics and Screening (IDS), National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands.*

The first vaccines against pertussis were introduced in the 1940s-1960s and were comprised of killed bacteria (wP vaccines). Despite the high effectiveness of wPs, high reactogenicity led to their replacement with acellular pertussis vaccines (aPs). aPs contain several *B. pertussis* antigens, including pertussis toxin (PT), filamentous hemagglutinin (FHA), pertactin (Prn), and fimbriae (Fim). We investigated the efficacy of various aP and wP vaccines against infection with modern Prn-expressing and Prn-deficient strains.
Naïve and vaccinated mice were challenged with Prn-producing (Prn$^+$) and Prn-deficient (Prn$^-$) strains and bacterial load was determined in the nose and lungs. Phase variation was studied using a Ligase Detection Reaction. FHA expression was determined by Luminex and Western blot. Antibody deposition on *B. pertussis* was studied by flow cytometry.
We show essential differences in protection against Prn$^+$ and Prn$^-$ strains in relation to the type and composition of pertussis vaccines, as well as the location in the airways. We describe the emergence of bacteria in the lower respiratory tract that have switched-off FHA expression due to phase variation in the *fhaB* gene. These mutants were positively selected for in Prn$^-$ strains following vaccination with aP but not wP vaccines. Of concern, Prn$^-$ FHA$^-$ strains are not recognized anymore by aP vaccine-induced opsonizing antibodies.
This study demonstrates that in addition to the loss of Prn as a protective antigen, *B. pertussis* strains can also switch-off FHA expression, suggesting that immunity to two of the most widely used pertussis vaccine antigens may be compromised.

WS.D4.01.05

Transphagocytosis, a novel mechanism for bacterial uptake by B cells

R. García Ferreras[1,2], *G. Ramírez Santiago*[1,2], *A. Cruz Adalia*[1,2], *J. Osuna Pérez*[1,2], *M. Torres Torresano*[1,2], *Y. R. Carrasco*[1], *E. Veiga Chacón*[1,2];
[1]*Centro Nacional de Biotecnología (CNB), Madrid, Spain,* [2]*CSIC, Madrid, Spain.*

It is now well established that B cells are antigen presenting cells (APC). Indeed, it is known that, *in vivo*, B cells are able to uptake soluble and surface-tethered antigens presented on different types of cells. However, the way of B cells to capture bacteria remains unknown. Interestingly, we have shown that B cells capture bacteria from previously infected dendritic cells (DC) during DC - B cells closed contact, a process called transphagocytosis. Uptaken bacteria were rapidly degraded by B cells. Bacterial antigens resulting from degradation were cross-presented to CD8+ T which resulted strongly activated and proliferated. Taking into account that only very few cells are able to activate naive CD8+ T cells triggering its proliferation, we propose transphagocytosis as a potent mechanism to generate a cytotoxic response. Therefore, we characterize that a previous exposition of Pathogen Associated Molecular Patterns (PAMPS) might improve these immune abilities by B cells against infection.

WS.D4.01.06

Human vaginal and skin dendritic cell subsets control ZIKA virus infection

***J. Eder**, T. B. Geijtenbeek;*
Academic Medical Center Amsterdam (AMC), Amsterdam Infection and Immunity Institute, Amsterdam, Netherlands.

ZIKA virus (ZIKV) is a member of the Flaviviridae family and recent outbreaks have shown that it is very infectious and infection has been associated with abnormal fetal brain development. ZIKV is transmitted through mosquito bites and sexual contact. However, little is known about first cell targets and subsequent viral dissemination as well as immune responses induced by infection. Here we investigated the role of dendritic cell (DC) subsets in ZIKV infection of human skin and vaginal mucosa, initial tissues involved in infection. Therefore, human primary DCs were isolated from skin, buffy coats and vaginal mucosa and infected with a wild-type ZIKV strain. Moreover, we used an ex-vivo infection model from skin and also embryonic neuronal cells as target cells during the different assays. Notably, mucosal and epidermal Langerhans cells did not become infected by ZIKV, whereas in contrast ZIKV efficiently infected human submucosal DCs. Infected DCs transmitted the virus to target cells, suggesting that DCs are involved in ZIKV dissemination. ZIKV infection of DCs induced a strong type I Interferon (IFN) response, DC maturation and expression of pro-inflammatory cytokines. The type I IFN response limits ZIKV infection as inhibition of IFN receptors enhanced ZIKV infection. These data strongly suggest that submucosal DCs are one of the first target cells for ZIKV and are involved in induction of innate and adaptive immunity to the virus. Dissecting the adaptive immune responses as well as viral dissemination is important to develop strategies to prevent ZIKV-associated pathologies.

Combined chemical genetics and data-driven bioinformatics approach identifies receptor tyrosine kinase inhibitors as host-directed drugs for intracellular bacterial infections

*C. J. Korbee[1], M. T. Heemskerk[1], D. Kocev[2], E. van Strijen[1], O. Rabiee[1], K. L. Franken[1], L. Wilson[1], N. D. Savage[1], S. Džeroski[2], T. H. Ottenhoff[1], **M. C. Haks**[1];*
[1]LUMC, Leiden, Netherlands, [2]Josef Stefan Institute, Ljubljana, Slovenia.

Antibiotic-resistance poses rapidly increasing global problems in combatting multidrug-resistant (MDR) infectious diseases like MDR tuberculosis, prompting for novel approaches including host-directed therapies (HDT). Intracellular pathogens like *Salmonellae* and *Mycobacterium tuberculosis* (*Mtb*) exploit host signaling pathways to survive intracellularly. Thus far, only very few HDT-compounds targeting host pathways have been identified for HDT. In a Library Of Pharmacologically Active Compounds (LOPAC)-based drug-repurposing screen, using a novel intracellular infection screening assay, we have identified multiple compounds, which target Receptor Tyrosine Kinases (RTKs) and inhibited intracellular *Mtb* and *Salmonellae* more potently than currently known HDT-compounds. By developing a data-driven *in silico* model based on confirmed targets from public databases, we successfully predicted additional efficacious HDT-compounds. These also appeared to target host RTK signaling and inhibited intracellular *Mtb* including MDR-*Mtb*. A complementary human kinome siRNA screen independently confirmed the role of RTK signaling and kinases (BLK, ABL1 and NTRK1) in host control of *Mtb*. These three approaches validate RTK signaling as a new drugable host pathway for HDT against intracellular bacteria (Nature Communications, 2018).

WS.D4.02.02

Host-directed, autophagy-modulating compounds restrict intracellular *Mycobacterium tuberculosis* and *Salmonella* Typhimurium infection in human macrophages

*M. T. Heemskerk, C. J. Korbee, J. Esselink, C. Carvalho dos Santos, F. Vrieling, I. Gordijn, L. Wilson, T. H. Ottenhoff, **M. C. Haks**;*
LUMC, Leiden, Netherlands.

The persistent increase of multidrug-resistant (MDR) *Mycobacterium tuberculosis* (*Mtb*) infections negatively impacts tuberculosis (TB) treatment outcomes, prompting for the development of alternative strategies in addition to conventional antibiotics. Host-directed therapies (HDT) pose such an alternative, especially since the success of *Mtb* can partly be explained by its successful manipulation of host signalling pathways in order to create a pathogen favourable intracellular environment. Similarly, *Salmonella* infections, causing a.o. typhoid fever, are accompanied by significant mortality and pose therapeutic difficulties because also this pathogen modifies host regulatory networks to ensure its intracellular survival. One key mechanism of host defence is autophagy, which is of particular interest for HDT given its important and versatile functions in TB pathogenesis. Here a commercially available library of compounds with proven and defined autophagy-modulating activity was screened for small molecules capable of inhibiting intracellular (but not extracellular) *Mtb* and *Salmonella* Typhimurium *(Stm)* survival.
Four FDA-approved compounds were found to act against (MDR-)*Mtb* and *Stm* in primary human macrophages in a host-directed manner, and displayed synergy with suboptimal doses of Rifampicin. To elucidate their mechanisms of action various functional assays were performed including monitoring of autophagy, lysosomal activity, and reactive oxygen species (ROS) generation. The results showed clear differences in the mechanisms targeted by each of the compounds. Current efforts, including studies in a zebrafish infection model, are directed to further dissect the mechanisms by which these autophagy-modulators decrease intracellular bacterial survival.

WS.D4.02.03

The Mal-IFN-γ receptor axis receptor axis and TIRAP-S180L polymorphism as determinants of susceptibility to pneumococcal disease

***N. Munoz-Wolf**[1], C. M. Ni Cheallaigh[2], M. Herrlein[3], D. Golenbock[4], K. A. Fitzgerald[4], L. A. O'Neill[1], E. C. Lavelle[1];*
[1]School of Biochemistry and Immunology, Trinity Biomedical Science Institute -Trinity College Dublin, Dublin, Ireland, [2]2Institute of Molecular Medicine, Trinity College Dublin & St. James's Hospital – Ireland., Dublin, Ireland, [3]Goethe University Frankfurt/Main, Frankfurt, Germany, [4]University of Massachusetts Medical School, Division of Infectious Disease & Immunology, Massachusetts, United States.

Genetic single-nucleotide polymorphisms (SNP) affecting immune receptors or their signalling components can influence susceptibility to infections. TIRAP encodes the MyD88-adaptor like protein (Mal), a bridging adaptor for TLR4 and TLR2. A SNP in TIRAP resulting in the substitution S180L alters susceptibility to invasive pneumococcal infection, tuberculosis and sepsis. $TIRAP^{L/L}$ homozygosity increases susceptibility, while heterozygotes $TIRAP^{S/L}$ are protected compared to $TIRAP^{S/S}$ "wild-types". We discovered a TLR-independent role for Mal in tuberculosis whereby it mediates interferon (IFN)-γ receptor (IFNGR) signalling which is affected in $TIRAP^{L/L}$ impairing autophagy and mycobacterial killing in macrophages. Here we investigated the role of Mal and the Mal-IFNGR axis in invasive pneumonia caused by *Streptococcus pneumoniae,* an important human pathogen that kills >1.6 million people/year.
We showed that Mal is required for protection against pneumococci, as evidenced by the hyper-susceptibility of $Tirap^{-/-}$ mice to invasive pneumonia. Despite the involvement of Mal in TLR2 and TLR4 signalling, $Tlr2/4^{DKO}$ immortalised macrophages (iBMMs) expressed comparable *Tnfa* mRNA to wild-types when infected with pneumococci or stimulated with TLR ligands, other than LPS and Pam3CSK. However, $Tirap^{-/-}$ and in particular $Tirap^{L/L}$ over-expressed *Tnfa* and *Il6* mRNA in response to all stimuli, a response that was exacerbated by pre-treatment with rIFN-γ. Besides, $Tirap^{-/-}$ and $Tirap^{L/L}$ were less efficient at killing pneumococci *in vitro* compared to $Tlr2/4^{DKO}$ and wild-types. Finally, infected $Tirap^{-/-}$ mice had increased alveolar infiltration of inflammatory monocytes. These results suggest a novel TLR-independent role for Mal during pneumonia highlighting its key role as a modulator of IFN-γ-induced inflammation in the lungs.

WS.D4.02.04

Dual RNA-seq unveils novel host-pathogen interactions during colonic bacterial infections

***F. Wan**;*
Johns Hopkins University, Baltimore, United States.

Attaching/Effacing (A/E) pathogens including enteropathogenic *Escherichia coli* (EPEC), enterohemorrhagic *E. coli* (EHEC), and the rodent equivalent *Citrobacter rodentium* (CR) are important causative agents of foodborne diseases. A/E pathogen infections cause severe morbidity and mortality in immunocompromised hosts with low interleukin-22 (IL-22); however the crucial host-pathogen interactions and the pivotal A/E virulence proteins (effectors) under immunocompromised conditions, remain elusive. We utilize a "dual RNA-sequencing" approach to simultaneously profile gene expression in the pathogen and the host, and identify an extracellular metalloprotease as a novel virulence factor during *C. rodentium* infection in the immunocompromised $Il22^{-/-}$ mice. Genetic deletion of the extracellular protease substantially attenuates *C. rodentium* infection-induced morbidity and mortality in $Il22^{-/-}$ mice, which underscores the pathophysiological relevance of bacterial extracellular proteases. Moreover, the extracellular protease deficiency impedes the inflammatory cytokine gene expression in the *C. rodentium*-infected $Il22^{-/-}$ colon. These findings reveal novel host-pathogen interactions during *C. rodentium* infection in $Il22^{-/-}$ mice, which could provide novel strategies to control A/E pathogen infections under low IL-22 immunocompromised conditions associated with chronic HIV infection, organ transplantation, and other diseases.
Supported in part by NIH Grant GM111682.

iNOS- AND NOX1- DEPENDENT ROS PRODUCTION MAINTAINS BACTERIAL HOMEOSTASIS IN THE ILEUM OF MICE

A. Kielland[1], *C. Matziouridou*[1], *S. Rocha*[1], *K. Rudi*[1], *O. A. Haabeth*[2], *H. Carlsen*[1];
[1]*Norwegian University of Life Sciences (NMBU), Ås, Norway,* [2]*University of Oslo, Oslo, Norway.*

The intestinal epithelium constitute a first line of defense against gut microbes, which includes secretion of various antimicrobial substances. Reactive oxygen species (ROS) are well characterized as part of the innate phagocytic immunity; however, a role in controlling microorganisms in the gut lumen is less clear.
Here, we demonstrate, through *in vivo* imaging, a remarkably high production of ROS in the ileum of normal healthy mice. The ROS production depends on the enzymes iNOS (NO producer) and NOX1 (superoxide producer). NO and superoxide rapidly combine to form peroxynitrite. Peroxynitrite is bactericidal and one of the important ROS in respiratory burst. Mice deficient in iNOS and NOX1 have increased bacterial load and a significant shift in the microbiota composition of the ileum. Furthermore, the ROS appear to prevent reflux of microbiota from large intestine and be of relevance for bacterial overgrowth and translocation.
Our data suggests a new role of ROS in regulating the bacterial content at the border of the small and large intestine. This may imply a unique role of ileum in maintaining homeostasis of gut microbes through production of peroxynitrite with potential importance for preventing reflux from the large intestine, bacterial overgrowth and translocation. Furthermore, as several conditions and diseases such as Crohn's disease and SIBO have been linked to impaired microbial homeostasis in ileum, these findings might provide new insights into pathogenesis related mechanisms that can indicate strategies for disease prevention.

Nucleotide-binding domain and leucine-rich repeat containing proteins (NLRs) are a group of intracellular pattern recognition receptors, involved in the regulation and induction of innate and adaptive immunity in mammals. However, the function of about half of the currently identified NLRs remains elusive. Here we provide a functional characterization of NLRP11, a primate-specific member of the NLR family. We show that NLRP11 is highly expressed in reproductive tissue and in immune cells, including myeloid cells, B cells and some B cell lymphoma lines. Overexpression of NLRP11 in human cells did not trigger key innate immune signalling pathways including NF-κB, type I interferon and caspase-1. By contrast, expression of NLRP11 repressed MyD88-induced NF-κB and TBK1-induced type I interferon responses. This effect was independent of the PYD domain and ATPase activity of NLRP11 but mediated by its LRR domain. Accordingly, knock-down of NLRP11 in human myeloid THP1 cells enhanced lipopolysaccharide (LPS) and Sendai Virus (SeV)-induced cytokine and interferon responses upon NLRP11 depletion. In summary, our work identifies a novel role of NLRP11 in the regulation of inflammatory responses in human cells.

Aspergillus fumigatus (AF) is the major etiologic agent of Invasive Aspergillosis (IA), a severe infection amongst immunocompromised individuals. A pivotal role in the host resistance to this pathogen is played by polymorphonuclear neutrophils (PMNs) and complement. The long pentraxin PTX3 exerts opsonic activity towards AF conidia, and enhances their phagocytosis and killing by PMNs via complement pathways. Here we characterized the molecular crosstalk between PTX3 and complement in the opsono-phagocytosis of AF. Complement activation on AF conidia was assessed by Western Blotting and ELISA using complement proteins and human sera depleted of selected complement components in the presence and absence of recombinant PTX3. In parallel experiments, AF phagocytosis and killing by human and murine PMNs was assessed *in vitro* by Flow Cytometry. We found that PTX3 promotes the selective recruitment of C3b on the conidial wall, by targeting the alternative pathway (AP) of complement. To our surprise, factor H (main inhibitor of AP) was necessary for this activity, thus pointing to a novel function (activating rather than inhibitory) of this factor when combined with PTX3. Consistent with this, factor H and complement receptor 1 (CR1, major receptor of C3b) were required for the pro-phagocytic and pro-killing properties of PTX3. Therefore, a cooperation was observed between factor H and PTX3 with an unexpected functional outcome: enhanced recruitment of C3b on AF. Given the potent opsonic activity of C3b (via CR1), we believe that this is a major mechanism of PTX3 in the promotion of AF phagocytosis and killing by PMNs.

WS.D4.03.02
Orchestration of systemic anti-fungal Th17 immunity and immune pathology by a single member of the mycobiome

Introduction: Th17 cells protect against bacteria and fungi, but also contribute to chronic inflammation. In humans, Th17 responses are particularly important against *Candida albicans,* a mucocutaneous fungal pathobiont. In contrast, the role of Th17 cells for other pathogenic fungal species is unclear. Pulmonary fungus-related disorders and sensitizations are often associated with chronic respiratory diseases such as asthma, COPD and cystic fibrosis. Also these patients show increased Th17 cytokine levels, which correlate with disease severity. However, the capacity of most fungal species to induce human Th17 responses and their potential contribution to pulmonary diseases is currently unclear.
Methods: We used antigen-reactive T cell enrichment (ARTE) for the *ex vivo* analysis of human T helper cell responses against 25 common human pathogenic fungal species.
Results: We show that *C. albicans* is the sole direct fungal inducer of Th17 cells in humans. For all other fungi tested, minor and variable fractions of Th17 cells were detected. Surprisingly, these Th17 cells, but not Th1 cells against the same fungal species, were strongly and selectively cross-reactive against *C. albicans*. Patients with pulmonary inflammation displayed elevated frequencies of cross-reactive *A.fumigatus* Th17 cells, suggesting their specific contribution to lung pathology. In particular in patients with allergic sensitization to *A.fumigatus,* increased Th17 responses strongly correlated with acute ABPA.
Conclusions: Our data identify *C. albicans* as the major fungal inducer of human Th17 responses. We provide a unique example how protective Th17 immunity may simultaneously promote immune pathology when deviated to different target antigens and tissues via heterologous immunity.

WS.D4.03.04
Inherited p40^{phox} deficiency differs from chronic granulomatous disease: Distinctive molecular, cellular and clinical phenotypes

A. van de Geer[1], *A. Nieto-Patlán*[2], *D. Roos*[1], *J. Casanova*[3], *T. W. Kuijpers*[4], *J. Bustamante*[2];
[1]*Sanquin, Amsterdam, Netherlands,* [2]*Laboratory of Human Genetics of Infectious Diseases, Necker Branch, INSERM U1163, Necker Hospital for Sick Children, Paris, France,* [3]*St Giles Laboratory of Human Genetics of Infectious Diseases, Rockefeller Branch, The Rockefeller University, New York, United States,* [4]*Emma Children's Hospital, Amsterdam, Netherlands.*

Chronic granulomatous disease (CGD) is a well-defined recessive primary immunodeficiency caused by loss-of-function mutations in any of the genes encoding four phagocyte NADPH oxidase subunits (p22^{phox}, p47^{phox}, p67^{phox}, and gp91^{phox}). In contrast, loss-of-function mutations in the *NCF4* gene, encoding the p40^{phox} subunit, have only been described once. We report 24 p40^{phox}-deficient patients from 12 additional families in eight countries. These patients display eight different *NCF4* mutations, homozygous in 11 families and compound heterozygous in another. Upon over-expression in NB4 neutrophil-like cells and EBV-transformed B cells *in vitro,* the mutant alleles were loss-of-function, except for one hypomorphic allele. Particle-induced NADPH oxidase activity in the patients' neutrophils was subnormal, whereas PMA-induced DHR oxidation, a widely used test for CGD diagnosis, was sometimes normal. Moreover, NADPH oxidase activity of EBV-transformed B cells was also subnormal, whereas that of mononuclear phagocytes was normal. Finally, unlike in CGD, neutrophil killing of *Candida albicans* and *Aspergillus fumigatus* hyphae was maintained, whereas that of *Staphylococcus aureus* was impaired both in CGD and in p40^{phox} deficiency. Patients suffer from auto-inflammation and peripheral infections, but not from invasive bacterial and fungal infections. Moreover, all patients are alive at ages 1-46 years and only four of them have received hematopoietic stem cell transplantation. In conclusion, inherited p40^{phox} deficiency underlies a distinctive condition, evoking a mild form of CGD, with inflammatory lesions and peripheral infections, but without invasive bacterial and fungal disease. Its detection should not rely on the usual clinical test of PMA-induced oxidation of substrates by neutrophils.

WS.D4.03.05
TRIM5α-mediated autophagy: Where HIV-1 restriction and molecular inflammation meet

A. P. Cloherty, J. L. van Hamme, R. Sarrami-Forooshani, N. A. Kootstra, T. B. Geijtenbeek, ***C. M. S. Ribeiro****;*
University of Amsterdam, Amsterdam, Netherlands.

Contemporary HIV-1 antiretroviral therapy is highly effective, however, treated HIV-1 patients suffer from severe comorbidities due to persistent viral replication and chronic inflammation. There is thus an urgent need to identify therapeutic targets to enhance antiviral immunity and control inflammation in treated HIV-1 patients.
Autophagy functions as an antiviral defense mechanism by degrading viruses and instructing adaptive T-cell responses. We were the first to establish that human TRIM5α mediates assembly of an autophagy-activating scaffold to HIV-1 components, which targets HIV-1 for autophagic degradation and restricts infection of a human dendritic cell (DC) subset. Here, we show a novel protective role for autophagy machinery in HIV-1 patients. We have recently identified a gene polymorphism in a regulator of TRIM5α-mediated autophagy that is associated with decreased plasma viral load and improved survival in HIV-1 patients from the Amsterdam Cohort Studies. This polymorphism correlates with increased autophagy levels and heightened $CD8^+$T-cell responses *in vitro*, as well as with decreased susceptibility to HIV-1 infection of emigrated DC subsets in *ex vivo* explant models. These findings underscore the pivotal role for autophagy in limiting HIV-1 replication and boosting antiviral T-cell immunity. Furthermore, our preliminary data identify a novel link between TRIM5α-mediated autophagy and virus-induced molecular inflammation. We have demonstrated that TRIM5α and ATG13 are key in the secretion of inflammatory mediators such as IL-1β and TNFα after viral infection.
Hence, our data underscore the *in vivo* relevance of autophagy mechanisms and the therapeutic potential of targeting autophagy to intervene in acute and chronic HIV-1 infections.

WS.D4.03.06
Type I interferon-dependent NETosis supports biofilm formation and survival of *Pseudomonas aeruginosa* during lung infection

E. Pylaeva*, S. Bordbari, I. Spyra, S. Lang, J. Jablonska;*
University Hospital, Ear, Nose, and Throat Department, Essen, Germany.

The enhanced predisposition to bacterial complications in cancer or viral infections is known. These clinical situations are often associated with elevated levels of type I interferons (IFN). As neutrophils are the major antibacterial responders in acute phase of infection, we set up to reveal the role of IFNs in the regulation of neutrophil bactericidal properties. In the model of acute *Pseudomonas aeruginosa* pneumonia we observed elevated bacterial load and lung tissue damage in WT mice, as compared to IFN-deficient animals. We observed enhanced neutrophil extracellular traps (NETs) release by WT lung neutrophils, accompanied by the elevated biofilm formation and survival of *P. aeruginosa*. Interestingly, infection with biofilm-negative *P. aeruginosa* revealed no differences in bacterial load between WT and IFN-deficient mice. Treatment of mice with rmIFN-beta raised biofilm formation. Disruption of NETs using DNase prevented biofilm formation. In agreement, treatment of mice with ROS scavenger N-acetylcysteine decreased NETs release, biofilm content and bacterial load in the lung, confirming the role of NETosis-dependent biofilm formation as supporter of bacterial survival. Summarizing, during *Pseudomonas* infection IFNs stimulate NETs release by neutrophils, which in turn supports biofilm formation by *Pseudomonas*. Biofilm protects bacteria from the immune system and leads to their persistence in the lung. Biofilms can also be responsible for the antibiotic-resistance typical for *Pseudomonas*, therefore targeting NETosis may help to develop effective treatment strategies for persistent infections with this pathogen.

Human cytomegalovirus reprograms hematopoietic progenitor cells into immunosuppressive monocytes to achieve latency

K. Zen*;*
Nanjing University, Atlanta, China.

The precise cell type hosting latent human cytomegalovirus (HCMV) remains elusive. Here we report that HCMV reprograms human hematopoietic progenitor cells (HPCs) into a unique monocyte subset to achieve latency. Unlike conventional monocytes, this monocyte subset possesses higher levels of B7-H4, IL-10 and iNOS, longer lifespan and strong immunosuppressive capacity. Cell sorting of peripheral blood from latently infected human donors confirms that only this monocyte subset, representing less than 0.1% of peripheral mononuclear cells, is HCMV genome-positive but immediate-early (IE)-negative. Mechanistic studies demonstrate that HCMV promotes the differentiation of HPCs into this monocyte subset by activating cellular signal transducer and activator of transcription 3 (STAT3). In turn, this monocyte subset generates a high level of nitric oxide (NO) to silence HCMV IE transcription and promote viral latency. By contrast, the US28-knockout HCMV mutant, which is incapable of activating STAT3, fails to reprogram the HPCs and achieve latency. Our findings reveal that via activating STAT3/iNOS/NO axis HCMV differentiates human HPCs into a longevous, immunosuppressive monocyte subset for viral latency.

WS.D4.04.02
Killer cell proteases target viral immediate-early proteins to control cytomegalovirus infection in a noncytotoxic manner

L. Shan*[1], J. Meeldijk[1], B. Blijenberg[1], A. Hendriks[1], K. J. van Boxtel[1], S. P. van den Berg[2], A. Svrlanska[3], T. Stamminger[4], M. R. Wills[2], N. Bovenschen[1];*
[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]University of Cambridge, Cambridge, United Kingdom, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Ulm University Medical Center, Ulm, Germany.

Human cytomegalovirus (HCMV) is the most frequent viral cause of congenital defects and can trigger devastating disease in immune-suppressed patients. Cytotoxic lymphocytes (*e.g.* $CD8^+$ T cells and NK cells) control HCMV infection by releasing the pore-forming protein perforin and five cytotoxic granzymes (GrA, GrB, GrH, GrK, and GrM) towards virus-infected cells. Perforin facilitates the cellular entry of granzymes, which are believed to kill infected host cells through cleavage of intracellular death substrates. However, it has recently been demonstrated that the *in vivo* killing capacity of cytotoxic T cells is limited. This raises the question whether cytotoxic lymphocytes can also control HCMV infection in a noncytotoxic manner. In the present study, we demonstrate that (primary) cytotoxic lymphocytes block HCMV dissemination and induce the degradation of viral immediate-early (IE) proteins IE1 and IE2 in HCMV-infected cells in a cell death-independent noncytotoxic manner at low effector:target cell ratios. Interestingly, both IE1 and/or IE2 are directly proteolyzed by all human granzymes, with GrB and GrM being most efficient. GrB and GrM cleave IE1 after Asp^{398} and Leu^{414}, respectively, resulting in IE1 dislocation, IE1 instability, and functional impairment of IE1 to interfere with the JAK-STAT signaling pathway. Furthermore, GrB and GrM cleave IE2 after Asp^{184} and Leu^{173}, respectively, resulting in IE2 dislocation and functional abolishment of IE2 to transactivate the HCMV UL112 early promoter. Taken together, our data indicate that cytotoxic lymphocytes can employ noncytotoxic ways to control HCMV infection via granzyme-mediated targeting of indispensable viral proteins during lytic infection.

WS.D4.04.03
Pathological role of anti-CD4 antibodies in HIV-infected immunologic non-responders under viral suppressive antiretroviral therapy

W. Jiang*, Z. Luo;*
Medical University of South Carolina, Charleston, United States.

Abstract
Increased mortality and morbidity occurs in human immunodeficiency virus (HIV)-infected patients who fail to increase $CD4^+$ T cell counts despite achieving viral suppression with antiretroviral therapy (ART). Here we identified an underlying mechanism. Significantly elevated plasma levels of anti-CD4 IgGs were found in HIV^+ immunologic non-responders ($CD4^+$ T cell counts ≤ 350 cells/μl) [median (interquartile range), 91.8 ng/mL (53.2-165.8)] compared to HIV^+ immunologic responders ($CD4^+$ T cell counts ≥ 500 cells/μl) [26.0 ng/mL (15.9-81.6)] and healthy controls [14.5 ng/mL (9.2-24.1)] ($P < 0.001$ between non-responders and responders or healthy controls, non-parametric Mann-Whitney test). Higher plasma level of anti-CD4 IgG correlated with blunted $CD4^+$ T cell recovery ($r = -0.53$, $P = 0.0002$, Spearman correlation test). Furthermore, purified anti-CD4 IgGs from HIV^+ immunologic non-responders induced NK cell-dependent $CD4^+$ T cell cytolysis [19.1% (5.8-50.3) vs. 0.04% (0.03-0.05) for treatment with anti-CD4 IgGs and anti-CD4-depleted IgGs respectively] and apoptosis [36.9% (26.6-44.5) vs. 15.4% (14.3-16.8) for treatment with anti-CD4 IgGs and anti-CD4-depleted IgGs respectively] through antibody-dependent cell-mediated cytotoxicity (ADCC) *in vitro*. We also found that anti-CD4 IgG-mediated ADCC exerts marginally increased apoptosis on naive relative to memory $CD4^+$ T cells ($P = 0.06$). Consistently, increased frequencies of $CD107a^+$ NK cells and profound decreases of naive $CD4^+$ T cells were observed in immunologic non-responders compared to responders and healthy controls *ex vivo*. These data indicate that autoreactive anti-CD4 IgGs may play an important role in the blunted $CD4^+$ T cell reconstitution despite effective ART.

HIV-1 exposure enhances sexual transmission of HCV by inducing Syndecan-4 on Langerhans cells

B. M. Nijmeijer[1], *R. Sarrami Forooshani*[1], *J. Eder*[1], *G. S. Steba*[2], *R. R. Schreurs*[1], *S. M. Koekkoek*[2], *R. Molenkamp*[2], *J. Schinkel*[2], *P. Reiss*[3,4], *M. L. Siegenbeek van Heukelom*[4,5], *M. van der Valk*[4], *C. M. Ribeiro*[1], *T. B. Geijtenbeek*[1];

[1]*Department of Experimental Immunology, Academic Medical Center, Amsterdam Infection and Immunity Institute, University of Amsterdam, Amsterdam, Netherlands,* [2]*Department of Medical Microbiology, Clinical Virology laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [3]*Department of Global Health, Academic Medical Center, and Amsterdam Institute for Global Health and Development , Academic Medical Center HIV Monitoring Foundation, Amsterdam, Netherlands,* [4]*Department of Internal Medicine, Division of Infectious Diseases, Amsterdam Infection and Immunity Institute, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [5]*Department of Dermatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

The significant rise in incidence of Hepatitis C virus (HCV) infection among HIV-infected men-who-have-sex-with-men (MSM) suggests that HCV under specific circumstances is transmitted via sexual contact. The mechanisms remain unclear. Here we investigated the molecular mechanism of sexual transmission of HCV. Analyses of mucosal anal biopsies from HIV-1-infected MSM identified Langerhans cells (LCs) within mucosal tissue. However, immature LCs were neither infected nor transmitted HCV to hepatocytes *in vitro* and *ex vivo*. As sexual transmission is mostly observed within HIV-1-infected individuals, we pre-exposed tissues with HIV-1 and, strikingly, HIV-1 pre-exposure significantly increased HCV transmission by LCs. HIV-1 replication is crucial for the increased HCV transmission as treating *ex vivo* tissue with HIV-1 replication-inhibitors significantly decreased HIV-1-induced HCV transmission. Next we identified the mechanism in HIV-1 exposed LCs. Notably, HCV transmission by HIV-1 exposed LCs was dependent on Syndecan-4, as silencing of Syndecan-4 abrogated transmission. The role of Syndecan-4 in HCV transmission was further confirmed using cell-lines expressing Syndecan-4. Furthermore, we showed that activation of LCs enhanced Syndcan-4-mediated transmission of HCV, which supports studies showing that other sexually acquired infections, increase HCV susceptibility. Thus, our data strongly suggest that HIV-1 replication as well as immune activation in mucosal tissues in HIV-1 infected MSM, changes LC function, allowing Syndecan-4 to capture and subsequently transmit HCV to hepatocytes. This novel transmission mechanism implicates also that the activation state of LCs is an important determinant for HCV susceptibility after sexual contact.This work was supported by Aidsfonds, grant number: 2014014

WS.D4.04.05

DUSP4 regulates STING and RIG-I mediated signalling in response to virus infection

H. Jiao, S. J. James, ***Y. Zhang****;*
National University of Singapore, Singapore, Singapore.

Detection of cytosolic nucleic acids by pattern recognition receptors including STING and RIG-I leads to activation of multiple signalling pathways that culminate in the production of type I interferons (IFNs) which are vital for host survival during virus infection. In addition, type I IFNs are also associated with autoimmune diseases. Hence, it is important to elucidate the mechanisms that govern their expression. In this study, the critical regulatory function of DUSP4 in innate immune signalling was demonstrated. It was found that DUSP4 knockout (KO) macrophages expressed increased level of type I IFNs in response to RIG-I and STNG activation, as well as influenza and HSV-1 infection compared to wildtype (WT) cells. This increased type I IFN expression in KO cells was associated increased activation of ERK and TBK1-IRF3 in KO cells compared to WT cells. Mice deficient in DUSP4 are more resistant to both RNA and DNA virus infection but are more susceptible to malaria compared to control. Mechanistically, DUSP4 inhibits TBK1 and ERK2 activation to suppress type I IFN production. Therefore, our study not only established DUSP4 as a common regulator of nucleic acid sensor signalling, but also shed light on the regulation of the type I IFN system.

WS.D4.04.06

A lncRNA promotes viral replication by modulating host cellular metabolism

P. Wang[1], *J. Xu*[1], *Y. Wang*[1], *X. Cao*[1,2,3];
[1]*Institute of Immunology, Second Military Medical University, Shanghai, China,* [2]*Institute of Immunology, Zhejiang University School of Medicine, Hangzhou, China,* [3]*Department of Immunology & Center for Immunotherapy, Institute of Basic Medical Sciences, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China.*

Viruses have evolved to alter the host metabolic pathways to ensure optimal niche for viral replication and survival. Identification of how viruses alter the host cellular metabolism is necessary for understanding viral infection and revealing targets for antiviral therapeutics. We previously demonstrated that long-non-coding RNAs (lncRNAs) regulate dendritic cell differentiation, and therefore, have a pleiotropic effect to the host immune system (1). Here we hypothesized that viruses utilize lncRNA to alter the host cellular metabolism that provides necessary energy and material for viral replication.
In this study, we identified that a group of lncRNAs were induced by the infections from a number of viruses. Functional screening demonstrated that the expression of one of these viral-induced lncRNAs, lncRNA-ACOD1, enhanced viral replication in both murine and human cells. In lncRNA-ACOD1 knockout mice, viral infection was significantly reduced in an IFN-independent manner. Gene expression profiling and metabolomics surveys revealed that viral infections led to significant host metabolic changes in wildtype hosts but the lncRNA-ACOD1 knockout totally abolished the metabolic alteration. Mechanistically, we demonstrated that lncRNA-ACOD1 directly binds to a metabolic enzyme, GOT2. The binding region on GOT2 is spatially adjacent to its substrate-binding site, and thus, the binding of lncRNA-ACOD1 enhanced GOT2's catalytic activity. The treatment of GOT2 or its metabolites restored viral replication in lncRNA-ACOD1 knockout mice, demonstrating that lncRNA-ACOD1-mediated viral replication is dependent on GOT2 catalysis. This work revealed a novel feedback mechanism of viral infection by altering host cellular metabolism through a lncRNA.

Targeting newly identified pathogenic monocyte subsets with immune-modulatory treatment resolves severe malaria

P. Niewold[1], *A. Cohen*[1], *C. van Vreden*[2], *D. R. Getts*[3], *G. Grau*[1], *N. King*[1,2];
[1]*University of Sydney, Sydney, Australia,* [2]*Ramaciotti Facilty for Human System Biology, Sydney, Australia,* [3]*Northwestern University, Chicago, United States.*

Severe malaria is caused by the mosquito-borne parasite *Plasmodium falciparum* and is associated with lethal complications including acute respiratory distress syndrome and cerebral malaria (CM). Current treatment has limited efficacy in advanced infection as it is primarily directed at the parasite. This fails to address the neurological damage and respiratory distress caused by host blood cell accumulation in the brain microvasculature and lung interstitium. Therefore, we sought to identify cells contributing to pathology as novel targets for immunemodulatory therapies.
In a preclinical mouse model of CM, highdimensional flow cytometry and computational analysis identified Ly6C^{hi}monocytederived Ly6C^{lo}monocytes and interstitial macrophages as the main pathological populations in the brain and lungs, respectively. Previous studies have shown immune modifying particles (IMP) target Ly6C^{hi}monocytes, preventing their migration to inflammatory foci. To this end, we treated mice with neurological signs of CM with 2 doses of IMP in combination with WHOrecommended anti-parasitic artesunate. This combination therapy resulted in 88% survival in animals that would otherwise succumb to disease within 36 hours. Treatment effectively reduced the accumulation of cells in the brain vasculature and lung, resulting in clearance of parasitaemia and immunity.
In conclusion, through detailed analysis of the immune response in severe malaria, we identified principal pathogenic immune subsets and targeted them with a novel combination therapy, resulting in increased survival in an otherwise lethal syndrome. This is the first specific immunemodulatory treatment addressing both hostmediated pathology and the parasite in severe malaria, revealing a novel avenue for human treatment.

The use of mass cytometry to study type 2 immune responses in the context of helminth infections

K. de Ruiter[1], *D. L. Tahapary*[1,2], *K. Stam*[1], *V. van Unen*[1], *E. Sartono*[1], *J. W. Smit*[3,1], *T. Supali*[2], *M. Yazdankbakhsh*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Universitas Indonesia, Jakarta, Indonesia,* [3]*Radboud University Medical Center, Nijmegen, Netherlands.*

Studies have shown that helminths can have a profound role in shaping immune responses to vaccines, allergens or autoantigens by inducing strong type 2 and regulatory responses. We used mass cytometry to gain insight into the immunomodulatory effects of helminths, by performing unbiased immune profiling of Indonesian adults who were infected with soil-transmitted helminths, before and 1 year after anthelmintic treatment, as well as healthy European volunteers. The use of our recently developed Cytosplore to analyse high-dimensional single-cell immunological data, allowed the identification of very distinct immune signatures in Europeans and Indonesians. Higher frequencies of Th2 cells (in particular CD161^{+} Th2 cells), ILC2s and regulatory T cells expressing CTLA-4 and ICOS were found in Indonesians that were infected, compared to Europeans. Except for ILC2s, the frequencies of these cell subsets decreased after 1 year of anthelmintic treatment. In addition, we assessed the functional capacity of cells, and observed a clearly higher production of Th2 cytokines upon stimulation with PMA/Ionomycin in infected Indonesians compared to Europeans, which was decreased after deworming. Subsets of CD4^{+} and CD8^{+} T cells, γδ T cells and ILC2s showed to be the main producers of Th2 cytokines. These results provide us with a detailed insight into the types of cells that participate in the strong type 2 and regulatory response induced by helminths.
This study was funded by the Royal Netherlands Academy of Arts and Science (KNAW).

WS.D4.05.03

The Notch signaling pathway controls basophil responses during helminth-induced type 2 inflammation

***L. M. Webb**, S. A. Peng, O. O. Oyesola, R. L. Cubitt, J. K. Grenier, C. G. Danko, E. D. Tait Wojno;*
Cornell University, Ithaca, United States.

Type 2 inflammation is characterized by production of the cytokines IL-4, IL-5 and IL-13 and promotes clearance of gastrointestinal helminth parasites, which infect over 2 billion people worldwide. Basophils are innate immune cells that drive expulsion of the murine helminth *Trichuris muris*. However, the molecular mechanisms that control basophil function and gene expression during helminth-induced type 2 inflammation remain unclear. We show that during *T. muris* infection, basophils localized to the intestine and upregulated components of the Notch signaling pathway, which regulates gene expression programs during development and inflammation. *In vitro*, Notch inhibition abrogated IL-33-elicited basophil IL-4 and IL-6 production by directly targeting *Il4* and *Il6*. Transcriptional profiling of Notch-deficient basophils revealed that Notch directs basophil responsiveness to inflammatory cues and effector gene expression. *In vivo*, Notch-deficient basophils did not localize effectively within the lamina propria of the intestine, at the site of infection, and displayed decreased interaction with $CD4^+$ cells. Consequently, mice lacking basophil-intrinsic Notch signaling had impaired worm clearance and decreased intestinal type 2 inflammation following *T. muris* infection. These findings demonstrate that Notch regulates basophil gene expression and effector function during helminth-induced type 2 inflammation, with repercussions for our understanding of type 2 immunity and for development of effective therapeutics aimed at this arm of host defense.

WS.D4.05.04

Type I Interferons Suppresses Anti-parasitic $CD4^+$T Cell Responses in Visceral Leishmaniasis

***R. Kumar**[1], P. Bunn[2], F. Rivera[2], N. Singh[3], S. Sundar[3], C. Engwerda[2];*
[1]Institute of Science, Banaras Hindu University, Varanasi, India, [2]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [3]Institute of Medical Science, Banaras Hindu University, Varanasi, India.

Introduction: Many pathogens, including viruses, bacteria, and protozoan parasites, suppress cell mediated immune responses through activation of type I Interferon (IFN-1) signalling. However, the role of IFN-1 during *Leishmania donovani* infection causing visceral leishmaniasis (VL) is not well known. Here we report that IFN-1 plays an important role in the pathogenesis of VL by impairing parasite clearance and suppressing pro-inflammatory cytokine production. **Methods:** Mice lacking type-1 IFN signalling (B6.IFNαR1$^{-/-}$ mice) and wild type (WT) C57BL/6 mice were infected intra-venously with $2x10^7$ *L. donovani* amastigotes. Parasite burden was measured at day 14, 28 and 56 post infections and serum cytokine levels was analysed. Intracellular cytokine staining and flow cytometry was performed to detect the $CD4^+$ T cell-derived IFN-γ production. Peripheral blood mononuclear cells (PBMCs) from VL controls were also collected to measure mRNA encoding IFN-1 related genes and whole blood assay was employed to measure the antigen specific immune response after IFN-1 signalling blockade. **Results:** B6.IFNαR1$^{-/-}$ mice showed enhanced pro-inflammatory cytokine production and better control of parasite burden in liver and spleen. IFN-1 signalling suppressed $CD4^+$ T cell-derived IFN-γ production and prevented Th1 response from controlling parasite replication. Studies in VL patients supported these findings and showed enhanced accumulation of mRNA encoding type I IFN signature genes in PBMCs that were reduced following successful drug therapy. The blockade of type-1 IFN signalling enhanced antigen specific IFN-γ production. **Conclusion:** Together, these results identify type-1 IFN signalling pathways as a potential therapeutic target to treat VL by enhancing anti-parasitic $CD4^+$ T cell responses.

WS.D4.05.05

Cross-presentation by pDC of cell-associated HIV is potentiated by non-cognate $CD8\ T^+$ cell pre-activation

***E. X. Hatton**, S. Isnard, M. Iannetta, J. Guillerme, A. Hosmalin;*
Institut Cochin, INSERM U1016, CNRS UMR8104, Université Paris Descartes, Sorbonne Paris Cité, Paris, France.

Human Plasmacytoid DC (pDC) cross-present antigens from apoptotic HIV infected cells, which contain both antigen and microbial stimuli. We studied MHC-restricted cognateand innate mechanisms leading to this cross-presentation.
We used HLA-A2 restricted HIV-Gag_{77-85}-specific $CD8^+$ T cell clones, UV-C-irradiated HIV-infected or uninfected H9 cells as antigen donor cells, and saquinavir to block direct viral presentation. DC populations were immunomagnetically and FACS-sorted to >95% purity, from HLA-A2+ or - donor buffy coats. We tested IFN-γ secretion by ELISA or intracellular production by flow cytometry.
IFN-γ secretion in response to cross-presentation of apoptotic H9-HIV cells by pDC was fully MHC-class I restricted, but intracellular IFN-γ production only partly. Inhibitors of HIV TLR-7 signaling strongly decreased the innate, non MHC-restricted intracellular IFN-γ production. PDC cultured with H9-HIV cells produced different cytokines. Among those, recombinant IFN-α or β, but not TNF-α, added to the $CD8^+$ T cell clones, in the absence of H9-HIV cells or pDC, induced intracellular IFN-γ production; they enhanced IFN-γ secretion triggered by cell-free, cognate stimulation through CD3 and CD28-bound beads. Conversely, neutralizing antibodies against these cytokines abolished the non-MHC-restricted intracellular IFN-γ production. Compared to pDC, purified cDC1 or cDC2 required additional TLR-3 or -2/4 stimulation to cross-present antigens from H9-HIV cells. Indeed, H9-HIV apoptotic cells induced maturation of pDC, but not cDC.
Our results show that pDC can detect HIV-infected cells by producing type I IFNs, which pre-activate $CD8^+$ T cell IFN-γ production and increase its release upon cognate interaction.

WS.D4.05.06

Memory CD8 T cell inflation versus tissue resident memory T cells: same patrollers, same controllers?

***S. P. M. Welten**, A. Oxenius;*
Institute of Microbiology, ETH Zürich, Zürich, Switzerland.

The induction of memory CD8 T cells residing in peripheral tissues is of considerable interest for T cell based vaccines as they can immediately exert effector functions and thus provide protection in case of pathogen encounter at mucosal and barrier sites. Cytomegalovirus (CMV)-based vaccines support the induction and accumulation of large amounts of effector memory CD8 T cells in peripheral tissues, a process called memory inflation. Tissue resident memory (T_{RM}) T cells are another subset of cells that take long-term residence in peripheral tissues. Both populations have gained substantial interest in exploiting for vaccine purposes; however, it is unclear which population is superior in providing long-term protection against a variety of pathogens and tumors. Here we compared the localization, maintenance and protective capacity of these distinct T cell subsets in the lungs. We found that inflationary T cells and T_{RM} cells have a unique phenotype and occupy distinct niches in the lung tissue. However, upon antigen re-challenge, inflationary T cells were able to adapt their phenotype and location. While the inflationary T cell pool was stably maintained for a prolonged period and dependent on IL-15-mediated signals, the number of T_{RM} cells in the lungs gradually declined over time. The different characteristics of T_{RM} and inflationary T cells also translated in distinct capacities to control various viral infections. Together these results bear relevance for vaccines aimed at eliciting memory T cells at mucosal sites.

WS.D4.06.01

A novel mechanism of neutrophil entry into epithelial cells is involved in damping inflammation but exposes a backdoor for bacterial invasion

***N. Y. SHPIGEL**;*
Hebrew University, Rehovot, Israel.

Neutrophil mobilization is a crucial response to protect the host against invading microorganisms. Neutrophil recruitment and removal is tightly regulated through apoptosis and phagocytosis by resident and recruited macrophages. Nevertheless, in many organs, macrophage mobilization across the barrier epithelium is dearth and cannot be a major mechanism for homeostasis of inflammation. We suggest that in some mucosal surfaces or barrier epithelium, like urinary and gall bladder or the mammary alveoli, phagocytosis of apoptotic neutrophils by macrophage may not be the only or most important mechanism of neutrophil safe disposal and homeostasis of inflammation. Here we propose a novel and previously unrecognized mechanism of neutrophil internalization and apoptotic death program in epithelial cells. Viable neutrophils trigger a mechanism that enables them to crawl into cytoplasmic double membrane compartments in the host cells. Next, internalized neutrophils lose the membrane compartment and undergo apoptotic cell death in the cytoplasm. We were able to demonstrate this incredible phenomena both in vitro on epithelial cell lines and in murine in vivo systems. This mechanism contributes to safe disposal of neutrophils and for the resolution of inflammation in some organs and disease processes. Moreover, some pathogenic bacteria take advantage of neutrophil cell invasion process, using it to invade epithelial cells, where they can proliferate to form intracellular bacterial communities. Bacteria invasion to epithelia may be of prime importance in the pathogenesis of major diseases such as bovine mastitis, urinary tract infection and typhoid fever, and might account for the chronic carriage and relapsing disease.

WS.D4.06.02

Lung surfactant lipids provide immune protection against non-typeable *Haemophilus influenzae* respiratory infection

B. Garcia-Fojeda[1,2], *Z. Gonzalez-Carnicero*[2], *A. De Lorenzo*[2], *C. Minutti*[1,2,3], *B. Euba*[1,4], *A. Iglesias-Ceacero*[2], *S. Castillo-Lluva*[2], *J. Garmendia*[1,4], *C. Casals*[1,2];
[1]*CIBER de Enfermedades Respiratorias, Madrid, Spain,* [2]*Universidad Complutense de Madrid, Madrid, Spain,* [3]*The Francis Crick Institute, London, United Kingdom,* [4]*Instituto de Agrobiotecnología, CSIC-Universidad Pública de Navarra, Mutilva, Spain.*

Non-typeable *Haemophilus influenzae* (NTHi) causes persistent respiratory infections in immunocompromised patients likely linked to its capacity to invade and survive within pneumocytes. In the alveolar fluid, NTHi is in contact with pulmonary surfactant, a lipoprotein complex that prevents alveolar collapse and constitutes the front line of defense against inhaled pathogens. The objective of this study was to investigate the effect of surfactant phospholipids on the host-pathogen interaction between NTHi and pneumocytes. For this purpose, we used two types of surfactant lipid vesicles present in the alveolar fluid: i) multilamellar vesicles (MLVs, > 1 μm diameter), which constitute the tensioactive material of surfactant, and ii) small unilamellar vesicles (SUVs, 40 nm diameter), which are generated after inspiration/expiration cycles, and are endocytosed by pneumocytes for their degradation and/or recycling. Results indicated that MLVs of surfactant inhibited adhesion of NTHi to pneumocytes and, consequently, NTHi invasion. In contrast, endocytosed surfactant lipids did not affect NTHi adhesion but inhibited entry of NTHi in pneumocytes. SUVs of lung surfactant were endocytosed via the scavenger receptor SR-BI, but not CD36, and anti-SR-BI antibodies abrogated surfactant inhibition of NTHi invasion. Endocytosis of SUVs inhibited Akt phosphorylation and Rac1 GTPase activation, key events in NTHi internalization. Lung surfactant administration in a mouse model of NTHi pulmonary infection amplified bacterial clearance, supporting the protective role of surfactant lipids against NTHi infection. These results suggest that decreased surfactant lipid levels reported in smokers and patients with chronic obstructive pulmonary disease may increase their susceptibility to infection by NTHi. Funding: SAF-2015-65307-R.

WS.D4.06.03

CD200R1L, a novel activating receptor on human neutrophils that induces ROS and NET release

M. Ramos[1], *J. Stok*[1], *C. Kesmir*[2], *T. Jansen*[1], *L. Meyaard*[1], *M. van der Vlist*[1];
[1]*UMC Utrecht; Oncode Institute, Utrecht, Netherlands,* [2]*Utrecht University, Utrecht, Netherlands.*

Inhibitory and activating receptors play a key role in modulating the amplitude and duration of immune responses during infection and are central in achieving immune balance in homeostatic conditions. One example is the paired CD200R gene family, which in humans comprises of one inhibitory, CD200R, and one putative activating member, CD200R1L. In contrast to literature, where has been reported that the activating CD200R1L is not expressed as a protein, we demonstrated that CD200R1L is endogenously expressed by human neutrophils. Our functional data show that this activating receptor can induce important cellular functions such as formation of reactive oxygen species (ROS) and release of extracellular traps (NETosis). Cross-linking CD200R1L with a monoclonal antibody elicited an FcγR-independent oxidative burst on primary neutrophils that relied on Syk, PI3Kβ, PI3Kδ and Rac GTPase signalling. By making use of the ROS inhibitor DPI we determined that CD200R1L elicited a classical NETosis process dependent on ROS generation by NADPH oxidase. Phylogenetic studies showed that CD200R1L was present in all examined species, implying that evolutionary conservation of this receptor was critical for protection against co-evolving pathogens. With few exceptions, activating CD200R1L receptors had longer branch lengths than inhibitory ones suggesting that activating receptors accumulated mutations at a faster pace. The faster evolution of these receptors agrees with the proposed theory that under pathogen pressure, activating receptors evolve quicker which would fit this receptor's functional capabilities. Based on our data, we hypothesize that CD200R1L represents a hitherto unidentified pathogen-recognition receptor on human neutrophils important for pathogen clearance.

Innate immune recognition of *Staphylococcus aureus* by dendritic cells is affected by antibiotic resistance mutations

T. P. Patton[1,2], *J. Jiang*[2,3], *R. J. Lundie*[1,2], *V. Oorschot*[2,4], *G. Ramm*[2,4], *A. Y. Peleg*[2,3,5], *M. A. O'Keeffe*[1,2];
[1]*Infection and Immunity Program, Monash Biomedicine Discovery Institute, Monash University, Melbourne, Australia,* [2]*Department of Biochemistry and Molecular Biology, Monash University, Melbourne, Australia,* [3]*Department of Microbiology, Monash University, Melbourne, Australia,* [4]*Monash Ramaciotti Centre for Cryo Electron Microscopy, Monash University, Melbourne, Australia,* [5]*Department of Infectious Diseases, The Alfred Hospital and Central Clinical School, Monash University, Melbourne, Australia.*

Introduction: Methicillin-resistant *Staphylococcus aureus* (MRSA) represents an emerging public health threat. Resistance to last-line antibiotics is on the rise, correlating with increased morbidity and mortality in the hospital setting. Recently, whole genome sequencing revealed that mutations conferring resistance to last-line antibiotics affect the composition of the bacterial cell membrane and wall. Here we investigate how these mutations affect innate immune recognition by dendritic cells (DCs) of the host.
Methods: Paired isogenic clinical isolates were obtained from patients suffering chronic infection with MRSA. Primary DC subsets were phenotyped in response to these bacterial stimuli; characterising inflammatory cytokine secretion, as well as surface phenotype. Differences in antigen uptake and trafficking by DC subsets were quantified via a combination of flow cytometry, electron microscopy and live cell imaging techniques.
Results: The acquisition of daptomycin resistance is associated with a decrease in immunological recognition by dendritic cells (DCs). This reduction reflects decreased expression of co-stimulatory markers CD40 and CD80, alongside a significant decrease in production of pro-inflammatory cytokines and chemokines. Furthermore, the recreation of individual point mutations in genes responsible for phospholipid biosynthesis found in resistant MRSA strains play a critical role in modulating immune recognition of resistant strains by DCs.
Conclusion: These findings highlight of a novel aspect of antibiotic resistance- showing for the first time that point mutations arising in MRSA during antibiotic therapy can result in decreased immunological recognition by dendritic cells.

WS.D4.06.05

Hemolysin liberates bacterial outer membrane vesicles for cytosolic lipopolysaccharide sensing

S. Chen[1], *Q. Liu*[1,2,3];
[1]*State Key Laboratory of Bioreactor Engineering, ShangHai, China,* [2]*Qingdao National Laboratory for Marine Science and Technology, Qingdao, China,* [3]*Shanghai Engineering Research Center of Maricultured Animal Vaccines, Shanghai, China.*

Induction: Inflammatory caspase-11/4/5 recognize cytosolic LPS from invading Gram-negative bacteria. Since extracellular or vacuole-constrained bacteria are thought to rarely access the cytoplasm, how their LPS are exposed to the cytosolic sensors is a critical event for pathogen recognition. Hemolysin was generally accepted to rupture cell membrane. Whether and how hemolysin participates in non-canonical inflammasome signaling remains uncovered.
Materials and Methods: LDH and cytokine release induced by bacterial or OMV infection were measured by a cytotoxicity or an ELISA kit, respectively. Subcellular cell fractions were extracted by a digitonin-based fractionation for LPS quantification. For OMVs-containing vacuole integrity detection, we constructed an eukaryotic expression plasmid for GFP tagged galectin-3 introduced into HeLa cells to observe the specks of galectin recruitment. In vivo, an oral infection model was used to detect bacterial colonization, gut inflammation, and enterocyte pyroptosis.
Results: Hemolysin-overexpressed enterobacteria triggered significantly increased caspase-4 activation in human intestinal epithelial cells. Hemolysin promoted LPS cytosolic delivery from extracellular bacteria through dynamin-dependent endocytosis. Further, hemolysin was largely associated with bacterial outer membrane vesicles (OMVs) and induced rupture of OMV-containing vacuoles, subsequently increasing LPS exposure to the cytosolic sensor. Accordingly, overexpression of hemolysin promoted caspase-11 dependent IL-18 secretion, gut inflammation, and enterocyte pyroptosis in orally-infected mice, which was associated with restricting bacterial colonization in vivo.
Conclusions: Hemolysin promotes noncanonical inflammasome activation via liberating OMVs for cytosolic LPS sensing, which offers insights into innate immune surveillance of dysregulated hemolysin via caspase-11/4 in intestinal antibacterial defenses.

Analysis of CD6-based peptides in experimental sepsis

C. Català[1], *M. Martínez-Florensa*[1], *M. Velasco-de Andrés*[1], *O. Cañadas*[2,3], *V. Fraile-Ágreda*[2,3], *S. Casadó-Llombart*[1], *N. Armiger-Borràs*[1], *M. Consuegra-Fernández*[1], *C. Casals*[2,3], *F. LOZANO*[1,4,5];

[1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), BARCELONA, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Respiratorias (CIBERES), Instituto de Salud Carlos III, MADRID, Spain,* [3]*Departmento de Bioquímica y Biología Molecular, Universidad Complutense de Madrid, Madrid, Spain,* [4]*Servei d'Immunologia, Centre de Diagnòstic Biomèdic, Hospital Clínic de Barcelona, Barcelona, Spain,* [5]*Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain.*

Sepsis still constitutes one of the most important causes of death worldwide, a fact aggravated by the appearance of multidrug resistant strains due to indiscriminate use of antibiotics. Receptors from the immune innate system recognize pathogen-associated molecular patterns (PAMPs) and can be a source of antimicrobial therapies alternative/adjunctive to antibiotics. CD6 is a lymphocyte-specific surface receptor of the scavenger receptor cysteine-rich superfamily (SRCR-SF) displaying bacterial-binding properties through recognition of PAMPs from Gram positive (lipoteichoic acid; LTA) and negative (lipopolysaccharide; LPS). The present work analysed the bacterial-binding properties of three conserved short peptides (11-mer) mapping at surface accessible locations from each of the three extracellular SRCR domains of human CD6 (CD6.PD1, GTVEVRLEASW; CD6.PD2 GRVEMLEHGEW; and CD6.PD3, GQVEVHFRGVW). All peptides showed relative high binding affinities for both LPS (K_d from 3.5 to 3,000 nM) and LTA (K_d from 36 to 680 nM). CD6.PD1 and CD6.PD3 peptides, but not CD6.PD2, also showed broad *in vitro* bacterial-agglutination properties.
In *in vivo* studies, the CD6.PD3 peptide excelled by dose- and time-dependent improving the survival of mice undergoing cecal ligation and puncture (CLP)-induced sepsis, a fact concomitant with decreased pro-inflammatory cytokine serum levels and bacterial load. CD6.PD3 also showed additive effects on survival of CLP-septic mice when combined with the broad spectrum bactericidal antibiotic Imipenem/Cilastatin. These results illustrate the therapeutic potential of peptides retaining the bacterial-binding properties of native CD6. Supported by Spanish MINECO (SAF2016-80535- R; PCIN-2015-070) and ISCIII [RD12/0015/0018 and CIBERES CB06/06/0002] -co-financed by European Development Regional Fund "A way to achieve Europe".

Primary neutrophil defects reveal the mechanisms of neutrophil extracellular trap (NET) formation and NETosis: a unique role for active cytoskeletal rearrangments

E. Sprenkeler[1], *A. Tool*[1], *T. K. van den Berg*[1], ***T. Kuijpers***[1,2];

[1]*Department of Blood Cell Research, Sanquin Research, and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [2]*Emma Children's Hospital, Amsterdam University Medical Center (AUMC), University of Amsterdam, Amsterdam, Netherlands.*

Although the formation and microscopic appearance of neutrophil extracellular traps (NETs), the physiological mechanisms triggering NET release and the concomitant cell death known as NETosis, have been studied since has been studied since the first report in 2004. The relevance of NET formation to disease and clinical translatability of this unconventional cellular mechanism remain poorly understood. Using neutrophils of patients with various rare genetically well-characterized disorders as human knockout models (including Chronic Granulomatous disease [CGD], granule deficiencies [GPS], degranulation defects [FHL5], ARPC1B and MKL1 deficiency), we have been able to unravel the consecutive steps required for NETosis to occur. Additional use of small compounds to inhibit specific cellular signaling pathways in neutrophils from healthy controls were used to verify the role of these mechanisms identified in patient neutrophils. Time courses indicated differences in the moment certain processes became active from cellular activation until DNA release using microcopy, Sytox Green kinetic determination and live cell imaging during the process of NETosis.
In this way, we have been able to dissect two phases and the signaling steps involved in the overall process of NETosis. In either of these two phases, our studies demonstrate that reactive oxygen species, serine proteases as well as specific granule components and the rearrangements of cytoskeletal elements have an essential and unique contribution in the active DNA release from human neutrophils. These data will be discussed in the view of the clinical manifestations.

WS.D4.07.02

Characterization of neutrophils generated in vitro from Hoxb8-transduced myeloid progenitor cells

A. Orosz, *A. Mócsai;*
Semmelweis University, Budapest, Hungary.

Background: Acute inflammation and neutrophil granulocytes have long been mentioned together, however the molecular background of the neuthrophils' function is still mostly unknown. Therefore we are hoping to uncover these molecular mechanisms using ex vivo generated neutrophil cells from the so called SCF ER-Hoxb8 progenitors. These bone marrow-derived progenitors are retrovirally transduced to express the Hoxb8 transcription factor in the presence of β-estrogen, in order to keep them in progenitor state for long periods of time. From them, unlimited amounts of neutrophils can be differentiated using certain cytokines. **Materials and methods**: Neutrophils were generated via growing progenitors in β-estrogen free medium supplemented with G-CSF. Cell surface markers were detected using flow cytometry. ROS production was measured according to cytochrome-c reduction. Adhesion and migration capabilities were tested using different stimulating agents. Fagocyting properties were measured using fluorescent *Staphylococcus aureus* and *Candida albicans*. **Results**: $CD45^+$ progenitor cell line can be cultured for long time.
$Ly6G^+$ neutrophils start to differentiate in 4 days. 5-6 days old neutrophils show strong adhesion upon PMA and IC stimulation. Hoxb8 neutrophils can also produce ROS upon various stimuli in vitro. Neutrophils appear in the circulation after adoptive transfer of progenitors into lethally irradiated recipient mice. In vivo generated neutrophils can migrate and carry out phagocytosis in inflammatory conditions. **Conclusions**: The SCF ER-Hoxb8 cell line can be a great alternative to the common- genetically modified mice-based methods in use to discover the molecular basis of the role of the neutrophils in inflammatory diseases both in vitro and in vivo.

WS.D4.07.03

Regnase-3 is an essential RNase for the Interferon pathway in tissue macrophages

M. Von Gamm[1], *A. Schaub*[1], *J. Lichti*[1], *M. Tschöp*[1], *V. Hornung*[2], *C. Schulz*[3], *M. Heikenwälder*[4], ***E. Glasmacher***[1];
[1]*Helmholtz Center Munich, Munich, Germany,* [2]*Gene Center, Munich, Germany,* [3]*LMU, Munich, Germany,* [4]*DKFZ, Heidelberg, Germany.*

Regnases are immune cell-expressed RNases. Regnase-1 degrades cellular and viral RNAs in macrophages and T cells, but the role of Regnase-3 remains unknown. Regnase-3-deficient (*Reg3*$^{-/-}$) mice develop severe lymphadenopathy, caused by extramedullary hematopoiesis and increased type-I-interferon signaling. CD19, as well as CD4- specific ablation of Regnase-3 in mice does not result in phenotypic changes, however LysM-specific deletion recapitulates this phenotype. Regnase-3 protein is regulated via IKK upon TLR activation, similarly to Regnase-1. However, Regnase-3 steady-state expression is specifically high in macrophages and in non-lymphoid tissues, different to Regnase-1. Whereas Regnase-1 transcription is controlled via NF-kB activity, Regnase-3 is transcriptionally regulated via TLR3 and TBK signaling. Although Regnase-3 deficiency does not affect phagocytic activity, it localizes to phagosomes in macrophages, is regulated via lysosomal degradation upon RNA agonist stimulation and interacts with TLR3. Therefore, Regnase-3 is the evolutionary counterpart to Regnase-1, functioning in the endocytosis and interferon pathway, ensuring tissue homeostasis.

A viral immunoevasin controls innate immunity by targeting the prototypical natural killer cell receptor family

O. Aguliar[1], ***R. Berry***[2], *M. Rahim*[3], *J. Reichel*[4], *B. Popovic*[4], *M. Tanaka*[1], *Z. Fu*[2], *G. Balaji*[2], *T. Lau*[1], *M. Tu*[3], *C. Kirkham*[1], *A. Mahmoud*[3], *A. Mesci*[1], *A. Krmpotic*[4], *D. Allan*[1], *A. Makrigiannis*[3], *S. Jonjic*[4], *J. Rossjohn*[2], *J. Carlyle*[1];
[1]*University of Toronto, Toronto, Canada,* [2]*Monash University, Clayton, Australia,* [3]*Univeristy of Ottawa, Ottawa, Canada,* [4]*University of Rijeka, Rijeka, Croatia.*

Natural killer (NK) cells play a key role in innate immunity by detecting alterations in self and non-self ligands via paired NK cell receptors (NKRs). Despite identification of numerous NKR-ligand interactions, physiological ligands for the prototypical NK1.1 orphan receptor remain elusive. Here, we identify a viral ligand for the inhibitory and activating NKR- P1 (NK1.1) receptors. This murine cytomegalovirus (MCMV)-encoded protein, m12, restrains NK cell effector function by directly engaging the inhibitory NKR-P1B receptor. However, m12 also interacts with the activating NKR-P1A/C receptors to counter-balance m12 decoy function. Structural analyses reveal that m12 sequesters a large NKR-P1 surface area via a ''polar claw'' mechanism. Polymorphisms in, and ablation of, the viral m12 protein and host NKR-P1B/C alleles impact NK cell responses in vivo. Thus, we identify the long-sought foreign ligand for this key immunoregulatory NKR family and reveal how it controls the evolutionary balance of immune recognition during host-pathogen interplay.

The interaction of the immune system and microbiota is paramount for the development of the immune system and the maintenance of gut homeostasis. In recent years bacterial symbionts have been found in previously considered sterile body sites, including human breastmilk. Therefore, it seems clear that translocation of bacteria occurs physiologically and this has been hypothesized to be controlled by immune cells. Here, we explore the ability of the probiotic bacterium *Lactobacillus plantarum* to survive within macrophages and provide some of the mechanisms involved in this process.
We show the ability of *L. plantarum* strains to survive within the RAW264.7 macrophage-like cell line up to 24 h and, to a lesser extent, inside mouse bone marrow-derived macrophages and human monocyte-derived macrophages. In the absence of antibiotics, *L. plantarum* strains are capable of extruding from immune cells after internalization, which is consistent with the extraintestinal translocation hypothesis. We also addressed the contribution of the complement system in *L. plantarum* internalization and survival: we found that both processes are dependent on bacterial opsonization and recognition by macrophage complement receptor 3. Additionally, by using human whole blood as a more complex model we observed that monocytes are capable of internalizing and sustaining a significant *L. plantarum* population.
Collectively, our work provides one of the first evidences of the capacity of probiotic bacteria to survive within macrophages, which we proved to be complement system-dependent. Therefore, we propose that monocytes/macrophages are important players during physiological bacterial translocation.

WS.D4.07.06

Nanovaccines to prevent listeriosis in the elderly

C. Alvarez-Dominguez[1], *R. Calderon-Gonzalez*[1], *H. Teran-Navarro*[1], *D. Salcines-Cuevas*[1], *M. Fresno-Escudero*[2];
[1]*Instituto de Formacion e Investigación Marques de Valdecilla, Santander, Spain,* [2]*Centro de Biología Molecular Severo Ochoa, Madrid, Spain.*

Introduction: Clinical cases of listeriosis in the elderly associate with meningitis or septicaemia. Listeriosis severe cases have increased in European countries, Spain in particular urging for safe vaccines. We have prepared new nanovaccine formulations for *Listeria monocytogenes* (LM) including two different adjuvants. Methods: We have *i.v* vaccinated old-mice, young adults and pregnant mothers and challenged them with a sub-lethal dose of wild type LM. Brains, livers in neonates and livers and spleens in adult mice are examine for viable bacteria, immune responses and cytokine profiles. We also collected clinical listeriosis cases and explore bacterial virulence and immune responses in sera and monocyte derived dendritic cells (MoDC). Results: Old-mice and young adults become protected with nanovaccine formulations using adjuvants that expands CD4 and CD8 immune responses, while neonates were better protected with adjuvants that only induce CD8 immune responses. Clinical cases of listeriosis in 2013-2015 and mice sera have defined two useful prognostic immune biomarkers to design listeriosis vaccines: high anti-GAPDH antibody titers and tumor necrosis factor (TNF)/interleukin (IL)-6 ratios. Discussion: Gold glyco-nanoparticles vaccines conjugated to short LM peptides and formulated with a pro-inflammatory Toll-like receptor 2/4-targeted adjuvant protects safely against elderly and neonatal listeriosis. Mice vaccinated with these nanovaccines did not develop listeriosis or brain diseases and immune responses shifted towards Th1/IL-12 pro-inflammatory cytokine profiles and high production of anti-LM antibodies, suggesting good induction of LM-specific memory. Moreover, these nanovaccine formulations were able to activate Th1 production of monocyte dendritic cells from listeriosis patients, suggesting they might be a good nanovaccine formulation to implement LM-specific immunity in the elderly.

WS.E1.01.01

A hot trick for efficient peptide exchange on MHC class I multimers

J. J. Luimstra[1], *M. A. Garstka*[2], *M. C. Roex*[1], *F. H. Falkenburg*[1], *J. Neefjes*[1], *H. Ovaa*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Xi'an Jiaotong University, Xi'an, China.*

Fluorescently-labelled major histocompatibility complex class I (MHC I) multimers are widely used for the detection, isolation and analysis of T cells in infection, autoimmunity and cancer. We developed temperature-induced peptide exchange as a fast and flexible approach to generate large sets of MHC I multimers with different specificities in parallel. We designed conditional ligands for two dominant alleles, H-2K^b and HLA-A*02:01, that form stable complexes at 4°C, but dissociate from MHC I at a defined elevated temperature to be exchanged for a peptide of choice. We quantified the peptide exchange by HPLC and mass spectrometry and found that upon temperature exposure, the conditional ligand could efficiently be exchanged for both high- and low-affinity peptides. We performed peptide exchange on prefolded MHC multimers and used them directly to detect CD8$^+$ T cells responses to viral epitopes in mice infected with lymphocytic choriomeningitis virus or cytomegalovirus. We next put our multimers to clinical practice by monitoring the efficacy of adoptive T cell transfer in control of cytomegalovirus reactivation in an allogeneic stem cell transplant recipient. These data illustrate the flexibility and simplicity of using our temperature-exchangeable MHC I multimers. With this strongly improved multimer technology, high-throughput assessment of T cell responses in small sample sizes with become feasible. We will provide examples of this.

WS.E1.01.02

Chemokines and integrins independently tune actin flow and substrate friction during intranodal migration of T cells

M. Hons[1,2,3], *A. Kopf*[3], *R. Hauschild*[1], *A. Leithner*[1], *F. Gärtner*[1], *J. Abe*[2], *J. Renkawitz*[1], *J. V. Stein*[2], *M. Sixt*[1];
[1]*Institute of Science and Technology Austria, Klosterneuburg, Austria,* [2]*Theodor Kocher Institute, University of Bern, Bern, Switzerland,* [3]*Institute of Scientific Instruments of the Czech Academy of Sciences, Brno, Czech Republic.*

Although much is known about the physiological framework of T cell motility and numerous rate-limiting molecules have been identified in loss-of-function approaches, an integrating functional concept of T cell motility is lacking. Here we used *in vivo* precision morphometry together with analysis of cytoskeletal dynamics *in vitro* to deconstruct the basic mechanisms of T cell migration within lymphatic organs. We challenged the persisting concept that T cell locomotion consists of rounds of protrusive activity at the leading edge and retractions at the rear. We used intravital two-photon microscopy to show that T cells were faster the more they elongated but the actual change of the cell shape was unessential. Contributions of the integrin LFA-1 and the chemokine receptor CCR7 were complementary rather than positioned in a linear pathway, as they are during leukocyte extravasation from the blood vasculature. Our data demonstrate that CCR7 controlled speed of cortical actin flows, whereas integrins mediated substrate-friction that sufficed to drive locomotion in the absence of considerable surface-adhesions.

WS.E1.01.03

Inside the infected lung - Watching immune cells battle *Aspergillus fumigatus*

S. Henneberg[1], *S. Krappmann*[2], *L. Bornemann*[1], *M. Hasenberg*[1], *J. Weski*[1], *A. Hasenberg*[1], *M. Gunzer*[1];
[1]*Institute for Experimental Immunology and Imaging, University of Duisburg-Essen, University Hospital Essen, Essen, Germany,* [2]*Microbiology Institute – Clinical Microbiology, Immunology and Hygiene, University Hospital and Friedrich-Alexander-University of Erlangen-Nürnberg, Erlangen, Germany.*

Infection with the ubiquitous mold *Aspergillus fumigatus* is a life-threatening disease for immunosuppressed patients. Inhaled conidia can germinate in the lung and invade the tissue, which causes the invasive aspergillosis (IA). Because its diagnosis is time consuming and unreliable, IA is often diagnosed too late and the mortality rate reaches up to 95%. For the prevention of IA, a better understanding of the normally effective pulmonary immune response is essential. Since immune responses in the lung are regulated tightly by the microenvironment, the effect of an infection on immune cell functionality is best analysed *in vivo*.
Therefore, we established a novel intravital lung imaging technique that does not irritate the lung and maintains near physiological lung conditions during image acquisition by avoiding a pneumothorax. By triggering recordings at defined and short-time stable lung dilations prior to exhalation via a feedback of the ventilated lung, our advanced microscopy setup allows focus-stable documentation of immune cell behaviour during an infection. With a blood vessel staining and the usage of mouse lines with conditional expression of fluorescent proteins, we are able to study neutrophils and macrophages inside the lung tissue. First promising results exhibit changes of the recruitment, invasion, interaction and uptake of inhaled conidia of these immune cells. Our novel approach enables the visualisation of pulmonary immune cell function at almost physiological conditions in vivo.
This will open up new possibilities for the research and the understanding of pulmonary immunity and ultimately also the prevention and protection of dangerous lung diseases.

WS.E1.01.04

Imaging of cytotoxic antiviral immunity while considering the 3R principle of animal research

L. Otto[1,2]*, G. Zelinskyy*[1]*, M. Schuster*[2]*, U. Dittmer*[1]*, M. Gunzer*[2]*;*
[1]*Institute for Virology, Essen, Germany,* [2]*Institute for Experimental Immunology and Imaging, Essen, Germany.*

Adoptive cell transfer approaches for antigen-specific $CD8^+$ T cells are used widely to study their effector potential during infections or cancer. However, contemporary methodological adaptations regarding transferred cell numbers, advanced imaging, and the 3R principle of animal research have been largely omitted. Here, we introduce an improved cell transfer method that reduces the number of donor animals substantially and fulfills the requirements for intravital imaging under physiological conditions. For this, we analyzed the well-established Friend retrovirus (FV) mouse model. Donor mice that expressed a FV-specific T cell receptor (TCR^{tg}) and the fluorescent protein tdTomato were used as source of antigen-specific $CD8^+$ T cells. Only a few drops of peripheral blood were sufficient to isolate ~150,000 naive reporter cells from which 1000 were adoptively transferred into recently FV-infected recipients. The cells became activated and functional and expanded strongly in the spleen and bone marrow within 10 days post infection. Transferred $CD8^+$ T cells participated in the antiviral host response within a natural range and developed an effector phenotype indistinguishable from endogenous effector $CD8^+$ T cells. Additionally, the generated reporter cell frequency allowed single cell visualization and tracking of a physiological antiretroviral $CD8^+$ T cell response by intravital two-photon microscopy. Highly reproducible results were obtained in independent experiments by reusing the same donors repetitively for multiple transfers. Our approach allows a strong reduction of experimental animals required for studies on antigen-specific $CD8^+$ T cell function and should be applicable to other transfer models.

WS.E1.01.05

Visualisation of immune receptor sequences via projection into high-dimensional space with Siamese neural networks

V. I. Nazarov[1]*, E. Ofitserov*[2]*, V. Tsvetkov*[3,1]*;*
[1]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, RAS, Moscow, Russian Federation,* [2]*Tula State University, Tula, Russian Federation,* [3]*Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

Big data is often incomprehensible for humans and its visualisation is crucial for inference. Immunological data is no exception. TCR and immunoglobulin repertoires are commonly visualised with t-SNE technique or graphs. These approaches require a lot of resources to compute distance matrix - chiefly Levenshtein, which is also resource demanding - between sequences in repertoires. These obstacles significantly limit the amount of data algorithm can process in reasonable time. To overcome this issue a method for mapping immune receptor sequences into high-dimensional space was developed. The method relies on Siamese neural networks to map sequences and designed loss function to compare them in the new vector space. The latter estimates distances between vectors, which correlate with Levenshtein distance between corresponding sequences.
This approach facilitates data visualisation in terms of resources, especially computation time. Resulting receptor sequence embeddings can be used for further visualisation with t-SNE or UMAP algorithms. In order to evaluate the versatility of our approach the model was trained on 2 millions TCR sequences and applied to visualisation of 30 000 sequences via t-SNE. After visualisation the model appeared to conserve the information about Levenshtein distance between neighbours better than t-SNE applied to Levenshtein distance matrix. Moreover, the visualisation computational time was at least 30 times less than computation of Levenshtein distance matrix and consequent t-SNE visualisation. The benefit of this model is that once trained it is cheap in resources to make another computation and visualisation as it can be used in other contexts without any changes.

WS.E1.01.06

Intravascular resident Natural Killer cells shape neutrophil dynamics in the pulmonary vasculature

J. Secklehner[1,2]*, K. De Filippo*[2]*, J. B. Mackey*[1,2]*, J. Vuononvirta*[2]*, X. Raffo Iraolagoitia*[1]*, A. McFarlane*[1]*, M. Neilson*[1]*, M. B. Headley*[3]*, M. Krummel*[3]*, N. Guerra*[2]*, L. M. Carlin*[1,2]*;*
[1]*Cancer Research UK Beatson Institute, Glasgow, United Kingdom,* [2]*Imperial College, London, United Kingdom,* [3]*University of San Francisco, San Francisco, United States.*

Neutrophils are the most abundant leukocyte in the pulmonary vasculature, critical in the immune response to pathogens. The lungs' immune system must be finely-tuned to provide protection against pathogens while limiting tissue damage that could impede gas-exchange. Other immune cells play a role in controlling neutrophils in the lung (e.g. macrophages in initiating and resolving inflammation in the alveoli), however, intravascular neutrophil regulation in early acute lung inflammation may be pivotal for patient outcome. Natural Killer (NK) cells are enriched in the lung compared to other tissues and functional NK:neutrophil interactions have been described in several organs and conditions. We hypothesised that NK cells cooperate in controlling neutrophils in the pulmonary vasculature.
Lung intravital microscopy, to directly visualize the cells *in vivo,* revealed that NK cells can remain stationary for long periods (>60min) within alveolar capillaries, where neutrophils are able to move quickly. Furthermore, we found that nearly all NK cells in the lung are intravascular. NK cells and neutrophils frequently interact for 5-10 minutes in capillaries and occasionally material is transferred from neutrophils to NK cells. NK depletion resulted in marked changes to neutrophil dynamics such as track length and duration (48.77±6 to 112.2±15µm and 2.50±0.3 to 4.77±0.7min respectively). Stimulation with endotoxin in NK depleted mice lead to a more pronounced increase in neutrophil numbers compared to control mice. We propose that a population of intravascular resident lung NK cells directly regulates neutrophil responses to inflammation. Understanding how these cells interact could allow us to locally influence neutrophil behaviour.

WS.E2E3.01.01

MHC class II-omics for full understanding of MHC class II antigen presentation

M. L. Jongsma[1]*, R. Wijdeven*[1]*, B. Cabukusta*[1]*, D. Borras*[1]*, P. Paul*[2]*, T. van den Hoorn*[2]*, J. Neefjes*[1]*;*
[1]*LUMC, Leiden, Netherlands,* [2]*NKI, Amsterdam, Netherlands.*

MHC class II molecules present exogenously derived peptides to T lymphocytes facilitating immune responses and are strongly linked to autoimmune diseases. To get full insight into the cellular pathways controlling MHC class II antigen presentation, we generated and integrated datasets obtained from three flow cytometry-based genome-wide screens: 1) an RNAi-based screen, 2) a CRISPR-Cas9 knockout screen and 3) a CRISPR-Cas9 transcriptional activation screen. The analysis so far revealed a transcriptional network of nine regulators controlling MHC class II transcription as well as a GTPase controlled transport mechanism of MHC class II containing compartments (MIIC) in human dendritic cells. We will present data on new routes and pathways in control of MHC class II antigen presentation. This will yield new leads for manipulating the immune system in the case of autoimmune diseases, infections and tumor immunology.

WS.E2E3.01.02

High affinity T cell receptor generate both active and memory cytotoxic response during a viral infection.

F. Luciani[1]*, S. Rizzetto*[1]*, A. Eltahla*[1]*, C. Cai*[1]*, E. Keoshkerian*[2]*, K. Wing*[2]*, D. Koppstein*[2]*, W. Van der Byl*[1]*, K. Shober*[3]*, M. Effemberger*[4]*, R. Bull*[1]*, A. R. Lloyd*[2]*, D. Busch*[3]*;*
[1]*School of Medical Sciences, Sydney, Australia,* [2]*Kirby Institute, Sydney, Australia,* [3]*Technical University Munich, Munich, Germany,* [4]*Technical University Munich, Munics, Germany.*

Cytotoxic CD8 T cells (CTL) play a key role in controlling viral infection by killing infected cells and establishing protective immunological memory. The affinity and diversity of T cell receptor (TCR) are critical factors that drive the activation and differentiation of CTL, but the molecular mechanisms underlying these dynamics remains elusive. We developed a novel single cell approach to measure and link TCR affinity, gene profiles using single-cell (sc)RNAseq,and functional status of CTL.We analysed >1000 antigen specific (Ag) CD8 T cells using autologous tetramers derived from longitudinal samples of early-phase HCV infections. By using VDJPuzzle, a bioinformatics pipeline to reconstruct full-length TCR from scRNAseq we surprisingly discovered in one subject a monoclonal CD8 T-cell response targeting an HLA-I-B07 restricted peptide (GPR) with high IFN-γ(1600 SFU/10^6cells) induction and a highly activated phenotype. Reversible streptamer technology revealed a high-affinity (K_{off}=8.1x10^{-4} sec^{-1})TCR for GPR peptide whilst scRNAseq, showed multiple subsets with distinct gene profiles in the GPR response. This included a rare memory precursor subset ($CD127^+KLRG1^-$) with a novel gene signature and a metabolic profile consistent with a resting state, oxidative phosphorylation and fatty acid metabolism. In contrast, a second polyclonal response targeting an HLA-IA01 restricted-peptide (ATD) was also found in the same subject, which by contrast generated low IFN-γand carried gene signatures distinct from the GPR-CTL response. The results suggest that the strength of TCR binding to cognate Ag shape the phenotype and kinetics of Ag specific CD8 T cell response. These findings are currently being validated on more subjects.

A Semi-Unsupervised Multivariate Algorithm for Mining and profiling High-dimensional Flow Cytometry Data

P. C. Martins Urbano[1], *L. Rosaria*[2], *W. Alkema*[2], *A. Koerber*[3], *E. de Jong*[4], *F. Hoentjen*[5], *I. Joosten*[1], *H. J. Koenen*[1];
[1]*Radboud university medical center, Department of Laboratory Medical Immunology, Nijmegen, Netherlands,* [2]*Radboud university medical center, Centre for Molecular and Biomolecular Informatics, Nijmegen, Netherlands,* [3]*University Hospital Essen, Department of Dermatology, Essen, Germany,* [4]*Radboud university medical center, Department of Dermatology, Nijmegen, Netherlands,* [5]*Radboud university medical center, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands.*

Introduction: Flow cytometry is an important technology for the diagnosis of life threatening diseases and has great potential for immune profiling of immune mediated inflammatory diseases (IMIDs). The current definition of diseases is largely based on 14th century medicine that is mostly based on the clinical manifestations but not on complex cellular and molecular interactions underlying disease pathology. Flow cytometry might provide IMID associated immune profiles that support diseases stratification, efficient therapy selection and therapy monitoring. Here we used flow cytometry combined with a semi-unsupervised multivariate algorithm and a machine learning tool to generate immune profiles in order to classify a variety of IMIDs.
Materials: Whole blood and peripheral blood mononuclear cells (PBMCs) from healthy controls, psoriatic (Ps), atopic dermatitis (AD) and inflammatory bowel disease (IBD) patients were collected and stained with five 10-color flow cytometry panels (1.General adaptive/innate cells, 2. T-cell differentiation/maturation, 3. B-cell differentiation/maturation, 4.Thelper cells and 5.Regulatory Tcells), measured by flow cytometry, followed by manual data analysis and subsequent unsupervised multivariate analysis and data mining by random forest machine learning.
Results: The multivariate algorithm combined with the machine learning tool are capable to stratify the IMID cohorts and the healthy volunteer cohort. Random forest analysis identified of several immune cell subsets that distinguish between those disease cohorts. However, many common denominators were found between PS, AD, and IBD.
Conclusion: We developed a semi-unsupervised analysis pipeline to profile and mine high-dimensional flow cytometry data that might be applied for IMID stratification.

Single cell transcriptomes define the cellular and molecular landscape of human lungs in asthma

F. Vieira Braga[1], *G. Kar*[1], *T. Gomes*[1], *E. S. Fasouli*[1], *P. Strzelecka*[1], *K. Polanski*[1], *M. Efremova*[1], *K. Mahbubani*[2], *A. Cvejic*[1], *K. Saeb-Parsy*[2], *O. A. Carpaij*[3], *M. Berg*[3], *S. Brouwer*[3], *K. Affleck*[4], *M. van den Berge*[3], *A. van-Oosterhout*[4], *M. Nawijn*[3], *S. A. Teichmann*[1];
[1]*Wellcome Trust Sanger Institute, Cambridge, United Kingdom,* [2]*Cambridge University, Cambridge, United Kingdom,* [3]*University of Groningen, Groningen, Netherlands,* [4]*GlaxoSmithKline, Stevenage, United Kingdom.*

The lung plays a critical role in both gas exchange and mucosal immunity. Acute and chronic disorders of the lung are a major cause of mortality worldwide, and some are expressed predominantly in the airways (such as asthma) or in the respiratory unit in lung parenchyma (such as emphysema). We comprehensively profiled the cells that make up both the human lung upper airway wall and the respiratory unit, as well as paired spleens and lymph nodes using single cell transcriptomics. We identified core signatures of lung resident immune cells in healthy individuals. We expanded our analysis beyond healthy individuals by performing single cell transcriptome analysis of whole airways biopsies and sorted CD4 T cells from asthmatic patients. We observed disease specific programs of epithelial cell differentiation and reshaping of the immune repertoire that takes place in asthma. We reconstructed cellular communication networks between immune and non immune cells specific for asthma. Our data constitute an invaluable resource for the community interested in immune responses localised to the lung.

WS.E2E3.01.05

DiSNE visualization and assessment of clonal kinetics reveals multiple trajectories of dendritic cell development

D. Lin[1], *A. Kan*[1], *J. Gao*[1], *E. Crampin*[2], *P. Hodgkin*[1], *S. Naik*[1];
[1]*Walter and Eliza Hall Institute, Melbourne, Australia,* [2]*University of Melbourne, Melbourne, Australia.*

A thorough understanding of cellular development is incumbent on assessing the complexities of fate and kinetics of individual clones within a population. Here, we develop a system for robust periodical assessment of lineage outputs of thousands of transient clones and establishment of *bona fide* cellular trajectories. We appraise the development of dendritic cells (DCs) in *fms*-like tyrosine kinase 3 ligand culture from barcode-labeled hematopoietic stem and progenitor cells (HSPCs) by serially measuring barcode signatures, and visualize this multidimensional data using developmental interpolated t-distributed stochastic neighborhood embedding (Di-SNE) time-lapse movies. We identify multiple cellular trajectories of DC development that are characterized by distinct fate bias and expansion kinetics, and determine that these are intrinsically programmed. We demonstrate that conventional DC and plasmacytoid DC trajectories are largely separated already at the HSPC stage. This framework allows systematic evaluation of clonal dynamics and can be applied to other steady-state or perturbed developmental systems.

WS.E2E3.01.06

CD4 T cell transcriptomics reveals novel diagnostic and mechanistic immune signatures of tuberculosis

J. G. Burel[1], *C. S. Lindestam Arlehamn*[1], *M. Pomaznoy*[1], *N. Khaan*[1], *G. Seumois*[1], *J. A. Greenbaum*[1], *D. DeSilva*[2], *R. Taplitz*[3], *R. H. Gilman*[4], *M. Saito*[5], *P. Vijayanand*[1], *A. Sette*[1], *B. Peters*[1];
[1]*La Jolla Institute for Allergy and Immunology, La Jolla, United States,* [2]*General Sir John Kotelawala Defence University, Colombo, Sri Lanka,* [3]*University of California San Diego, La Jolla, United States,* [4]*Johns Hopkins University Bloomberg School of Public Health, Baltimore, United States,* [5]*Tohoku University, Sendai, Japan.*

In the context of infectious diseases, cell population transcriptomics are useful to gain deeper insight into protective immune responses, which is limited using traditional whole blood approaches. As part of the Human Immune Project Consortium (HIPC) program, we are aiming to decipher CD4 T cell immune signatures of tuberculosis (TB) in the context of controlled (latent TB) and uncontrolled (active TB) infection. We found an *ex vivo* gene expression signature in memory CD4 T cells that could differentiate between latent TB and TB negative subjects, as well as novel markers that are expressed in TB-antigen specific CD4 T cells in the context of latent TB. We further explored the inter-individual variability of gene expression within the latent TB cohort and identified immune parameters associated with higher risk of developing active TB. Finally, comparison of the transcriptomic profile of memory CD4 T cells of latent and active TB subjects after antigen-specific *in vitro* stimulation identified TB-specific T cell immune signatures of controlled infection versus disease. Overall, our approach has identified a plethora of TB-associated T cell immune signatures that allowed us to gain mechanistic insights into the key CD4 T cell components contributing to TB protective immunity. Additionally, our findings can be translated into new diagnostic and prognostic tools, in particular, identifying latent TB infected individuals at risk of developing active TB.

WS.E4.01.01

Mechanotransduction as a novel immune checkpoint in NK cell cytotoxicity

M. Barda-Saad, *A. Ben-Shmuel, O. Matalon, J. Kivelevitz, B. Sabag, N. Joseph, G. Biber;*
Bar-Ilan University, Ramat-Gan, Israel.

Natural killer (NK) cells are a potent weapon of the immune system against viral infections and tumor growth. The actomyosin network generates forces through the activity of actin filaments and myosin motors. This machinery is responsible for the conversion of mechanical forces into biochemical signals in a process termed mechanotransduction. However, the mechanism by which mechanotransduction controls the immune response, and specifically lymphocyte activity, is poorly understood. Here, we demonstrate that actomyosin retrograde flow (ARF) controls NK cell response through a novel interaction between beta-actin with the SH2-domain containing protein tyrosine phosphatase-1 (SHP-1), converting its conformation state, thereby regulating NK cell cytotoxicity. Actin dynamics govern SHP-1 conformational structure dictating its catalytic activity. Indeed, blocking actin dynamics results in reduced SHP-1 activity, by confining SHP-1 to its inactivated “closed” conformation. This reduced enzymatic activity of SHP-1 leads to increased phosphorylation of SHP-1 substrates, an elevation of intracellular calcium flux, and NK cell cytotoxicity. Our data suggest that SHP-1 plays a major role as a sensor of ARF-generated forces in the process of mechanotransduction, and reveal a novel mechanism by which regulation of SHP-1 by ARF dictates NK cell killing decisions. Our data identify ARF as a master regulator of the lymphocyte response.

WS.E4.01.02

Combining FACS, High-Resolution Mass-spectrometry, and Single Cell Sequencing Reveals Interactome Effects of Translational Control

M. D. Stadnisky, *R. Halpert, S. Siddiq, J. Spidlen, J. Almarode, M. Velazquez-Palafox, I. Taylor, C. Freier;*
FlowJo, LLC & Becton, Dickinson and Company, Ashland, United States.

Algorithms can target advertisements based on volunteered content and social network in microseconds, yet precision medicine lags in infancy. To break this societal Munchausen by proxy, we generated a framework for immune health by creating a social network of immune cells, modeling both internal state and interactions with other cells. To do this, we analyze and combine data sets including (1) FACS with high-resolution mass-spectrometry-based proteomics and (2) more than 20 single cell whole transcriptome datasets. With (truly) quantitative protein and gene expression data for 28 human hematopoietic cell populations, and more than 10,000 proteins and genes measurements per cell, we generate an interactome for these cells and layer in both transcriptional and translational controls. Using these as internal 'sentiments', we develop a deep steady state social network such that perturbations to the internal state of individual cells (e.g. in the context of disease) can be modeled.
Using three examples, (1) CD8 T cell exhaustion, (2) alternate macrophage activation, and (3) dendritic cell dysfunction, we show how perturbations in immune cell gene and protein expression affect the network of immune cells, and ultimately the immune system. Finally, we propose a set of assays to establish a patient steady state profile, and we describe how to build a precision, predictive social network for an individual's immune system.

WS.E4.01.03

Helper T cell extracellular vesicles couple delivery of effector CD40L to antigen recognition

E. B. Compeer[1], *D. G. Saliba*[1], *P. F. Céspedes*[1], *Š. Bálint*[1], *K. Korobchevskaya*[1], *C. Cassioli*[2], *M. L. Dustin*[1];
[1]*University of Oxford, Oxford, United Kingdom,* [2]*University of Siena, Siena, Italy.*

Most, if not all, cell types release extracellular vesicles (EV) that play a role in local and systemic intercellular communication by transferring protein, lipids and RNA between cells. Exosomes, a subset of EVs, arise through exocytosis of multivesicular bodies that lead to release of their intraluminal vesicles, which are mostly formed by vesicle budding and scission from endosomal membranes by the Endosomal Sorting Complexes Required for Transport (ESCRT). We recently discovered a parallel route of EV generation in CD4 T-cells. We found that >80% of TCR at the immunological synapses' center, formed with supported planar bilayers (SLB) containing peptide-MHCII and ICAM1, are released from the T-cell surface. These EV thus can be defined as synaptic ectosomes (SE) based on budding from the plasma membrane.
Mass spectrometry analysis of SE demonstrates the presence of TCR signaling and ESCRT proteins, corroborating our earlier data. While CD40L was not normally detected in SE we could recruit CD40L to SE by incorporating CD40 into SLBs. Super-resolution microscopy on SLBs shows that the majority of SE are TCR positive, with half of the TCR T-EV positive for CD40L, in presence of TCR and CD40 engagement. Exposure of human dendritic cells (DC) to CD40L-SE induced DC maturation. We are investigating the form of CD40L that is stored and translocated in T-cells for packaging and release with TCR at the IS resulting in a feed forward activation of DC with potential for intrinsic peptide-MHC specificity.

WS.E4.01.04

Itaconate is an anti-inflammatory metabolite that activates Nrf2 via alkylation of KEAP1

D. G. Ryan;
Trinity Biomedical Sciences Institute, Dublin, Ireland.

The endogenous metabolite itaconate has recently emerged as a regulator of macrophage function. However, the precise mechanism of itaconate action in macrophages remains poorly understood. Here we report that itaconate is required for the activation of the anti-inflammatory transcription factor nuclear factor-erythroid 2 p45-related factor 2 (Nrf2) by LPS. We find that itaconate directly modifies proteins via alkylation of cysteine residues, a novel post-translational modification we've termed 2,3-dicarboxypropylation. Itaconate alkylates cysteines 151, 257, 273, 288 and 297 on the Kelch-Like ECH-Associated Protein 1 (Keap1) enabling Nrf2 to increase expression of downstream genes with antioxidant and anti-inflammatory capacity. The activation of Nrf2 is required for the anti-inflammatory action of itaconate. We describe the use of a new cell-permeable itaconate derivative, 4-octyl itaconate (OI), which is protective against LPS-induced lethality *in vivo* and decreases cytokine production. We show that type I interferons (IFN) boost immunoresponsive gene 1 (*Irg1*) expression and itaconate production. Furthermore, we find that itaconate production limits the type I IFN response indicating a negative feedback loop involving IFNs and itaconate. Our findings demonstrate that itaconate is a critical anti-inflammatory metabolite acting via Nrf2 to limit inflammation and modulate type I IFNs.

WS.E4.01.05

Sugar sweet signalling; Exploration of dendritic cell lectin receptors and their immune modulatory signalling pathways

R. J. E. Li, *J. E. Rodriguez-Camejo, J. Lübbers, A. Zaal, C. R. Jimenez, S. R. Piersma, T. V. Pham, R. R. de Goeij- de Haas, S. J. van Vliet, Y. van Kooyk;*
Cancer Center Amsterdam - VU University medical center, Amsterdam, Netherlands.

Dendritic cells (DCs) are key inducers of the adaptive immune response. They possess a multitude of different pattern recognition receptors (PPRs), including Toll-like receptors (TLRs), and C-type Lectin Receptors (CLRs) in order to elicit tailor-made immune response against invading pathogens. CLRs have gained much attention as endocytic PRRs, but also for their immune modulatory functions. Strikingly, several carbohydrate ligands are shared among different CLRs, yet each seems to propagate a unique signalling cascade. Additionally, CLR triggering can modulate the signalling pathways of TLRS, to modify or prolong the TLR-induced response.
We recently showed that carbohydrates have a huge impact on DC polarizion or suppression of T cell responses. Carbohydrates such as High Mannose-, LewisX-, or LewisY-containing ligands displayed differential IL-10 and IL-12 expression profiles by DC after concomitant LPS stimulation. In contrast, α2-3- or α2-6-sialic acid-containing ligands skew DCs towards the induction of T regs. These carbohydrates target differential CLRs such as DC-SIGN and Siglec, respectively. To gain further insight the immunogenic signalling pathways of the DC-expressed CLR DC-SIGN and its interference with TLR signalling, as well as the tolerogenic signalling pathways through Siglec, we coupled different carbohydrate ligands to a dendrimeric structure, thereby offering multivalent ligand presentation. For insight in the underlying signalling pathways, we applied phosphoproteomics to investigate differences in DC protein phosphorylation upon specific CLR-ligand engagement, and next generation sequencing on a transcriptional level. Detailed analysis of these reveal an immunogenic or tolerogenic DC fingerprint through carbohydrate-CLR interaction, and include significant changes in immunogenic signalling pathways.

1Molecular mechanisms underlying vascular and inflammatory cell network at endothelial and macrophage levels are still unclear. Here we found that microvascular inflammation associates with changes in Notch signaling at endothelium/monocyte interface including loss of endothelial Notch4 and the acquisition of the Notch ligand Dll4 in both cell types.
We showed that endothelial DLL4 induces circulating monocytes to polarize into a M1-type pro-inflammatory macrophages ($CD40^{high}CD64^{high}CD200R^{low}$ HLA-$DR^{low}CD11b^{low}$) eliciting the production of IL-6. Dll4 and IL-6 are both Notch-dependent and are required for macrophage polarization through selective down and upregulation of M2- and M1-type markers, respectively. Subsequently, we investigated the ability of DLL4 to interfere with M2 polarization. We found that DLL4 triggers a specific alteration of the IL-4 induced M2 phenotype through a significant inhibition of M2 markers (CD11b, CD206, CD200R). DLL4 also induces caspase3/7-dependent apoptosis specifically in M2 differentiating macrophages while DLL1 had no effect. DLL4 signals via Notch1 and DLL4-mediated apoptosis is Notch-dependent. Fully differentiated M2 macrophages became resistant to DLL4 action**.** DLL4 upregulates gene expression, upon M2 upon differentiation, affecting the Notch pattern (Notch1, 3, Jag1) and activity (Hes1), transcription (IRF5, STAT1) that associates with decrease in Akt but not STAT6 phosphorylation. In conclusion, our findings reveal an interplay between DLL4/Notch and IL-6/IL-6R or IL-4/IL-4R signaling pathways supporting M1 differentiation and impairing M2 differentiation via apoptosis.

Advancing knowledge on human dendritic cell types and activation states through the design and study of in vitro differentiation models.

*S. Balan[1,2], C. Arnold-Schrauf[1], A. Abbas[1], N. Couespel[1], J. Savoret[1], F. Imperatore[1], A. Villani[3], T. Vu Manh[1], N. Bhardwaj[2], **M. Dalod**[1,4];*

Our understanding of the biology of human dendritic cells and our ability to harness them clinically are hampered by lack of adequate in vitro models of these cells. Ideally, such in vitro models should combing high yields of different types of dendritic cells in the same culture and their amenability to genetic or pharmacological manipulation. To overcome this bottleneck, we developed a method of differentiation of human CD34+ precursors leading to high yields of all the three major types of human blood dendritic cells, namely plasmacytoid dendritic cells, type 1 (CD141-positive) conventional dendritic cells and type 2 (CD1c-positive) conventional dendritic cells. Phenotypic, functional and single cell RNA sequencing analyses were performed to ensure of the identity of the dendritic cell types derived in vitro and of their strong homology with their ex vivo isolated counterparts. This culture system also revealed novel molecular mechanisms governing the differentiation and/or expansion of human dendritic cell types which will be discussed in this presentation. Combining several such recent novel in vitro models for the differentiation of distinct types of human mononuclear phagocytes will greatly facilitate the simultaneous and comprehensive study of primary, otherwise rare, types of human dendritic cells or macrophages, including their mutual interactions.

GM-CSF and M-CSF signaling is integrated at chromatin level during human monocyte polarization

*R. M. Rodriguez[1], B. Suárez Álvarez[1], **P. Díaz Bulnes**[1], J. L. Lavín[2], A. M. Ascensión[3], M. Gonzalez[2], A. Baragaño Raneros[1], C. Martin-Martin[1], A. Puig-Kröger[4], A. L. Corbí[5], M. J. Araúzo-Bravo[3], A. M. Aransay[2], C. López Larrea[1];*
[1]Traslational Immunology Laboratory, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA); Hospital Universitario Central de Asturias (HUCA), Oviedo, Spain, [2]BioGUNE, Bizkaia, Spain, [3]Computational Biology and Systems Biomedicine Research Group, Biodonostia Health Research Institute, San Sebastián, Spain, [4]Laboratorio de Inmuno-Metabolismo, Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, [5]Centro de Investigaciones Biológicas, Consejo Superior de Investigaciones Científicas (CSIC), Madrid, Spain.

Over the last few years, myelopoietic growth factor signaling has emerged as an essential player during monocyte polarization. Due to the apparent antagonism between GM-CSF and M-CSF and their central role during monocyte differentiation, both factors have been proposed as suitable therapeutic targets. Nonetheless, since both cytokines can be simultaneously present in the inflamed tissue it is not clear how signaling is integrated during cell fate decisions or whether monocytes are able to fully reverse their phenotypes in response to apparently conflicting polarization cues. Previous studies showed that a preformed chromatin state generated during differentiation or in response to a given stimulus can influence how subsequence activation cues modify gene expression, indicating that the chromatin acts as an integration node during monocyte cell fate decision in the inflammation site. To better understand how undifferentiated monocytes integrate GM-/M-CSF signaling at the epigenetic level we performed DNA methylation analysis and ATAC-seq in *ex vivo* isolated human monocytes. Our results revealed a global and irreversible demethylation trend associated with M-CSF and GM-CSF exposure. In addition, chromatin accessibility analysis showed an extensive epigenetic remodeling after only 12 hours exposure in genes typically associated with monocyte polarization. Finally, by specific inhibition of the canonical GM-CSF receptor signaling modules, we were able to dissect the epigenetic changes associated with the JAK-dependent (STAT5, PI3K and MAPK) and JAK-independent signaling pathways. In summary, our results indicate that M-CSF and GM-CSF signaling is rapidly integrated at chromatin level in order to generate stable gene expression patterns during monocyte differentiation.

Dendritic Cells (DCs) are important regulators of immune responses. So far, the distinct functional roles of human tissue DC subpopulations remain largely unknown. In the here presented study, we directly isolated DC subpopulations from various human lympho-hematopoietic tissues (thymus, spleen, bone marrow, tonsils, cord blood, peripheral blood). We performed up to 20-paramter FACS analyses for the study of 230 cell surface molecules. We found that the percentages of the three main DC subpopulations of $CD1c^+$ DCs, $CD141^+$ DCs, and pDCs were varying depending on the analyzed tissue. We next investigated the transcriptional profile of cell-sorted DC subpopulations using comprehensive bio-informatic data analyses. Our data are supported by investigation of DC subset localization and functional studies. Overall, we conclude that human DCs of the lympho-hematopoietic system are mainly defined by ontogeny, while non-lympho-hematopoietic DCs (lung, skin) seem to be additionally influenced by modulatory signals from the tissue microenvironment.
The here presented data will help to elucidate the implication of human DC subpopulations in the initiation of immune responses.

Dendritic cells modulation by mesenchymal stem cell promises a protective microenvirment at the feto-maternal interface: improved outcome of pregnancy in abortion prone mice

***M. Eskandarian**, A. Yaftiyan, A. Jahangiri, S. Moazzeni;*
Tarbiat modares university, Tehran, Iran, Islamic Republic of.

Introduction: Recurrent spontaneous abortion is one of the most common complications of pregnancy. A major fraction of RSA is related to disorder of the maternal immune system, especially malfunction of dendritic cells (DCs). MSCs have been shown to exert immunomodulatory effects on immune cells especially dendritic cells. The current study investigates whether MSCs are capable to modulate the pattern of maternal immune response via the induction of functional changes in decidual DCs, and finally improves the fetal survival.
Materials and Methods: For this issue, adipose derived mesenchymal stem cells were intraperitonealy administered to abortion prone pregnant mice (CBA/J ×DBA/2) at fourth day of gestation. On day 14.5 of gestation, after determination of abortion rates, the number, phenotype and maturation state of decidual dendritic cells were analyzed using the flow cytometry.
Results: We found that MSCs therapy could decrease the abortion rate significantly and at the same time increases the frequency of decidual DCs. MSCs administration also remarkably decreased the expression of MHC-II, CD86 and CD40 markers on decidual DCs in MSC-treated group. In contrast, CD11b significantly increased in these group compared to non-treated mice.
Conclusions: Our results indicated that MSCs could change the microenvironment of decidua through secretion of various components or direct cell-cell contact and correct the immune cell disorders by modulating the DCs function.

Gene scan analysisby detection of GTdel in exon 2in NCF1 gene for AR-CGD with p47 defect

***M. Y. Koker**, B. Saraymen;*
Erciyes Medical school, Kayseri, Turkey.

CGD patients have 5 different gene which is most popular for genetic mutations. But in patients with residual oxidase activity in DHR assay mostly have mutation in NCF1 gene defect result in p47-phox defect. Most of mutation in CGD and NCF1 gene are result from hot-spot mutation(C.75_76delGT) in exon which results in p.[Try26HisFx26]. One of the fastest method for detection of mutation in these patients are gene scan analyisis by using microstellite analysis for detection of pseudogene/gene ratio in NCF1 gene. When the gene scan peak ratio is 1:1, usually this means that one allele there is the normal cofiguration of two pseudogenes and one NCF1 gene. On the other allele we then find one pseudogene, one NCF1 gene and one fusion gene of the 5'part NCF1 gene and the 3'part pseudogene. The gene scan detects the 5'part of the pseudogenes and the NCF1 genes. That leads in such a case to three genes with the deltaGT (pseudogene) and three genes with the GTGT configuration (like in NCF1 genes). Thus, the ratio is 3:3 = 1:1. When the fusion genes are inactive, so you can regards this as a heterozygote for NCF1 deltaGT. In such a person, there is a no defect in oxidase activity, p47 expression or microbicidal activity. We have dizayn a gene-scan diagram first time in the literatüre.

P.A1.01.06

Resident macrophages in the skin interconnect immune and nervous system

J. Kolter[1,2], *R. Feuerstein*[1], *N. Hagemeyer*[3], *P. Zeis*[4], *N. Paterson*[4], *D. Grün*[4], *T. Lämmermann*[4], *M. Prinz*[3], *P. Henneke*[1];
[1]*Center for Chronic Immunodeficiency, Freiburg, Germany,* [2]*Faculty of Biology, University of Freiburg, Freiburg, Germany,* [3]*Institute of Neuropathology, Freiburg, Germany,* [4]*Max-Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany.*

Since dermal macrophages but not monocytes are central for the defense against *Staphylococcus aureus*, we reasoned that heterogeneous mechanisms of macrophage replacement coexist in the skin. Here, we scrutinized the origin of dermal macrophages and a potential postnatal specification into subpopulations by utilization of reporter mice, fate-mapping strategies and transcriptomics.
We found that dermal macrophages underwent fundamental changes after birth. While the population initially uniformly expressed the fractalkine receptor at high level (CX_3CR1^{bright}), only a small fraction remained positive in adult mice. CX_3CR1^{bright} macrophages were only slowly replaced after bone marrow transfer and exhibited long persistence after tamoxifen-dependent fate mapping in *Cx$_3$cr1$^{creER/+}$:R26-yfp* mice. In contrast, other dermal macrophages were short-lived and received major bone-marrow input. Single cell RNA sequencing revealed six major macrophage clusters in the skin of which one corresponded to the CX_3CR1^{bright} population. The respective subset closely and exclusively colocalized to sensory nerve axons in the dermis of adult mice and showed a distinct expression signature with over 500 upregulated genes including anti-apoptotic and migratory markers in bulk transcriptomic analysis. Specific expression of markers connected to the nervous system along with bidirectional migration along nerve axons and uptake of myelin point towards a role interconnecting immune and nervous system, e.g. in the context of inflammatory nerve damage.
Collectively, these data point to a sub-specification of skin macrophages leading to heterogeneity in phenotype, function and origin within the very same tissue.

P.A1.01.07

Defining the role of E-cadherin in hematopoiesis

R. A. Krimpenfort*, M. Nethe;*
Sanquin Blood Supply, Amsterdam, Netherlands.

During erythropoiesis red blood cells (RBCs) are generated to adsorb and transport oxygen which is a fundamental process to sustain life. The generation of RBC's importantly relies on stem cells in the bone marrow which produce RBC's during erythropoiesis. During erythropoiesis erythroblasts, precursors of RBC's, mature into RBCs in the close proximity of a central macrophage which is hypothesized to control erythropoiesis. Little, however is known about the mechanism by which these erythroblasts adhere and detach from this central macrophage and how these macrophages allow maturation and formation of erythrocytes. Intriguingly, the cell adhesion protein E-cadherin, which expression is in general restricted to epithelial cells has been indicated to be expressed in the erythroid cell lineage. Moreover, induction of E-cadherin expression marks myelodysplastic syndrome (MDS) which is an age-related bone marrow malignancy characterized by dysplastic lesions in the bone marrow and a hampered production of myeloid cells. MDS often develops into acute myeloid leukemia (AML) and is therefore in general viewed to display precursors of AML. Since E-cadherin functions as an important tumor suppressor in epithelial tissue it questions to what extend E-cadherin similarly can acts as a tumor suppressor during development of blood-borne cancers like AML. E-cadherin expression is indeed frequently silenced by promoter hypermethylation in AML. The aim of this study is therefore to dissect the role of E-cadherin in hematopoiesis and development of myeloid malignancies by using a novel mouse model which allows somatic inactivation of E-cadherin in the hematopoietic cell lineage.

P.A1.01.09

Selective expansion of lineage-primed progenitors guides emergency haematopoiesis

D. Lin*, P. Hodgkin, S. Naik;*
Walter and Eliza Hall Institute, Melbourne, Australia.

Single hematopoietic stem and progenitor cells (HSPCs) are demonstrated to be lineage-primed in the steady state using clonal fate tracking and single cell RNA profiling. However, how single cell fate is regulated during emergency conditions that lead to skewing of lineage production is largely unknown. Here, we tag individual HSPCs with unique and heritable DNA barcodes and track their fate *in vivo* under Fms-like tyrosine kinase 3 (Flt3) ligand (FL) induced emergency state, which mediates a specific increase in dendritic cell (DC) numbers. We observe dramatic clonal expansion of HSPCs that accounts for the majority of emergency DC generation, with more profound contribution from multipotent clones than those with restricted fate. Importantly, such expansion is selective towards the DC lineage, as production of other lineages remain unchanged at the clonal level.
In contrast, we observe minimal contribution by recruitment of other clones. Collectively, our results suggest that excess FL guides emergency DC development by selectively enhancing proliferation and differentiation of pre-existing progenitors along the DC trajectory, without diverging fate from non-DC primed progenitors. Thus, this suggests that lineage program within single HSPCs are already stably established and fate 'plasticity' via extrinsic regulation is not the major mechanism. These findings provide new insight into the control and regulation of fate during hematopoiesis.

P.A1.01.11

Investigation of BATF-dependent gene expression signatures in plasmacytoid dendritic cells

R. Mann-Nüttel[1], *S. Ali*[1,2], *P. Petzsch*[3], *K. Köhrer*[3], *H. Xu*[4], *P. Lang*[4], *S. Scheu*[1];
[1]*Institute of Medicinal Microbiology and Hospital Hygiene, Heinrich Heine University Düsseldorf, Düsseldorf, Germany,* [2]*Cluster of Excellence EXC 1003, Cells in Motion, University of Münster, Münster, Germany,* [3]*Biomedical Research Facility, Heinrich Heine University Düsseldorf, Düsseldorf, Germany,* [4]*Institute of Molecular Medicine, Heinrich Heine University Düsseldorf, Düsseldorf, Germany.*

Plasmacytoid dendritic cells (pDCs) are known to produce large amounts of type I interferon (IFN) during viral infections. Contradicting the previous dogma, we found that only a small subpopulation of pDCs produces type I IFN after TLR9 activation. Microarray experiments revealed that the transcription factor *Batf* (basic leucine zipper ATF-like transcription factor) is highly expressed in these type I IFN-producing pDCs. While the function of BATF for T helper cell subset differentiation and B cell class switching has been well described, no biological role of BATF in pDCs has been shown so far.
Analyzing *Batf*$^{-/-}$ mice and wildtype (WT) littermates we found an increased frequency of pDCs in Flt3-L cultures from bone marrow (BM) of *Batf*$^{-/-}$ mice. While splenic pDCs from *Batf*$^{-/-}$ mice and WT controls expressed equivalent levels of MHC class II and costimulatory molecules, surface levels of the canonical DC marker CD11c were markedly reduced in *Batf*$^{-/-}$ pDCs. Further, analyzing the expression of key transcription factors involved in DC development in pDCs derived from Flt3-L BM cultures and BM cells *ex vivo*, we found an increased expression of pDC specific transcription factors E2-2 and SPI1B in *Batf*$^{-/-}$ pDCs, indicating a possible role for BATF in pDC differentiation.
Additionally, results from gene expression profiling of sorted *in vitro* generated WT vs. *Batf*$^{-/-}$ pDCs stimulated with the TLR9 ligand CpG or left untreated will be presented.
In summary, our results hint at a role of BATF in pDC differentiation. Further analyses will focus on unraveling the underlying molecular mechanisms.

P.A1.01.12

Developmental heterogeneity of early life dendritic cells

N. E. Papaioannou[1], *J. Salvermoser*[1,2], *N. Salei*[1,2], *M. Pasztoi*[1], *R. Schuchert*[2,3], *S. E. W. Jacobsen*[4,5], *C. Schulz*[2,3], *B. U. Schraml*[1,2];

Dendritic cells (DCs) are immune sentinels that initiate, polarize and orchestrate adaptive and innate immune responses. Early life DCs differ both quantitatively and qualitatively from those in adults. Neonatal DCs, for instance, promote immune responses less efficiently than their adult counterparts, because they trigger reduced T cell proliferation. Additionally, they produce low levels of immunostimulatory cytokines resulting in Th2 biased immune responses. As a consequence, neonates are more susceptible to infection with certain pathogens than adults.
Using a model for fate mapping of conventional DC precursors (CDP) with yellow fluorescent protein (YFP), we have revisited the development of DCs during mouse embryogenesis, as well as in perinatal and adult mice. Surprisingly, we find that $CD11c^+MHCII^+CD11b^+$ splenocytes, which phenotypically resemble CDP-derived $CD11b^+$ DCs that label strongly with YFP in adult mice, were poorly labeled in embryonic and neonatal mice. Combined with additional fate mapping experiments for primitive and definitive hematopoietic progenitors our data suggest that DCs exhibit age-dependent heterogeneity in terms of their ontogeny. Currently, we are investigating the impact of this developmental heterogeneity on the capacity of early life DCs to respond to pathogenic stimuli and initiate immune responses. Taken together, our data suggest that a layered DC development may contribute to the qualitatively altered DC responses in early life.
This work is supported by an ERC Starting Grant awarded to BS (ERC- 2016-STG-715182).

P.A1.01.13

Therapeutic targeting of hexosamine biosynthetic pathway in acute myeloid leukemia

***R. PARAMESWARAN**, A. Asthana;*
CASE WESTERN RESERVE UNIVERSITY, CLEVELAND, United States.

Acute myeloid leukemia (AML) is the most common acute leukemia among adults with an overall poor prognosis. For 40 years there has been minimal improvement in treatment beyond induction chemotherapy or allogeneic stem cell transplantation. Targeting cell metabolism is a promising avenue for future cancer therapy. We found that enzymes involved in metabolic hexosamine biosynthetic pathway (HBP) is increased in AML patients. The HBP metabolizes glucose and glutamine to produce UDP-N-acetylglucosamine (UDP-GlcNAc) which is the substrate for O-GlcNAcylation, a post translational modification on cytosolic and nuclear proteins. We found that glutamine-fructose-6-phosphate-amidotransferase (GFAT), the rate limiting enzyme of HBP pathway and O-GlcNAc transferase (OGT), which catalyzes the addition of GlcNAc to proteins are significantly increased in different AML patient subtypes as well as different AML cell lines. Inhibiting GFAT pushes AML cells to differentiate, causes cell cycle arrest, inhibits cell proliferation and finally leads to apoptotic cell death, sparing normal cells. Knockdown of OGT enzyme using OGT Sh-RNA also led to AML cell differentiation and cell death. Finally, targeting of HBP *in vivo* leads to significant clearance of tumor cells in an AML xenograft mouse model, with minimum toxicity. This study reveals an important role of HBP in keeping AML cells in the un-differentiated and malignant state and sheds light into a new area of potential AML therapy by targeting HBP pathway.

Mesoporous Silicon Microparticles enhance inflammatory responses in human macrophages

***I. Real Arévalo**[1,2], B. Amorós-Pérez[1], A. Revilla[1,2], L. Diego-González[1], B. Martín-Adrados[1], R. Martín-Palma[3], E. Martínez-Naves[1], M. Gómez del Moral[2];*
[1]Departamento de Inmunología. Facultad de Medicina. Universidad Complutense, Madrid, Spain, [2]Departamento de Biología Celular. Facultad de Medicina. Universidad Complutense, Madrid, Spain, [3]Departamento de Física Aplicada, Universidad Autónoma de Madrid, Madrid, Spain.

Introduction: Mesoporous silicon microparticles (MSMPs) possess unique chemical stability, adjustable pore size, extensive surface area, biocompatible and biodegradable nature, that offer large advantages over current adjuvants or vehicles. We have previously described that peptide-loaded MSMPs enhance antigen specific T-cell activation by human monocyte derived dendritic cells. Macrophages are important APCs whose activity can be polarized to a proinflammatory (M1) or anti-inflammatory (M2) phenotype. Aim: Our goal was to investigate how macrophages respond to MSMPs.
Methods: MSMPs were fabricated by electrochemical treatment of silicon wafer. M1 or M2 Macrophages were obtained after 7 days of incubation with GM-CSF or M-CSF respectively, from $CD14^+$ monocytes isolated from Peripheral blood mononuclear cells (PBMCs) using immunomagnetic microbeads. M1 and M2 phenotype was assessed by gene and phenotype expression by quantitative real-time PCR and flow cytometry respectively. Cytokines were quantified in culture supernatants by ELISA. Endocytosis was assesed by flow cytometry using FITC labeled MSMPs
Results: Our results showed that that MSMPs are efficiently endocyted by both M1 and M2 polarized macrophages, in a process that is in part mediated by Scavenger receptors. Enhanced CD80, CD86, HLA-DR and CD163 markers on the cell surface in both M1 and M2 macrophages were observed after MSMP endocytosis. There was an increase of TNFα, IL6 and IL12 secretion in M1 macrophages treated with MSMPs. No production of IL-10 was observed in M1 or M2 cell supernatants.
Conclusions: Microparticles of mesoporous silicon are endocytosed by macrophages favouring a proinflammatory profile (M1) and inhibiting the IL-10 production.

P.A1.01.15

Developmental origin and cellular identity of cardiac macrophages in steady state and in response to stress

***C. Schulz**[1], T. Weinberger[1], V. Schneider[1], E. Gomez Perdiguero[2];*
[1]Ludwig-Maximilians-University, Munich, Germany, [2]Institut Pasteur, Paris, France.

Background: Macrophages are the most prominent immune cells in myocardial tissue and play a critical role in pathological conditions. However, the quantitative contribution of embryonic and bone marrow (BM) hematopoiesis to the cardiac macrophage pool under steady state and in response to stress has been unknown. Methods/Results: In this study we mapped the origin and fate of the different macrophage lineages in mouse models of ischemia-reperfusion injury (I/R) and Angiotensin II-induced fibrosis (AT-II). Using FLT3-Cre mice and radiation-independent BM chimera, we found that under steady state a considerable amount of cardiac macrophages develops independently of definitive hematopoiesis. In response to both I/R and AT-II, we observed an increase in the number of BM-derived macrophages in the heart. However, this increase was only transient and the number of BM-derived macrophages declined over time reaching steady state numbers after 30 days. After AT-II infusion, we found an increase of BM-derived macrophages in areas of myocardial and interstitial fibrosis, whereas after I/R-injury there was a profound influx of BM-derived macrophages in the infarct region and its adjacent remote area. The influx of BM-derived macrophages could be significantly reduced by deletion of CCR2. Conclusion: Embryonic macrophages are the major contributors to the pool of cardiac tissue-resident macrophages in adult mice. In the acute phase of inflammation, BM macrophages invade the heart but do not persist in significant numbers in myocardial tissue. Our findings are of potential relevance for understanding the cardiac immune response and for the therapeutic targeting of macrophages in inflammatory conditions.

P.A1.01.16

TCDD-mediated activation of aryl hydrocarbon receptor alters microRNAs (miRs) expression in Granulocytic Myeloid Derived Suppressor cells (G-MDSCs) and Splenic Resident Granulocytes (SRG) via shared and unique pathways of differentiation

***N. P. Singh**, D. Jackson, U. P. Singh, S. Sumpter, P. Nagarkatti, M. Nagarkatti;*
University of South Carolina School of Medicine, Columbia, United States.

TCDD is an AhR ligand and has potent immunosuppressive effects on humans and animals. Recently, we have shown that TCDD triggers induction of myeloid derived suppressor cells (MDSCs) in peritoneal cavity. In this study, we investigated the effect of TCDD on the regulation of miRs in Granulocytic MDSCs (G-MDSCs) and splenic resident Granulocytes (SRG) in mice. To this end, mice were treated with vehicle or TCDD (10 µg/kg bw) and 48 hours post injection, G-MDSCs from peritoneal wash and SRG from spleen were sorted (>95-96% purity) and microRNA arrays were performed using total RNAs. There was significant alterations in the expression of 78 miRs in both G-MDSCs and SRG. Out of the 78 miRs, 19 miRs were upregulated in G-MDSCs but downregulated in SRG, 16 miRs were downregulated in G-MDSCs but upregulated in SRG, 32 miRs were upregulated in both G-MDSCs and SRG, and the remaining 11 miRs were downregulated in both G-MDSCs and SRG. Upon analysis of TCDD-dysregulated miRs using IPA, more than 25 diseases and pathways are regulated. Thse dysregulated miRs play a common role in the development of several diseases including cancer and inflammatory diseases. This study demonstrate for the first time that TCDD regulates miRs that are both shared and unique to G-MDSCs and SRGs, thereby suggesting that while G-MDSCs are similar in some ways to SRGs, they may be at different stages of differentiation. The present study was supported by NIH grants (R01ES019313, R01MH094755, R01AI123947, R01 AI129788, P01 AT003961, P20 GM103641, R01 AT006888).

P.A1.01.17

Precise delineation and transcriptional characterization of bovine blood dendritic-cell and monocyte subsets

***S. C. Talker**[1,2], A. Baumann[1,2], G. T. Barut[1,2], I. Keller[3], R. Bruggmann[3], A. Summerfield[1,2];*
[1]Institute of Virology and Immunology, Bern and Mittelhäusern, Switzerland, [2]Department of Infectious Diseases and Pathobiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [3]Interfaculty Bioinformatics Unit and Swiss Institute of Bioinformatics, University of Bern, Bern, Switzerland.

A clear-cut delineation of bovine bona fide dendritic cells (DC) from monocytes has proved challenging, given the high phenotypic and functional plasticity of these innate immune cells and the marked phenotypic differences between species.
Here, we demonstrate that, based on their expression of Flt3, CD172a, CD13, and CD4, a precise identification of bovine blood conventional DC type 1 and 2 (cDC1, cDC2), plasmacytoid DC (pDC), and monocytes is possible with cDC1 being $Flt3^+CD172a^{dim}CD13^+CD4^-$, cDC2 being $Flt3^+CD172a^+CD13^-CD4^-$, pDC being $Flt3^+CD172a^{dim}CD13^-CD4^+$, and monocytes being $Flt3^-CD172a^{high}CD13^-CD4^-$. The phenotype of these subsets was characterized in further detail, and a subset-specific differential expression of CD2, CD5, CD11b, CD11c, CD14, CD16, CD40, CD71, CD163, CD205, and CADM1 was found. Subset identity was confirmed by transcriptomic analysis and subset-specific expression of conserved key genes. We also sorted monocyte subsets based on their differential expression of CD14 and CD16. Classical monocytes ($CD14^+CD16^-$) clustered clearly apart from the two $CD16^+$ monocyte subsets probably representing intermediate and non-classical monocytes described in human. The transcriptomic data also revealed differential expression of molecules involved in antigen presentation, pathogen sensing, and migration, and therefore gives insights into functional differences between bovine DC and monocyte subsets.
The identification of cell-type- and subset-specific gene expression will assist in the quest for “marker molecules” that – when targeted by flow cytometry – will greatly facilitate research on bovine DC and monocytes. Overall, species comparisons will elucidate basic principles of DC and monocyte biology and will finally help to translate experimental findings from one species to another.

Th1 expansion is restrained by IFN-γ-induced adherence-independent macrophages and restored by PD-L2 blockade

***E. Tavukcuoglu**, G. Esendagli;*
Hacettepe University Cancer Institute Department of Basic Oncology, Ankara, Turkey.

Monocyte-to-macrophage differentiation is simultaneously induced ex-vivo and regulated according to the cytokine milieu and the matrix adherence. This study originates from a random laboratory observation while testing stimulatory potential of macrophages differentiated in suspension cultures. Under defined conditions lacking activation stimuli, exposure to a low concentration of interferon (IFN)-γ gave rise to macrophages with impaired T-cell stimulation capacity. B7 family of immune regulatory ligands, CD80, CD86, ICOS-LG, B7-H3, and especially PD-L1 and PD-L2, were modulated on the IFN-γ-induced adherence-independent monocyte-derived macrophages. These cells supported helper T-cell (Th) activation but had limited capacity to stimulate Th1 differentiation and proliferation when compared to the control macrophages. PD-L2, which has been identified with contradictory effects on T-cell responses, was highly present on both control and IFN-γ-induced cells. The blockade of this PD-1 ligand significantly accelerated Th1 proliferation and restored the secretion of effector cytokines, especially IL-2 and IFN-γ. Collectively, the high and constitutive expression of PD-L2 on macrophages did not impede the establishment of functional capacity in Th-cells but interfered with Th1 proliferation and cytokine production. Therefore, our data indicate the role of macrophage PD-L2 as a safety measure that reins acceleration of Th1 responses.This project was supported by Hacettepe University Research Fund (Project no. TSA-2017-12739).

P.A1.01.20

Role of serum Hypoxia-Inducible Factor (HIF)-1α in patients with COPD

***k. upadhyay**, a. ali, p. sohal, a. yadav, s. p. bhatt, r. guleria;*
all india institute of medical sciences, new delhi, India.

Introduction: - HIF-1α protein is a master transcriptional regulator of the adaptive response to hypoxia which increases with initiation of oxidative stress. However, the significance of this protein in COPD patients with smoking habit is still unknown.
Aim: – The study aims to evaluate the role of HIF-1α in smoker COPD patients with an emphasis to its association with disease severity.
Method: - In this case controlled study, we enrolled 57 COPD patients, along with 15 smokers without COPD and 15 healthy individuals (as control sets). The mean age of patients was 54.6 (± 9.32) years and controls 50.0 (± 9.8). The study set included 62% smokers, 25% non-smokers, 7% tobacco chewers and 6% ex-smokers. Sandwich Enzyme-linked immune Sorbent Assay (ELISA) method was used for analyzing serum HIF-1α.
Results: - A significantly higher HIF-1α level was observed in COPD patients with smoking habit, indicating a positive association with hypoxia, smoking status and severity of disease (p=0.03). However, the mean value of HIF-1α was not significantly different in smokers without COPD and healthy controls.
Conclusion: - Our study indicates positive association of HIF-1α levels with smoking habit of COPD patient and severity of the disease unlike the smokers without COPD suggesting that activation of HIF-1α pathway in COPD.

P.A1.01.21

Evolutionary conservation of bone marrow-derived antigen presenting cells

***R. van den Biggelaar**[1], V. Rutten[1,2], W. van Eden[1], C. Jansen[1];*
[1]Utrecht University, Utrecht, Netherlands, [2]Pretoria University, Pretoria, South Africa.

Dendritic cells (DCs) are antigen presenting cells (APCs) that bridge the innate and the adaptive immune system. Many studies on DCs are based on *in vitro* differentiation of human monocyte- or murine bone marrow-derived progenitor cells into APCs in the presence of GM-CSF and IL-4. Whether these cells resemble their *in vivo* counterpart is still under debate. Recently, culture methods have been developed to generate chicken bone marrow-derived APCs. We aim to characterize this heterogenic cell population in chickens and to study "evolutionary conservation" of APCs in this non-mammalian species. Cells isolated from femurs and tibiae of chicken embryos were cultured in the presence of recombinant chicken IL-4 and GM-CSF. At day 7, these immature APCs were matured by LPS stimulation. Flow cytometry, fluorescent microscopy, and RT-qPCR were performed to characterize these cells. The majority of the cells are CD11b/c^{+}CD206 (MRC1)$^{+}$CD117 (cKit)$^{+}$CD40^{+}. Within this population, half of the cells are MHCII^{high}CD80^{high}CD115 (CSF1R)^{low} and resemble mammalian DCs. The other cells are MHCII^{low}CD80^{low}CD115 (CSF1R)^{high} and resemble macrophage-like cells. The latter are larger in size and have a higher phagocytosis capacity than MHCII^{high} cells. Similar subpopulations have been observed in murine bone marrow-derived DCs. However, murine macrophage-like MHCII^{low} cells are known to lack expression of CD40 or cKit, in contrast to the MHCII^{low} subpopulation that we have observed. Despite these differences, murine and avian bone marrow-derived APCs show high similarity, suggesting an evolutionary conservation of APC marker expression and potentially their role within the immune response in mammalian and non-mammalian species.

P.A1.01.22

TIPE2 Protein Specifies the Functional Polarization of Myeloid-derived Suppressor Cells during Tumorigenesis

***D. Yan**[1], J. Wang[1,2], M. Xu[1,2], O. Adeleye[1], Y. Chen[3], X. Wan[1];*
[1]Chinese Academy of Sciences, Shenzhen, China, [2]Jinan University, Guangzhou, China, [3]University of Pennsylvania, Philadelphia, United States.

Myeloid-derived suppressor cells (MDSCs) are "polarized" myeloid cells that effectively promote tumorigenesis by inhibiting anti-tumor immunity. How myeloid cells acquire the pro-tumoral properties during tumorigenesis is poorly understood. We report here that the polarity protein TIPE2 (tumor necrosis factor-α-induced protein 8-like 2) mediates the functional polarization of MDSCs by specifying their pro- and anti-tumoral properties. Tumor cells induced the expression of TIPE2 in Gr1^{+}CD11b^{+} cells through reactive oxygen species (ROS). TIPE2 in turn increased the expression of pro-tumoral mediators such as CCAAT/enhancer-binding protein-β while inhibited the expression of anti-tumoral mediators. Consequently, tumor growth in TIPE2-deficient mice was significantly diminished, and TIPE2-deficient MDSCs markedly inhibited tumor growth upon adoptive transfer. Pharmaceutical blockade of ROS inhibited TIPE2 expression in MDSCs and reduced tumor growth in mice. These findings indicate that TIPE2 plays a key role in the functional polarization of MDSCs and represents a new therapeutic target for cancer immunotherapy.

Identification and characterisation of XCR1+ avian conventional dendritic cells

*Z. Wu[1], M. McGrew[1], H. Sang[1], D. Hume[2], **A. Balic**[1];*
[1]The Roslin Institute, Edinburgh, United Kingdom, [2]University of Queensland, Brisbane, Australia.

Comparative transcriptomic studies have enabled the identification of conventional dendritic cells (cDC) in a large number of different mammalian species and more recently chickens (J Immunol. 2014. 192(10):4510-7). While these studies elegantly demonstrate the evolutionary conservation of cDC in aminotes, little information is available on the specific developmental and functional biology of avian cDC. This is largely due to the lack of specific reagents and immunological tools to identify these cells in the chicken. We have developed specific reagents that in combination with the CSF1R-eGFP transgenic reporter chicken allow the specific identification, characterisation and isolation of chicken cDC. We will show that expression of Flt3 and the chemokine XCR1 enables the discrimination between chicken cDC and macrophages as well as isolation for functional studies. In mammals cDCs can be classified into two functionally distinct lineages, in contrast we are can identify only a single cDC subset in chickens. While this chicken cDC subset closely resembles the mammalian cDC1 subset, substantial differences also also observed, likely reflecting the unique biology of the avian immune system. Furthermore while we readily detect cDC in avian tissues, in contrast to mammals we are unable to detect either circulating cDC nor cDC progenitors in chickens. In this presentation we will discuss the specific developmental and functional biology of avian cDC and contrast this to what is known of mammalian cDC, as well as present an update in on the progress making a cDC knockout line of chickens. In particular we will discuss the implications of only having a single identifiable cDC lineage in chickens.

P.A1.01.24

Distinct progenitor lineages contribute to the heterogeneity of plasmacytoid dendritic cells

*P. F. Rodrigues[1], L. Alberti-Servera[1,2], A. Eremin[1], G. E. Grajales-Reyes[3], R. Ivanek[1,4], **R. Tussiwand**[1];*
[1]Department of Biomedicine University of Basel, Basel, Switzerland, [2]Department of Human Genetics and VIB Center for the Biology of Disease, Leuven, Belgium, [3]Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO, United States, [4]Swiss Institute of Bioinformatics, Basel, Switzerland.

Plasmacytoid dendritic cells (pDCs) are an immune subset devoted to the production of high amounts of type 1 interferons in response to viral infections. Whereas conventional dendritic cells (cDCs) originate mostly from a common dendritic cell progenitor (CDP), pDCs have been shown to develop from both CDPs and common lymphoid progenitors. Here, we found that pDCs developed predominantly from IL-7R^{+} lymphoid progenitor cells. Expression of SiglecH and Ly6D defined pDC lineage commitment along the lymphoid branch. Transcriptional characterization of SiglecH^{+}Ly6D^{+} precursors indicated that pDC development requires high expression of the transcription factor IRF8, whereas pDC identity relies on TCF4. RNA sequencing of IL-7R^{+} lymphoid and CDP-derived pDCs mirrored the heterogeneity of mature pDCs observed in single-cell analysis. Both mature pDC subsets are able to secrete type 1 interferons, but only myeloid-derived pDCs share with cDCs their ability to process and present antigen.

Mitochondrial dynamics in macrophage biology

A. H. R. Agnellini[1], *R. Sanchez*[1], *C. Tezze*[1], *G. I. Toffolo*[1], *M. Sandri*[1], *B. Molon*[2], *L. Scorrano*[3], *A. Viola*[1];
[1]*Department of Biomedical Science, University of Padova, Padova, Italy, Padova, Italy,* [2]*Barbara Molon, Padova, Italy,* [3]*Department of cellular Biology, Università degli studi di Paova, Padova, Italy.*

Recent evidence highlights that mitochondrial dynamics unroll specialized functions in the immune system, regulating T cell metabolism and fate. However, the effective relevance of mitochondria in myeloid cell biology remains to be elucidated. Among myeloid cells, macrophages represent a key component of the innate immune system, playing critical roles in host defence and homeostasis. In order to investigate the functional significance of mitochondrial dynamics in macrophages, we generated a tissue-specific conditional knock out mouse model, presenting the selective deletion of optic atrophy 1 (OPA-1) in lysozyme M expressing cells. OPA1-/- mice show a significant reduction of all myeloid populations in all tissues analysed (i.e. blood, spleen, liver and bone marrow). *In vitro*, the absence of OPA1 in macrophages promotes migration, phagocytosis and reactive oxygen species production, but impairs M1/M2 polarization. In order to understand the impact of OPA1 in macrophages polarization in vivo, we analyzed macrophages during muscle regeneration after cardiotoxin injury. Interestingly, we observed slow regeneration in OPA1-/- mice followed by macrophages accumulation. Our project aims to understand how OPA1 deletion orchestrate macrophages metabolism and polarization.

P.A1.02.02
Murine scavenger receptor CD163 is a marker for a specific IRF8-dependent resident macrophage subpopulation in the bone marrow

L. Fischer-Riepe[1], *J. Schulte-Schrepping*[2], *M. Pohlen*[3], *J. Fischer*[4], *T. Ulas*[2], *C. Schulz*[5], *S. Vettorazzi*[6], *F. Rosenbauer*[4], *J. Tuckermann*[6], *J. Schultze*[2], *J. Roth*[1], ***K. Barczyk-Kahlert***[1];
[1]*Institute of Immunology, University of Muenster, Muenster, Germany,* [2]*Genomics and Immunoregulation, Life and Medical Sciences Institute, University of Bonn, Bonn, Germany,* [3]*Institute of Immunology, University of Muenster; Department of Medicine A, Hematology and Oncology, University Hospital of Muenster, Muenster, Germany,* [4]*Institute of Molecular Tumor Biology, University of Muenster, Muenster, Germany,* [5]*Medizinische Klinik und Poliklinik I, Klinikum der Universität München, Ludwig-Maximilians-Universität, Munich, Germany,* [6]*Institute of Comparative Molecular Endocrinology (CME), University of Ulm, Ulm, Germany.*

CD163 is a scavenger receptor exclusively expressed on monocytes/macrophages. Anti-inflammatory factors like glucocorticoids (GC) and IL-10 increase the CD163 expression. CD163 has been excessively studied in man and rat, nevertheless very little is known regarding the structure and regulation of CD163 expression in mice. Here we discovered a $CD163^+$ macrophage population in the murine bone marrow which descends from embryonic progenitors in the yolk sac and is dependent on the transcription factor IRF8.
We could show, that freshly isolated bone marrow cells (BMC) have shown high expression of CD163, which decreased during *in vitro* culture. Stimulation of BMCs with GC restored CD163 expression. This effect was not that pronounced in bone marrow-derived macrophages (BMDM). We identified two monocyte/macrophage subsets in murine BM defined by the expression of CD163. $CD163^+$ BMC were phenotypically and functionally distinct from $CD163^-$ BMC. This specific $CD163^+$ population was missing in the bone marrow and spleen of IRF8-/- mice but not in the other organs tested. Moreover, *in vitro* treatment with GC failed to induce CD163 expression in BMC isolated from $IRF8^{-/-}$ mice. Cell fate studies in Csf1rMer-iCre-Mer;RosaLSL-GFP mice revealed yolk sac origin of $CD163^+$ macrophages. We could observe a strong infiltration of $CD163^+$ cells in allergic, bacterial and parasite disease models. Moreover, the adoptive cell transfer of $CD163^+$ BMC ameliorated the signs of disease in local *S. aureus* infection.
Thus, CD163 expression in murine BM (and spleen) is restricted to a small subpopulation of monocytes/macrophages which is originally, phenotypically and functionally distinct from $CD163^-$ monocytes/macrophages.

Tissue-resident macrophages play an important role in the clearance of IgG-opsonized particles and immune complexes via the interaction with IgG receptors, the so-called Fc-gamma receptors (FcγRs). To date most studies investigating the phagocytosis of opsonized particles made use of *in vitro* cultured monocyte-derived macrophages. For comparison, we investigated the FcγR expression on tissue macrophages, both stained in tissue sections and *ex vivo* when freshly purified from those same human tissues. Upon isolation of primary human macrophages from bone marrow, spleen, liver and lung, we observed that macrophages from all studied tissues expressed high levels of FcγRIIIa, which was in direct contrast with blood monocyte-derived macrophages. Moreover, expression levels of FcγRI were highly variable. Kupffer cells in the liver were the only tissue-resident macrophages that expressed the inhibitory IgG receptor FcγRIIb, which is likely to have an important role by their anatomical position in filtering the blood from the portal vein without excessive pro-inflammatory reactivity. Functional experiments with isolated splenic red pulp macrophages demonstrated the contribution of FcγRs in phagocytosis. In sum, our immunohistochemistry data combined with *ex vivo* immunostainings and functional assays of isolated human tissue macrophages indicated that tissue-resident macrophages are different from monocyte-derived macrophages showing distinct tissue-specific FcγR expression patterns.

Introduction: Normal human peripheral blood monocytes include the so-called classical ($CD14^{hi}CD16^-$), intermediate ($CD14^{hi}CD16^+$) and non-classical ($CD14^{-/lo}CD16^+$) monocytes. Despite the presence of these monocytic cell compartments has previously been reported in healthy subjects, data about their kinetics through life as well as their relative distribution in secondary lymphoid tissues, remains very limited. Material and methods: Here we investigated the distribution of the distinct subsets of monocytic cells in 11 cord blood and 177 peripheral blood healthy samples through life and their relative distribution in 9 bone marrow, and 11 lymph node and spleen samples. Results: Overall, we identified five distinct subsets of mature monocytic cells in peripheral blood, bone marrow, lymph node and spleen. In cord blood and individuals ≥50y up to 92y ($p<0.05$), higher numbers of classical monocytes were found, while the highest number of intermediate and non-classical monocytes was observed few days after birth ($p<0.05$). In addition, a decreased frequency of circulating $CD62L^+$ classical monocytes was detected in both lymph nodes and spleen tissues vs peripheral blood ($p<0.01$). Conclusions: Altogether, these results support the notion that classical monocytes are recruited to different tissues, where greater numbers of intermediate and non-classical monocytes are generated; in turn, these later two cell populations might recirculate into the bloodstream through the lymph system. This study provides also novel information on age-related kinetics of circulating monocytic subsets, to be used as a frame of reference for normal values. Grants: CB16/12/00400 (CIBER-ONC) and PI13/01412, ISCIII (Ministerio de Economía y Competitividad, Madrid, Spain and FONDOS FEDER).

Signalling networks governing hematopoietic stem cells differentiation during inflammation and pathology

M. De Zuani, *M. Hortová Kohoutková, S. S. Jose, J. Frič;*
International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic.

The differentiation of hematopoietic stem and progenitor cells (HSPCs) to the myeloid and lymphoid lineages is a tightly regulated process that occurs almost exclusively in the bone marrow. Several signals coming from the host as well as from microbial components are able to skew the differentiation of HSPCs toward different cell fates, also acting directly on HSPCs receptors. Similarly, pathological condition (as infections or cancer) and the physiological process of aging are correlated with an altered hematopoiesis which promotes myelopoiesis over lymphopoiesis. A growing body of evidence suggests that HSPCs respond directly to microbial ligands signalling trough TLRs. This process is particularly relevant in the light of the fact that HSPCs are able to recirculate from the bone marrow to the blood stream, thus getting exposed to several PAMPs. However, the dynamics and involvement of TLRs and CLRs signalling during HSCs differentiation have been only poorly investigated.

Taking advantage of flow cytometric techniques and co-culture with 3D organoids, we show that PRRs ligation by microbial products is able to drive human HSPCs differentiation. Thus, we aim to unravel the molecular mechanisms underlying this process by analysing the role of downstream signalling and the activation of specific genetic programs in a human model of hematopoiesis.
The research is supported by European Social Fund and European Regional Development Fund—Project MAGNET (No. CZ.02.1.01/0.0/0.0/15_003/0000492)

Transmembrane adaptor protein LST1 is expressed in leukocytes of the myeloid lineage. Previous study has revealed mild effects of LST1 deficiency on the outcome of influenza infection in mice. Except for this specific case, its overall function at the organismal level is still to be determined. At the molecular level, LST1 was shown to interact with cytoskeleton regulating proteins and to promote the formation of tunneling nanotubes. It also contains an ITIM motif in its intracellular tail, which was shown to bind phosphatases SHP-1/2 in monocytes. To study the physiological function of LST1 we have performed a thorough analysis of LST1-deficient mice. At steady state, these mice displayed no apparent phenotype. However, when we challenged LST1-deficient mice with pro-inflammatory stimuli some aspects of their responses were altered. Intraperitoneal injection of viral mimetic PolyI:C resulted in significant reduction in splenic $CD8^+$ T cell percentages. However, the most striking differences were observed when we induced acute colitis in these mice by dextran sodium sulphate, as a model of disease, where myeloid cells are heavily involved. We found significantly better course of acute colitis in LST1-deficient animals in all observed parameters. This was accompanied by alterations in splenic monocyte populations. Interestingly, we also saw the same significant decrease in CD8+ splenic T cells as after polyI:C injection. Collectively our data suggest, that LST1 is not required for leukocyte development and immune system homeostasis, but it is involved in the regulation of several types of immune responses. Financed by GACR P302/12/G101.

Experimental human endotoxemia results in accelerated maturation of the neutrophil compartment in the human bone marrow

E. van Grinsven[1,2], *S. van Staveren*[1,2], ***M. Hassani***[1,2], *K. Tesselaar*[1], *G. Leijte*[3], *M. Kox*[3], *P. Pickkers*[3], *N. Vrisekoop*[1,2], *L. Koenderman*[1,2];
[1]*Laboratory of translational immunology, Utrecht, Netherlands,* [2]*University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Radboud University Medical Center, Nijmegen, Netherlands.*

Neutrophils are thought to be short-lived cells and are produced in extremely high numbers in the bone marrow (>10^{11} cells/day). Nevertheless, solid data to support this hypothesis is lacking. We investigated the proliferation and maturation of the neutrophil compartment in humans during homeostasis and experimental human endotoxemia, as *in vivo* model for acute systemic inflammation .
Bone marrow and blood were obtained from healthy volunteers before and during acute systemic inflammation evoked by intravenous challenge with endotoxin (lipopolysaccharide, 2 ng/kg) . By differential CD16/CD11b staining promyelocytes, myelocytes, metamyelocytes, banded cells and mature cells were identified and sorted for analysis on cytospins. Differentiation was also studied with a phenotyping panel, containing Ab against CD305, CD49d, , CD16, CD62L, CD11b, CD35, CD66b, CD13, CD11c and CD10. Four hours after endotoxin-challenge, the neutrophil compartment exhibited signs of accelerated maturation, characterized by an increased number of cells with more mature characteristics in all neutrophil fractions. Although large numbers of banded neutrophils were found in the peripheral blood, these cells in the bone marrow did not decrease. Also, the number of $CD62L^{low}$ neutrophils increased in both blood and bone marrow.
In conclusion, our study shows that the neutrophil compartment in the bone marrow of healthy volunteers responds immediately to systemic inflammatory cues and shows signs of accelerated maturation. During short term inflammation, the release of neutrophils with banded or hypersegmented nuclei does not lead to depletion of these cells in the bone marrow.

P.A1.02.08
Multiparametric *in situ* characterisation of macrophages in gastric cancer

Y. Huang[1,2], *M. Wang*[1,2], *Y. Sun*[2], *N. Di Costanzo*[1,2], *C. Mitchell*[3], *A. Achuthan*[4], *R. Busuttil*[1,2], *J. Hamilton*[4], *A. Boussioutas*[1,2,4];
[1]*Upper Gastrointestinal Translational Research Laboratory, Peter MacCallum Cancer Centre, Melbourne, Australia,* [2]*Sir Peter MacCallum Department of Oncology, The University of Melbourne, Melbourne, Australia,* [3]*Department of Pathology, Peter MacCallum Cancer Centre, Melbourne, Australia,* [4]*Department of Medicine, The University of Melbourne, Royal Melbourne Hospital, Melbourne, Australia.*

Introduction: Tumour-associated macrophages (TAMs) are one of the most important components of the microenvironment in gastric cancer (GC) and have been shown to exhibit immune suppressive and tissue remodelling properties. The M1/M2 system is commonly used to classify TAMs but may represent an oversimplification of a continuum of macrophage phenotypes. Despite intense characterisation of *in vitro* polarised macrophages, their heterogeneity *in situ* is not well understood. We performed a comprehensive study to identify and characterise the macrophage populations in the GC microenvironment and to determine their relevance to clinical outcome. **Materials and Methods:** A macrophage specific seven-colour immunohistochemistry panel was applied to 56 formalin-fixed paraffin-embedded GC patient specimens. Multiple images of each specimen were analysed to account for tumour heterogeneity. Samples were phenotyped using the inForm software (PerkinElmer). Cell number and spatial distribution were analysed with R. **Results:** Seven unique TAM subtypes were identified. The predominant subtype located at the tumour margin (interface of tumour and adjacent tissue) consisted of CD68+CD163+CD206+ cells while the CD68+IRF8+ population was significantly increased within the tumour core. However, the presence of neither population was correlated with patient outcome. The CD163+ (CD206-) TAMs were associated with improved survival in patients where these macrophages were both abundant in the tumour core and in direct contact (10µm) with the tumour cells. **Conclusions:** Macrophages are heterogeneous even within the same tissue. Spatially resolving their density and co-localisation with the tumour cells could help understand their interactions, provide better survival predictions and identify possible therapeutic candidates for GC patients.

CD11b Expressionin CGD patients and its use in X-CGD carrier detection

M. Y. Koker, *B. Saraymen, E. Bentli;*
Erciyes medical school, Kayseri, Turkey.

Chronic granulomatous disease (CGD) is a rare primary immunodeficiency disorder of phagocytes resulting in impaired killing of bacteria and fungi. X-linked CGD have been reported to be responsible for approximately 65% of all CGD cases and AR-CGD is 35% of them.
The CD11b antigen is known as the integrin αM subunit. CD11b is highly expressed on neutrophils, monocytes and macrophages. Oxidative burst activity and the expression of CD11b_CD18 have been used as indicators of leukocyte activation status. CD11b_CD18 integrins on the PMN membrane not only mediate cell adhesion, but they also marker for activation of protein tyrosine kinases.Neutrophil function were controlled with DHR assay in 24 samples 8 controls, 8 X-CGD patient, 8 X-CGD Carrier. Than, this assay were done with CD11b antibody and PMA by using same blood samples without dihydrorhodamine 123 . For this purpose 100 microL fresh peripheral blood sample is used for standart flow cytometric procedure. After stimulation of (PMA), the expression CD11b on neutrophil was measured by flow cytometric analysisThe results were compared with DHR 123 assay. There was a highly significant correlation between DHR assay and CD11b with stimulation analysis in flow cytometry application in all this samples. Especially CD11b with stimulation testing in the X-CGD Carrier mothers of neutrophil percentages exactly the same from both DHR 123 assay. Beside DHR assay, specific antibody for CD11b could also be used for functional evaluation of neutrophil. It is useful for alternative parameter for diagnosis and carrier screening of X-CGD patients like in DHR-123 assay.

Blood-stage malaria potently initiates both innate and adaptive immune responses, inclusive of the activation and modulation of the mononuclear phagocyte network. *Plasmodium* infection results in a profound loss of embryonically established tissue-resident macrophages primarily in the spleen, heavily involving the liver and lungs; and whose numbers are restored following clearance of *Plasmodium* parasites. During acute blood-stage malaria, both self-renewing tissue-resident macrophages and blood monocytes contribute to the repopulation of the emptied niches of splenic red-pulp macrophages and liver Kupffer cells, unlike lung alveolar macrophages that are capable of refilling their niche mainly through self-renewal. Despite *Plasmodium* infection, the local tissue microenvironment of spleen and liver allows the replenished macrophages to gain almost identical gene expression profiles and turn-over kinetics as the original foetal-derived counterparts. Thus, the mononuclear phagocytic system has developed distinct, but effective tissue-dependent strategies to efficiently refill available niches, which were rendered accessible during the *Plasmodium* infection.

P.A1.02.11

Myeloid-Derived Suppressor Cells originate from bone marrow are induced by G-CSF and persist in septic shock

E. Lereclus[1,2]*, T. Daix*[3]*, E. Guérin*[4,1]*, B. François*[3,2]*, J. Feuillard*[1,4]*, S. Alain*[2]*, R. Jeannet*[1]*;*
[1]UMR CNRS 7276, Medicine University, Limoges, France, [2]UMR Inserm 1092, Medicine University, Limoges, France, [3]Medical-surgical ICU, Dupuytren Teaching Hospital, Limoges, France, [4]Hematology Laboratory, Dupuytren Teaching Hospital, Limoges, France.

Introduction: Myeloid-derived suppressor cells (MDSC) are composed by a polymorphonuclear (PMN-MDSC) and a monocytic (M-MDSC) subset. Their functions are well described in cancer but it remains unclear how they are produced and recruited during sepsis. **Methods:** 57 immunocompetent patients hospitalized in Limoges Hospital for an acute infection were enrolled and regrouped according to their clinical severity: infection, sepsis and septic shock. We followed the level of M-MDSC and PMN-MDSC by flow cytometry in Peripheral Blood (PB) at D0, D3, D7 and D14. Plasma was collected to perform pro-inflammatory cytokines analysis. 20 residual Bone Marrow (BM) samples for thrombocytopenia diagnosis at admission were availabled for MDSC analysis. BM without hematological diseases were used for cultured assay. **Results:** When compared to healthy controls at admission, all patients showed an increase of MDSC absolute number in PB regardless of severity. Similarly, cytokine storm is visible in all patients, but cytokine decrease is slower in the most severe patients. MDSC were functional *in-vitro* and normal BM were able to produce M-MDSC and PMN-MDSC in presence of G-CSF and GM-CSF. Finally, MDSC are present in the BM of septic and septic shock patients with thrombocytopenia. **Conclusion:** We demonstrated that MDSC are produced by the BM following an infection and released rapidly in the PB. Interestingly, a sustain or increase number of MDSC after 3 days of hospitalization is linked to the severity of the sepsis and cytokine level in PB. Survival analyses are under investigation.

P.A1.02.12

Identification of monocytes from Asian elephant (*Elephas maximus*) by flow cytometry confirms a large population of PBMC with a diverse morphological profile

T. Maehr[1,2]*, A. Dastjerdi*[2]*, J. Lopez*[3]*, F. Steinbach*[1,2]*;*
[1]School of Veterinary Medicine, Guildford, United Kingdom, [2]Animal and Plant Health Agency (APHA), Weybridge, United Kingdom, [3]Chester Zoo, Upton by Chester, United Kingdom.

Asian elephants (*Elephas maximus*) are a critically endangered species where captive and wild populations threatened by a range of pathogens such as Elephant endotheliotropic herpesviruses (EEHV). EEHV can cause a fatal haemorrhagic disease (HD) in juveniles and the inability to culture the virus in combination with a lack of understanding of the elephant's immune system has hampered the development of efficient prophylactic. Specifically, only a few reagents are available for the analysis of the elephants' immunity, which may play a critical role in containing herpesvirus infections.
We assessed a panel of commercially available monoclonal antibodies (mAb's) for cross-reactivity and suitability to characterise elephant subsets. Initial flow cytometric analysis of peripheral blood mononuclear cells (PBMCs) revealed a forward and side scatter (FSC/SSC) pattern that is different when compared to other species, indicating a large putative monocyte population (>30%). This was corroborated by the staining pattern of an anti-bovine CD14 mAb found to have inter-species reactivity with elephant PBMCs whereby $CD14^{+}$ cells corresponded to two potential monocyte subsets in FSC/SSC plots. In addition, an anti-MHCII, an anti-CD3 and a mAb against B cells react with elephant leukocytes. Together these Ab's indicate an unusual composition of immune cells in Asian elephant that requires further investigation into the correlation with age and to better understand how monocytes dominate the PBMCs.

P.A1.02.13

Functional alterations in monocytes derived from bone marrow of patients with myelodysplastic syndrome

L. B. Cameirão[1]*, N. S. Bacal*[2]*,* ***L. Marti***[3]*;*
[1]Hospital Israelita Albert Einstein - Clinical Pathology Laboratory, São Paulo, Brazil, [2]Centro de Hematologia de São Paulo and Hospital Israelita Albert Einstein, São Paulo, Brazil, [3]Hospital Israelita Albert Einstein - Instituto Israelita de Ensino e Pesquisa Albert Einsten, São Paulo, Brazil.

Background Myelodysplastic syndrome (MDS) comprises heterogeneous group of clonal hematopoietic stem cell diseases with variable clinical course and risk of evolution to acute myeloid leukemia. Immunophenotypic changes of monocytic lineage are often seen in MDS. **Aims**: To evaluate functionality of monocytes with abnormal CD56 expression isolated from bone marrow of MDS patients. **Methods:** All samples were obtained after patients or controls signed an informed consent approved under CAAE number 33739214.8.0000.0071. All patient samples (05) and controls (03) were evaluated for presence of anomalous CD56 expression and for monocytes subsets percentage using flow cytometry. Monocytes with abnormal CD56 expression were isolated using anti-CD56/CD14 magnetic beads. The isolated cells were cultured with GM-CSF and IL-4 in order to verify their ability of differentiation into dendritic cells . Monocytes phagocytic potential was also evaluated using phagocytosis assay with fluorescent *E. coli* bioparticles. **Results:** All patient samples presented phenotypic anomalies, and significant decrease in intermediate monocyte subpopulation compared to controls (p=0.0082). Dendritic cells derived from CD56 monocytes showed important morphological alterations in size and decreased/absence of dendrites formation. We also observed immunophenotypic changes in expression of molecules such as decreased HLA-DR and CD209 compared to controls (p=0.0035; p=0.049) respectively. Moreover, there was a significant decrease in phagocytic capacity in monocytes from MDS patients (p<0.001). **Conclusion:** Dendritic cells derived from MDS patients with or without aberrant expression of CD56 showed morphological and immunophenotypic alterations. Monocytes also displayed reduced phagocytic capacity. These changes are important and should be investigated in the context of disease development.

P.A1.02.14

Investigating the Role of Tetraspanin 5 in Tumour Associated Macrophages

M. Moamin[1]*, P. Monk*[1]*, J. Saint Pol*[2]*, E. Rubinstein*[2]*, M. Muthana*[1]*;*
[1]UNIVERSITY OF SHEFFIELD, Sheffield, United Kingdom, [2]Inserm/Universite Paris-Sud, Paris, France.

Rationale: Tumour-associated macrophages (TAMs) actively promote all aspects of tumour initiation, growth, and metastasis. Following exposure to tumour-derived factors we see a significant increase in TSPAN5. We **hypothesise** that TSPAN5 plays a role in supporting the pro-tumour activities of TAMs
Methodology: qPCR was used to determine the expression of TSPAN5 in human monocytes, monocyte derived macrophages (MDMs) and MDMs cultured in tumour-conditioned medium. Expression of TSPAN5 was also confirmed at the protein level. Accell siRNA knockdown was performed to determine the role of TSPAN5 in MDM phenotype and function. NextSeq500 was performed to identify how TSPAN5 influences gene expression in BMDMs prepared from C57Bl/6 wild-type (WT) and TSPAN5 knockout (KO) mice.**Findings:** TSPAN5 was differentially expressed by human monocytes and MDMs. Following differentiation from monocytes to MDMs, the expression of TSPAN5 was significantly reduced, however culturing MDMs in tumour-conditioned medium significantly increased the expression of TSPAN5. This expression was also evident in TAMs located in patient derived breast cancer tissue (n=20). Interestingly, this accounted for 44% of TAMs. Knockdowns of TSPAN5 enhanced MDM migration and cell clustering and analysis of NextSeq500 (n=3) revealed significant changes in genes involved in cell adhesion (Fn1, Cdh11, Lamb1, Cyr61, Postn and Wisp2) and immune regulation (PTGS2, GPX8 and Crip2) in BMDMs from $TSPAN5^{KO}$ mice compared to WT mice. **Conclusion:** TSPAN5 is expressed by TAMs and this may regulate important macrophage properties. **Future studies** will focus on the role of TSPAN5 in preclinical mammary model in C57BL/6 WT and TSPAN 5^{KO} mice.

P.A1.02.15

Cellular Mechanisms Controlling Surfacing of AICL Glycoproteins, Cognate Ligands of the Activating NK Receptor NKp80

S. Neuss[1]*, Y. Bartel*[1]*, C. Born*[1]*, S. Weil*[2]*, J. Koch*[2]*, C. Behrends*[3]*, M. Hoffmeister*[3]*, A. Steinle*[1]*;*
[1]Institute for Molecular Medicine, Goethe University Frankfurt, Frankfurt am Main, Germany, [2]Institute for Tumor Biology and Experimental Therapy, Georg-Speyer-Haus, Frankfurt am Main, Germany, [3]Institute of Biochemistry II, Goethe University Frankfurt, Frankfurt am Main, Germany.

AICL glycoproteins are cognate activation-induced ligands of the C-type lectin-like receptor NKp80 which is expressed on virtually all mature human NK cells. NKp80-AICL interaction stimulates NK cell effector functions such as cytotoxicity and cytokine secretion. Notably, AICL and NKp80 are encoded by adjacent genes in the natural killer gene complex (NKC) and are co-expressed by human NK cells. Whereas AICL is intracellularly retained in resting NK cells, exposure of NK cells to pro-inflammatory cytokines induces AICL surfacing and susceptibility to NKp80-mediated NK fratricide. Here, we characterize molecular determinants of AICL glycoproteins causing intracellular retention thereby controlling AICL surface expression. Cysteine 87 residing within the C-type lectin-like domain (CTLD) not only ensures stable homodimerization of AICL glycoproteins by disulfide bonding, but is also required for efficient cell surface expression of AICL homodimers. In contrast, cytoplasmic lysines act as negative regulators targeting AICL for proteasomal degradation. An atypical and three conventional N-linked glycosylation sites in the AICL CTLD critically impact on maturation and surfacing of AICL which is strictly depending on glycosylation of at least one conventional glycosylation site. However, while extent of conventional N-linked glycosylation positively correlates with AICL surface expression, the atypical glycosylation site impairs AICL surfacing. Stringent control of AICL surface expression by glycosylation is reflected by the pronounced interaction of AICL with calnexin and the impaired AICL expression in calnexin-deficient cells. Collectively, our data demonstrate that AICL expression and surfacing is tightly controlled by several independent cellular post-translational mechanisms.

P.A1.02.16

Impact of obesity on the function and replenishment of hepatic macrophages in acute liver injury-mediated liver regeneration

G. Panetas[1], *L. Assmus*[1], *F. Gondorf*[2], *C. Kurts*[1], *I. Förster*[2], *W. Kastenmüller*[1], *Z. Abdullah*[1];
[1]*Institute of Experimental Immunology, Bonn, Germany,* [2]*Molecular Immunology and Cell Biology, Life and Medical Sciences Institute, Bonn, Germany.*

Obesity often leads to chronic inflammatory liver diseases such as non-alcoholic fatty liver disease and non-alcoholic steatohepatitis. Increasing number of obese patients show a significant risk factor for drug-induced liver injuries and poor liver regeneration after resection of liver mass. Macrophages are key players, supporting tissue regeneration after injury. In this study, the composition of liver myeloid cells, hepatic macrophage function and replenishment were investigated after liver injury, in a model of obesity-induced inflammation. The composition of myeloid cells in livers of obese mice, was investigated with flow cytometry. Sorted liver macrophages from mice on high fat diet, were cultured with apoptotic cells or bacteria to determine their phagocytic capacity *in vitro.* Furthermore, acute liver injury was induced with carbon tetrachloride (CCl_4) and serum levels of liver enzyme ALT were measured. Liver macrophages 30 days post injury, were stained with liver resident and bone marrow derived macrophage markers for flow cytometry and immunofluorescence. The composition of myeloid cells in the livers of mice on high fat diet, have reduced Kupffer cell number and increased infiltration of neutrophils, inflammatory macrophages and monocytes. Additionally, hepatic macrophage show impaired phagocytosis of both dead cells as well as bacteria *in vitro*. Furthermore, in the liver of mice on high fat diet, hepatic macrophages were unable to acquire a Kupffer cell phenotype following acute liver injury. Identifying the cellular and molecular mechanisms by which obesity might affect the function and phenotype of macrophages in liver regeneration will potentially open avenues to novel therapeutic concepts.

P.A1.02.17

Differential cellular programs of conditionally immortalized yolk sac and bone marrow macrophages

C. Schulz[1], *C. Stremmel*[1], *S. Elhag*[1], *A. Zehrer*[1], *B. Walzog*[1], *H. Häcker*[2], *E. Hammer*[3];
[1]*Ludwig-Maximilians-University, Munich, Germany,* [2]*Department of Infectious Diseases, St. Jude Children's Research Hospital, Memphis, United States,* [3]*Department of Functional Genomics, University of Greifswald, Greifswald, Germany.*

Introduction: Yolk sac (YS) hematopoiesis gives rise to tissue macrophages in many organs. However, the cellular program of these macrophages is incompletely understood. Methods/Results: We conditionally immortalized hematopoietic precursors of YS and bone marrow (BM) origin using estrogen-inducible Hoxb8, and differentiated them into mature macrophages. We than compared in detail their cellular identity and functions. Using proteome and gene expression analysis, we found that macrophages derived from BM progenitors developed a phenotype reminiscent of classically activated macrophages, whereas macrophages differentiated from YS progenitors displayed an increased abundance of anti-inflammatory proteins. Further, we identified differences in macrophage metabolism and functions. Conclusion: Our findings suggest that, when compared under standardized conditions ex vivo, distinct molecular programs are present in YS vs BM macrophages. This adds a novel perspective to the regulation of macrophage functions and could provide opportunities for their therapeutic Manipulation.

P.A1.02.18

Towards a better understanding of lung interstitial macrophages identity

J. Schyns[1,2], *D. Pirottin*[1,2], *F. Bureau*[1,2,3], *T. Marichal*[1,2,3];
[1]*Laboratory of Cellular and Molecular Immunology, GIGA-Research, University of Liège, Liège, Belgium,* [2]*Faculty of Veterinary Medicine, University of Liège, Liège, Belgium,* [3]*Walloon Excellence in Life Sciences and Biotechnology (WELBIO), Wallonia, Belgium.*

Lung interstitial macrophages (IM), constituting the non-alveolar lung macrophage compartment, have been shown to exhibit tolerogenic properties at steady-state by inhibiting the ability of dendritic cells to induce allergic type 2 responses against inhaled aeroallergens. Recently, several reports have provided experimental evidence that IM represent a heterogeneous population in the steady-state lung, and encompass at least two subpopulations, each of them likely carrying their own identity, e.g., phenotype, localization, differentiation program, and function. In order to assess the heterogeneity of IM in an unbiased way, droplet-based single-cell RNA sequencing experiments were performed on the IM pool, revealing three subpopulations of IM at the steady-state. Differentially expressed genes among the subpopulations allowed us to find specific surface markers that identify these phenotypically and functionally distinct subpopulations by flow cytometry, a crucial step to assess the identity of IM, and how such identity is imprinted by the local environment to fulfill the functional needs of the lung mucosa.

P.A1.02.19

IFN-γ-induced STAT3 activation as an alternative pathway in acute myeloid leukemia

G. Tunali, *D. Yoyen-Ermis, G. Esendagli;*
Hacettepe University Cancer Institute, Department of Basic Oncology, Ankara, Turkey.

Introduction: Even though IFN-γ is implicated in anti-tumor immunity, immunoregulatory pathways can simultaneously induce upon exposure to this cytokine. In addition to signal transducer and activator of transcription 1 (STAT1), which is main pathway that leads to cytostatic and immune-provoking effects of IFN-γ, STAT3 can also be activated. STAT3 promotes cancer cell growth, survival and immunosuppression. Here, we investigated the influence of IFN-γ exposure on STAT3 induction in acute myeloid leukemia (AML) cells.
Methods: AML cell lines (THP-1, U937, HL-60) were treated with all-trans retinoic acid (ATRA) or 1α,25-dihidroxyvitamin D3 (D3) to modulate their differentiation status. Maturation of AML cells were assessed by cytology and flow-cytometric immunophenotyping. Bone marrow samples from AML or myelodysplastic syndrome patients and $CD11b^+$ myeloid cells from healthy donors were also studied. Cells were stimulated with recombinant IFN-γ for different time periods. Phospho-STAT3 (pSTAT3), total-STAT3 (tSTAT3), pSTAT1 and tSTAT1 levels were assayed by Western-Blot.
Results: STAT3 was efficiently induced with transient IFN-γ stimulation and pSTAT3 levels were compatible to that of pSTAT1. Hence, all samples studied were responsive to IFN-γ. This effect was augmented when AML cells previously underwent ATRA or D3 maturation conditions. STAT3 pathway was transiently activated in healthy myeloid cells but long-term (48h) exposure to IFN-γ had a positive feedback effect on pSTAT3 and tSTAT3 levels in AML cells.
Conclusion: In contrast to its anti-tumor actions, IFN-γ can effectively stimulate STAT3 in AML cells, supporting immunosuppressive characters and pro-survival activities. Targeting STAT3 in AML may complement immunotherapies which are related to IFN-γ-mediated immunity.

P.A1.02.20

Monocytes bearing G551D-CFTR mutation present a high RANK/MCSF co-expression: first evidence of a facilitated osteoclastogenesis in cystic fibrosis patients?

M. Jourdain[1], *D. Abdallah*[1], *C. Guillaume*[1], *N. Ronan*[2], *Y. McCarthy*[2], *E. Flanagan*[2], *B. J. Plant*[3], *J. Jacquot*[1], ***F. Velard***[1];
[1]*EA 4691 BIOS, Reims, France,* [2]*University College Cork National University of Ireland, Cork Cystic Fibrosis Center, Cork, Ireland,* [3]*University College Cork, Dept. of Respiratory Medicine, Cork, Ireland.*

Bone fragility and low bone mineral density often affect children and young adults with cystic fibrosis (CF) disease. Due to the presence of CFTR in monocytes, we hypothesized that it may impact monocyte differentiation and activation in osteoclasts. Osteoclast precursors fuse and differentiate to form bone-resorbing multinuclear osteoclasts upon stimulation by two essential factors, the M-CSF and the RANKL.
We examined the expression level of M-CSFR and RANK receptors on blood monocytes from G551-D CF patients by flow cytometry, prior to and at nine and twelve months after receiving CFTR potentiator ivacaftor.
Compared to healthy controls, our first set of data demonstrates higher level of a double $M\text{-}CSFR^{high}/RANK^{high}$ subpopulation on monocyte of G551-D CF patients, which was reduced by *in vivo* ivacaftor treatment. Moreover, we examined *ex vivo* differentiation and activation of healthy monocytes into osteoclasts for a 21-days period with/or without the addition of Inh-172 drug, an inhibitor of CFTR chloride channel activity. Interestingly, multinuclear osteoclasts derived from Inh172-treated healthy monocytes were largest, more adherent, and were prone to generate large pits and trenches of dentin resorption. In addition, multinuclear osteoclasts derived Inh172-treated healthy monocytes released reduced level of bioactive lipid mediator sphingosine 1-phosphate (S1P), a key mediator in the directed migration of osteoblast/osteoclast precursors attached to the bone surface. Altogether, these data highlight the critical regulatory role of CFTR in M-CSFR and RANK receptors expression in monocytes, and suggest CF bone disease as a new, cell-type-monocyte dysfunction disease. Vaincre la Mucoviscidose and Vertex Inc. provided funding supports.

P.A1.02.21
Long-term effects of microglial depletion on tau pathology and spatial memory

*H. Lund[1,2], **K. Zhu**[1,2], M. Pieber[1,2], M. Ohshima[3], K. Blomgren[3], X. Zhang[1,2], R. A. Harris[1,2];*
[1]Department of Clinical Neuroscience, Applied Immunology and Immunotherapy, Karolinska Institutet, Stockholm, Sweden, [2]Center for Molecular Medicine, Karolinska Hospital at Solna, Stockholm, Sweden, [3]Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden.

A hallmark of Alzheimer's disease pathology is neurofibrillary tangles comprising hyper-phosphorylated tau. Microglia are resident myeloid cells of the CNS that are implicated in neuro-inflammatory and neurodegenerative disorders. To investigate the reciprocal relationship between microglia and tau pathology we first characterized the microglial response in a mouse model of progressive tau accumulation (hTau mice). We did not detect changes in microglia surface receptor expression, proliferation, cytokine production, morphology or transcriptional profile in aged hTau mice indicating a lack of pathogenic microglia responses to tau aggregation. To assess the direct impact of microglia on tau pathology and associated neurological deficits we developed a protocol for long term microglial depletion in CX3CR1^{CreER}R26^{DTA} mice and crossed them with hTau mice. We then depleted microglia for 3 months which resulted in exacerbation of spatial memory function. These results indicate that microglia have a neuroprotective role during Alzheimer's related tau pathology.

P.A1.02.22
Newborn babies have high number of immature *monocytes expressed CD116* in peripheral blood than adults

***M. Y. Koker**, S. Özsoy, B. Bingöl, S. Kütük, Ç. Karaca;*
Erciyes medical school, Kayseri, Turkey.

Monocytes are able to differentiate to dendritic cells (DCs) under inflammatory situations. Different monocyte subsets show distinct inflammatory cytokine profiles and differentiation potential under steady-state and inflammatory situations. The major subset of monocytes consists of CD14-high CD16-negative (CD14++CD16−). Commited dendritic cell originated from immature monocytes. In humans (hpre-CDC) that develops from committed DC progenitors (hCDPs) in the BM. We have measured the number of immature monocytes (pre-CDC) with CD34+CD38+ CD116+ expression by flow cytometry with acquisition of a million cells from peripheral blood in 10 newborn and 10 adults. To determine the physiological distribution of hpre-CDCs in humans, we examined, peripheral blood, of newborn and adult for small numbers of pre-CDCs travel through the blood and replace cDCs in the peripheral organs, maintaining homeostasis of the highly dynamic cDC pool. Monocyte-derived circulating short-lived pre-CDCs are high in newborn (mean:57 cells/million cells) than adults (mean:7 cells/million cells). We assume that any organ includes epithelial cells, endothelial cells, fibroblasts, stromal cells, and hematopoietic cells are a source of GM-CSF secretion. Circulations of CD116+ short-lived pre-CDCs undergo maturation when going through the vascular environment with high GM-CSF secretion to microenviroment.

P.A1.02.23
Ssu72 phosphatase regulates tissue-resident macrophage function

***E. Park**[1], S. Lee[1], C. Lee[1,2];*
[1]Department of Molecular Cell Biology, Sungkyunkwan University School of Medicine, Suwon 16419, Korea, Republic of, [2]Department of Health Sciences and Technology, SAIHST, Sungkyunkwan University, Seoul 06351, Korea, Republic of.

Dynamic alterations of phosphorylation state of many cellular signaling-mediated proteins regulate their molecular and cellular fates. Ssu72 is dual protein phosphatase that can act upon tyrosine or serine/threonine residues and transcription/RNA-processing factor. Ssu72 has been characterized as an RNA polymerase II carboxy-terminal domain phosphatase that specifically catalyses serine-5-p dephosphorylation. Recently, we reported that Ssu72 functions as a cohesin-binding phosphatase and interplays with Aurora B kinase for regulation of duplicated sister chromatid separation, and that the deletion of hepatocyte specific Ssu72 led to the development of a high incidence of fatty liver diseases. Ssu72 is known to be expressed in a tissue-specific manner, and we found that Ssu72 expressed in adipose tissue, especially strongly in brown adipose tissue. In this aspect, we generated conditional knock out mice which Ssu72 is deleted specifically in adipose tissue and found that the deficiency of Ssu72 leads to BAT dysfunction compared to wild type mice. Interestingly, we observed not only dramatically reduction of macrophage population but also defective M2 macrophage generation in Ssu72-deficient BAT. Thus, we further generated myeloid cell specific Ssu72 knockout mouse model. This study will include the physiological relevance of Ssu72 loss-of-function in tissue-resident macrophage.

Differential Recovery Of Intrathymic Microenvironments That Follows Thymus Damage Results In Qualitative Changes In T-cell Reconstitution

***A. Alawam**, A. J. White, W. E. Jenkinson, G. Anderson;*
University of Birmingham, Birmingham, United Kingdom.

Following ablative therapies used for cancer treatment, damage to the thymus disrupts it ability to support T-cell development. This results in delayed T-cell reconstitution and a period of immunodeficiency that leaves patients susceptible to potentially fatal infections. Thus, examining mechanisms that control thymus regeneration, and identifying new approaches to boost thymus recovery, are important in devising new therapeutic strategies to improve immune reconstitution.
We have used sub-lethal irradiation (SLI) in a mouse model of thymic injury, and performed systematic examination of the recovery of both thymocytes and the thymic microenvironment. Following SLI, we find the generation of CD4$^+$CD8$^+$ thymocytes and their CD4$^+$ and CD8$^+$ progeny occurs in two distinct waves. Analysis of early thymic progenitors indicates that while an initial and transient wave of recovery occurs via a radioresistant intrathymic progenitor, a second sustained wave occurs via thymus entry of bone marrow progenitors. Surprisingly, concurrent analysis of the thymic microenvironment indicates cortial thymic epithelial cell numbers remain constant, suggesting they are radioresistant and available to support thymocyte development. In contrast, medullary thymic epithelial cells and dendritic cells are depleted following damage. Consistent with this, recovery of medulla-dependent Foxp3$^+$ regulatory T-cells occurs after the generation of conventional CD4$^+$ thymocytes.
In summary, our findings suggest that following damage, distinct thymic areas show differential recovery kinetics that impact upon the quality of new T-cell production. Ongoing studies are examining whether known regulators of thymus recovery, including KGF and LTβR stimulation, can restore medullary microenvironments to ensure balanced recovery of T-cell development.

P.A2.01.02
Effect of IL-15 cytokine on the adhesion and migration properties of CD4+CD28null T-lymphocytes in rheumatoid arthritis patients

*M. A. Moro García[1], L. García Jartín[1], E. Bueno García[1], A. García Torre[1], P. Castro Santos[2], R. Díaz Peña[2,3], **R. Alonso Arias**[1,2];*
[1]Hospital Universitario Central de Asturias, Oviedo, Spain, [2]Facultad de Ciencias de la Salud, Universidad Autónoma de Chile (Fondecyt Regular 1151048), Talca, Chile, [3]Inmunología, Centro de Investigaciones Biomédicas (CINBIO), Universidade de Vigo, Vigo, Spain.

CD4+CD28null T-lymphocytes are cells with terminal differentiation that appear after repeated antigenic stimulation and are found at high levels in patients with rheumatoid arthritis (RA). The main objective of this work was to study the adhesion and migration capacity of these cells and the effect of the cytokine IL-15 on these properties. The experiments were performed with peripheral blood samples from patients with RA, where the CD4+ T-lymphocytes were isolated. To study the adhesion ability of CD4+CD28null cells CD11a, CD49d, CD44, CCR5 and CX3CR1 molecules were studied by flow cytometry. The basal level of all these molecules was higher in CD4+CD28null T-lymphocytes. Moreover, IL-15 induced a significant increase in CD11a and CD44 in CD4+CD28null T-cells. Cell migration was studied in CD4+ T lymphocytes isolated and cultured in "transwell". Migrated cells were significantly higher in the wells with IL-15 and the majority of these cells were CD4+CD28null. This effect was IL-15 dose and time dependent. We also studied the activation and activity of Rho A, Rac 1 and Cdc42, proteins involved in cell migration. Both the basal levels of Rho A and the activated RhoA, Rac1 and Cdc42 were clearly higher in CD4+CD28null T-cells. In conclusion, CD4+CD28null T-cells exhibited very different migratory and adhesion properties compared to CD4+CD28+ T-cells in AR. This could be interesting when designing different therapeutic targets to try to prevent the migration and accumulation of these cells in locations where they could exert a pathogenic function and thus, slow down the progression of the disease.

Antigen and adjuvant trafficking within and outside of early life lymph nodes

F. Auderset[1,2,3], *A. Rochat*[1,2,3], *P. Fontannaz*[1,2,3], *C. Tougne*[1,2,3], *P. Lambert*[1,2,3], *C. Siegrist*[1,2,3];
[1]*Department of Pathology and Immunology, Faculty of Medicine, University of Geneva, Geneva, Switzerland,* [2]*World Health Organization Collaborating Center for Vaccine Immunology, Faculty of Medicine, Geneva, Switzerland,* [3]*Center for Vaccinology, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland.*

A key determinant of B cell responses is the delivery of antigens to B cells and follicular dendritic cells. Small soluble antigens gain access to B cell follicles through the conduit system, whereas larger antigens are captured by the subcapsular (SCS) macrophages lining the sinus of the lymph node (LN) and transferred to follicular B cells. Neonatal immunization is known to elicit poor and delayed germinal center (GC) B cell responses, suggesting suboptimal B cell targeting and activation. Given their role in antigen capture and delivery, we studied the postnatal development of SCS macrophages and show that they develop very slowly after birth, appearing in LNs only at 3 weeks of age. To investigate the consequences of their absence in neonates, we compared the fate of fluorescent small and large antigens by injecting OVA-FITC or PE, respectively, adjuvanted to the ASO3 oil-in-water adjuvant. Surprisingly, we observed $ASO3^+Ag^+$ cells in contralateral non-draining LNs of 1-wk-old and 3-wk-old mice 24 hours post-immunization, independently of the size of the antigen.
This resulted in local activation and proliferation of $CD4^+$ T cells and development of GCs. This process was oil-in-water adjuvant-dependent and likely resulted from the expression of monocyte chemo-attractants in distant LNs. Our data suggest lymph node impaired barrier and systemic diffusion of vaccine formulations containing oil-in-water adjuvants. Overall, ontogeny exerts a profound influence on antigen/adjuvant retention and diffusion, which should be taken into account when designing vaccine formulations considered for use in early life.

The transcription factor PLZF (promyelocytic leukemia zinc finger) encoded by the BTB domain containing 16 (*Zbtb16*) gene is expressed during the development of invariant natural killer T (iNKT) cells to direct the acquisition of their effector program. In this study we addressed the role of PLZF acetylation in iNKT cells by analyzing the development these cells in mice expressing a constitutive acetylated form of PLZF (PLZFon mice). We found that the constitutive activation of PLZF repressed the development of all iNKT cell subsets (NKT1, NKT2, and NKT17). This developmental block is intrinsic to iNKT cells as assessed by reconstitution experiments. In these mice iNKT cells are blocked at the $CD44^{low}$ to $CD44^{high}$ transition, do not upregulate IL-17Rb, and produce mostly IL-4 and IL-13, indicating that the block occurs at an early precursor stage. Finally, we found in normal mice that the acetylase EP300, known to induce PLZF acetylation in vivo, is expressed at the early $CD44^{low}$ stage 1 of development, indicating that a similar activation could take place during normal iNKT cell development. In addition, we found that the deacetylase HDAC3 and SIRT1, also PLZF partners, are expressed at the $CD44^{high}$ stage, indicating that PLZF suppression could be alleviated at the subsequent developmental stage. Overall, our study reveals a non-expected suppressive rather than activating role of PLZF while promoting iNKT cell development and proposes a model where a tight control of its acetylation/deacetylation during developmental stages regulates lineage specification of this population.

The adjuvant LT-K63 overcomes neonatal limitations in germinal center induction by circumventing the induction of suppressive regulatory cells

S. P. Bjarnarson[1,2], *A. A. Aradottir Pind*[1,2], *G. J. Magnusdottir*[1,2], *G. Del Giudice*[3], *I. Jonsdottir*[1,2];
[1]*Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavík, Iceland,, Reykjavik, Iceland,* [2]*Department of Immunology, Landspitali, the National University Hospital of Iceland, Reykjavik, Iceland,* [3]*GSK Vaccines, Siena, Italy.*

Introduction: High susceptibility to infectious diseases and low vaccine responses characterizes the neonatal and infant period due to immature immune system. Formulating antigens with adjuvants may enhance vaccine immunogenicity and efficacy. T follicular helper (Tfh) cells play an important role in germinal center (GC) reaction, production of antibody secreting cells (AbSCs) and memory B cells, whereas follicular T regulatory cells (Tfr) can suppress Tfh and GC B cells numbers. We evaluated the effects of the adjuvant LT-K63 on Tfh and regulatory cells in relation to its enhanced neonatal vaccine-induced humoral response. Materials and Methods: The frequency of Tfh, Tfr, regulatory T cells (Tregs), IL-10-secreting B cells (B10), GC B cells, plasmablasts and plasma cells, was assessed in 7-28 days old and adult mice, and 4, 8, 14 and 21 days after neonatal parenteral immunization with pneumococcal conjugate (Pnc1-TT) w/wo LT-K63. Vaccine-specific AbSCs and Abs were also measured. Results: Maturation of Tfh, Tfr cells, Tregs and B cells was age-dependent, in neonates a larger fraction of $CD4^+$ T cells and B cells differentiated into IL-10-secreting Tregs or B10 and B10-phenotype differed. Upon immunization LT-K63 enhanced neonatal induction of Tfh compared to vaccine alone and increased the ratio of $T_{FH}/T_{FR,}$ but decreased Treg and B10. Accordingly, LT-K63 enhanced the induction of GC B cells, plasmablasts, plasma cells, vaccine-specific AbSC and Abs. Conclusion: The adjuvant LT-K63 contributes to enhanced T_{FH} differentiation and induction of GC B cells by circumventing the induction of suppressive regulatory cells, contributing to enhanced and persistent vaccine responses.

Telomere length on individual chromosome arms in patients with immunopathology and healthy donors

M. S. Barkovskaya, ***E. A. Blinova****, J. V. Konyahina, A. E. Sizikov, D. V. Demina, V. A. Kozlov;*
Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation.

Telomere length is an important factor characterizing immune system, its decreasing indicates a premature aging in immune-mediated diseases. The distribution of telomere repeats on different chromosomes has an individual telomere profile in humans. The purpose of this study was to estimate the telomere lengths in the individual chromosome arms in patients with rheumatoid arthritis (RA), (n=6, the median age 51.5 (50-54)) and bronchial asthma (BA), (n=6, the median age 43,5 (37-57)) in comparison with healthy donors. Two groups of donors were selected strictly by age and each consisted of 6 human. Written informed consents were obtained from persons enrolled in the study. RA and BA were diagnosed by clinicians according to ACR/EULAR-2010 and GINA-2017.
Metaphase spreads obtained from PBMCs were used. For measurement of the telomere length Q-FISH with $(C_3TA_2)_3$ PNA-probe was applied. The new MeTeLen software was developed to estimate the telomere repeats quantity (http://www.bionet.nsc.ru/en/development/application-development/development-of-a-computer/metelen.html) in metaphase images.
When comparing the telomere length, it was found, that telomeres on p-arms of chromosome 15 in RA and 9 in BA are significantly shorter than in corresponding group of donors ($p< 0.05$, Mann-Whitney U-test). Also the common telomere profiles obtained from groups of patients and donors were evaluated. Analysis revealed a number of identical and distinctive features in distribution of significantly short (9q, 15q, 17p, 22q) and long (3p, Xp) telomeres (Wilcoxon-signed-runk test). This may be consequence of a proliferative stress in the immunopathology or instead a congenital feature, that accelerates immunosenescence and play role in pathogenesis of studied diseases.

P.A2.01.07

Type I Interferons (IFNs) are toxic during neonatal influenza virus infection

A. J. Carey[1], *O. K. Kumova*[1], *A. J. Fike*[1], *Y. M. Mueller*[2], *P. D. Katsikis*[1,2];
[1]*Drexel University College of Medicine, Philadelphia, United States,* [2]*Erasmus University Medical Center, Rotterdam, Netherlands.*

Although Type I IFNs constitute an efficient innate defense mechanism, type I IFN production and IFN receptor (IFNαβR) signaling can also serve to amplify proinflammatory responses, increasing respiratory tract damage. We questioned the role of Type I IFNs during neonatal influenza infection. Three-day old and 8-week old adult C57Bl/6 mice were infected with influenza virus and followed for mortality. Three-day old mice were exquisitely sensitive to influenza virus infection and exhibited high mortality and viral load. To test the role of Type I IFNs, IFNαβ receptor deficient mice ($IFN\alpha\beta R^{-/-}$) and age-matched C57/Bl6 mice were infected on the third day of life. Surprisingly, the $IFN\alpha\beta R^{-/-}$ mice had an improved survival rate of 80%, compared to the C57/Bl6 survival rate of 15%. We further confirmed this deleterious effect of type I IFN by treating neonatal mice intranasally with IFNβ 24 hours after influenza infection. Treating with IFNβ after influenza infection accelerated and increased mortality in the neonatal mice ($p<0.05$). When neonatal mice, however, were treated with IFNβ before influenza virus infection on days 1 and 2 of life, and then infected on day of life 3, mice were protected ($p<0.01$). Thus, IFNβ treatment timing in relation to neonatal influenza infection is critical for the function of IFN. Our studies reveal that Type I IFNs are toxic in the neonate in the setting of a viral infection.

Immunomodulatory activity of Lactobacillus isolated from human milk and baby stools

***M. C. de Almagro**, G. Cifuentes, M. García, J. A. Moreno, J. Jiménez, M. Rodríguez-Palmero;*
Laboratorios Ordesa, Sant Boi, Spain.

During the first moths of life, babies have an immature immune system. Breastmilk contains different immunomodulatory compounds that help the infant fight infections and favors a proper maturation of the immune system. Among these breastmilk components bacteria can be found. Probiotics are bacteria regarded as "good bacteria" due to their health benefits when used correctly. To identify new functional probiotics, a proprietary library of *Lactobacillus* isolated from human milk and stools from babies exclusively breastfed, was screened for immunomodulatrory activities. First, probiotics safety was assessed by measuring the cytotoxicity produced by the bacterial lysate as well as the bacterial supernatant in HT29 and THP1 cells. *Lactobacillus* ability to modify the levels of 11 cytokines was measured by Luminex and ELISA in basal conditions and upon LPS or TNFα treatment, obtaining several candidates with antiinflamatory and tolerogenic characteristics (IL-10 secretion and TNFα decrease upon challenge). Among those candidates, two strains with good growth properties up to the pilot scale, were selected. Therefore, two *Lactobacillus* strains isolated from baby stools with inmunomodulatory activity which could potentially be used in baby formula have been found. Support: this project is supported by Centro para el Desarrollo Tecnológico Industrial (CDTI)

VDJ-recombination shapes the clone-size distribution of naive T-cells

***P. C. de Greef**[1], T. Oakes[2], B. Gerritsen[3], J. Heather[2], R. Hermsen[1], B. Chain[2], R. J. de Boer[1];*
[1]Utrecht University, Utrecht, Netherlands, [2]University College London, London, United Kingdom, [3]Yale School of Medicine, New Haven, United States.

The clone-size distribution of the human naïve T cell receptor (TCR) repertoire is unknown, and measuring it is not feasible because of the vast repertoire diversity. We report a strong relation between the frequency of TCR alpha- and beta-chains of naive T-cells in blood samples from adult volunteers and the probability of these sequences to be generated by V(D)J-recombination in the thymus. This strong relation is unexpected because in adults, only a small fraction of naive T-cells is produced by the thymus, while the vast majority are a result of peripheral division. To examine if VDJ-recombination probabilities can indeed explain the frequency differences between TCRs in the naive compartment, we developed simple mathematical models describing naive T-cell dynamics, and compared their predictions with sequencing data. We establish the presence of a small fraction, but a large number, of TCR-sequences that are abundant and frequently generated by the thymus (i.e. the alpha- or beta-chains have a high VDJ-recombination probability). These results demonstrate an unexpectedly large role for VDJ-recombination probabilities in shaping the naïve clone-size distribution, casting doubt on the role that cognate signals play in determining clone-sizes of naive T-cell repertoires.

P.A2.01.10

Young serum and its-derived extracellular vesicles potentially rejuvenate aged T cell immunity & immune tolerance (Supported by NIH R01AI121147 to D-M. S.)

***S. Dong-Ming**, J. Oh, W. Wang;*
University of North Texas Health Science Center, Fort Worth, United States.

Aging results in thymic involution, with declined output of naïve T cells resulting in accumulation of exhausted $CD28^{-neg}$ T cells, involved in immunosenescence; and increased output of self-reactive T cells, related to development of self-reactivity-resulted chronic inflammation. Both conditions establish a risk for increased morbidity and mortality in the elderly. Therefore, it is of great importance to develop rejuvenating strategies able to attenuate these. A promising "rejuvenation factor" present in young blood has been found to be able to make aged neuron "younger". However, it is uncertain whether and how young serum-derived factors work on aged immune system. Herein, we tested rejuvenation in aged human (>70YO) peripheral blood mononuclear cells (PBMCs) with young human serum in humanized mouse model, and in the naturally-aged mouse (>16MO) atrophied thymus with young mouse serum-extracted extracellular vesicles(EVs)/exosomes, in which full of epigenetic regulators are encapsulated. We determined young human serum, but not PBS, was able to reduce $CD28^{-neg}$ cells in CD4 and CD8 subsets, with reduction of global methylation, and increased cell numbers and activation of Bim^+ cells. We also found young murine serum-derived EVs, but not non-EV supernatant, were able to attenuate inflammation in both the periphery and central nerve system of old mice, attributed to partially reversed thymic involution and improved function in thymocyte negative selection. Our results in rejuvenation of T cells on both peripheral immunosenescence and central immune tolerance serve as an impetus to encourage us to determine the underlying mechanism, which is hypothesized due to young serum-provided epigenetic intervention.

P.A2.01.11

Distinct pattern of differentiation and responsiveness of chicken $CD8\alpha\alpha^+\gamma\delta$T cells

***M. Gu**, K. Yu, Y. Kye, B. Park, T. Park, S. Han, C. Yun;*
Seoul National University, Seoul, Korea, Republic of.

The aim of the present study was to investigate phenotypically distinct subset of γδT cells in the periphery and, more importantly, their function. In chickens, CD8 expression subdivides peripheral γδT cells into 3 subsets ($CD8^-$, $CD8\alpha\alpha^+$, and $CD8\alpha\beta^+$ γδT cells). Interestingly, unlike other subsets, $CD8\alpha\alpha^+$ γδT cells were absent in the thymus while they are present in all other organs examined. It is important to note that $CD8\alpha\alpha^+$ γδT cells did not convert into other subsets when stimulated with PMA/IL-2 whilst other subsets were able to become $CD8\alpha\alpha^+$ γδT cells. Furthermore, $CD8\alpha\alpha^+$ γδT cells in the periphery exhibited high expression of CD25, CD28 and CD44 compared to other subsets. These results indicated that $CD8\alpha\alpha^+$ γδT cells are most likely the form of terminally differentiated subset. To further investigate the response to innate and TCR stimuli, we prepared supernatant from total splenocytes treated with LPS (LPS supernatant), which contains major inflammatory cytokines (IL-1β, IL-6 and IL-23). γδT cells were treated with the LPS supernatant and/or αCD3/28 monoclonal antibodies (for TCR stimulation). We found that LPS-induced mediators induced proliferation of $CD8\alpha\alpha^+$ γδT cells which was mostly CD5 negative, while TCR stimulation induced proliferation of $CD5^+CD8\alpha\alpha^+$ γδT cells. These results suggested that proliferation of $CD8\alpha\alpha^+$ γδT cells with a distinct CD5 expression pattern displayed distinct response to innate (inflammatory cytokines) and adaptive (TCR stimulus) signal. Collectively, chicken $CD8\alpha\alpha^+$ γδT cells have heterogeneity of responsiveness to innate and TCR stimuli, which may help for investigating and understanding their functional role in infection and inflammation.

Invariant Natural Killer T (iNKT) cells are innate-like T lymphocytes, the development of which depends on the transcription factor PLZF. We aimed in this study to assess the contribution of the canonical TCR Va14-Ja18 alpha chain in driving iNKT1, 2, and 17 developmental programs. Analysis of iNKT cell development in conventional Va14-Ja18 transgenic (Tg) mice, where the Va14-Ja18 transgene is expressed as early as the $CD4^-CD8^-$ double negative stage, shows that the Va14-Ja18 chain does not favor the entry of iNKT cells into a specific developmental program. However, we found that iNKT cell specification is affected in CD4-Vα14-Ja18 Tg mice, where the transgene is controlled by a CD4 promoter retarding its expression at the $CD4^+CD8^+$ double positive stage. In these mice, we observed an increase in the $T\text{-}bet^-ROR\gamma t^-$ subset that we found to represent early iNKT cell precursors rather than NKT2 cells. These cells have a block in the transition from the developmental $CD44^{low}$ stage 1 to $CD44^{high}$ stage 2 and a defect in acquiring IL-17Rb at the $CD44^{low}$ stage 1, revealing an earlier developmental block. Analysis performed at the transcription and protein levels showed a reduced expression of Egr-2 and its target gene PLZF in developing iNKT cells from CD4-Va14-Ja18 Tg mice. Moreover, we observed that these cells perceived a weaker TCR signal that is likely at the origin of their altered downstream TCR signaling and subsequent developmental defect. Overall, our study highlights TCR signal strength, and not Va14-Ja18 chain, as an important regulator of iNKT cell lineage specification.

Plasma cells (PCs) produce antibodies that mediate immunity after infection or vaccination. In contrast to PCs in the bone marrow, PCs in the gut have been considered short-lived. Here, we studied PC dynamics in the human small intestine by cell-turnover analysis in organ transplants and by retrospective cell birth dating measuring carbon-14 in genomic DNA. We identified three distinct PC-subsets: A $CD19^+$PC-subset was dynamically exchanged, whereas of two $CD19^-$PC-subsets; $CD45^+$PCs exhibited little and $CD45^-$PCs no replacement, and had a median age of 11 and 22 years, respectively. Accumulation of $CD45^-$PCs during ageing and the presence of rotavirus-specific clones entirely within the $CD19^-$ PC-subsets support selection and maintenance of protective PCs for life in human intestine

Most studies on T cells have focused on conventional T cells that respond to peptides from viruses, bacteria and other pathogens. However, the human immune system contains large populations of unconventional T cells that recognise lipid antigens or Vitamin B derivatives presented by CD1 and MR1 molecules, respectively. Surprisingly, little is known about the role of these T cells in human immunity, largely owing to a lack of specific reagents to identify these cells. We have produced CD1 tetramers that contain endogenous mammalian lipid antigens or antigen-specific CD1 tetramers that contain lipid antigens derived from *Mycobacterium tuberculosis* (Mtb). We show that we can clearly identify both endogenous and Mtb reactive CD1 tetramer positive cells from healthy human blood. Moreover, using MR1 tetramers, we identify previously undescribed populations of Mucosal-Associated Invariant T (MAIT) cells within mouse and human thymus. We use a combination of multicolour flow cytometry, RNA-seq and gene deficient mice to characterise these poorly understood unconventional T cell populations and provide novel insight into the molecular mechanisms that underpin their development and function.

P.A2.01.15

Human iNKT cell subsets during thymic development & in the periphery

J. Perroteau[1], *L. Hesnard*[1], *M. Devilder*[1], *L. Gapin*[2], *E. Scotet*[1], *X. Saulquin*[1], *L. Gautreau-Rolland*[1];

[1]Centre de Recherche en Cancerologie et Immunologie Nantes-Angers, Nantes, France, [2]National Jewish Health - University of Colorado, Denver, United States.

Invariant Natural Killer T (iNKT) cells are unconventional T lymphocytes that express both NK receptors and a semi-invariant αβ TCR (T Cell Receptor). This TCR is restricted by the CD1d molecule presenting glycolipid antigens, and among them, αGalactosylCeramid (αGalCer) is a ligand of all iNKT cells. Recently, three principal subsets of iNKT cells have been described in mice, based on transcription factor expression and cytokine production: NKT1, NKT2 and NKT17 cells (Lee et al., 2013). However, the existence of specialized iNKT subsets remains uninvestigated in humans.

We previously studied the thymic maturation of human antigen-specific conventional T cells (Hesnard et al., 2016) thanks to a highly sensitive tetramer-based immunomagnetic cell separation approach (Legoux et al., 2010). Here, we adapted this strategy to enrich human iNKT cells, with fluorescent αGalCer-CD1d tetramers, from human thymuses and peripheral blood. A ten-parametric flow cytometry analysis, comprising transcription factors and membrane antigens, has allowed retracing the development of iNKT cells in humans.

We determined the presence of iNKT cells in the human thymus at a frequency of 1.10^{-6} among CD3+ cells. Most of them were CD4+CD8- and CD4-CD8-, but CD4+CD8+ and CD4-CD8+ subsets were also revealed. The activation status of these subsets showed a classical thymic differentiation with the loss of coreceptor expression over the thymic development. Finally, no functionally specialized iNKT subsets were depicted in the thymus, unlike in periphery. Altogether, these results suggest that human iNKT cells' development follows the kinetic model and that the establishment of distinct subsets is acquired in periphery.

P.A2.01.16

Tumor suppressor BAP1 is essential for thymic development and proliferative responses of T lymphocytes

S. Rutz, *T. Arenzana, A. Seki, C. Eidenschenk, D. Arnott, Z. Modrusan, A. Dey;*

Genentech, South San Francisco, United States.

BAP1 is a ubiquitously expressed nuclear deubiquitinating enzyme studied mostly for its tumor suppressor function. Loss-of-function mutations of BAP1 have been identified in a variety of solid tumor types, and are strongly linked to metastasis and poor prognosis.Surprisingly, we found that tamoxifen-induced BAP1 deletion in adult mice resulted in severe thymic atrophy and complete loss of the T cell lineage. B cell development was also abrogated suggesting a broader function for BAP1 in maintaining the lymphoid, but not the myeloid lineage. BAP1 deficiency resulted in a block at the DN3 stage prior to the pre-T cell receptor checkpoint. Peripheral T cells in CD4.Cre-driven T cell-conditional BAP1 KO mice exhibited a defect in homeostatic and antigen-driven expansion, showed strongly reduced production of Th1 and Th17 cytokines, and were completely protected from T cell-mediated autoimmunity. Deletion of BAP1 resulted in suppression of E2F target genes and defects in cell cycle progression, which was dependent on the catalytic activity of BAP1. Similar to the role of the BAP1 homolog Calypso in Drosophila, loss of BAP1 led to strongly increased global mono-ubiquitination of histone H2A at lysine 119 (H2AK119ub) throughout the T cell lineage, in particular in immature thymocytes. Histone PTM profiling by MS also identified diminished histone H3S10 phosphorylation, a hallmark of mitosis, further demonstrating a crucial role for BAP1 in regulating G2/M transition in T lymphocytes. Our findings uncover a non-redundant epigenetic function for BAP1 in regulating and maintaining proliferative capacity within the lymphoid lineage.

P.A2.01.17

Impaired balance of CD45RA and CD45RO membrane expression of blood T- lymphocytes in children with hepatitis: common features of autoimmune and chronical viral diseases?

E. Semikina[1], *A. Toptygina*[2], *A. Potapov*[1], *E. Kopyltsova*[1], *A. Surkov*[1], *S. Akulova*[1];

[1]) Federal State Autonomous Institution, Moscow, Russian Federation, [2]G.N.Gabrichevsky Research Institute for Epidemiology and Microbiology, Moscow, Russian Federation.

The impaired balance of CD45RA+ and CD45RO+ lymphocytes (lphs) in pediatric patients (pts) with autoimmune diseases can reflect the severity of permanent immune process, but the main reason is unclear: is it the primary immune dysregulation or the result of long-term inflammation? We compared the frequency of significant deviations of CD45RA/CD45RO expression in 25 children with autoimmune hepatitis (AIH) and 25 with chronical hepatitis C (HC), groups were equivalent with ages (7-15 y.o.), genders, and disease activity. The CD45RA and CD45RO membrane expression on peripheral blood lphs was determined with four-color flow cytometry (BD FacsCalibur, Cell-Quest Software, BD Biosciences MultiTest CD45RA/CD45RO/CD3/CD4 & CD45RA/CD45RO/CD3/CD8 MABs). The CD45RA/CD45RO expression was examined in the gates of T-cells (CD3+), T-helpers (CD3+CD8+) and T-cytotoxic lphs (CD3+CD8+) separately . The individual CD45RA/CD45RO balance was compared with previously determined normal age-related levels. The advanced (forestalling to age) CD45RO expression at CD3+ and CD3+CD4+ was found in 6 of AIH pts (24%) and in 7 of HC pts (26%). The advanced CD45RO expression at CD3+CD8+ lphs was found only in 1 HC patient. The proposed negative correlation between age and CD45RA+ lphs and positive correlation between age and CD45RO+ lphs and was proven for CD3+ and CD3+CD4+ gates, not for CD3+CD8+. We suppose that "pre-mature ageing" of some lph's populations can be an unspecific event in chronical immune diseases independently of main pathological reason, but can be useful for long-term follow-up.

P.A2.01.18

The corepressor NCOR1 regulates the survival of single-positive thymocytes

*L. Müller[1], D. Hainberger[1], **V. Stolz**[1], P. Hamminger[1], H. Hassan[2], T. Pregleji[1], N. Bucheron[1], S. Sakaguchi[1], J. Wiegers[3], A. Villunger[3], J. Auwerx[4], W. Ellmeier[1];*
[1]Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria, [2]Dept. of Biochemistry (Shankar Campus), Abdul Wali Khan University (AWKUM), Mardan, Pakistan, [3]Innsbruck Medical University, Biocenter, Division of Developmental Immunology, Innsbruck, Austria, [4]Ecole Polytechnique Fédérale de Lausanne, Laboratory of Integrative and Systems Physiology, Lausanne, Austria.

Nuclear receptor corepressor 1 (NCOR1) is a transcriptional regulator bridging repressive chromatin modifying enzymes with transcription factors. NCOR1 regulates many biological processes, however its role in T cells is not known. Here we show that *Cd4*-Cre-mediated deletion of NCOR1 (NCOR1 cKO^{Cd4}) resulted in a reduction of peripheral T cell numbers due to a decrease in single-positive (SP) thymocytes. In contrast, double-positive (DP) thymocyte numbers were not affected in the absence of NCOR1. The reduction in SP cells was due to diminished survival of NCOR1-null postselection TCRβ^{hi}CD69^{+} and mature TCRβ^{hi}CD69^{-} thymocytes. NCOR1-null thymocytes expressed elevated levels of the pro-apoptotic factor BIM and showed a higher fraction of cleaved caspase 3-positive cells upon TCR stimulation *ex vivo*. However, staphylococcal enterotoxin B (SEB)-mediated deletion of Vβ8^{+} CD4SP thymocytes was normal, suggesting that negative selection is not altered in the absence of NCOR1. Finally, transgenic expression of the pro-survival protein BCL2 restored the population of CD69^{+} thymocytes in NCOR1 cKO^{Cd4} mice to a similar percentage as observed in WT mice. Together, these data identify NCOR1 as a crucial regulator of the survival of SP thymocytes and revealed that NCOR1 is essential for the proper generation of the peripheral T cell pool.

P.A2.01.19

Association of cystatin-3 gene polymorphisms with schizophrenia

***R. Zakharyan**[1,2], V. Hayrapetyan[1], L. Karapetyan[2], A. Arakelyan[1,2];*
[1]Institute of Molecular Biology NAS RA, Yerevan, Armenia, [2]Russian-Armenian University, Yerevan, Armenia.

Schizophrenia (SCZ) is a severe mental disease characterized by interplay between genetic and environmental factors. Despite a number of studies performed in the field of schizophrenia research, the molecular mechanisms of the disorder are still unclear. Previous studies including our own have demonstrated that alterations in immune response are contributory factors for schizophrenia. Cystatins are large group of proteins with diverse biological activities including immune response. The aim of the current study was to investigate the potential association of SCZ with rs3827143 single nucleotide polymorphism (SNP) of the gene (CST3), encoding cystatin-3 protein.
A total of 231 unrelated individuals of Armenian nationality (121 SCZ patients and 110 healthy controls) were genotyped using polymerase chain reaction with sequence-specific primers (PCR-SSP). Distribution of genotypes were checked to correspondence to Hardy-Weinberg equilibrium. Statistical analysis was performed using Pearson's Chi-square test. According to the data obtained, the frequency of the CST3 rs3827143*G allele was significantly lower in the group of SCZ patients compared to controls (p=0.0005, OR=0.52, 95%CI: 0.36-0.76). The same tendency was found for the carriage of the CST3 rs3827143*G minor allele (p=0.0024, 95%CI: 0.39-0.73). These data suggested that the CST3 rs3827143*G genetic variant can be considered as a protective factor against SCZ development, at least in Armenian population. Further studies are required to uncover the complete set of variants contributing to this disorder.

P.A2.01.20

CHMP5 is a quantitative TCR signal sensor required for T cell development

***S. Adoro**[1], J. Shim[2], L. H. Glimcher[3];*
[1]Case Western Reserve University School of Medicine, Cleveland, United States, [2]University of Massachusetts Medical School, Worcester, United States, [3]Dana Farber Cancer Institute and Harvard Medical School, Boston, United States.

A self-tolerant and diverse pool of T-cells is essential for adaptive immunity but the mechanism of generation of these T-cells in the thymus remains the subject of intense investigations. Through still poorly understood posttranslational mechanisms, precursor CD4^{+}CD8^{+} double-positive thymocytes are selected for maturation into the peripheral T-cell pool guided by the affinity of their T-cell receptor (TCR) interaction with self-peptides presented by thymic epithelial major histocompatibility complex molecules. While low-affinity TCR interactions induce 'positive selection' leading to T-cell generation, high-affinity TCR ligands induce 'negative selection' by apoptosis, consequently eliminating potentially self-reactive T-cell clones. How signals emanating from the same receptor can generate such diametrically opposite outcomes continues to perplex immunologists. We have identified the endosomal-sorting complex required for transport protein CHMP5 as a key sensor of TCR signal thresholds that promote thymocyte selection. Notably, thymocyte-specific loss of CHMP5 abolished T-cell development in a manner partly dependent on the ability of CHMP5 to stabilize Bcl-2 proteins in TCR-signaled thymocytes. Absent CHMP5, positively selected thymocytes underwent apoptosis that was partially rescued by genetic deletion of the apoptosis activator *Bim* or by transgenic overexpression of Bcl-2. We found that not only was CHMP5 posttranslationally stabilized by the deubiquitinase USP8, it also functioned as an adaptor to orchestrate normal client protein substrate ubiquitination in developing thymocytes. Collectively, our studies have uncovered an unexpected checkpoint during positive selection mediated by CHMP5 and identify CHMP5 as an essential component of the posttranslational machinery required for T-cell development.

Human MAIT cell count forms a surrogate for general immune health

*S. Danielli, I. Nassiri, E. Mahe, R. Cooper, R. Watson, H. Al-Mossawi, P. Klenerman, **B. P. Fairfax**;*
University of Oxford, Oxford, United Kingdom.

Human mucosal associated invariant T-Cells (MAIT) form a subset of CD8^{+} cells with recombined T-cell receptor (TCR) alpha chains containing the product of *TRAV1-2* with either *TRAJ-33*, *TRAJ-20* or *TRAJ-12*. MAIT cells have a distinct gene expression profile with high expression of *KLRB1* encoding CD161 and *RORC* encoding the transcription factor RORγt. Whilst MAIT cells are conserved from mice to humans, the determinants of number and their gene expression pattern in humans are poorly understood. Using TCR mapped from purified CD8^{+} T-cell RNA-sequencing data (196 samples from 102 individuals) we define a proxy for MAIT count with which we deconvolute a MAIT specific gene signature that out-performs single-cell sequencing data from the same individuals. We replicate previous findings of a rapid decline in MAIT count with age and we further find that MAIT count correlates with other signatures of immune health including T-cell clonality and anti-viral and pro-inflammatory gene expression signatures in NK cells and monocytes, from the same individuals, respectively. Within MAIT cells we find 155 genes whose expression is associated with age, including *AHRR*, *PTPRB* and *GPR15*. We also observe 20 sex associated genes within MAIT cells. Finally, we demonstrate a number of other TCR within CD8+ T-cells are correlated with MAIT count, suggesting shared factors controlling MAIT cell count over life and other subsets.

STRAUSS: Population-wide STudy on Risk of Anti-Ulcer medications for SubSequent anti-allergic drug prescription

***E. Jensen-Jarolim**[1,2], M. Kundi[3], E. Untersmayr[1], I. Pali-Schöll[1,2], B. Reichardt[4], G. Jordakieva[1,2,5];*
[1]Institute of Pathophysiology and Allergy Research, Center of Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, [2]The Interuniversity Messerli Research Institute, Medical University Vienna, University of Veterinary Medicine Vienna, University of Vienna, Vienna, Austria, [3]Center for Public Health, Medical University of Vienna, Vienna, Austria, [4]Sickness Fund Burgenland, Austria , Burgenland, Austria, [5]Department of Physical Medicine, Rehabilitation and Occupational Medicine, Medical University of Vienna, Vienna, Austria.

Background: Anti-ulcer medications, such as proton pump inhibitors (PPI), are amongst the most frequently prescribed drugs in Europe. In recent years, however, evidence for an association between gastric pH modulation and allergic sensitization has been reported. To evaluate this suspected association, we aimed to assess the frequency of prescribed anti-allergy treatment following acid-inhibitors prescription in Austria. **Methods:** Data from health insurance claim records 2009-2013 were assessed in a population-based analysis, covering 8.2 million (approx. 97%) of the Austrian population. Consecutive prescriptions of gastric acid-inhibitors (PPI, H2-receptor antagonists, sucralfate, prostaglandin E2) followed by anti-allergic drugs (antihistamines, desensitization therapy) prescriptions were analysed Austria-wide. As control condition, consecutive prescriptions of other common medications (lipid-modifying and antihypertensive drugs) followed by anti-allergics were analysed in a regional subgroup (Burgenland) controlling for age and gender. **Results:** The specific hazard for the prescription of anti-allergic drugs was doubled in the overall population (1.96 [95%CI:1.95-1.97]) and triplicated in the regional data set [3.07 (95%-CI:2.89-3.27)], after prescription of gastric acid inhibiting drugs ($p<10^{-17}$). These findings were more prominent in women (p<0.001 compared to males). Age and gender adjusted hazard ratio was 2.05 (95%CI:1.91-2.19), and elevated independent of preceding acid-inhibitor type. The risk increased age-dependent from 1.47 (95%CI:1.45-1.49) in <20 year olds, up to 5.20 (95%-CI:5.15-5.25) in >60 year olds. **Conclusions:** We found a highly significant association between acid-inhibiting and subsequent anti-allergic drug prescriptions. These population-wide findings are in line with previous mechanistic and observational studies, in both animals and humans, further supporting a causal relationship between gastric acid-modulation and allergic sensitization.

P.A2.02.01
CMV-infection in chronic heart failure patients contributes to a higher inflammatory status

M. A. Moro García, A. García Torre, E. Bueno García, B. Díaz-Molina, J. Lambert, ***R. Alonso Arias****;*
HOSPITAL UNIVERSITARIO CENTRAL DE ASTURIAS, OVIEDO, Spain.

Chronic heart failure (CHF) is characterized by high levels of proinflammatory mediators and disease progression may be a result of the deleterious effects exerted by endogenous cytokine cascades on the heart and the peripheral circulation. CMV-infection is the best known inducer of the differentiation of T lymphocytes in elderly and also contributes to the immunosenescence found in CHF patients. To analyze the association between CMV-serostatus and inflammation in CHF we study 40 patients (age: 55,5±6,9 years), 13 CMV-seronegative and 27 CMV-seropositive. Cytokine levels were quantified using a multiplex system (Luminex) and peripheral blood mononuclear cells (PBMC) were isolated and stimulated in vitro for 72 hours with anti-CD3 and LPS. Higher levels of IL-1b, IL-6, TNF, IL-17A and IL-12p70 ($p<0,05$) were found in the serum of CMV-infected patients compared to CMV-uninfected patients. No differences in IFN-γ, IL-2, IL-4 or IL-10 levels were found. Moreover, inflammation was related not only to CMV-infection, but also to anti-CMV antibody titers which showed positive correlation with IL-1b, IL-6, TNF and IL-17A ($p<0.05$).
When PBMC were stimulated in vitro, significant differences were also found between both groups of patients. PBMC from CMV-seropositive patients produced higher levels of proinflammatory cytokines in response to anti-CD3 treatment, whereas no differences were found in response to LPS stimulation. This could be due to the greater differentiation of CD4+ and CD8+ T-lymphocytes found in CMV-seropositive patients.
In conclusion, inflammation found in CHF patients may be related to dynamics of CMV-infection presumably as a consequence of their effects on T-lymphocyte differentiation.

P.A2.02.02
T-LGL leukemia cells display features of exhausted and senescent T cells

J. L. J. Assmann*, M. J. Kallemeijn, A. W. Langerak;*
Dept. of Immunology ErasmusMC, Rotterdam, Netherlands.

Background: Large granular lymphocyte leukemia is a rare heterogeneous hematological disorder that has a chronic disease course and mostly affects the elderly. LGL leukemia is estimated to account for 2-5% of all chronic lymphoproliferative disorders. Most commonly TCRαβ+ CD8+ T cells are affected, even though in rarer cases the γδ T cell lineage can be affected as well . Chronic (antigenic) stimulation is hypothesized to be one of the key players in disease onset. Since the disease largely presents with come of age, and since immuno-senescence is a well described phenomenon in the ageing individual, here we tried to identify if T-LGL leukemia cells of both lineages present characteristics of senescence and/or exhaustion at phenotypical, functional and gene expression levels.
Results: Based on our observations through 15-color flow cytometry and qPCR analysis, phenotypically and transcriptionally T-LGL leukemia cells were exhausted rather than senescent. On a functional level, the T-LGL cells adopted the senescence-associated secreting phenotype, which is characterized by overproduction of cytotoxins. Additionally, T-LGL leukemia cells showed diminished proliferation capacity and resistance to apoptosis, which is correlated with immuno-senescence.
Conclusion: Collectively, our data indicate that T-LGL leukemia cells adopt the most detrimental characteristics from both senescence and exhaustion, thereby secreting large amounts of cytotoxins without resulting in full replicative senescence and apoptosis, respectively. We further hypothesize that this could eventually result in the accumulation of terminally differentiated, activated, cytotoxic and apoptosis-resistant T-LGL leukemia cells that concomitantly induce heterogeneous disease characteristics in patients.

P.A2.02.03
T cell phenotypes in cytomegalovirus infected young adults are similar to those seen in elderly adults and are associated with reduced vaccine responses

G. Bowyer*[1], N. Venkatraman[1], T. Lambe[1], N. Brenner[2], C. Mair[1], T. Waterboer[2], S. Gilbert[1], A. Hill[1], K. Ewer[1];*
[1]The Jenner Institute, Oxford, United Kingdom, [2]Infection and Cancer Epidemiology, DKFZ, Heidelberg, Germany.

Introduction: CMV has been associated with reduced vaccine responses in both elderly and younger adults, although the underlying mechanisms are currently unclear, particularly in younger adults.
Methods: We conducted a Phase I clinical trial of viral-vectored Ebola vaccine candidates ChAd3-EBO-Z and MVA-EBO-Z in healthy young adults (18-50years). We assessed the impact of CMV serostatus on vaccine-specific T cell and antibody responses. We also compared T cell phenotypes in these adults with CMV- and CMV+ adults aged 60-80years to determine the differential impacts of CMV serostatus and age.
Results: CMV seropositivity was associated with significantly reduced vaccine responses and striking differences in the global T cell repertoire with a shift towards late-differentiated memory T cells expressing CD57 and killer cell lectin-like receptor G1 (KLRG1). The proportion of vaccine-specific $CD4^+$ and $CD8^+$ T cells expressing these markers was significantly higher in CMV+ individuals and negatively correlated with vaccine responses - 0.71% vs 0.27% of the $CD4^+$ and 19.9% vs 4.10% of the $CD8^+$. $CD57^+KLRG1^+$ $CD4^+$ cells were expanded in both CMV+ young and CMV+ older individuals but not CMV- individuals regardless of age.
Conclusions: This study suggests that CMV, which has previously been associated with immunosenescence and reduced vaccine immunogenicity in elderly populations, can impact negatively on vaccine responses in young adults. Expansion of a subset of $CD4^+$ T cells expressing terminal differentiation markers in association with CMV serostatus and not age suggests that CMV acquisition rather than age might be responsible for reduction of some vaccine responses in elderly cohorts.

P.A2.02.04
Landscape of naive T cell repertoire changes with human age

E. Egorov[1,2], S. Kasatskaya[1,3], T. Nakonechanya[1], M. Pogoerlyy[1], M. Shugay[1], D. Chudakov[1,2,3], ***O. Britanova****[1];*
[1]IBCH, Moscow, Russian Federation, [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation, [3]Center for Data-Intensive Biomedicine and Biotechnology, Skolkovo Institute of Science and Technology, Moscow, Russian Federation.

Human aging is associated with profound changes in T cell immunity, compromising our ability to withstand the new challenges including response to infections and vaccination. These changes may further result in the imbalanced immune response leading to nonspecific inflammation provoking neurodegenerative and cardiovascular disorders, increasing risk of cancer development and autoimmune diseases. Prolonged peripheral proliferation could be associated with the functional deficiency of naive T cells that fail to differentiate towards memory phenotype upon a specific antigenic challenge. How uniform is the naïve T cells proliferation on the periphery remains questionable. To shed the light on the nature of ongoing age-related changes, here we focused on the comparative analysis of intrinsic characteristics of TCR repertoires for the bulk naive CD8+, bulk naive CD4+, naive RTE-enriched CD31+CD4+ and naive non-RTE CD4+ T cells derived from peripheral blood of young versus elder healthy donors. We revealed several notable changes in characteristics of T cell repertoire. Characteristics of TCR beta CDR3 repertoires changed significantly in CD4 and CD8, both RTE-enriched and mature naive CD4 T cell subsets. Biochemical characteristics in the middle of TCR beta CDR3 also changed prominently. Relative publicity of CD4 but not CD8 naïve T cells repertoire increased. We propose several explanations for these phenomena, and call for further studies of the mechanisms causing the observed changes and of consequences of these changes in respect of the possible wholes formed in the landscape of naïve T cells TCR repertoire. This work was supported by the Russian Science Foundation project №16-15-00149.

P.A2.02.05
Progressive long-term avidity decline of CMV- but not EBV-specific CD8 T cell clonotype repertoires

B. Couturaud*[1], M. Allard[1], L. Carretero-Iglesia[1], D. E. Speiser[1,2], M. Hebeisen[1], N. Rufer[1,2];*
[1]Lausanne University Hospital Center and University of Lausanne, Epalinges, Switzerland, [2]Ludwig Cancer Research, University of Lausanne, Epalinges, Switzerland.

Efficient T cell responses rely on the TCR-pMHC-CD8 binding avidity that controls all essential T cell functions. However, it still remains unknown whether the TCR-ligand avidity is a determining factor for the clonal selection and evolution of antigen-specific T cells over time. Here, we studied the TCRαβ repertoire composition and selection over a period of 15 years combined with TCR-pMHC-CD8 binding avidity analyses of large panels of CMV- and EBV-specific CD8 T cell clones. We found that the TCRαβ clonotype composition of both CMV- and EBV-specific T cell responses remains remarkably stable during the studied period. Nevertheless, within the CMV-specific clonotype repertoires, we observed the preferential selection and expansion over time of clonotypes of lower TCR-pMHC avidity and higher CD8 binding dependency, correlating with reduced functional capacities. In contrast, the clonal evolution of the EBV-specific clonotype repertoires was highly preserved, with the presence of the same clonotype distribution (i.e. dominant versus sub-dominant, low versus high TCR avidity, CD8 binding-independent versus -dependent) over time. Our results indicate that the TCR-pMHC-CD8 binding avidity represents a major determinant of clonal selection and evolution in long-lasting CMV-specific T cells, consistent with the current concept of clonal senescence of high avidity T cells with aging. However, this is not the case for EBV-specific CD8 T cell repertoires, in which the clonal composition and distribution once established is kept highly constant for at least 15 years. These findings suggest distinct mechanisms regulating the long-term outcome of CMV- versus EBV-specific CD8 T cell responses in humans.

P.A2.02.06

Cigarette Smoke exposure during pregnancy increase the susceptibility of the inflammation process in the central nervous system (CNS) of the offspring

A. C. S. Durão[1], *W. N. Brandão*[2], *N. Ghabdan*[2], *J. S. Peron*[2], *T. Marcourakis*[1];
[1]*Faculty of Pharmaceutical Sciences, São Paulo, Brazil,* [2]*Institute of Biomedical Sciences, São Paulo, Brazil.*

During the implantation phase, the embryo is more vulnerable to external influences such as cigarette smoke, which can increase the risk of fetal developmental delay and immune system abnormalities. This study evaluated the effect of cigarette smoke exposure during pregnancy on an inflammatory response in the CNS of the offspring. C57BL/6 mice were exposed to 3R4F cigarette smoke, or synthetic air, from vaginal plug to offspring birth. At the 3rd day of life, offspring were separated for the following studies: 1) *in vitro*: brains were dissected and a mixed glial culture was prepared. After 21 days, the cells were stimulated with 100 ng/mL LPS or culture medium. After 24h, the pro-and anti-inflammatory cytokines were evaluated by CBA, as well as GFAP, CD11b, CD80 and CD86 by flow cytometry. 2) *in vivo*: animals were challenged with LPS (1 mg/kg) or saline i.p.. After 4h, the mice were euthanized and the CNS removed for PCR analysis. The *in vitro* experiments showed a proliferation of astrocytes and an increase in proinflammatory cytokines in the cells from animals exposed to cigarette smoke and challenged with LPS when compared to the control. *In vivo* the PCR Array showed that mice exposed to cigarette smoke and LPS had decreased expression of the CCR2, MHCII and SOCS1 genes. Our results suggest that exposure to cigarette smoke during pregnancy increases the inflammation response in the CNS of the offspring after an inflammatory stimulus. Financial Support: FAPESP, CNPq

P.A2.02.07

LKB1 expressed in dendritic cells governs the development of thymus-derived regulatory T cells

L. R. Pelgrom[1], *F. Otto*[1], *A. Ozir-Fazalalikhan*[1], *A. Sergushichev*[2], *M. N. Artyomov*[3], *H. H. Smits*[1], ***B. Everts***[1];
[1]*LUMC, Leiden, Netherlands,* [2]*ITMO University, St. Petersburg, Russian Federation,* [3]*Washington University, St. Louis, United States.*

Liver Kinase B1 (LKB1) plays a key role in cellular metabolism by controlling AMPK activation. However, its function in dendritic cell (DC) biology has not been addressed. Here, we found that in vitro cultured murine DCs that lack LKB1 displayed impaired AMPK, but heightened mTOR activation, and expressed higher levels of costimulatory molecules and CCR7 upon TLR stimulation, show stronger migratory capacity, resulting in stronger T cell priming capacity *in vitro* and, following adoptive transfer, *in vivo.* Surprisingly however mice with a DC-specific deficiency in LKB1 (CD11c-cre / LKB1-fl/fl [CD11cΔLKB1]) displayed reduced effector T cell responses in models of immunization. Instead, CD11cΔLKB1-mice harbored a dramatically expanded population of helios$^+$Foxp3$^+$ thymus-derived functional regulatory T cells (tTregs), already during steady state, which provides a mechanistic basis for the impaired response to immunization. Consistent with this Treg-dominated immune signature, CD11cΔLKB1-mice failed to develop proper anti-tumor immunity and were resistant to induction of allergic asthma. Mechanistically, we found that specifically thymic CD11b$^+$ cDCs from CD11cΔLKB1-mice displayed an enhanced ability to promote tTreg differentiation which correlated with elevated antigen processing and presentation in these cells. Together, our findings identify LKB1 as a key regulator of DC activation thereby governing the development of tTregs and outcome of immune responses.

Association of human obesity with PD-1 exhaustion phenotype in T cells

R. Flores-Mejia[1], *J. I. Leon-Pedroza*[2,3], *A. Monroy-Guzman*[4], *O. Rodriguez-Cortes*[5], *R. Chacon-Salinas*[2], *E. Hernandez-Leon*[6], *E. Calderon-Austria*[6], *C. V. Gaona-Aguas*[6], *S. A. Estrada-Parra*[2];
[1]*SEPI, Escuela Superior de Medicina. Instituto Politecnico Nacional, México, D.F., Mexico,* [2]*Depto. Inmunologia, Escuela Nacional de Ciencias Biologicas. Instituto Politecnico Nacional, México, D.F., Mexico,* [3]*Hospital General de Mexico, Ciudad de Mexico, Mexico,* [4]*Hospital General de Mexico, México, D.F., Mexico,* [5]*SEPI, Escuela Superior de Medicina. Instituto Politecnico Nacional, México, D.F., Mexico,* [6]*Escuela Superior de Medicina. Instituto Politecnico Nacional, México, D.F., Mexico.*

Lymphocytes are able to display in chronic inflammatory conditions, a diminished functional state known as exhaustion. Protein PD (Programmed Death)-1. inhibits activation and proliferation of T cells. Besides, obesity creates a chronic inflammatory state associated with insulin resistance (IR), but if this inflammation is capable of generate lymphocyte exhaustion is unknown. Patients and methods. Adults between 18 and 60 years old, with normal weight, overweight and obesity, and without other immunologic conditions or acute or chronic infection previously diagnosed, were recruited at the Diabetes Prevention Clinic at General Hospital of Mexico. All of them give their informed consent to participate and were studied through clinical examination, 75g oral glucose tolerance test and metabolic panel. Expression of PD-1 in peripheral blood lymphocytes, both CD45RO and CD45RA was conducted through flow cytometry. Statistical analysis was done with Student's t, one way ANOVA, MANOVA, chi-squared and Pearson's correlation. Results: Obesity and IR were associated with higher serum of C reactive protein, total leukocyte count, lymphocyte count and CD4 T cells. Individuals with obesity had higher counts of lymphocytes CD4+CD45RA+PD1+ than those without obesity (1.3 SD 0.5 vs. 11.4 SD 9.7; p = 0.02). Those subjects less insulin sensitive (Matsuda index < 4.0) had more T cells CD4+CD45RO+PD1+ than those having Matsuda index > 4.0 (28.9 SD 11.9 vs. 12 SD 3.1, p = 0.034). Conclusions: IR is associated with an inflammatory phenotype with activated lymphocytes expressing more PD-1, while obesity is associated with a phenotype in which naïve lymphocytes express more PD-1. Introduction:
Prenatal betamethasone is routinely administered to pregnant women at risk of preterm delivery to improve survival of the newborn. Even though glucocorticoids induce a plethora of effects on immune cells there is little known whether this treatment might affect the development of the offspring's immune system. Here we investigate the immunological long-term consequences of prenatal glucocorticoid administration in different mouse models of disease.
Methods: Time-pregnant females were treated with betamethasone one day before birth. Experimental allergic asthma was induced in C57BL/6 offspring by sensitization and challenge with ovalbumin. The kinetics of postnatal seeding of peripheral immune organs was assessed in the same strain. The TCR repertoire and development of autoimmunity was monitored in the adult offspring of NOD (diabetes) and MRL/MpJ-Fas^{lpr}/J (lupus) mice.
Results: Delayed seeding of T and B cells was observed in offspring of betamethasone-treated animals. In the NOD model, prenatal betamethasone treatment decreased the frequency of pathogenic T cells and the incidence of type 1 diabetes. In contrast, in the lupus-prone MRL/lpr strain, prenatal glucocorticoids induced changes in the T cell repertoire that resulted in more autoreactive cells. No differences were observed in allergic airway response after ovalbumin sensitization and challenge in prenatally-treated animals.
Conclusion: Prenatal steroid treatment, by inducing changes in the T cell receptor repertoire, has unforeseeable consequences on development of autoimmune disease. Our data should encourage further research to fully understand the consequences of this widely used treatment.

P.A2.02.10

Aging causes loss of CD122-mediated responsiveness to interleukin-2 in CD8$^+$T cells

D. Pieren, N. Smits, ***T. Guichelaar****;*
National Institute for Public Health and the Environment, Bilthoven, Netherlands.

Interleukin-2 is fundamental to supporting both responsiveness of effector CD8$^+$ T cells (Tc) and suppression by CD25$^+$Foxp3$^+$ regulatory T cells (Treg). Aging has a debilitating impact on the immune system, as marked by the loss of responsiveness of Tc and impaired interleukin-2 production. Moreover, expression of CD122 among Tc and frequencies of Tregs rise. Studies in young mice showed interleukin-2 to favour Tc responses when directed to the CD122 of its receptor, or to favour Treg functionality when directed preferentially to CD25 of the interleukin-2 receptor. Towards unraveling interleukin-2 functionalities at old age, we questioned whether interleukin-2 would reverse the defective Tc response at old age when favouring interleukin-2 binding to CD122 or preventing interleukin-2 binding to CD25. We supplemented anti-CD3-stimulated spleen cell suspensions of young and aged mice with interleukin-2 in the presence of antibodies blocking interaction specifically with CD25 or CD122. Activation of T cells was measured by proliferation and expression of CD69 using flow cytometry. Our study on directing exogenous interleukin-2 to CD122 or CD25 shows that interleukin-2 promotes activation of young Tc cells via CD122, but interleukin-2 never promotes responsiveness of Tc at old age. Moreover, blocking of CD25 enhanced interleukin-2-mediated Tc activation at young age, suggesting a suppressive role for CD25$^+$ Tregs. This modulatory effect was absent at old age. Thus, hyporesponsiveness to interleukin-2-mediated triggering of CD122 contributes to impaired activation of CD8$^+$ T cells at old age. Insight in dysfunctional responsiveness to interleukin-2 may improve our understanding of weakened immunity occurring among the elderly.

P.A2.02.11

Immunomodulation by the transcription factor FOXO3 and its pharmacological activation

J. Hartwig[1], *F. Sotzny*[1], *S. Bauer*[1], *J. Kurreck*[2], *C. Skurk*[3], *C. Scheibenbogen*[1];
[1]*Institute for Medical Immunology, Berlin, Germany,* [2]*University of Technology, Berlin, Germany,* [3]*Department of Cardiology, Berlin, Germany.*

Introduction: FOXO3 is a transcription factor crucial in regulation of cell metabolism, stress resistance and immunity. It is regulated by posttranslational modifications. However, mechanistic insight in FOXO3 effects on immune cell function is still limited. Therefore, the effect of FOXO3 on immune cell function as well as a pharmacological modulation of FOXO3 (e.g. metformin) will be studies in this project. Finally, different SNPs within the FOXO3 gene famous for their association with aging will be analyzed regarding their functional influence on immune cells. Material & Methods: AMPK activation (pT172) was analyzed by Western Blot. AMPK mediated phosphorylation of FOXO3 (pS413) was determined using Flow Cytometry (FC). Reactive oxygen species (ROS) production (DCFH-DA) and cytokine response (TNFα, IFN-, IL-10) was analyzed by FC. mRNA expression of FOXO target genes was assessed by qRT-PCR. Allelic discrimination PCR was used for FOXO3 SNP genotyping. Results: Preliminary data show an AMPK and FOXO3 activation under metformin treatment. This is confirmed by a repression of the FOXO3 target PCK2. Furthermore, Immune cells treated with metformin show reduced ROS and pro-inflammatory cytokine production. In addition, the anti-inflammatory cytokine IL-10 is increased under metformin. An association of three different gain-of-function SNPs in the FOXO3 gene, which were recently published to be associated with aging did not show a functional influence on cytokine or ROS production. Conclusion: Taken together, the results indicate that FOXO3 can be activated with metformin leading to an anti-inflammatory phenotype which might explain its anti-aging effect. DFG sponsored project

P.A2.02.12

Differential effect of cytomegalovirus infection with age on the expression of CD57, CD300a, and CD161 on T-cell subpopulations

F. Hassouneh[1,2], *N. Lopez-Sejas*[1], *C. Campos*[1], *B. Sabchez-Correa*[2], *R. Tarazona*[2], *R. Solana*[1], *A. Pera*[1];
[1]*Instituto Maimónides de Investigación Biomédica de Córdoba -Universidad de Córdoba, Cordoba, Spain,* [2]*Immunology Unit, University of Extremadura, Cáceres, Spain.*

Introduction: Immunosenescence is a progressive deterioration of the immune system with aging. It affects innate and adaptive immunity limiting the response to pathogens and to vaccines. Chronic cytomegalovirus (CMV) infection is probably one of the major driving forces of immunosenescence and its persistent infection results in functional and phenotypic changes to the T-cell repertoire. **Methods:** we analyzed the effect of CMV-seropositivity and aging on the expression of CD300a and CD161 inhibitory receptors and CD57 marker on CD4+ and CD8+ T-cell subsets. **Results:** regardless of the T-cell subset, CD57−CD161−CD300a+ T-cells expand with age in CMV-seropositive individuals, whereas CD57−CD161+CD300a+ T-cells decrease. Similarly, CD57+CD161−CD300a+ T-cells expand with age in CMV-seropositive individuals in both subsets and CD57−CD161+CD300a− T-cells decrease in CD8+ but not in CD4+ T-cells. Besides, in young individuals, CMV latent infection associates with the expansion of CD57+CD161−CD300a+ and CD57−CD161−CD300a+ CD4+ and CD8+ T-cells. Moreover, in young individuals, CD161 expression on T-cells is not affected by CMV infection. Changes of CD161 expression were only associated with age in the context of CMV latent infection. Besides, CD300a+CD57+CD161+ and CD300a−CD57+CD161+ phenotypes were not found in any of the T-cell subsets studied, indicating that in the majority of T-cells, CD161 and CD57 do not co-express. **Conclusions:** our results show that CMV latent infection impact on the immune system depends on the age of the individual, highlighting the importance of including CMV serology in any study regarding immunosenescence. P.A2.02.13

Investigation of intraperitoneal trafficking of lymphocytes in immunodeficient mice

R. Kugyelka, *L. Prenek, A. Lehmann, K. Olasz, T. Berki, P. Balogh, F. Boldizsár;*
University of Pécs, Department of Immunology and Biotechnology, Pécs, Hungary.

The zeta chain-associated protein of 70 kDa (ZAP-70) plays a key role in T cell development and signalling. ZAP-70 homozygous knockout (ZAP-70$^{-/-}$) mice have no mature T cells in their peripheral lymphoid organs and blood. Previously we have shown that the adoptive transfer of wild-type thymocytes reconstitutes this immunodeficiency. We have found that the intraperitoneal (i.p.) route of administration is the most efficient, so we investigated the mechanism of lymphocyte trafficking after i.p. injections.
We used a single i.p. injection to deliver CFSE-labeled donor thymocytes to ZAP-70$^{-/-}$ recipients. We sacrificed animals after various time points and investigated the cellular composition of omentum, peripheral and mesenteric lymph nodes, and spleen. In the mesentery and omentum we analysed the localization of CFSE^{+} donor cells; we also investigated the role of various adhesion molecules (selectins, integrins) and chemokines in the process.
We have found that after i.p. injection donor thymocytes leave the peritoneum and form aggregates in the mesentery along lymphoid vessels and in the omentum, however no donor-originated cells were visible in peripheral or mesenteric lymph nodes. The aggregates found in the omentum are most likeley located in milky spots. Our results suggest that the omentum is an important location for thymocyte entry from the peritoneum in immunocompromised mice, as well.
To gain further insight into the peritoneal trafficking we plan to investigate the possible alterations in trafficking after i.p. injection under different contitions (inflammation, stromal deficiency).

Characterization of human dendritic cells from elderly patients stimulated *in vitro* with viral proteins from hamster polyomavirus

A. Müller[1], *N. Maier*[1], *S. Lüth*[2], *W. Dammermann*[2], *K. Hanack*[1];
[1]*University of Potsdam, Institute of Biochemistry and Biology, Potsdam, Germany,* [2]*Brandenburg Medical School Theodor-Fontane, University Hospital Brandenburg, Center of Internal Medicine II, Brandenburg an der Havel, Germany.*

Introduction: Dendritic cells act as highly potent antigen-presenting cells and stimulate T- and B lymphocyte activation to drive immune responses. In elderly persons this potency is strongly reduced due to immunosenescence which leads to insufficient immune responses after vaccination. Increasing age is affecting innate as well as adaptive immune processes, e.g. phagocytic activity, antigen presenting capacity or antigen-specific activation of T- and B lymphocytes. To investigate this further *in vitro*, dendritic cells of young as well as elderly persons were stimulated with viral antigens and characterized in terms of their antigen-specific activation.
Methods: Human monocytes of young and elderly persons were isolated and differentiated *in vitro* to naive dendritic cells using GM-CSF and IL-4. Antigen activation was performed by adding a viral antigen (VP1) in different concentrations (2.5-20 µg/mL). *In vitro* activated dendritic cells of both groups were analyzed and compared by flow cytometry, immunofluorescence and interleukin production.
Results: Human dendritic cells could be activated antigen-specifically *in vitro* by using an antigen concentration of 10 µg/mL as optimum. The expression of different activation markers could be demonstrated and correlated with the production of proinflammatory cytokines. *In vitro* generated dendritic cells of elderly persons showed a reduced activation and capacity to stimulate naive T cells.
Conclusions: There is a high clinical need for improved vaccines to treat elderly persons. The characterization of antigen-specific responses *in vitro* could lead to a better development of vaccine formats in the future.

P.A2.02.15

Oxidative stress and inflammation support the accumulation of highly differentiated T cells in the bone marrow in old age and negatively correlate with Diphtheria antibody titers in the periphery

L. Pangrazzi[1], *E. Naismith*[1], *A. Meryk*[1], *K. Trieb*[2], *B. Grubeck-Loebenstein*[1];
[1]*University of Innsbruck, Innsbruck, Austria,* [2]*Welsklinikum, Wels, Austria.*

Aging induces a basal level of inflammation throughout the body, a condition known as "inflammaging", which contributes to immunosenescence. It has been demonstrated that memory T cells and long-lived plasma cells home to bone marrow niches, well organized structures which promote the survival of these cells. CD4^{+} and CD8^{+} effector memory T cell survival is promoted by IL-7 and IL-15 while maintenance of long-lived plasma cells is supported by APRIL and IL-6. IL-7 is important for long-lived memory T cells while IL-15 is mostly important for highly differentiated T cells, accumulation of which is associated with mortality in old age. The expression of effector memory cell and proinflammatory factors were investigated in bone marrow mononuclear cells (BMMCs) using qPCR and FACS, finding that, with age, IL-7 and APRIL decrease while IL-15, IL-6, TNF, IFNγ and IL1β increase. Incubation of BMMCs with ROS scavengers N-acetylcysteine and vitamin C reduced the levels of both cytokines in this cell population. Furthermore, proinflammatory molecules promoted the accumulation of highly differentiated CD28^{-} T cells, which further support inflammation. A negative correlation was found between ROS, inflammation and senescent CD8^{+} T cells in the BM, and Diphtheria antibody titers in the serum. Our results indicate that oxidative stress and inflammation may contribute to the age-related impairments in the maintenance of immunological memory. Highly differentiated and senescent CD8^{+} T cells in the BM may impair the maintenance of long-lived plasma cells, leading to reduced production of antibody in the periphery as a consequence.

P.A2.02.16

Defective DNA repair contributes to the aging-related accumulation of a CD25^{Low} regulatory T cell population

***D. K. J. Pieren**, N. A. Smits, M. E. Dollé, T. Guichelaar;*
National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands.

Aging has a detrimental impact on T cells. Regulatory T cells (Tregs) accumulate with age and have therefore gained attention in studies on aging. However, the driving force behind the accumulation of Tregs has remained undefined. Gradual accumulation of DNA damage is one of the biological factors that are fundamental to the process of aging. We here aimed to define aging-related accumulation of Tregs and questioned whether defective DNA repair would drive the accumulation of Tregs.
We defined aging of Tregs in wild-type mice at young and old age, and in genetically modified young mice that express a dysfunctional form of the DNA repair protein *excision repair cross-complementing group 1* (Ercc1$^{-/\Delta 7}$). *Ercc1$^{-/\Delta 7}$* is known to cause accelerated development of numerous aging-related pathologies and a reduced lifespan. We phenotypically analyzed CD4$^+$Foxp3$^+$ Tregs with a broad panel of aging markers by flow cytometry and defined subpopulations among these cells using cluster analysis by dimensionality reduction (tSNE).
Multidimensional analysis revealed elevated numbers of Tregs in young *Ercc$^{-/\Delta 7}$* mice and in old wild-type mice compared to young wild-type mice. The major subpopulation comprising this elevated number of Tregs in both naturally aged wild-type mice and in *Ercc1$^{-/\Delta 7}$* mice could be discerned uniquely by low CD25 expression. Furthermore, these CD25^{Low} Tregs show high expression of aging-related markers PD-1 and CD44.
Thus, our study shows that deficiency of DNA repair accelerates the aging-related accumulation of Foxp3$^+$ Tregs. This accumulation is mainly due to the rise of a CD25^{Low} subpopulation.

P.A2.02.17

Deacetylases transcript and protein expression in primary T cell in the context of ageing

***G. M. Toma**[1], D. Quandt[2], B. Seliger[1];*
[1]Martin-Luther University, Halle-Wittenberg, Institute of Medical Immunology, Halle (Saale), Germany, [2]Martin-Luther University, Halle-Wittenberg, Institute of Anatomy, Halle (Saale), Germany.

The capacity of the immune system to protect the organism declines with age, this is observed in the increased susceptibility to infections and decreased efficiency of vaccination. Postranslational modifications of proteins (PTMs) contribute to this by the accumulation of misfolded proteins. One of the most abundant PTMs is acetylation. This process is regulated by: acetyltransferases (ex: p300) and deacetylases. Deacetylases are historically called histone deacetylases (HDACs), but their range of substrates is much wider. The 3rd class of deacetylases is called Sirtuins (SIRT). SIRT1, 3 and 6 have been shown to have a role in the ageing process. Our aim is to analyze if the deacetylases expression levels change during ageing. For this purpose, CD4+ and CD8+ T cells have been sorted magnetically from PBMCs of healthy blood donors from 2 age groups (< 30 yo and > 60 yo) and have been stimulated with plate bound aCD3 and soluble aCD28 for 48h, then the transcript expression of HDACs and Sirtuins has been assessed by qPCR and the protein expression by flow cytometry. Additionally, the constitutive transcript expression of CD4+ and CD8+ T cells has been compared to non-T cells. Sirtuin expression was found higher in T cells, while Sirtuin and p300 expression was decreased in aged CD4 T cells. These results will be linked to proliferation assays and flow cytometry analysis of the T cell subsets. The results of our study will provide insights into the role of deacetylases in the ageing T cells.

Comparative analysis of B-cell repertoires induced by live yellow fever vaccine in young and middle aged dinors

***M. A. Turchaninova**[1], A. N. Davydov[2], A. S. Obraztsova[3,4], M. Lebedin[1], D. Staroverov[1], E. M. Merzlyak[1], O. V. Britanova[1], D. M. Chudakov[1,2,4];*
[1]Institute of Bioorganic Chemistry, Moscow, Russian Federation, [2]CEITEC, Masaryk University, Brno, Czech Republic, [3]Lomonosov State University, Moscow, Russian Federation, [4]Skolkovo Institute of Science and Technology, Moscow, Russian Federation.

Aging is associated with a dysregulation of immune function and age-related changes are reported in many cell populations. These changes include attenuated response to vaccines, an exhausted immune repertoire displaying a substantially lower diversity of T cell receptors as well as impaired antigen-driven selection mechanisms. Recent advances in next-generation sequencing technology have allowed us to perform high-resolution characterization of the antibody repertoire, and of the changes that occur following vaccination in different ages donors. In present study we employed 5'RACE UMI-based full length error-free immunoglobulin profiling to compare plasma cell antibody repertoires in young and old donors vaccinated with live yellow fever vaccine. Our analysis has revealed age-related differences in the responding antibody repertoire ranging from distinct IGH CDR3 repertoire properties to differences in somatic hypermutation profiles and antibody lineage tree structure. Young vaccinated individuals respond with a repertoire containing significantly longer CDR3, implying potentially higher sequence diversity. Elder individuals tend to respond to a new challenge with IGH variants carrying shorter CDR3s with higher content of hydrophobic and strongly interacting amino acid residues. Clonal lineage structure analysis reveals that elder individuals have higher total number of newly acquired hypermutations. But at the same time in elder individuals, replacement-to-silent ratio among the newly acquired unique somatic hypermutations was significantly lower compared to the young donors. Overall, our findings suggest that younger individuals respond with a more diverse antibody repertoire and employ a more efficient somatic hypermutation process than elder individuals in response to a newly encountered pathogen. The work was supported by the grant RSF 14-14-00533.

Introduction: Calpains and their inhibitor calpastatin form a self-regulatory calpain-calpastatin system (CCS) of limited proteolysis controlling proliferation and apoptosis. Their role for proliferation and aging of human T cells and for thymocyte differentiation was assessed here together with some mechanistic aspects of their maintenance and function.
Methods: Peripheral blood mononuclear cells were obtained from healthy young, elderly and centenarians, while thymocytes were obtained from infants undergoing heart surgery. Cells were left untreated or treated with specific membrane-permeable calpain inhibitors. Lymphocyte proliferation was assessed by flow cytometry using VPD450 dividing cell tracking. Amounts and activities of calpains, as well as the amounts of calpastatin and of phosphorylated NFκB, PLCγ, and p56Lck were assessed in different T cell and thymocyte populations by flow cytometry. Expression of the CCS genes and of some relevant miRNAs identified by the NGS was performed by qRT-PCR.
Results: Calpains are differently active in all populations of T lymphocytes and thymocytes. In the periphery, this activity is necessary for proliferation and cytokine secretion and associated with adequate phosphorylation of signaling molecules. It is sustained by constitutive expression of the CANP-1, CANP-2 and CAST genes correlated with certain miRNAs. With aging, the amounts and activities of calpains change in parallel with impaired proliferation and cytokine secretion, but are maintained at "young" levels in the centenarian T cells.
Conclusion: Constitutive activity of calpains in resting thymocytes and T cells seems indispensable for appropriate differentiation and function of these cells and is modified during aging.

The strategy of the human memory B cell response changes throughout life

***R. Carsetti**[1], E. Piano Mortari[1], O. Grimsholm[2], A. Aranburu[2];*
[1]Bambino Gesù Children Hospital IRCCS, Rome, Italy, [2]Department of Rheumatology and Inflammation Research, Gothenburg, Sweden.

Immunological memory, including memory B cells (MBCs), plasma cells (PC) and their antibodies, is generated by the reaction to infection and vaccination, and protects us from re-infection. Two populations of memory B cells have been described, switched and IgM memory B cells, that execute different and non-interchangeable functions. We have shown before that, whereas switched memory B cells are mostly generated in the germinal centers at all ages, IgM memory B cells can be distinct in three types with different developmental history: innate, remodelled and germinal-center-derived IgM memory B cells. CD27 is the cell surface marker able to identify most MBCs in human. The intensity of CD27 expression changes with age. We now show that, independently of the expressed immunoglobulin isotype, in infants MBCs express low levels of CD27 (CD27^{dull}). In the adult most MBCs are CD27^{bright}. CD27dull and CD27bright MBCs represent two distinct and sequential MBC developmental stages. Stringent Ag-driven pressure selects CD27dull into the CD27bright MBC pool. Our results identify the actors and the strategy of the human MBC response throughout life and give the rationale for the design of age-tailored vaccination protocols.

***In vivo* dynamics of thymic T cell differentiation revealed by a new Timer approach**

A. D. Paduraru[1], *D. Bending*[1], *T. Crompton*[2], *M. Ono*[1];
[1]*Imperial College London, London, United Kingdom,* [2]*University College London, London, United Kingdom.*

It is a central interest in thymus biology to understand how temporally dynamic molecular mechanisms control thymic T cell development *in vivo*. It is therefore important to clarify the temporal sequences of thymic T cell differentiation, but this is difficult due to a lack of tools to analyse the temporal dynamics of differentiating T cells.
Since thymic T cell differentiation is driven by T cell receptor (TCR) signalling, we recently established a new tool, Timer of cell kinetics and activity (Tocky) and developed a Timer reporter for a TCR downstream gene, *Nr4a3*. Timer protein spontaneously changes emission spectrum from blue to red, enabling investigations of the temporal dynamics of molecular and cellular events following TCR signalling *in vivo*.
We first determined the decay rates of Timer-blue and -red fluorescence in order to establish *Nr4a3*-Tocky as a quantitative tool to investigate TCR signal dynamics. Timer-blue fluorescence had a half-life of 4 hours, while Timer-red one was over 5 days. Therefore, blue fluorescence reports real-time transcription, while red fluorescence reports transcriptional history. We then used *Nr4a3*-Tocky to study thymic T cell development. Within $CD4^+CD8^+$ double-positive cells, Timer blue expression occurred mostly in the $CD69^+$ fraction. In $CD4^+$ and $CD8^+$ single-positive cells, Timer was expressed by $GITR^{high}$ cells. Finally, we show the temporal sequences of differentiation events for regulatory T cell differentiation using multidimensional analysis.
In conclusion, we establish *Nr4a3*-Tocky as a new tool for analysing the temporal dynamics of cellular differentiation, and using this, we demonstrate how T cells develop across time during selection processes *in vivo*.

The role of NF-kappaB transcription factors in virtual memory (Tvm) cells

D. P. Ellis[1], *T. Fulford*[2], *R. Grumont*[1], *R. Slattery*[1], *S. Gerondakis*[1];
[1]*Monash University, Melbourne, Australia,* [2]*Peter Doherty Institute, Melbourne, Australia.*

Virtual memory (T_{VM}) cells are a subset of memory phenotype CD8 T cells that arise naturally in naïve, lympho-replete mice. In contrast to conventional memory CD8 T cells that are generated following an antigen-dependent T cell effector immune response, T_{VM} cells develop from naïve $CD8^+$ T cells in response to cytokine-dependent homeostatic proliferative signals, in particular interleukin (IL)-15.
Utilizing two murine models, we show that the NF-κB transcription factor RelA plays a T cell-intrinsic role in the homeostatic maintenance of T_{VM} cells. Lethally irradiated mice reconstituted with $RelA^{-/-}$ foetal liver-derived hematopoietic stem cells (HSCs) fail to maintain a $RelA^{-/-}$ T_{VM} cell population. This phenotype, which appears in part due to an inability to compete with residual ($RelA^{+/+}$) T_{VM} cells for survival/proliferation signals coincides with reduced expression by $RelA^{-/-}$ T_{VM} cells of the IL-2/15 receptor β-chain (CD122). Conditional inactivation of RelA in T cells ($Lck^{cre}Rela^{fl/fl}$ mice) reveals an issue in maintenance with these mice exhibiting a decline in the T_{VM} cell population from 6 weeks of age to ~50% of normal numbers by 12 weeks, after which this reduced level of T_{VM} cells is maintained throughout adult life. In addition to a reduced expression of CD122, IL-7 receptor α-chain (CD127) expression is lower on $Lck^{cre}Rela^{fl/fl}$ T_{VM} cells when compared to age-matched littermate controls ($Lck^{cre}RelA^{wt/wt}$ mice), a finding suggestive of an IL-7 survival defect. Collectively, these results indicate RelA controls the homeostatic maintenance of T_{VM} CD8 T cells by regulating the expression of cytokine receptors important for T_{VM} cell survival and division.

Foliate lymphoid aggregates (FLAgs) - a novel member of serosal lymphoid organoids in mice

P. Balogh[1], *J. Xinkai*[1], *O. Jacobsen*[1], *G. Bedics*[1], *B. Botz*[2,3];
[1]*Department of Immunology and Biotechnology, Pécs, Hungary,* [2]*Department of Pharmacology and Pharmacotherapy, Pécs, Hungary,* [3]*3Molecular Pharmacology Research Group, Szentágothai Research Center, Pécs, Hungary.*

The involvement of non-mucosal lymphoid compartments of the abdominal cavity in the systemic immune responsiveness is almost completely unexplored. In addition to the milky spots within the omentum (MS), small congregates of leukocytes have been described in adipose tissue (fat-associated lymphoid clusters – FALCs). Here we report the identification of a novel form of serosal lymphoid organoids that can efficiently collect intraperitoneal B cells and B-lymphoma cells.
Using a spontaneous high-grade B-cell lymphoma a novel set of lymphoid tissues has been observed, which is characterized by a foliate appearance linked to visceral fat and omental adipose tissue as well as peritoneal membrane, denoted as Foliate Lymphoid Aggregate (FLAg). Their tissue architecture and developmental requirements were studied using whole-mount immunohistochemistry revealing an early macrophage-rich condensation followed by gradual enrichment of B cells, leading to FLAg-like transformation. In Rag-/- mice these structures are absent, whereas the transfer of purified B cells restores them. B cells show a partial segregation from T cells that appear to accumulate in the central regions. These FLAg structures are initially demarked and encapsulated by a rim of macrophages displaying LYVE-1 antigen, and are sensitive for clodronate liposoma-mediated depletion, which also blocks subsequent B-cell entry. In vivo bioimaging tracing reveals that both normal B cells and high-grade B-cell lymphoma cell efficiently home upon intraperitoneal transfer. These data reveal the existence of novel visceral lymphoid tissue formations which may influence abdominal immune surveillance.

Early dynamics of mucosal NK cells in the small intestine of infants

A. Sagebiel[1], *F. Steinert*[1], *S. Lunemann*[1], *C. Koerner*[1], *R. Schreurs*[2], *M. Altfeld*[1], *D. Perez*[3], *K. Reinshagen*[3], ***M. J. Bunders***[1];
[1]*Heinrich Pette Institute, Hamburg, Germany,* [2]*AMC, Amsterdam, Germany,* [3]*UKE, Hamburg, Germany.*

Introduction Most of our understanding of the infant NK cells is based on studies investigating blood while there is lack of understanding of the development of NK cell compartment in tissues such as the intestine. **Methods** Immune cells were isolated from human infant and adult small intestines (n=28) and assessed using 18-parameter flow cytometry. **Results** By performing t-SNE analysis including 15 parameters NK cells could be identified as $lin\text{-}CD127^-CD56^+$ cells. In infants, NK cells comprised 33% of the overall lymphocyte population compared to only 5% in adult intestines. The reduction of intestinal NK cells coincided with an increase of T cells, resulting in a log10 decrease of the NK-T cell ratio in adults (p=0.0001). The majority of these large numbers of infant NK cells could be considered as being tissue-resident based on their expression of CD103, and CD49a, while CD69 was higher on NK cells derived from adult tissues. In infants, mucosal NK cells featured a characteristic NK cell phenotype $Eomes^+$, $NKG2A^+$ and higher KIR expression as well as over four times more perforin (53.8%, p=0.011) than adult mucosal NK cells. Stimulation resulted in degranulation ($CD107a^+$) of almost all infant mucosal NK cells compared to adults (p=0.005). In sum, NK cells in infant intestines had a characteristic NK cell phenotype whereas in adults $Nkp44^+CD103^+Eomes^{low}$ persevered. **Conclusion** Large numbers of tissue-resident NK cells are present early in life in the intestinal mucosa. Upon reduction of classical NK cells in the infant mucosa $CD103^+Nkp44^+$ ILC-1-like innate cells in adult epithelium persist.

The thymus is the primary lymphoid organ where naïve T cells are generated, however, with the exception of age, the parameters that govern its function in healthy humans remain unknown. Herein, we characterized the variability of thymic function among 1,000 age- and sex-stratified healthy adults of the *Milieu Intérieur* cohort, using quantification of T-cell Receptor (TCR) Excision Circles (TRECs) in peripheral blood T cells as a surrogate marker of thymopoiesis. Age and sex were the only non-heritable factors identified that impact thymic function. TREC levels decreased with age (5% per year, $P=3x10^{-98}$) and were higher in women compared to men (66% increase, $P=2x10^{-15}$).

In addition, genome-wide association study revealed a common variant within the T-cell receptor *TCRA-TCRD* locus, between the *DD2* and *DD3* gene segments (rs2204985, P=1.9x10^{-8}), which associated with variable TREC numbers. Strikingly, transplantation of human hematopoietic stem cells with the rs2204985 GG genotype into immunodeficient mice led to thymopoeisis with higher TREC levels, increased thymocyte counts and a higher TCR repertoire diversity. Our population immunology approach revealed a genetic locus that controls thymopoiesis in healthy adults, with potentially broad implications in precision medicine.

P.A2.03.04
Accelerated aging of the immune system in childhood and adolescent neuroblastoma survivors

*P. Burilova[1], K. Bendickova[1], S. S. Jose[1], T. Kepak[2,3], Z. Krenova[2], **J. Fric**[1];*
[1]Center for Translational Medicine (CTM) International Clinical Research Center (ICRC), Brno, Czech Republic, [2]Pediatric Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, [3]Pediatric Oncology Translational Research (POTR), International Clinical Research Center (ICRC), St. Anne's University Hospital Brno,, Brno, Czech Republic.

Senescence of immune cells is characterized by the decline of immune functions including adaptive as well as innate responses and is associated with a number of pathologies linked to aging, including a higher susceptibility to infections or cardiovascular diseases. While senescence of adaptive immunity is relatively well described, mechanism of aging-related senescence in myeloid cells is only poorly understood. Senescence progression has been associated with several chronic inflammatory disorders but more interestingly has been observed in survivors of cancer therapy. The intensive therapeutic approach generates negative burden for patients' immune system, fueling persistent sterile chronic inflammation. By-products of cancer therapy or severe tissue damage, called damage-associated molecular patterns (DAMPs), often accumulate within the adjacent tissue and eventually spread within the blood stream. Myeloid cells and their progenitors are capable of binding DAMPs via TLRs, this results in pro-inflammatory cytokines production and initiation of inflammation. Here we address the impact of long-term administration of 13-cis-retinoic acid and topotecan currently available for neuroblastoma therapy, and DAMPs triggers to accelerated onset of immunosenescence caused by persistent low-grade inflammation. Distribution of monocytes into subsets and phagocytic activity from patient samples with neuroblastoma, the most frequent extra-cranial solid tumor in early childhood is analyzed. Furthermore, the possible impact of mentioned triggers to hematopoiesis is tested in vitro using human induced pluripotent stem cells derived myeloid cells. This project aims to develop new prognostic markers allowing to assess the progress of immunosenescence in order to prevent further serious complications, which occur long-term after the successful therapy.

P.A2.03.05
T-bet$^+$ CD8αα TCRαβ intraepithelial lymphocytesprecursor progress through a PD-1 stage and depend on C-myc

***J. Hummel**, K. Ebert, J. Fixemer, Y. Tanriver;*
University Medical Center, Freiburg i.B., Germany.

Intraepithelial lymphocytes (IELs) are a heterogeneous resident T cell population within the epithelial barrier in the small intestine and can be divided into natural (CD8αα TCRαβ or TCRγδ) and induced (CD8αβ TCRαβ) IELs. Thymic IEL precursors (IELPs) of natural CD8αα TCRαβ IELs are post-selected T cell receptor positive (TCRαβ$^+$) T cells that lack expression of the classical co-receptors CD4 and CD8 (double negative, DN) and NK1.1, which distinguishes them from natural killer T cells. We could recently refine this definition by demonstrating that lineage restriction in IELPs towards data CD8αα TCRαβ IELs is gradually imposed by the T-box transcription factor T-bet. Here, we demonstrated by employing a newly developed PD-1 fate map and conditional T-bet knockout mice that all natural IELs progress through a PD-1$^+$ stage, that is gradually lost upon T-bet expression. This transition is regulated by the transcription factor C-myc, as T cell-specific conditional C-myc knockout mice lack T-bet$^+$ IELPs, while PD-1$^+$ IELPs are still present. Using *C-myc$^{\Delta CD4}$* OT1-OVA chimera as a model of agonist-selected IELPs, we could show that high-avidity interaction cannot compensate for the loss of C-myc in IELPs. Thus, the loss of C-myc does not affect the agonistic selection of the IELP population leading to DN TCRαβ$^+$NK1.1$^-$ IELPs but lacking the final matured T-bet$^+$ IELP. Hence, the pronounced upregulation of C-myc during thymic IELP development is essential for the induction of T-bet, which in turn regulates proliferation and differentiation.

P.A2.03.06
Immunization-induced thymic atrophy as a contributing factor in strain differences in rat susceptibility to EAE

*M. Nacka-Aleksic[1], M. Stojanovic[1], I. Pilipovic[2], D. Kosec[2], **G. Leposavic**[1];*
[1]Department of Physiology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia, [2]Immunology Research Centre "Branislav Janković", Institute of Virology, Vaccines and Sera "Torlak", Serbia, Belgrade, Serbia.

Introduction: It is suggested that impaired thymopoiesis in autoimmune diseases contributes to their perpetuation. To prove this hypothesis, influence of immunization for EAE on thymopoiesis and the putative thymic-dependent changes in the periphery were examined in susceptible (Dark Agouti, DA) and resistant (Albino Oxford, AO) rats. Methods: On the 13th day post-immunization, expression of differentiation/maturation markers of conventional T cells and regulatory CD4+Foxp3+CD25+ cells (nTregs) on thymocytes, their apoptosis and proliferation, frequency of recent thymic emigrants (RTEs) and CD28^{null} cells in CD4+ and CD8+ peripheral blood lymphocytes (PBLs), and thymic expression and circulating levels of cytokines influencing thymus/thymopoiesis were investigated. Results: In rats of both strains increase in proinflammatory-cytokine circulating levels followed by thymic atrophy and changes at multiple thymocyte developmental points, leading to decreased number of the most mature CD4+ and CD8+ TCRαβ^{hi} thymocytes and frequency of RTEs among PBLs (as in chronobiological aging), was found. This was more prominent in DA rats. Consistently, compared with AO rats, in DA rats were found higher frequencies of cytolitic CD28^{null} cells (contributing to target tissue damage) among CD4+ PBLs and cytolitic granzyme B+ CD4+ T cells in spinal cord. Additionally, compared with non-immunized controls, DA rats exhibited greater decline in thymic nTreg generation (reflecting diminished thymic IL-7, IL-2 and IL-15 expression) than AO ones. Conclusions: The study suggests that differences in thymopoiesis, and consequently nTreg generation and CD4+CD28^{null} cell frequency in the periphery, contribute to strain differences in EAE clinical presentation. (Grant 175050, MESTD, Republic of Serbia).

P.A2.03.07
INF-g and TNF-α serum concentrations and frequency of IFN-g and TNF-α genotypes in children with primary immunodeficiency and recurrent respiratory tract infections (without significant immunological abnormalities)

***A. Lewandowicz-Uszyńska**[1,2], G. Pasternak[1,2], K. Bogunia-Kubik[3];*
[1]Wroclaw Medical University, Wrocław, Poland, [2]Provincial Hospital J. Gromkowski, Wrocław, Poland, [3]Polish Academy of Sciences, Wrocław, Poland.

The aim of the study was to evaluate the concentrations of INF-γ and TNF-α in children with primaryimmunodeficiency (PID). The studyincluded 93 children: 30 patients with PID, 43 RRTI, 20 healthy children (control group). The concentrations of INF-γ, TNF-α, and INF-γ and TNF-α polymorphisms were determined. The polymorphism of the TNF-alphaencodinggene (TNFA; rs1800629; -308 G / A) and IFN-gamma (IFNG; rs2430561; +874 T / A) were determined. Genotyping was done by melting curve analysis. This method is based on real-time PCR, ie PCR, where the detection of amplified DNA can be madeduring the reaction without the need for separated detection after the reaction. LightSNiPAssay (TIB MOLBIOL) and Probes Master MIX (Roche) were used for typing. Amplification was performed on LightCycler® 480 Multiwell Plate 96 plates on the LightCycler 480 II (Roche). The research was carried out in the Laboratory of Clinical Immunogenetics and Pharmacogenetics of the Institute of Immunology and Experimental Therapy, Polish Academy of Sciences in Wroclaw. No statistically significant differences in serum INF-γ, TNF-α, serum levels were observed in the examined children. The frequency of genotypes TNFA and IFNG in the group of patients (N = 93):TNF-alpha (TNFA; rs1800629; -308 G / A) in All studiem groups was the rarest GA, the most common GG. IFN-gamma (IFNG; rs2430561; +874 T / A) in All studiem groups was the rarest genotype AA, the most common AT.

P.A2.03.09
Chronic disease development increases with suppression of acute infectious diseases in the population - a case controlled pilot study of 166 cases

***S. Mahesh**[1], M. Mallappa[1], G. Vithoulkas[2];*
[1]Centre For Classical Homeopathy, Bangalore, India, [2]University of the Aegean, Alonissos, Greece.

Introduction: The change of the world's leading cause of morbidity and mortality from infectious to non communicable diseases over the past few decades cannot be attributed to the increase in hygiene or change in lifestyle alone. This raises the question - whether the manner in which immune system morphs in response to suppression of acute inflammation is detrimental to the general health of the population. This study aimed to test the hypothesis that the development of chronic diseases increases with suppression of acute infections in the population
Materials and Methods: Teenagers opting for treatment at Centre For Classical Homeopathy, Bangalore, India were analysed for their medical history and categorised into 4 groups Group 1: Present acute infections only - recurrent or not. (control group) Group 2: Present acute infections - at least one in the past 1 year with present chronic diseases diagnosis. Group 3: Present chronic disease diagnosis with history of recurrent infections in the past. Group 4: Present chronic disease diagnosis with no history of recurrent infections in the past. Results: The trend of the chronic diseases was to cluster in group 4. The most prevalent 3 chronic conditions viz., allergic bronchitis, allergic rhinitis and chronic headaches also showed a tendency to cluster in group 4.
Conclusions: This study shows that there is a tendency for chronic diseases to be significantly higher in people without acute infections. This data may be used further to evaluate the role of different treatment modalities that suppress acute inflammation in the body.

P.A2.03.10
A network of transposable elements controls CD4 T cell fate

A. Malbec*, V. Adoue*, B. Binet*, J. Fourquet, O. Joffre;*
CPTP, Université de Toulouse, CNRS, Inserm, UPS, Toulouse, France.

CD4 T lymphocytes are highly efficient at protecting the host against endogenous and exogenous dangers. Their efficiency comes at least in part from their ability to adapt their phenotype and function to the threat detected by the cells of the innate immune system. T helper cell differentiation and commitment are strictly controlled by epigenetic mechanisms. They are necessary to establish lineage-specific gene expression programs while repressing genes associated with alternative fates. Combining genome-wide transcriptomic and epigenetic studies with functional assays, we revealed a role for a non-histone chromatin protein in CD4 T cell programming. CD4 T cells deficient for this molecule show exacerbated Th1 priming and increased Th2 cell plasticity toward the Th1 lineage. Mechanistically, we show that the deregulation of the Th1 gene expression program results from a loss of repression of a network of transposable elements. Refined bioinformatic analyses indicate that these transposons either flank and repress Th1 gene cis-regulatory elements or behave themselves as Th1 gene enhancers. In conclusion, we identified a new molecular player that ensures T cell lineage integrity by repressing a repertoire of transposable elements that have been exapted into cis-regulatory modules to shape and control the Th1 gene network.

P.A2.03.11
Beta2 integrin receptor-mediated regulation of γδ T cells

C. L. McIntyre*[1], L. Monin Aldama[2], C. S. Goodyear[1], A. Hayday[2,3], V. L. Morrison[1];*
[1]University of Glasgow, Glasgow, United Kingdom, [2]Francis Crick Institute, London, United Kingdom, [3]Kings College London, London, United Kingdom.

γδ T cells play an essential role in immune surveillance and have protective effects against several types of cancer. This has led to the development of γδ T cells as a cancer therapeutic, however the mechanisms of γδ T cell regulation and migration *in vivo* are poorly understood. αβ T cell migration and function is dependent on β_2 integrins, which are leukocyte-specific adhesion molecules, however their role in γδ T cell biology has not been fully elucidated. β_2 integrin-deficient mice develop spontaneous skin and/or oral mucosal inflammation, associated with an expansion of γδ T cells. We hypothesised that β_2 integrins are a novel regulator of γδ T cells. β_2 integrin knockout (CD18 KO) mice were used to evaluate the effect of integrin loss on γδ T cell phenotype and localisation under steady-state conditions and determine the molecular mechanism responsible for expansion. CD18 KO mice had a tissue-specific (i.e., spleen, blood, lungs, small intestine and uterus) increase in γδ T cells, suggesting the expansion is not inflammation-dependent. Interestingly, this increase in γδ T cell numbers was due to the specific expansion of $V\gamma6^+$ IL-17-producing γδ T cells. These findings are the first to highlight a potential negative regulatory role of β_2 integrins in $V\gamma6^+$ cells, indicating a new mechanism of control for this subset of γδ T cells. Further work is required to determine the mechanism of regulation, with the aim to elucidate a novel γδ T cell regulatory pathway to help inform the use of these cells in cancer therapeutics.

P.A2.03.12
Do thymic γδT cells count on the antigen receptor for effector differentiation?

S. Medrano-Garcia*[1,2], A. V. Marin[1,2], H. De La Figuera[1], J. R. Regueiro[1,2], M. Muñoz-Ruiz[3], E. Fernandez-Malavé[1,2];*
[1]Complutense University, Madrid, Spain, [2]Hospital 12 de Octubre Research Institute (imas12), Madrid, Spain, [3]The Francis Crick Institute, London, United Kingdom.

Whether the T cell receptor (TCR) is critical for the generation of effector γδ T cell subsets in the thymus is unclear. A popular view proposes that TCR signal "strength", which is normally dependent on surface TCR expression, is a major determinant of the generation of γδ T cells producing either IFN-γ or IL-17. We have recently reported that *Cd3g*$^{+/-}$ *Cd3d*$^{+/-}$ (CD3DH) mice had reduced surface TCR expression and signaling in thymic γδ T cells, and exhibited a marked depletion of IFN-γ-producing γδ T cells. Here, we have revisited the TCR signal strength model using CD3δ KO mice, whose surface TCRγδ levels are higher than in CD3DH but lower than in WT. We also analyzed CD3δ/CD3γ doubly-KO mice expressing a human CD3δ transgene (hDTg), which display consistently higher surface TCRγδ than WT. Along the developmental pathway of IFN-γ-producing γδ T cells (defined by sequential CD122 and NK1.1 expression), CD3δ KO showed a markedly increased $CD122^+NK1.1^-$ compartment and $CD122^+NK1.1^+$ cells with reduced surface NK1.1, when compared to WT. These two subsets were comparable in frequency and surface NK1.1 in hDtg and WT mice. Anti-CD3 i.p. injection reversed the apparent blockade at the $CD122^+NK1.1^-$ stage of CD3δ KO. On the other hand, the relative abundance of putative IL-17-commited γδ T cells ($CD27^-CCR6^+$) was reduced in CD3δ KO but augmented in hDTg mice, particularly in a unique population displaying the highest TCR levels. Our study supports the existence of distinct TCR expression/signaling requirements for effector γδ T cell differentiation in the thymus.

P.A2.03.13
Dielectric properties of serum in children with recurrent respiratory tract infections

G. Pasternak*[1,2], D. Łuczycka[3], K. Pentoś[3], K. Gul[1,2], M. Kaźmierowska-Niemczuk[1], A. Lewandowicz-Uszyńska[1,2];*
[1]Wroclaw Medical University, Wrocław, Poland, [2]Provincial Hospital J. Gromkowski, Wrocław, Poland, [3]Wroclaw University of Environmental and Life Sciences, Wrocław, Poland.

Despite the improvement of living conditions, availability of medicines and various methods of treatment, recurrent respiratory tract infections continue to occur and are a frequent clinical problem of children of our climate zone (moderate warm intermediate nature). It results, among others, from the geo-climatic conditions, lifestyle, and maturation of the immune system (especially in humoral immunity) in developmental age. One of the reasons for these ailments is a variety of abnormalities in the immune system that may have of primary or secondary nature. We are still looking for new conditions that may underlie recurrent infections. Various screening assays are also being tested to demonstrate quickly and easily abnormalities in selected parameters of the immune system, so that detailed, cost-intensive and time-consuming immunoassays can be performed in justified cases.
The aim of the study was to examine the occurrence of dependence between selected physical parameters of serum such as: electrical conductivity, electrical permeability, dielectric loss factor, and blood tests results in the following: blood counts, serum glucose concentration, micronutrient concentrations, and selected parameters of the immune system: concentrations of the main classes of immunoglobulins (IgG, IgA, IgM and IgE), complement hemolytic activity, and neutrophil function in patients suffering from recurrent respiratory tract infections compared to those without recurrent infections.
During the impedance spectroscopy of the tested samples, there was a differentiation of the obtained measurement results. In order to develop the obtained measurement and analytical data, a correlation matrix was determined and a grouping of the analyzed cases was carried out.

P.A2.03.14
Phenotypic characterization of immune cells from premature neonates with extreme low birth weight

K. Qazi Rahman*;*
Stockholm University, Stockholm, Sweden.

Background: The development of the immune system begins during the first trimester, but continues to develop after birth. Premature children have a compromised immune system with regard to both quantitative and qualitative aspects. There is an increased risk of sepsis, necrotizing enetrocolitis and pneumonia-all common causes of mortality, primarily in the group of neonates with extremely low birth weight (ELBW).
Objective: To characterize innate and adaptive immune compartments of ELBW infants 14 days after birth.
Materials and methods: Peripheral blood mononuclear cells (PBMC) were collected 14 days after birth from 79 ELBW premature infants, participating in a randomized double-blind placebo-controlled study of probiotic supplementation. As a control, PBMCs from 29 full-term (FT) infants at 14 days of age were used. Mononuclear cell populations were analyzed by multi-colour flow cytometry.
Results: The proportions of CD4 and CD8 T cells, regulatory T cells, NK cells and monocytes were significantly lower in PBMC of ELBW premature infants compared to FT infants. On the contrary, γδ T cell- and NKT cell frequencies were comparatively high in the ELBW infants. Further, an elevated CD4:CD8 ratio was observed in ELBW premature infants. The expression levels of homing receptors CCR4 and CCR9 on T cells were high, while monocyte expression of HLA-DR and CD86 was very low in ELBW infants.
Conclusion: We provide an extensive characterization of the peripheral immune compartment of ELBW premature infants that provides important information for future studies on immune function and possible therapeutic interventions.

P.A2.03.15

Infant Immune Responses following Pertussis Vaccination in Pregnancy

T. Rice[1], *D. Diavatopoulos*[2], *B. Donaldson*[1], *M. Bouqueau*[1], *H. Sallah*[1], *B. Kampmann*[1,3], *B. Holder*[1];
[1]*Imperial College London, London, United Kingdom,* [2]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Vaccinology Theme, MRC Unit, Gambia.*

Introduction: Following a surge in pertussis cases in the UK disproportionately affecting young infants, a maternal vaccination program was introduced. We established a longitudinal study to investigate the impact of maternal Tdap (tetanus, diphtheria, acellular pertussis) immunisation on the developing infant immune system, including antibody production and cellular responses to *Bordetella pertussis* following vaccination of both mothers and infants.
Methods: Blood was collected from Tdap-vaccinated/unvaccinated pregnancies: maternal at booking (8-21weeks), maternal and cord at birth, and infants at 7weeks and 5months (pre- and post- their primary immunisations). Antibody levels directed against pertussis vaccine antigens (Prn, FHA, PTx, DTx, TTx) were measured using a fluorescent bead-based multiplex immunoassay. Cellular responses to *Bordetella pertussis* were measured by whole blood stimulations with strains of heat-killed pertussis (wild-type, Prn-negative, Prn/FHA-negative) followed by multiplex cytokine analysis.
Results: Maternal Tdap vaccination significantly increases vaccine-specific antibody titres in women infants before primary immunisation. Post-childhood vaccination antibody titres were the same between babies born to vaccinated and unvaccinated pregnancies by 5 months of age. Cytokine responses to *B.pertussis* in vaccinated and unvaccinated groups were strain-dependent, with several cytokines elevated in response to the Prn/FHA-negative strain. Age-dependent cytokine responses were seen, that may be altered in infants from vaccinated pregnancies.
Conclusion: Maternal pertussis vaccination boosts protective antibody prior to the first dose of infant vaccination.
There was no impact on infants' antibody response to DTaP vaccination. Like adults, infants mount strain-dependent cytokine responses to *B.pertussis* that are not impacted by maternal vaccination. Age-dependent effects are under investigation.

P.A2.03.16

Age-related defects in efferocytosis are reversed by inhibiting p38 MAPK activity in aged volunteers

R. C. van de Merwe, *R. P. De Maeyer, A. N. Akbar, D. W. Gilroy;*
University College London, London, United Kingdom.

Ageing is associated with chronic inflammation, which may be due to failed resolution. As p38 MAPK regulates pro-resolution pathways including efferocytosis, we investigated p38 MAPK signaling in aged versus young humans using a skin blister model of self-limiting acute inflammation. Thereafter, we used the p38 MAPK inhibitor losmapimod to discern p38 MAPK's role in the onset and resolution of inflammation in the aged. Cantharidin (0.1%) was applied topically to young (<40 years) and aged (>65 years) human volunteers. A cohort of aged volunteers were exposed to losmapimod (15mg BID/PO) for 4d prior to cantharidin application. Blister exudates were collected at 24+72h and were analysed by flow cytometry. Phospho-p38 MAPK was increased in HLA-DR+ blister cells in aged compared to young volunteers. In aged volunteers (-losmapimod) early apoptotic cells accumulated at the 72h resolution time point; a finding not observed in young volunteers. Furthermore, PMN clearance in aged volunteers (-losmapimod) did not correlate with $CD14^{hi}$ mononuclear phagocyte (MPs) numbers in contrast to young volunteers. This indicated failed apoptotic body clearance in the aged, which we hypothesise arises from defective efferocytosis. Aged MPs expressed lower TIM-4, a molecule involved in apoptotic body clearance, compared to younger counterparts. In aged volunteers losmapimod elevated TIM-4 expression on MPs, increased MP numbers at resolution, and rescued the correlation between MP numbers and PMN clearance. Inhibition of p38 MAPK in aged humans alters the cellular profile of cantharidin blisters, and may enhance efferocytosis during the resolution of inflammation by increasing TIM-4 expression on MPs.

P.A2.03.17

Homeostatic cytokines revert primed $CD8^+$ T cells to naïve-like memory stem cell variants through epigenetic and transcriptional reprogramming

G. Frumento[1,2], ***K. Verma***[1], *W. Croft*[1,3], *A. White*[1], *Z. Nagy*[4], *S. Kissane*[5], *S. P. Lee*[1], *G. Anderson*[1], *P. Moss*[1,6], *F. E. Chen*[1,2,6];
[1]*Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom,* [2]*NHS Blood and Transplant, Birmingham, United Kingdom,* [3]*Centre for Computational Biology, University of Birmingham, Birmingham, United Kingdom,* [4]*Institute of Inflammation and Ageing, Univeristy of Birmingham, Birmingham, United Kingdom,* [5]*Technology Hub, University of Birmingham, Birmingham, United Kingdom,* [6]*Centre for Clinical Haematology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

INTRODUCTION: Upon activation, human naïve T-cells are believed to differentiate into memory cell subsets along a one-way pathway, acquiring effector function but diminishing proliferative capacity and survival. Two subsets of phenotypically naïve $CD8^+$ T-cells (T_{SCM} and T_{MNP}) with stem cell features, memory traits and enhanced proliferative potential have also been described although there is little understanding on how they are generated. Here we analyzed the epigenetic and transcriptional regulation of T-cell differentiation/de-differentiation upon stimulation with homeostatic cytokines.
METHODS: CD8+ T_N cells were isolated from cord or peripheral blood for *in-vitro* stimulation with homeostatic cytokines. Cells were sorted on the basis of membrane expression of CD45RA and CCR7 for analysis of open chromatin by ATAC-seq, for transcriptional analysis by microarray and for phenotypic and functional assays.
RESULTS: We demonstrate that Interleukin-7 can de-differentiate recently-differentiated memory $CD8^+$T cells into revertant T_N-like cells (T_{Nrev}). We show that these T_{Nrev} share phenotypic and functional characteristics with T_{SCM} and T_{MNP} including high proliferative and differentiation capacity and polyfunctionality when re-stimulated. ATAC-seq indicates that T_{Nrev} fit between recently differentiated central memory and effector memory T-cells. Phenotypic reversion is seen to be driven by Notch signaling pathway, ETS family transcription factors, Stat1 and Stat4.
CONCLUSION: Our study provides a novel model for $CD8^+$ T_N differentiation and a unifying theory for the generation of T_{SCM} and T_{MNP}. We suggest that cytokine-dependent reversion of recently-differentiated $CD8^+$ T-cells replenishes the early-memory T-cell pool for preserving long-term immunity. This mechanism can be used to generate *in-vitro* engineered early-memory T-cells for immunotherapy.

Human milk-derived extracellular vesicles can modulate epithelial and immune cell responses

M. I. Zonneveld[1,2], *M. J. van Herwijnen*[1], *M. M. Fernandez-Gutierrez*[3], *A. de Groot*[4], *M. Kleinjan*[1], *T. M. van Capel*[5], *A. J. Sijts*[4], *L. S. Taams*[6], *J. Garssen*[2,7], *E. C. de Jong*[5], *M. Kleerebezem*[3], *E. N. Nolte-'t Hoen*[1], *F. Redegeld*[2], ***M. H. M. Wauben***[1];
[1]*Utrecht University, Faculty of Veterinary Medicine, Department of Biochemistry & Cell Biology, Utrecht, Netherlands,* [2]*Utrecht University, Faculty of Science, Department of Pharmaceutical Sciences, Utrecht, Netherlands,* [3]*Wageningen University, Department of Animal Sciences, Host-Microbe Interactomics Group, Wageningen, Netherlands,* [4]*Utrecht University, Faculty of Veterinary Medicine, Department of Infectious Diseases and Immunology, Division Immunology, Utrecht, Netherlands,* [5]*University of Amsterdam, AMC, Department of Experimental Immunology, Amsterdam, Netherlands,* [6]*King's College London, School of Immunology and Microbial Sciences, Department Inflammation Biology, London, United Kingdom,* [7]*Nutricia Research, Utrecht, Netherlands.*

Breast milk is nature's first functional food with distinctive functions: it provides nutrition and it supports the development of the gastrointestinal (GI) tract and the immune system. Remarkably, little is known about the precise constituents in breast milk responsible for these effects. Previous research focused on the identification of individual functional milk components while the functionality of macromolecular components in milk remained largely understudied. Extracellular vesicles (EV), submicron lipid bilayer enclosed vesicles released by cells for intercellular communication, belong to these macromolecular milk components. Recently, we unveiled a novel functional milk proteome associated to milk-EVs. Next, we analyzed functional effects of milk EVs in various in vitro assays and found that physiological concentrations of milk EV support epithelial barrier function, by increasing epithelial cell migration via the p38 MAP kinase pathway. Furthermore, milk EV inhibited agonist-induced activation of TLR3, 7 and 9 and inhibited activation of CD4+ T cells by temporarily suppressing T cell activation without inducing tolerance or suppressive regulatory T cells. Integrative analysis of these data with our milk EV-proteome data indicated that EVs contain multiple proteins that can modulate signaling pathways involved in migration, TLR signaling and T cell activation at various levels. Our results demonstrate that human milk EV are multi-signaling vehicles that can selectively control the activation and inhibition of various signaling pathways that are crucial for immune homeostasis and the development of the infant GI tract. (This study was performed within a partnership program by Nutricia Research and the Dutch Technology Foundation STW (11676)).

P.A2.03.19

Aggravated aging-related immune changes areassociated with inflammation and cardiovasculardisease in end-stage renal disease patients: baselinefindings from the iESRD study

***K. Shu**, Y. Chiu;*
Far Eastern Memorial Hospital, New Taipei City, Taiwan.

Patients with end-stage renal disease (ESRD) exhibit accelerated aging of the immune system and increased risk for cardiovascular disease, but the etiology and overall contribution of immune system aging, or immunosenescence, to cardiovascular disease is not well understood. We performed a comprehensive lymphocyte and monocyte immunophenotyping in 412 ESRD patients on maintenance hemodialysis and 57 age-matched healthy individuals. Compared with healthy individuals, ESRD patients had decreased levels of naive CD4+ and CD8+ T cells and increased levels of terminally differentiated (CCR7-CD45RA+) T EMRA cells and intermediate monocytes (CD14++CD16+). These changes not only were significantly correlated with age but also were enhanced by longer dialysis vintage. Lymphocyte and monocyte aging also correlated with other established cardiovascular risk factors, including hemoglobin and high-sensitivity C- reactive protein. In multivariable-adjusted logistic regression models, the combination of high terminally differentiated CD8+ T EMRA cell level and high intermediate monocyte levels, as a predictive immunophenotype, was independently associated with the existence of coronary artery disease (OR=2.29, 95% CI=1.2~4.5, p=0.016) as well as cardiovascular disease including stroke and peripheral arterial occlusive disease (OR=2.32, 95% CI=1.2~4.4, p=0.008). We also found evidence that terminal differentiated T cells were enhanced by the uremic toxin indoxyl sulfate. Our work indicates that cardiovascular disease in the ESRD population might be enhanced by the presence of accelerated aging-associated immune changes consequent to long-term exposure to uremic toxins.

P.A2.03.20

The source of IL-1β expression and its role in type 2 diabetes mouse models

***J. Wehner**, S. Wiedemann, D. T. Meier, S. P. Häuselmann, M. Böni-Schnetzler, M. Y. Donath;*
University of Basel, Basel, Switzerland.

Type 2 diabetes is an inflammatory disease and a worldwide problem. A critical aspect of type 2 diabetes is insulin resistance and the impairment of beta cell function in which cytokines play a key role. Cytokines, in particular IL-1β, mediate chronic low-grade inflammation in pancreatic islets. However, the primary source of IL-1β in islets is unclear.
We hypothesize β-cells or macrophages as potential producers of IL-1β. While β-cells are the main cell type in islets, it is unknown if they are able to process pro-IL-1β to IL-1β. Macrophages are known as potent producers of IL-1β, but rare in numbers in pancreatic islets. Pro IL-1β overexpression could reveal the processing and causal effect of IL-1β from different sources.
We use two strains of mice in our study:
- Inducible β-cell specific pro-IL-1β overexpressing
- Constitutive myeloid cell specific pro-IL-1β overexpressing
We investigated resulting phenotypes in vivo and in vitro.

P.A2.03.21

Proliferation of T-regulatory cells and expression by them of CTLA-4 under the influence of humoral factors of homeostatic proliferation in healthy donors.

***D. Shevyrev**, E. Blinova, E. Pashkina, L. Grishina, V. Kozlov;*
Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation.

Homeostatic proliferation (HP) is the main mechanism of T-cells pool reconstitution in adulthood. It is a well-known fact about the link between HP and disturbance of peripheral tolerance, which normally provided by T-regulatory cells (Treg). However it remains unclear why these cells can't prevent autoimmunity under HP. The purpose of this study is to improve our knowledge about effects of IL-7 and IL-15 - the main humoral factors of HP on T-regulatory cells.The study included 6 healthy donors. Treg-cells proliferation and ones expression of CTLA-4 were analyzed under HP cytokines (50ng/ml for IL-7 and IL-15) and antiCD3+IL-2 (1mkg/ml and 100ME/ml respectively) during 7-day cultivation with PBMC in ratio 1:1. Immune-magnetic separation was used for Treg-cell isolation (purity>95%). Phenotyping of cells was performed by flow cytometry.The research revealed, that IL-7 and IL-15 can effectively maintain Treg-cells by number and phenotype, but Treg-cell proliferation was significantly lower than in $CD4^+$T-lymphocytes under HP factors. In addition, it was found considerable decline of CTLA-4 surface expression on Treg-cells unlike for $CD8^+$T-lymphocytes under HP cytokines ($p<0,05$).We identified that proliferation of Treg-cells under HP factors is much lower than in $CD4^+$T-lymphocytes, which can lead to a delay of Treg-pool reconstitution under lymphopenia and may represent another mechanism of link between HP and autoimmune disorders. In addition, we revealed decrease of CTLA-4 expression - one on Treg-cells under influence of HP cytokines that also can contribute disruption of self-tolerance and development of autoimmunity. This study was funded by RFBR and Novosibirsk region, project №17-44-540167.

Introduction: Patients who survive sepsis can develop long-term immune dysfunction, with expansion of M2 macrophages and regulatory T cells. However, there is no evidence of these alterations in the pediatric sepsis. Aim: To investigate the role of age in the genesis of immunosuppression following sepsis. Methods: infant and adult mice were submitted to sepsis and treated with antibiotic. On day 15 after infection, Treg cells frequency and the activation of IL-33/Th2 cytokines/ILC2/M2 macrophages axis were performed. Furthermore, surviving sepsis mice were inoculated intranasally with *Pseudomonas aeruginosa* or injected subcutaneously with B16LucF10 cell line. Moreover, blood samples from sepsis-surviving patients were collected and the Treg cells and Th2 cytokines were evaluated.
Results: Here we showed that sepsis surviving-infant mice, in contrast to adults, were resistant to secondary infection and controlled the tumoral growth suggesting the non-development of immunosuppression.
Mechanistically, infant group exhibited a decrease in *Foxp3* expression, lower phosphorylation of SMAD2/3 and reduction in Tregs cell expansion and FOXP3 stability. Furthermore, infant mice presented lower IL-33 and Th2 profile cytokines (IL-4 and IL10) production as well as lower expansion of ILC2 cells, leading to progressive decrease in the M2 macrophages and Tregs cell expansion. Importantly, sepsis-surviving pediatric patients, in contrast to adults, did not exhibit increase in Treg cell, IL-33 and IL-10 in their peripheral blood. Conclusion: These findings demonstrate for the first time that the sepsis immunosuppression is related to the age. Thus, a better understanding of the process could lead to differential therapeutic treatments of adult and pediatric sepsis.

Transcriptional and functional landscape of HERV-K (HML-2) in aging

***A. Autio**[1], T. Nevalainen[1,2], B. Mishra[1], M. Hurme[1,2];*
[1]Faculty of Medicine and Life Sciences, University of Tampere, Tampere, Finland, [2]Gerontology Research Center (GEREC), University of Tampere, Tampere, Finland.

An estimated 8% of the human genome consists of endogenous retroviruses (HERV), which are genetic remnants from past retroviral infections. Millions of years' worth of mutational decay has rendered most HERV proviruses inactive, yet some still contain intact reading frames and can even code for functional products. Upregulation of these retroelements has been observed in aging and senescent cells.
To study the aging-associated changes in the intensity of transcriptional activation of recently integrated HERV-K (HML-2) subfamily, we utilized RNA-sequencing of PBMCs obtained from elderly cases (n=7, age 90) and young controls (n=7, age 26-32, median age 28). The correlations in expression between endogenous genes and proviruses were calculated and gene set enrichment analysis (GSEA) was done. The known gene ontology (GO) terms of genes may indicate biological processes that the similarly expressed proviruses are involved in.
We found that a third (33/91) of the HERV-K (HML-2) proviruses were relatively strongly expressed (read count >=16). The general level of expression was similar across age groups, yet hierarchical clustering of samples indicated aging-associated differences in expression patterns. Three proviruses were significantly differentially expressed. The proviral expression in the old individuals was associated with a greater number of biological processes (GO terms).
Our study of the expression of HERV-K (HML-2) proviruses in old and young individuals has provided candidate biological processes that may be involved in the interplay of genes, proviruses, and aging. Further investigation of these processes could uncover potential links between proviruses and aging-associated changes, such as immunosenescence and inflammaging.

Cereblon regulates hematopoietic stem cell self-renewal

A. A. Akuffo[1,2], *J. M. Billington*[1], *D. E. Muench*[3], *J. L. Cleveland*[1], *H. L. Grimes*[3], *P. K. Epling-Burnette*[1];
[1]*H. Lee Moffitt Cancer Center, Tampa, United States,* [2]*University of South Florida, Tampa, United States,* [3]*Cincinnati Children's Hospital Medical Center, Cincinnati, United States.*

Introduction: Cereblon (CRBN), an E3 ubiquitin ligase substrate receptor and target of immunomodulatory drugs, is ubiquitously expressed in hematopoietic lineages, including hematopoietic stem cells (HSCs) [lineage$^-$Sca$^-$1$^+$c-Kit$^+$SLAM$^+$(LSKs)]. Immunomodulatory drugs restore erythropoiesis and suppress malignant clonal stem-cell expansion in chromosome 5q-deleted myelodysplastic syndrome, suggesting that CRBN may regulate hematopoiesis.
Materials and Methods: HSCs, progenitors, and mature populations were assessed in the bone marrow (BM) and peripheral blood (PB) of *Crbn* deficient mice (*Crbn*$^{-/-}$) and wild-type littermates (*Crbn*$^{+/+}$). To assess if *Crbn* loss induces functional differences in HSC, we performed chimeric bone marrow (BM) transplants, short-term *in vitro* colony formation and forced LSK self-renewal *in vivo* with 5-fluorouracil (5-FU) treatment. RNA sequencing of LSKs was used to identify targets controlled by CRBN. Pimonidazole staining (active in <1% O_2) was used to assess LSK localization within the endosteal niche.
Results: *Crbn*$^{-/-}$ mice have increased numbers of mature and committed myeloid populations in the peripheral blood and BM in association with increased colony numbers and increased mature myeloid populations following chimeric HSC transplants. Notably, however, total LSKs and LSK subpopulations in the BM are reduced 3-5-fold in *Crbn*$^{-/-}$ mice, and this is accompanied by lethal BM failure following repeated 5-FU dosing. Interestingly, RNA-seq analysis revealed markedly reduced expression of the hypoxia-inducible factor HIF1α in *Crbn*$^{-/-}$ LSK and lower pimonidazole staining by LSKs.
Conclusions: Collectively, these findings suggest that loss of CRBN impairs endosteal niche localization of LSK, which triggers HSC proliferation and premature exhaustion.

P.A2.04.02
Traf2 and Nck-interacting Kinase Is a Conserved Regulator of Self-Renewal and Quiescence in Hematopoietic and Leukemia Stem Cells

M. A. Amrein[1], *E. D. Bührer*[1], *S. Höpner*[1], *C. Jaeger*[1], *C. Riether*[1,2], *A. F. Ochsenbein*[2];
[1]*Department of BioMedical Research, University of Bern, Bern, Switzerland,* [2]*Department of Medical Oncology, Inselspital, Bern University Hospital, Bern, Switzerland.*

The Traf2 and Nck-interacting kinase (TNIK) is a member of the germinal center kinase (GCK) family. TNIK is known effector kinase of TRAF6, TRAF2 and beta-catenin and is involved in the integration of NFk-B, JNK and Wnt-Signaling. We found *Tnik* to be widely expressed in hematopoietic cells, including hematopoietic stem cells (HSCs). To explore how TNIK signaling regulates HSCs and leukemia stem cells (LSCs), we generated a constitutive *Tnik*$^{-/-}$ mouse. Under steady-state conditions Tnik deficiency resulted solely in a decreased frequency of quiescent long term HSCs, while the *in vitro* self-renewal capacity and the composition of bone marrow (BM), blood and spleen remained unchanged. Next we tested the responsiveness of *Tnik*$^{-/-}$ HSCs in response to hematopoietic injury and stress. Recovery after injection of 5-fluorouracil was significantly improved in *Tnik*$^{-/-}$ mice compared to littermate controls. Moreover, the reconstitution potential in competitive BM chimeras was significantly improved in *Tnik*$^{-/-}$ HSCs compared to competitor *Tnik*$^{wt/wt}$ HSCs. Interestingly, in a murine model of chronic myeloid leukemia (CML) Tnik deficiency severely impaired the self-renewal capacity of LSCs *in vitro* and *in vivo*. To summarize, we have described for the first time a role for Tnik in the regulation of quiescence and self-renewal in HSCs and CML LSCs. Overall our data suggests that TNIK might be an attractive therapeutic target to improve hematopoietic reconstitution or to eliminate CML LSCs. The exact mechanisms by which TNIK regulates self-renewal and quiescence in HSCs and LSCs remains to be studied.

Foxp3$^+$ regulatory T cells (T_{reg} cells) play a key role in maintaining immune homeostasis and in modulating immune reactions during infection and disease. Hence it is important to understand the molecular mechanisms that regulate their development. Here we report that the BTB zinc finger transcription factor MAZR (also known as Patz1) crucially controls Foxp3$^+$ regulatory T cell generation and differentiation. We detected that MAZR was highly expressed in the thymus and gradually downregulated during progressive T cell development. Interestingly, lowest MAZR expression levels were found in terminally differentiated Foxp3$^+$ T_{reg} cells. By comprehensively analyzing mice with a T cell-specific deletion (*Cd4*-Cre) of MAZR (MAZR-cKO) we observed that the deletion of MAZR led to a substantial increase in Foxp3$^+$ Treg cells *in vivo*. Moreover, naïve MAZR-null CD4$^+$ T cells differentiated with an enhanced frequency into *in vitro*-generated iT_{reg} cells, while retroviral-mediated enforced expression of MAZR impaired the generation of T_{reg} cells both *in vitro* and *in vivo*. In DSS-induced colitis, MAZR-cKO mice were better protected against disease than their WT littermates, and *ex vivo*-isolated MAZR-null T_{reg} cells displayed slightly enhanced suppressive activity compared to WT cells. However, in an adoptive T cell transfer colitis model, MAZR-null T_{reg} cells did not display an enhanced protective activity, which also correlates with RNA-seq data revealing only minor transcriptional changes in MAZR-null T_{reg} cells. Together, our data strongly suggest that MAZR is a negative regulator of Foxp3$^+$ T_{reg} cell development and differentiation. Support by: FWF-Projects P23641,P26193,P29790; and by Horizon-2020 Marie-Sklodowska-Curie grant (No:675395).

Invariant natural killer T cells (iNKT) expressing RORγt represent a minor subset of CD1d-restricted iNKT cells with phenotypic and functional features related to Th17 cells. In this study, we aimed to understand RORγt$^+$ iNKT17 cells distribution and the sequence of events accompanying their thymic development. We found that early HSA^{high} RORγt$^+$ iNKT cell precursor are not exclusive to the iNKT17 lineage, and show that mature HSA^{low} iNKT17 cells develop through CCR6$^-$CD138$^-$ stage 1', CCR6$^-$CD138$^+$ stage 2', and CCR6$^+$CD138$^+$ final stage 3'. Stage 1' iNKT17 cells do not produce IL-17 and have the propensity to apoptosis. They will progressively express RORγt, acquire the capacity to produce IL-17, cease division, and became less prone to apoptosis. iNKT17 cells do not reside in the thymus contributing, in addition to apoptosis, to their minor partition in the thymus. Finally, we found that iNKT17 cells perceive a strong TCR signal that could promote their entry into a specific "Th17 like" developmental program impacting their survival and emigration. Overall, our studies unravel a thymic developmental sequence for iNKT17 cells, which can be of great use to study molecular mechanisms regulating this developmental program.

P.A2.04.05
Heterogeneity of CD8$^+$ terminally differentiated effector T-cells (TEMRA): chemotactic features and effector potential of different subsets

L. Burkhardt[1,2], *I. Kotko*[1,2], *S. Schlickeiser*[1,2], *D. Kunkel*[2], *A. Jurisch*[1], *C. Giannini*[1,2], *B. Sumpf*[1,2], *S. Reinke*[2], *M. Streitz*[1], *D. Wendering*[1,2], *M. Schmück-Henneresse*[1,2], *H. Volk*[1,2];
[1]*Institute for Medical Immunology, Berlin, Germany,* [2]*Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Berlin, Germany.*

Terminally differentiated effector memory CD8$^+$ T-cells (TEMRA) are triggered by chronic antigen exposition and can either be defined conventionally as CD3$^+$CD8$^+$CCR7$^-$CD45RA$^+$ T-cells or as CD3$^+$CD8$^+$CD57$^+$CD28$^-$ T-cells. TEMRA are ambiguously described as highly pre-activated or rather 'senescent' T-cells. Moreover, they show beneficial features during chronic viral infections but also worst effects on tissue regeneration.
We hypothesized, that these opposing findings implicate the phenotypic and functional heterogeneity of CD8$^+$ TEMRA cells.
Previous phenotyping by multiplex mass cytometry (CyTOF) affirmed the presumed heterogeneity within the TEMRA population. Thus, we could define four major subpopulations within TEMRA (CCR7$^-$CD45RA$^+$) using CD57 and CD28. Further, we discovered a specific subset expressing CD182 (IL8R/CXCR2) within the CD57$^+$CD28$^-$ TEMRA. This receptor is shown to trigger chemotaxis of the CD57$^+$CD28$^-$CXCR1$^+$CXCR2$^+$ TEMRA towards IL8 and seems to be required for the accumulation of this unique subset at sites of sterile intratissue inflammation. This goes in line with our data on the accumulation of CD8$^+$CD57$^+$CD28$^-$ TEMRA in fracture hematomas causing a delayed healing. Additionally, this subset showed strong cytotoxic potential, indicated by the high expression of CD107a after PMA/Ionomycin stimulation. Furthermore, a distinct subset of CD28$^+$CXCR1$^-$CXC2$^-$CXCR3$^+$CCR5$^+$ TEMRA migrated towards CXCL9, CXCL10 and CCL3. Interestingly, the inflammatory potential (TNFα/IFNγ/IL2) of TEMRA subsets increased with the expression of the CD28 molecule. Whereas, CD28$^-$ subsets showed the lowest inflammatory capacity, they required less stimulatory signals and are more resistant to negative checkpoint signals. The data supports the differential impact of TEMRA subpopulations on inflammation/immunity dependent on the respective chemokine receptor expression and inflammatory/cytotoxic potency.

P.A2.04.06

Developmental origins of distinct adipose tissue macrophages in health and disease

***Q. Chen**, R. Christiane;*
School of Biological Sciences, Singapore, Singapore.

Adipose tissue macrophages (ATMs) are the main leukocytes found in the visceral adipose tissue (VAT) which play an important role not only in an effective cell debris clearance, but also in controlling tissue immune surveillance as well as lipid buffering.
Because of the prenatal ontogeny of many tissue-resident F4/80^{hi} macrophages, such as in the liver and lungs, we addressed the question of the origin and turnover kinetics of distinct subpopulations of ATMs in young, aged and obese mice. To determine whether ATMs are derived from adult bone marrow (BM) or from embryonic haematopoiesis, we exploited a *Kit*$^{MerCreMer/R26}$ fate mapping mouse - where YFP expression can be induced by tamoxifen injections in early BM progenitors - to monitor the turnover rates driven by the BM input in distinct VAT myeloid cell populations. In lean young mice, our fate map analysis revealed the presence of two CCR2-independent F4/80^{hi} populations with slow turnover kinetics when compared to conventional monocyte-derived CCR2^{+} macrophages which are rapidly refilled by BM-derived monocytes. During aging and in particular in obesity, a third F4/80^{hi} ATM population expressing high levels of CD11c infiltrates the VAT showing a fast turnover dynamics and a clear BM-dependency. Taken together, our data identifies distinct ATMs subpopulations in the VAT which in normal healthy conditions can maintain them self almost independently from any BM input, but under inflammatory conditions, such as obesity, are rapidly replenished by BM-derived monocytes.

P.A2.04.07

Influence of influenza A virus infection on thymic development of Foxp3^{+} regulatory T cells

***Y. Elfaki**[1], M. Gereke[2,3], N. Tafrishi[4,5], I. Schmitz[4,5], D. Bruder[2,3], S. Floess[1], J. Huehn[1];*
[1]Helmholtz Centre for Infection Research, Experimental Immunology, Braunschweig, Germany, [2]Helmholtz Centre for Infection Research, Immune Regulation, Braunschweig, Germany, [3]Otto-von-Guericke University, Institute of Medical Microbiology, Infection Control and Prevention, Magdeburg, Germany, [4]Helmholtz Centre for Infection Research, System-oriented Immunology and Inflammation Research, Braunschweig, Germany, [5]Otto-von-Guericke-University, Institute for Molecular and Clinical Immunology, Magdeburg, Germany.

Foxp3^{+} regulatory T cells (Tregs) are crucial for maintenance of self-tolerance and regulation of inflammatory responses against pathogens. The majority of Tregs develops within the thymus, termed thymus-derived Tregs (tTregs). Since influenza A virus (IAV) infection has been reported to cause transient thymic involution, it might potentially impact tTreg development and thereby have long-lasting consequences for immune homeostasis and self-tolerance. Thus, this project aims at dissecting the influence of IAV infection on tTreg development. To this end, thymi of IAV-infected Foxp3^{hCD2}×RAG^{GFP} mice were analyzed during the time course of infection. Under the experimental conditions chosen, IAV infection caused maximum thymic involution at day 10 post infection accompanied by a significant increase in the frequency of thymic CD25^{+}Foxp3^{+} Tregs as well as their CD25^{-} Foxp3^{+} precursors. Interestingly, the absolute number of Tregs only slightly decreased during thymic atrophy, while the number of conventional CD25^{-}Foxp3^{-} thymocytes decreased significantly. Caspase 3/7 staining of newly-developing cells showed that these differences are likely not the result of preferential survival of Tregs, since both CD25^{+}Foxp3^{+} tTregs as well as CD25^{-}Foxp3^{-} thymocytes displayed an equal survival within atrophied thymi. Together, these results suggest that IAV infection does not lead to a depletion of Tregs, but rather accelerates their differentiation or promotes their retention within the thymus, while leading to an accelerated exit of conventional T cells. Currently, a mathematical model is being developed to test different hypotheses underlying the causes of thymic atrophy and its consequences on the peripheral T cell population.

P.A2.04.08

The RxR agonist Bexarotene promotes the induction of human iTregs, and reduces Th17 differentiation *in vitro*

***C. Gaunt**, A. Coles, J. Jones;*
University of Cambridge, Cambridge, United Kingdom.

Introduction: Retinoic acid (RA) promotes TGF-β-dependent differentiation of CD4+Foxp3+ iTregs from naïve CD4+ cells, and inhibits Th17 differentiation, by binding to the conditionally-permissive RA receptor (RAR)/retinoid X receptor (RXR) heterodimer. It is unknown if RXR agonists can modulate the iTreg/Th17 axis in humans, and whether this is dependent upon RAR-mediated signals. Here we investigate the effect of Bexarotene, a selective RxR agonist currently in trial as a multiple sclerosis re-myelinating therapy, on human iTreg/Th17 induction *in vitro*. **Materials and Methods:** Naïve CD4 cells from 15 healthy controls were cultured for 7 days in serum-free, and therefore RA-free media under: (i) iTreg (IL-2, TGF-β, anti-IFN-γ, anti-CD3/CD28) or (ii) Th17 (IL-2, TGF-β, IL-6, IL-1β, IL-23, anti-IFN-γ, anti-IL-4, anti-CD3/CD28) conditions ± Bexarotene (1 µg/ml), ATRA (40 nM), 9-Cis-RA (100 nM). At D7, the cells were harvested for immune-phenotyping and their ability to suppress the proliferative responses of naïve T cells to CD3/28 stimulation determined. Bisulphite sequencing was performed or sorted Foxp3+ cells to determine the methylation state of the TSDR (Treg specific demethylation region). **Results:** In the absence of RA, Bexarotene increased the differentiation of functionally suppressive iTregs, and decreased Th17 induction, from naïve cells. Similar effects were seen with RA. No additive effects were observed with RA and Bexarotene were combined. In keeping with the literature, iTregs induced in this study remained methylated at the TSDR. **Conclusions:** The RXR agonist Bexarotene alters the iTreg/Th17 axis in humans, in favour of iTreg induction. This supports a potential immune-regulatory role for Bexarotene.

P.A2.04.09

Study on the role of microRNA in the function of Treg-of-B cells

***Y. Huang**, C. Chien, B. Chiang;*
Graduate Institute of Immunology, Collage of Medicine, National Taiwan University, Taipei City, Taiwan.

Introduction: In our previous study, we found that splenic B cells could induce naïve CD4+CD25- T cells into CD4+CD25+Foxp3- regulatory T cells in cell-cell contact manner, termed Treg-of-B cells. Here, we aim to further study the microRNAs profile of Treg-of-B cells, and identify some significant microRNAs that might be engaged in the suppressive function, development or fitness on Treg-of-B cells.
Materials and Methods: Splenic B220+ and naïve CD4+CD25- T cells were purified from female BALB/c mice. We analyzed the surface molecules of Treg-of-B cells by flow cytometric analysis. T cell proliferative response with tritium-thymidine incorporation assay was used to assay Treg-of-B cells suppressive ability and ELISA to analyze cytokine secretion. TaqMan low-density array was used to study microRNAs expression profile, and TaqMan Q-PCR and northern blot were used for validation.
Results: The results suggested that Treg-of-B cells expressed regulatory-related surface markers and secreted regulatory cytokine. According to array data, it is indicated that certain microRNAs differentially expressed in Treg-of-B cells in the condition of fresh-isolation or stimulation. Then, we also studied its effect on the down-stream target genes. Most importantly, the impact of microRNAs on suppressive function of Treg-of-B cells will be further clarified in this research.
Conclusions: In our study, we assay the effect of microRNAs on target gene and suppressive function of Treg-of-B cells. With our efforts, we hope to have more information on the function and development of Treg-of-B cells and contribute to Treg-based therapies which might be applied for the treatment of immunological diseases.

P.A2.04.10

AR-CGD (p67 defect) with kabuki syndrome presenting Arnold Chiari malformation

***M. Y. Koker**[1], B. Saraymen[1], N. Köker[1], K. Boztug[2];*
[1]Erciyes medical school, Kayseri, Turkey, [2]Ludwig Boltzmann Institute, Medical University of Vienna, Vien, Austria.

we will present the first chronic granulomatous disease (CGD) case with kabuki syndrome. Our patient with autosomal recessive CGD (p67 defect) has also kabuki syndrome with Chiari malformation. Structural brain abnormality have only occasionally described in kabuki syndrome.Patient have an history of 2 cranial operation for Chiari malformation and clinical finding was resolved, but due to repeated infection history we do DHR assay for neutrophil function. DHR results showed that stimulation index was SI: 1 (no oxidase activity) which is specific for CGD. We did genetic analysis in this consanguineous family and we founded a nonsense homozygote mutation p.[Arg77X] in NCF2 gene. Additional genetic test like NGS have been done by Kaan Boztug lab and kabuki syndrome with heterozygote missense mutation (R132Q) in KMT2D gene was founded.Patient clinical condition is well and waiting for the bone marrow transplantation. Kabuki syndrome with Arnold chiari malformation is very rare clinical presentation. This male patient has also CGD, so it is the first case in the literature.

P.A2.04.11

Human CD4$^-$CD8$^-$ MAIT cells are a functionally and transcriptionally distinct subset that can be derived from the main CD8$^+$ MAIT cell pool

*J. Dias[1], C. Boulouis[1], J. Gorin[1], R. van den Biggelaar[1,2], K. G. Lal[1,3,4], A. Gibbs[5], L. Loh[6,7], M. Y. Gulam[8], S. Bari[9], W. Y. Hwang[9,10,11], D. F. Nixon[6,12], S. Nguyen[13], M. C., United States, [13]Department of Microbiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States.

Mucosa-associated invariant T (MAIT) cells are a large subset of unconventional T cells that recognize microbial riboflavin metabolites presented by the MHC class I-like protein MR1. The majority of the human MAIT cell population either expresses the CD8α co-receptor and lacks CD4 (CD8$^+$), or is double-negative for CD4 and CD8 (DN). It is currently unclear if these subsets separated by CD8 expression are functionally distinct and if they represent distinct developmental lineages. Here, we show that the two MAIT cell subsets express distinct patterns of classical and innate-like T cell transcription factors and divergent transcriptional programs. CD8$^+$ MAIT cells have higher levels of receptors for IL-12 and IL-18, as well as co-stimulatory receptors. The differences in PLZF, RORγt, T-bet, and Eomes expression are more pronounced in mucosal tissue-derived CD8$^+$ MAIT cells. CD8$^+$ MAIT cells displayed superior functionality following stimulation with riboflavin-autotrophic and -auxotrophic strains of *Escherichia coli* or mitogens. Interestingly, DN MAIT cells from human fetal tissues and umbilical cord blood display a more mature phenotype and accumulate over gestational time with reciprocal contraction of the CD8$^+$ subset. Culture of CD8$^+$ MAIT cells in the presence of chronic T cell receptor stimulation leads to the accumulation of DN MAIT cells. Finally, DN MAIT cells are biased towards IL-17 production and have higher propensity for apoptosis. Overall, our study defines key differences in the transcriptional and functional profile between human CD8$^+$ and DN MAIT cells and their apparent derivative relationship.

P.A2.04.12

Functional diversity of cytotoxic- versus helper-type human CD8$^+$ memory T cells

***L. Loyal**[1,2], S. Warth[1], R. Stark[3], M. Frentsch[1], A. Thiel[1];*

[1]Regenerative Immunology and Aging, BCRT/Charité, Berlin, Germany, [2]International Max Planck Research School for Infectious Diseases and Immunology, Berlin, Germany, [3]Sanquin Blood Supply Foundation, Amsterdam, Netherlands.

CD4$^+$ memory T cells are organized into diverse T *helper* subsets such as Th1, Th2, Th17, Th17+1 and Th22 type cells characterized by distinct functions with highly specialized cytokine secretion and chemokine receptor expression patterns. Their differentiation is dependent on the cytokine milieu during activation inducing divergent differentiation programs based on the transcription factors TBX21, GATA3, RORC and AHR. In pathogenic settings, CD8$^+$ memory subsets secreting specialized cytokine combinations comparable to CD4$^+$ T *helper* subsets have been described too. We demonstrate that similar chemokine receptor patterns utilized for this T *helper* subset delineation are sufficient to systematically separate corresponding specialized CD8$^+$ memory T cell subsets Tc1, Tc2, Tc17, Tc17+1 and Tc22. These subsets exhibit differentiation-inducing transcription factor expression patterns comparable to the CD4$^+$ Th subsets as well as matching cytokine secretion profiles of IFNγ, IL-4, IL-13, IL-17, IL-22 and IL-10. While Tc1 and Tc17+1 display classical CD8$^+$ T cell related cytotoxic signature, Tc2, Tc17 and Tc22 cells possess a non-cytotoxic phenotype and express the CD4 *helper* molecule CD40L. Here we provide a fast and simple tool to identify the functionally divergent CD8$^+$ T cell subset directly *ex vivo*. We are applying this panel to systematic patient screenings (psoriasis, atopic dermatitis, MS, SLE) in order to identify relevant signatures of functionally distinct Tc subsets that contribute to the clinical profiles and provide useful information for potential treatment targets and agent effectivity.

P.A2.04.13

Distinct survival niches for memory T helper cells in spleen and bone marrow

***M. Mursell**, S. Hojyo, K. Tokoyoda;*

Deutsches Rheuma-Forschungszentrum, Berlin, Germany.

Introduction: CD4 T helper (Th) lymphocytes are an essential part of immunological memory. During the primary immune response, a subpopulation of antigen-experienced Th cells migrates into the bone marrow (BM) and resides there as the major population of memory cells in dedicated survival niches consisting of IL-7-expressing stromal cells. In addition to IL-7, IL-2 and IL-15 have been reported to contribute to the homeostasis of memory Th cells in the spleen or BM. However, molecular evidences have not been elucidated so far which factors are critical for the survival of memory Th cells in the spleen and BM.
Materials & Methods: To determine the roles of these factors, several (conditional) knock-out mice and antibodies were used in murine immune responses to protein antigens, mimicking systemic vaccines. Moreover, the co-localization of memory Th cells with cytokine-expressing cells was analyzed histologically in both spleen and BM using knock-in reporter mice.
Results: The interference of IL-7 signalling impaired the survival of splenic but not BM memory Th cells *in vivo*. IL-15 signalling had no impact on both memory cells. Interestingly, interference of the IL-2 signalling or depletion of regulatory T cells (Tregs) dramatically reduced the numbers of both memory cells. Histological analyses uncovered that Tregs indirectly contribute to the maintenance of memory Th cells.
Conclusion: Splenic memory Th cells require IL-7 and Tregs whereas BM cells depend on Tregs. The requirement of IL-7 distinguishes the survival niches for memory Th cells in the spleen and BM.

P.A2.04.14

Shaping effector and memory T cell differentiation through the immunosuppressive drug Leflunomide

***S. Scherer**[1], S. Oberle[2], D. Zehn[1];*

[1]Technical University of Munich, Freising, Germany, [2]Lausanne University Hospital, Lausanne, Switzerland.

Introduction: Leflunomide is an immunosuppressive drug frequently used to treat autoimmune diseases such as rheumatoid arthritis and multiple sclerosis. It is widely considered that it does so by inhibiting the proliferation of lymphocytes upon interfering with the de novo synthesis of pyrimidines. However, the exact mechanisms are not fully understood.
Materials and Methods: To address this issue we treated mice with Leflunomide during the course of an acute Listeria monocytogenes infection and monitored the virus specific CD8+ T cell response.
Results: We observed that Leflunomide treatment goes along with significant reductions in the numbers of pathogen-specific T cells. Interestingly, the residual T cells in treated mice were enriched for cells with a memory precursor phenotype while effector T cells were strongly reduced. Functional studies revealed that these precursor cells and the subsequently formed memory T cells are fully functional and we found that their global gene expression profiles were largely undistinguished from the corresponding cell populations formed in control mice. Moreover, we observed that T cells activated for 30 hours without Leflunomide proliferated normally when transferred into infected and Leflunomide treated mice.
Conclusions: Our results contrast the concept that Leflunomide simply causes proliferation arrest of T cells. Instead it suggests that Leflunomide blocks during the early T cell activation phase the acquisition of effector T cells programs while memory formation seems to be preserved. We see this treatment as a unique opportunity to ravel new mechanisms that determine the branching of CD8+ T cells into effector cells and memory precursors.

P.A2.04.15

Gestational age-dependent IgG glycosylation pattern in preterm infants

***N. Twisselmann**[1], Y. Bartsch[2], J. Pagel[1], M. Ehlers[2], C. Härtel[1];*

[1]Department of Child and Adolescent's Health, University of Lübeck, Lübeck, Germany, [2]Department of Nutritional Medicine, University of Lübeck, Lübeck, Germany.

Preterm infants acquire reduced amounts of immunoglobin G antibodies (IgG Abs) via trans-placental transport making them prone to development of infections in early life. The functional properties of IgG Abs are regulated by the Fc N-linked glycosylation patterns. Agalactosylated and asialylated Abs correlate with pro-inflammatory immune responses in e.g. rheumatoid arthritis, while galactosylated and sialylated IgG Abs mediate anti-inflammatory properties and increase during pregnancy. However, Fc glycosylation in preterm infants and their role in disease development are unknown.
We collected serum samples from n=83 infants with different gestational ages (23-34 weeks) and term infants as controls and additionally included n=18 mother-infants-pairs. Total IgG was purified and hydrolyzed with recombinantly expressed EndoS enzyme. The resulting N-glycan were purified and further investigated by high performance liquid chromatography.

The mother-infant-pairs show no difference in galactosylation and sialylation of the Fc N-linked glycan. The analysis of the gestational age-dependent glycosylation patterns revealed decreased galactosylated and sialylated Fc N-linked glycan with lower gestational age and increased agalactosylated and asialylated patterns. Within the highest risk group of 23 to 26 weeks of gestational age, there was no significant difference in Fc glycosylation in preterm infants developing sepsis or chronic lung disease.
The data suggest that Fc N-linked glycosylation is more prone to be pro-inflammatory with lower gestational age, but the transfer of Fc glycosylation is not selective. Further investigations with a bigger cohort are needed to determine the functional role in detail.

P.A2.04.16
Cellular survival niches for memory T helper cells in the spleen and bone marrow

***T. Wu**, S. Hojyo, K. Tokoyoda;*
DRFZ, Berlin, Germany.

Introduction: Immunological memory provides long-term protective immunity against pathogens that have been encountered before. Memory is maintained by memory cells generated in the primary challenge. We have so far shown that the majority of memory T helper (Th) cells are maintained as resting cells in IL-7$^+$collagen XI$^+$ stromal survival niches of the bone marrow (BM) and that B cells negatively regulate the generation of BM memory Th cells. However, the role of B cells in the maintenance of memory Th cells in the BM remains unknown. Here we show the role of CD20$^+$ cells in the maintenance of memory Th cells in the BM as well as spleen. **Method:** Serological ablation approach, e.g. anti-CD20, anti-IgD and anti-IgM treatments, was applied in mice generating memory Th cells. To identify the target cells, flow cytometry and confocal microscopy were used. **Results:** Deletion of CD20$^+$ cells expanded the numbers of memory Th cells in the spleen and BM, while deletion of IgD$^+$ and IgM$^+$ cells did not. Deletion of IgM$^+$ cells rather reduced the numbers of memory Th cells in the BM. **Conclusion:** CD20$^+$IgD$^-$IgM$^-$ cells negatively regulate the maintenance of memory Th cells in the spleen and BM, whereas IgM$^+$ cells support the maintenance of memory Th cells in the BM.

P.A2.04.17
Distinct Rap1 relays and donwstream pathways regulate T helper cell differentiation

***Y. F. Yazicioglu**[1,2,3], H. I. Aksoylar[3,4], R. Pal[3,4], N. Patsoukis[3,4], V. A. Boussiotis[3,4];*
[1]Department of Medicine, University of Heidelberg, Heidelberg, Germany, [2]Cerrahpasa Faculty of Medicine, Istanbul University, Istanbul, Turkey, [3]Division of Hematology-Oncology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [4]Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States.

Rap1 is a small GTPase with a crucial role in canonical signaling events in hematopoietic cells. Integrin activation represents one of the best studied cellular processes in which Rap1 is implicated with its downstream effectors Rap1-interacting adaptor molecule (RIAM) and RapL. RIAM regulates integrin activation by altering the conformation of leukocyte function-associated antigen-1 (LFA-1) beta chain, whereas RapL interacts with LFA-1 alpha chain (LFA-1α). While the role of Rap1-mediated integrin activation in regulating migratory and homing properties of immune cells has been extensively studied, whether the Rap1 signaling axis regulates T helper lineage-decision as well as effector-memory T cell differentiation remains unclear. In this study, we employed mice expressing constitutively active Rap1-GTP in T cells with or without conditional knock-out of RIAM or LFA-1α. Using this approach, we aimed to investigate mechanistically the contribution of Rap1 signaling axis and its downstream effectors in T helper cell differentiation. Our results revealed that Rap1-GTP transgenic mice exhibited enhanced regulatory T (Treg), Th17 and T follicular helper (Tfh) cell differentiation in secondary lymphoid organs including Peyer's Patches under steady-state conditions. Endogenous effector-memory T cell pool was consistently enlarged in Rap1-GTP transgenic mice. We found that development of effector-memory and Foxp3+ regulatory T cells was primarily mediated by RIAM while Tfh differentiation was mediated through LFA-1α. Our results identify a novel function of Rap1 signaling in fine-tuning T helper differentiation and pave the way for further studies to dissect the role of specific Rap1 relays and downstream signaling pathways in T helper cell fate.

P.A2.04.18
Immunorehabilitology: Present and Perspectives. From Immunotherapy to Personalized Targeted Immunorehabilitation

***R. Sepiashvili**;*
Peopels Friendship University of Russia,RUDN University, Moscow, Russian Federation.

Development and introduction of modern clinical diagnostic tests (that allow to evaluate the functional system of immune homeostasis) into medical practice, a huge body of evidence on the leading role of the immune system in pathogenesis most acute and chronic diseases and even identification of specific nosological forms of immune-mediated diseases forced the scientists to search and develop new tools and techniques that have therapeutic effects on the impaired immune homeostasis and restore it to the normal state. The introduction of a novel concept - immunorehabilitation - was an impetus for the accumulation of new knowledge and a catalyst for research in clinical immunology. The first papers on this topic were published over 35 years ago by Revaz Sepiashvili who breathed life into the concept of immunorehabilitation. He was lucky to be at its origin. He became not only the founder of the brand new scientific field - immunorehabilitation, but also the founder of a new medical science - immunorehablitology.Immunorehabilitology is a research area concerned with the recovery of immune system functional activity to physiologically normal levels under the effect of complex systemic therapeutic and preventive measures (both pharmacological and non-medical ones) to provide the recovery from acute diseases or stable clinical immunological remission with minimal (or even without) recurrences in chronic conditions. In this paper, the author returns to the roots and recalls the way that medical science has gone before coming to understand immunorehablitology and tells about current successes and its development prospects.This publication was prepared with the support of the"RUDN University Program 5-100".

P.A2.04.19
Accumulation of functional multi-potent hematopoietic progenitors in peripheral lymphoid organs of mice over-expressing IL-7 and Flt3-ligand

*F. Klein[1], L. von Muenchow[1], G. Capoferri[1], S. Heiler[1], M. Mitrovic[1], C. Engdahl[1], L. Alberti-Servera[1], J. Andersson[1], R. Ceredig[2], A. Rolink[1], **P. Tsapogas**[1];*
[1]University of Basel, Basel, Switzerland, [2]National University of Ireland, Galway, Ireland.

Interleukin-7 (IL-7) and Flt3-ligand (FL) are two cytokines important for the generation of B cells, as manifested by the impaired B cell development in mice deficient for either cytokine or their respective receptors, and by the complete block in B cell differentiation in the absence of both cytokines. In order to further study their synergistic effect in lymphopoiesis *in vivo*, we generated mice constitutively over-expressing both IL-7 and FL. These double transgenic mice develop splenomegaly and lymphadenopathy characterized by tremendously enlarged lymph nodes even in young animals. We find a synergistic effect of the two cytokines in the expansion of bone marrow lymphoid and myeloid progenitors, including Lineage$^-$kit$^+$Sca1$^+$ (LSK), Common Lymphoid Progenitors (CLP) and pro/pre B cells, while Hematopoietic Stem Cells (HSC) are reduced by FL over-expression. Analysis of peripheral organs of these mice identified the presence of increased numbers of these progenitors in spleen and lymph nodes. When transplanted into irradiated wild-type mice, double transgenic lymph node cells show long-term multi-lineage reconstitution of hematopoietic lineages, further confirming the presence of functional hematopoietic progenitors therein. Our results provide further *in vivo* evidence for the concerted action of IL-7 and FL on lymphopoiesis and suggest that extra-medullary niches, including those in lymph nodes, can support the survival and maintenance of hematopoietic progenitors that under physiological conditions develop exclusively in the bone marrow.

P.A2.04.20
Relacja niskiego stopnia stanu zapalnego z ograniczeniem czynnościowym u osób starszych

***B. Morawin**, A. Tylutka, J. Chmielowiec, P. Rozpedowski, A. Zembron-Lacny;*
Faculty of Medicine and Health Sciences, Zielona Gora, Poland.

The age-related changes in skeletal muscle system are the result of chronic activation of macrophages, which leads to an increase in pro-inflammatory cytokines. The increase in circulating pro-inflammatory factors, such as TNFα, is far less than that seen in acute infection; thus the ageing effects on pro-inflammatory cytokine expression are considered to be a chronic low-grade state. The purpose of the study was to identify the inflammatory mediators responsible for deficit in functional fitness and to explain whether inflammation is related to changes in body composition and the decline of muscle strength in the elderly. Eighty women and men (71.2 ± 5.7 years) from the University of the Third Age (U3A) participated in the study. The pro-inflammatory cytokine TNFα (0.081 ± 0.036 pg/mL) as wells as soluble receptors sTNFR1 (154.75 ± 33.65 pg/mL) and sTNFR2 (331.66 ± 68.42 pg/mL) did not reached dangerously high levels. However, hsCRP concentration was significantly elevated (>3 mg/L) in the elderly with high fat mass (FM 33.3 ± 6.0 kg). The hsCRP level was correlated with FM (r=0.452, *P*<0.01). The result of 6-minute walking test was 442.7 ± 77.1 m, which shows good functional status in seniors from U3A. The elderly classified as obese and overweight were distinguished by low functional status and low isokinetic hand strength. The generation of inflammatory mediators in students of U3A was related to changes in body composition, isometric strength, and age-related changes in functional fitness. This study was financially supported by a project **2016/21/N/NZ7/03329** PRELUDIUM 11 from the National Science Centre, Poland

P.A2.04.21

Immunological changes in women and men over 60 years of age depending on coexisting disease entities

***A. Tylutka**, B. Morawin, J. Chmielowiec, A. Matejuk, A. Zembron-Lacny;*
Faculty of Medicine and Health Sciences, Zielona Gora, Poland.

p.p1 {margin: 0.0px 0.0px 0.0px 0.0px; font: 12.0px 'Times New Roman'; color: #212121; -webkit-text-stroke: #212121; background-color: #ffffff} span.s1 {font-kerning: none} span. s2 {font: 8.0px 'Times New Roman'; font-kerning: none}It is now known that the changes in the immune system in the elderly associated with the pool of T-lymphocytes consist mainly in the reduction of the number of naïve T cells and the increase in the number of memory lymphocytes and a reduction in the CD4/CD8 ratio <1. The aim of this study was to analyze cells of the immune system and the influence of physical activity on the improvement of immunological parameters. In research took part 99 students from The University of the Third Age and the control group (n=30) at the age of 21. U3A students were divided into two age groups, 60-70 and 70+. As a result of health questionnaires, the following disease entities were selected among the examined persons: arterial hypertension, diabetes, hyperthyroidism and hypothyroidism and rheumatoid arthritis. Using a flow cytometry a comparative analysis of cells with a phenotype $CD4^+CD45RA$ and $CD4^+CD45RO$, $CD8^+CD45RA$ and $CD8^+CD45RO$ as well as CD4/CD8 ratio was conducted.Statistically significant differences were observed between older and younger people in the $CD4^+CD45RO$ cell population ($p<0.0001$), $CD8^+CD45R0$ ($p<0.01$) and CD4/CD8 ($p<0.01$). Significance is also evident between active and inactive elderly in the population of $CD4^+CD45RA$ ($p<0.05$). The results of the study showed how physiological aging affects the population of immune cells, and additionally it has been proven that regular physical activity has a beneficial effect on the rejuvenation of the immune system.

Hospital Universitario La Princesa, Madrid, Spain, [7]IIS, Fundación Jiménez Díaz, Madrid, Spain.

The treatment and prognosis of myocarditis rely on an early diagnosis. However, acute myocarditis frequently mimics acute myocardial infarction (AMI) in its clinical presentation with different medical management and prognostic implications. There is a lack of a reliable tool for early differential diagnosis between these conditions. Using miRNA microarrays, we detect the expression of mmu-miR-721 mainly in Th17 cells, key players of myocardial damage in myocarditis. miRNA-721 is present in the plasma of mice with acute myocarditis, encapsidated into extracellular vesicles (EV) secreted by Th17 cells, but not in the plasma of mice with AMI. We identify hsa-miRNA-Chr8.96 as the miR-721 human homolog, that is selectively expressed into EV in the plasma of acute myocarditis patients upon clinical presentation. Analysis of the expression of hsa-miRNA-Chr8.96 in the EV-plasma compartment of 207 participants from five independent cohorts reveals a high potential diagnostic value of myocarditis patients compared to healthy controls (AUC: 0.9872) and AMI patients (AUC: 0.9652). Our data highlight hsa-miRNA-Chr8.96 as the first non-invasive biomarker for the diagnosis of acute myocarditis patients.

Identification of high risk myelodysplastic syndrome via migration analyses of blood neutrophils - a diagnostic approach

*M. Schuster[1], M. Möller[2], **L. Bornemann**[1], C. Bessen[1], C. Sobczak[1], S. Schmitz[1], L. Witjes[3], A. Kündgen[2], N. Pundt[4], B. Pelzer[1], C. Ampe[3], M. Van Troys[3], R. Haas[2], U. Germing[2], L. Martens[3,5], K. Jöckel[4], M. Gunzer[1];*
[1]Institute for Experimental Immunology and Imaging, Essen, Germany, [2]Department of Hematology, Oncology and Clinical Immunology, Düsseldorf, Germany, [3]Department of Biochemistry, Ghent, Belgium, [4]Institute for Medical Informatics, Biometry and Epidemiology, Essen, Germany, [5]VIB-UGent Center for Medical Biotechnology, Ghent, Belgium.

Autonomous migration is essential for immune cells and has prognostic and diagnostic potential, yet clinical diagnostic lacks standardised migration assays. Here, we introduce a robust method to determine migration patterns of human neutrophils. We generated data from >130 healthy donors and compared them to patterns from patients suffering from myelodysplastic syndrome (MDS), whose majority show impaired neutrophil functions. In clinical routine, MDS diagnosis and prognosis is both time- and money-intensive and an easily quantifiable parameter would tremendously facilitate clinical work.
We established a standardised assay to analyse random 2-D migration of human neutrophils using time-lapse microscopy and automated cell tracking. Blood of healthy donors and MDS patients was provided by both, the Heinz-Nixdorf Recall MultiGeneration study (HNMGS) and the MDS registry, Düsseldorf, respectively.
Among the participants of the HNGMS, we found comparable baseline values with little variability concerning age group and sex. Individual values were highly reproducible and the response to known migration triggers was independent of the triggered receptor expression. Importantly, the migration pattern almost completely collapsed in patients suffering from severe types of MDS. In fact, induced neutrophil migration strongly correlated with the IPSS-R score, allowing a reliable identification of the high-risk cases.
In this study, we provide evidence that neutrophil migration is a quantifiable, reliable and minimally invasive readout for MDS prognosis. The long-term goal is to develop a robust platform for the routine testing of human leucocyte migration and identify migration-associated disease settings.

P.A3.01.03

Biomarkers of gut bariier damage in the early diagnostics of necrotizing enterocolitis

***S. Coufal**[1,2], A. Kokesova[3], H. Tlaskalova-Hogenova[1], J. Snajdauf[3], M. Rygl[3], M. Kverka[1];*
[1]Laboratory of Cellular and Molecular Immunology, Institute of Microbiology, CAS, v.v.i., Prague, Czech Republic, [2]Faculty of Science, Charles University, Prague, Czech Republic, [3]Department of Pediatric Surgery, 2nd Faculty of Medicine, Charles University, Motol University Hospital, Prague, Czech Republic.

Introduction: Necrotizing enterocolitis (NEC) is severe disease of gastrointestinal tract (GIT) affecting mainly preterm neonates and neonates after surgery for congenital malformation of GIT. Current NEC diagnostics does not allow to timely distinguishing NEC from other GIT disorders or sepsis. The aim was to test suitable biomarkers of gut barrier damage for early diagnostics of NEC. **Methods:** We included 42 infants with suspected NEC and 12 healthy infants as controls. The urine samples were collected in 6-hour intervals for 48 hours from the moment of NEC suspicion or after surgery for congenial developmental malformation of GIT. Serum samples were collected at the moment of NEC suspicion and one week later. Total and caspase cleaved cytokeratin-18 (CK-18), Trefoil factor 3 (TFF-3) and Intestinal-Fatty Acid Binding Protein (I-FABP) were measured using ELISA. **Results:** Individuals suffering from NEC had significantly higher I-FABP levels than individuals suffering from sepsis or healthy individuals.
There was significant decrease of I-FABP during NEC therapy. The levels of TFF-3 were significantly elevated both in infants suffering from NEC or sepsis in comparison with healthy individuals. The levels of CK-18 did not differ among groups. There were no significant differences in biomarkers levels between infants with spontaneous or surgery related NEC. By addition of the I-FABP examination to the standard NEC diagnostics we revealed 9 radiologically and ultrasonographically negative patients, who developed NEC later.
Conclusion: I-FABP is suitable biomarker for the early diagnostics of both spontaneous and surgery related NEC. Supported by IGA 13483, GAUK 326815, AZV 15-28064A.

P.A3.01.04

A comparative study between anti-endomysial antibodies and anti-transglutaminase antibodies in the management of celiac pediatric patients.

***C. García-Miralles**, J. Delgado, M. Amengual;*
Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Tauli I3PT, Sabadell, Spain.

Introduction: Anti-transglutaminase antibodies (tTG) and anti-endomysial antibodies (EMA) are used as immunological markers for the diagnosis of celiac disease (CD). The objective of this study is to verify the concordance between anti-tTG and EMA in the diagnosis and follow-up of CD.
Methods: Retrospective study of the 2015-2017 period with the inclusion of 2267 pediatric patients who underwent the determination of EMA by immunofluorescence (INOVA®) and the detection of anti-tTG by ELISA (Immunocap®). To verify concordance, anti-tTG cut-off point was established by using a ROC curve, in which 300 patients were included: 150 patients with anti-tTG values >3 U/mL and negative EMA, and 150 patients with anti-tTG values >3 U/mL and positive EMA. ATA negative values (<3 U/mL) were excluded.
Results: The anti-tTG cut-off point was stablished at 7.1 U/mL, with a sensitivity of 87% and a specificity of 92%. During this period, 3055 analytical test of 2267 patients were analyzed, 2715 negative and 225 positives by both methods (96.2% concordance). Regarding the discrepancies, 100 serum samples were positive for EMA and negative for anti-tTG. Four of those patients were diagnosed of CD. On the other hand, 15 serum samples were positive for anti-tTG and negative for EMA. Two of those patients were diagnosed of CD.
Conclusion: The screening of both EMA and anti-tTG allowed the diagnosis of CD to 6 patients who had serological discrepancies, to whom the intestinal biopsy was avoided. Both methods behave similarly in the diagnosis and follow-up of CD.

P.A3.01.05

Protein biomarkers predictive of multivalent response to a novel dengue vaccine

*V. Hindie[1], P. Croteau[1], S. Aziri[1], S. Lo[1], J. Sui[1], L. Cortes[1], E. Kallas[2], R. P. Sekaly[3], **E. Paramithiotis**[1];*
[1]CAPRION BIOSCIENCES INC., MONTREAL, Canada, [2]University of Sao Paulo, Sao Paulo, Brazil, [3]Case Western Reserve University, Cleveland, United States.

Dengue fever is the most prevalent mosquito-borne disease of humans, and is caused by the dengue virus (DENV) which is comprised of four serotype groups that circulate globally. Protective antibodies against one DENV serotype offer limited protection against the others. Therefore, a vaccine that protects against all four serotypes has been highly desirable. We analyzed plasma from a Phase II trial of TV003, a live-attenuated vaccine composed of all four DENV serotypes, to identify predictive biomarkers of vaccine efficacy. Pre-dose, day 6 and day 15 post vaccination timepoints were analyzed from seronegative (n=17) or seropositive subjects (n=18). The samples were depleted of abundant proteins and processed to tryptic peptides for multiple reaction monitoring mass spectrometry (MRM-MS) using a previously defined assay composed of 298 host plasma proteins associated with the immune response. Overall protein detection rate was 96% with a study wide 9% median CV of the process controls used and 71% of the targeted proteins were detected in >50% of the samples. Supervised and non-supervised study sample grouping and network analysis of the differentially expressed proteins was done. Oligovalent responders had consistently elevated expression of pro-inflammatory proteins at baseline and later timepoints compared to multivalent responders, and network analyses indicated that the IL6 and acute phase response pathways were induced. In contrast, multivalent responders at baseline had comparatively elevated cellular activation, proliferation, and migration as well as neutrophil function. These results suggest that baseline inflammation can reduce multivalent DENV serotype response. Funded by NIH/NIAID and the Butantan Institute.

P.A3.01.06

T cell receptor signatures in cytomegalovirus carriers

***A. Huth**[1], X. Liang[1,2], S. Krebs[3], H. Blum[3], A. Moosmann[1];*
[1]DZIF Research Group "Host Control of Viral Latency and Reactivation" (HOCOVLAR), Helmholtz Center Munich, Munich, Germany, [2]HRYZ Biotech Co., Shenzhen, China, [3]Laboratory for Functional Genome Analysis (LAFUGA), Gene Center, LMU Munich, Munich, Germany.

The herpesvirus human cytomegalovirus (CMV) causes a persistent infection in its host. Primary infection and reactivation can cause severe diseases in immunodeficient carriers, who cannot keep the virus in check. T cells are crucial for control of the virus and the presence of specific T cells is associated with protection against CMV disease.
We characterized the highly diverse T cell receptor (TCR) repertoire that humans mobilize to fight CMV. Virus-specific T cells were enriched by stimulation of blood cells from healthy donors with defined CMV epitope peptides. We performed high-throughput TCRβ sequencing, and subsequently compared TCR read frequencies in the stimulated sample compared to the unstimulated and a control peptide stimulated sample. In this way, we identified hundreds of CMV-specific TCRs against different CMV epitopes.
Enrichment of virus-specific T cells was exclusive to CMV-positive donors. The T cell response was often dominated by one or a few TCR clonotypes. Several TCR sequences with identical specificity were highly similar on the amino acid level and expressed by multiple donors. The cumulative *ex vivo* frequency of these TCR families was considerably higher in CMV-positive than CMV-negative individuals.
Virus-specific TCR families shared between virus carriers will be valuable in disease monitoring, for instance as an indicator of the presence of CMV-specific T cells. In addition, such TCRs are predestined to be used for adoptive T cell transfer, since they are tolerant to a wide range of HLA-self peptide complexes and are therefore less likely to cause autoimmunity in the recipient.

P.A3.01.07

Intake of soy isoflavones and vitamin D decreased inflammation, fecal serine protease activity, and had no effect on antioxidants in irritable bowel syndrome

***M. Jalili**[1], H. Vahedi[2], H. Poustchi[2], A. Hekmatdoost[3];*
[1]CMBG, BI, NTNU, Trondheim, Norway, [2]TUMS, Tehran, Iran, Islamic Republic of, [3]SBMU, Tehran, Iran, Islamic Republic of.

Introduction Irritable bowel syndrome (IBS) is a common gastrointestinal disorder in women. Isoflavones and vitamin D can regulate the estrogen receptors in colon, so our objective was to study the effect of isoflavones, vitamin D, and co-administration of them on inflammation markers, intestinal permeability and antioxidant status in women with IBS.
Materials and Methods Eligible IBS patients were allocated randomly to four groups: isoflavones (40 mg) +placebo of vitamin D (I+P), vitamin D (50000 IU) +placebo of isoflavones (D+P), isoflavones and vitamin D (I+D), and placebos of isoflavones and vitamin D (P+P). In a double-blind randomized clinical trial, 100 participants received treatments for 6 weeks. Five ml blood and fecal samples was taken at week0 and 6, plasma separated and tumor necrosis factor-α (TNFα), nuclear factor κβ (NFκβ), total antioxidant capacity (TAC) were measured. Serine protease (SrPr) activity was determined in feces. One-way ANOVA used to compare groups and $P<0.05$ considered as significance level.
Results Plasma TNFα, NFκβ and fecal SrPr was reduced in all treatment groups compared to placebo group, however the reduction level was statistically significant in all three treatment groups for NFκβ and SrPr ($p<0.001$), in I+P and I+D groups for TNFα ($P=0.003$ and 0.002 respectively). There were no significant changes in TAC levels.
Conclusion administration of soy isoflavones alone or with vitamin D reduced plasma inflammatory markers and improved intestinal permeability index by lowering fecal SrPr activity.

P.A3.01.08

Alterations in natural Dendritic Cell (DC) subsets in advanced cancer patients.

***A. Kaur**, J. Adhikaree, H. Franks, P. Patel, A. M. Jackson;*
Division of Cancer and Stem Cells, School of Medicine, University of Nottingham, Nottingham, United Kingdom.

The activity of natural DC is key for invoking immunity and for the success of immune checkpoint blockade for advanced cancer patients. Nivolumab and Ipilimumab block the inhibitory receptors namely PD-1 and CTLA-4 receptors on T cells allowing them to restore their anti-cancer functions. An understanding of the condition of natural DC subsets in these patients will assist in early stratification of responders, and may yield approaches to enhance the function of DC in other patients. We therefore measured the abundance and phenotype of 4 circulating DC subsets in cancer patients using a multi-parametric flow cytometry assay and compared it with data obtained from healthy controls. This assay has been performed for 16 patients with glioblastoma, 5 patients with advanced melanoma (currently on checkpoint inhibitor therapy) and 19 matched healthy donors. The average number of DC subsets in patient blood compared to healthy donor samples were 4476 vs 5056 of CD1c+ DC/mL, 193 vs 252 of CD141+ DC/mL, 1265 vs 2957 of plasmacytoid DC/mL (p-value=0.002) and 5760 vs 4265 of SLAN DC/mL respectively. A significant reduction in particular was observed in blood plasmacytoid DC subset in cancer patients as compared to healthy donors ($P<0.05$). As number of DC are important to efficiently activate the T cells after checkpoint inhibitor treatment, we believe that the number and phenotype of DC subsets may differ among responding and non-responding patients and this could further help identify the patients who would benefit the most with the therapy.

P.A3.01.09

Prognostic value of elevated T helper 17 and T helper regulatory cells related inflammatory serum markers in pathogenesis of septic polytrauma patients.

***S. Khurana**, P. Mathur, M. Kumari, N. Bhardwaj, S. Sagar, S. Kumar, A. Gupta, R. Aggarwal, K. Soni, R. Malhotra;*
All India Institute of Medical Sciences, New Delhi, New Delhi, India.

Introduction: Sepsis is a fatal immunological disorder and its pathophysiology remains poorly understood. It leads to high mortality rates, increased hospital stays and associated costs, especially in trauma patients. The present study was conducted to ascertain the role of T-helper lymphocyte-related inflammatory serum cytokines in trauma patients with blood culture positive with gram negative bacteria.
Materials & Methods: This study was conducted in a cohort of 40 polytrauma patients, bead-based cytometric analysis was used to quantify extracellular levels of sixteen serum cytokines using the multi-analyst kits using flowcytometry, in the serum on the day of obtaining positive blood culture and on day 4, post antimicrobial treatment. The cytokine profiles were compared with those in equal number of healthy controls and then correlated to clinical outcomes.
Results: A total of 40 patients and 40 healthy controls were included in the study. Of these, 24 patients (60%) were discharged while 16 (40%) had a fatal outcome. Statistically significantly elevated levels of serum IL-6, IFN-γ, TNF-α, IL-17A, IL-17F, and IL-4 were observed in septic patients, while lowered IL-13 levels correlated significantly with favourable outcome in these patients.
Conclusion: An elevated T helper17 and T helper regulatory cytokine response was observed. The unique cytokine profile of septic polytrauma patients is still poorly understood. More studies with larger sample size and stringent exclusion criteria are needed to be able to answer the question of identifying a reliable cytokine profile for prognostication of high risk septic trauma patients.

P.A3.01.10

A novel whole blood assay for detecting and profiling vaccine-induced *Bordetella pertussis* specific T-cells

N. Lambert[1], *V. Corbière*[2], *J. van Gaans*[1], *M. Duijst*[1], *E. Simonetti*[3], *E. van Schuppen*[3], *D. Diavatopoulos*[3], *A. Misiak*[4], *K. Mills*[4], *P. Versteegen*[1], *G. Berbers*[1], *C. van Els*[1], *F. Mascart*[2];
[1]*National Institute of Public Health and the Environment, Bilthoven, Netherlands,* [2]*Université Libre de Bruxelles, Brussels, Belgium,* [3]*Radboud University Medical Center, Nijmegen, Netherlands,* [4]*Trinity College Dublin, Dublin, Ireland.*

Introduction: Pertussis, a severe respiratory infectious disease caused by the bacterium *Bordetella pertussis* (*Bp*), remains endemic despite vaccination. No correlates of protection have been identified yet. *Bp*-specific CD4+CD3+IFNg+ T-cells are thought to play an important role in durable protection against infection and transmission. Novel sensitive and robust assays are needed to study the magnitude and differentiation of (vaccine-induced) antigen-specific T-cells in order to advance the development of improved pertussis vaccines.
Materials and methods: In a Dutch clinical study, 11-15 year-old healthy volunteers were boosted with an acellular pertussis vaccine. Whole blood samples, taken at day 0 (pre-booster), 14 and 28 (post-booster) were stimulated with *Bp* antigens overnight and production of cytokines was measured intracellularly and in supernatants by flow cytometry.
Results: Following vaccination, *Bp*-specific Th1 and/or Th2-cytokine producing T-cells increased to 0.02-0.5% of the CD4+CD3+ T-cell population. Supernatant analyses are ongoing. Standardized analysis of flow cytometric data is being explored. Currently, inclusions are being finalized and overall results will be presented.
Conclusions: We have shown that our novel whole blood assay is capable of detecting low frequency T-cell responses against *Bp*. Further analysis is ongoing to assess the Th1/Th2/Th17-profiling capacity of the assay and whether different T-cell profiles can be detected in booster responses of differently primed teenagers.
The PERISCOPE project has received funding from the Innovative Medicines Initiative 2 Joint Undertaking under grant agreement No 115910. This Joint Undertaking receives support from the European Union's Horizon 2020 research and innovation programma and EFPIA and BMGF.

P.A3.01.11

IFNγ-preconditioning treatment increases immune system-related proteins in extracellular vesicles derived from human endometrial mesenchymal stromal cells

F. Marinaro[1], *F. Sánchez-Margallo*[1], *V. Álvarez*[1], *R. Blázquez*[1], ***E. López***[1], *B. Macías-García*[1], *M. Gómez-Serrano*[2], *I. Jorge Cerrudo*[2], *J. Vázquez*[2], *J. García-Casado*[1];
[1]*Centro de Cirugía de Mínima Invasión, Cáceres, Spain,* [2]*Centro Nacional Investigaciones Cardiovasculares CNIC, Madrid, Spain.*

Introduction: Endometrial Mesenchymal Stromal Cells (endMSCs) are multipotent cells with clear immunomodulatory effects. These cells release extracellular vesicles (EV-endMSCs), although their role in immune and inflammatory response is still under investigation. Here we show the proteomic profile of EV-endMSCs together with the effect of IFNγ-preconditioning.
Materials and Methods: EndMSCs were isolated from human menstrual blood, expanded *in vitro* and characterized by flow cytometry (n=3). EndMSCs were treated with IFNγ (3ng/ml) for 6 days, IFNγ was removed and supernatants were collected after 4 further days. EV-endMSCs were isolated from supernatants and protein extracts underwent high-throughput multiplexed quantitative proteomics based on iTRAQ labeling and mass spectrometry analyses. Enrichment analyses, using Gene Ontology (GO) and Reactome databases, were performed to evaluate the functional classification of the proteins identified.
Results: EndMSCs expressed CD56, CD44, CD29, CD90, CD105 and CD73 stemness markers, while EV-endMSCs expressed the exosome-related proteins CD9 and CD63. In the proteomic profiling, 1802 proteins were identified and 856 proteins belonged to GO term "extracellular vesicle" ($p<0.01$). Quantitative analyses showed 55 upregulated proteins after IFNγ treatment ($p<0.05$). Enrichment analyses revealed that 26 proteins were associated to the Innate Immune Response (i.e. M-CSF, C1Inh, STAT1) and 11 proteins to the Adaptive Immune Response (i.e. Cathepsin S, CD166 antigen, Beta-2-microglobulin). Moreover, 23 out of the 55 proteins were also related to the Reactome category "Immune system".
Conclusions: EV-endMSCs proteomic profiling reveals that IFNγ treatment upregulates immune system-related proteins, revealing their theurapeutic potential for the treatment of immune-mediated diseases.

P.A3.01.12

Fecal calprotectin interlaboratory comparisons

M. Martin[1], *M. López-Hoyos*[2];
[1]*Centro de Hemoterapia y Hemodonación de Castilla y León, Valladolid, Spain,* [2]*Hospital Universitario Marqués de Valdecilla, Santander, Spain.*

Calprotectin is a dimer of calcium binding proteins mainly present in neutrophil's cytosol. Elevated fecal calprotectin happens as a consequence of the migration of neutrophils to the intestinal mucosa due to any intestinal inflammation. Taken together with clinical signs and symptoms, this non-invasive test helps avoiding colonoscopies. Two rounds of an interlaboratory comparison were run along 2017, shipping stool aliquots from 4 different patients to 21 clinical labs. Samples were given after informed consent in HU Marques de Valdecilla. Each participant lab analyzed samples by their routine method. Both qualitative and quantitative results were reported. Robust statistics for interlaboratory comparison were performed following guidelines in ISO 13528. Three out of the 4 samples were assigned positive by consensus of at least 75% of participants, whereas the 4th sample remained inconclusive so far only a 47% of labs reported it positive. It was reported to contain 280 µg/g calprotectin. Samples yielding positive results were reported to 344-3819 µg/g calprotectin. Some patients have been reported to have slightly raised levels of fecal calprotectin, who would only need monitoring. Those of them suffering from a low-grade inflammatory bowel disease (IBD) will usually evolve to higher calprotectin levels. It will be therefore useful for labs and interlaboratory comparisons can help narrowing their grey zones.

P.A3.01.13

Flow cytometry: identifying biomarkers for the diagnosis of organ-specific autoimmune diseases and response to treatment

A. Teniente-Serra[1], *M. Fernández*[2], *B. Soldevila*[1], *E. Pizarro*[3], *C. Ramo-Tello*[1], *R. Pujol-Borrell*[4], ***E. Martínez-Cáceres***[1];
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain,* [2]*Germans Trias i Pujol Research Institute (IGTP), Campus Can Ruti, Badalona, Spain,* [3]*Hospital de Mataró, Mataró, Spain,* [4]*Hospital Universitari Vall d'Hebron, Barcelona, Barcelona, Spain.*

In the last years, the significant development in the field of biomedical research has lead to the need to define new biomarkers for diagnosis, prognosis or monitoring of diseases. Multiparametric flow cytometry has been positioned as one of the most useful technologies for monitoring immune-mediated diseases.
For this purpose we designed an exhaustive flow cytometry panel which allows to analyse minor lymphocyte subpopulations in peripheral blood, and validated it in several autoimmune diseases:
1) We found changes in peripheral blood lymphocyte compartments of type 1 diabetes patients at onset of the disease.
2) In Graves' disease patients, a different pattern of lymphocyte subpopulations was identified in patients clinically stable who maintain the presence of anti-TSH autoantibodies, compared to those without autoantibodies.
3) In Multiple sclerosis, we found changes in lymphocyte subpopulations identified in untreated relapsing-remitting patients and progressive forms compared with healthy donors. The influence of immunomodulatory therapies on lymphocyte subpopulations was also analysed in a cross-sectional study.
Analysing the influence of therapies on lymphocyte subpopulations, we identified in a prospective study that Multiple sclerosis patients treated with fingolimod had different patterns of subpopulations, able to discriminate responders versus non-responders to the therapy , in a 12 month follow-up.
In conclusion, characterization of minor lymphocyte subpopulations in peripheral blood, by multiparametric flow cytometry, is a useful tool to identify potential biomarkers for the diagnosis and response to treatment of organ-specific autoimmune diseases, and by extension to other immune-mediated diseases.

P.A3.01.14

Peptidylarginine deiminase 4 gene polymorphisms associate with systemic lupus erythematosus and lupus nephritis

L. Massarenti[1,2], *D. Damgaard*[1,3], *C. Enevold*[1], *N. Ødum*[2], *C. H. Nielsen*[1,3], *S. Jacobsen*[4];
[1]*Institute for Inflammation Research, Center for Rheumatology and Spine Disease, section 7521, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark,* [2]*Department of Immunology and Microbiology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [3]*Section for Periodontology, Department of Odontology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [4]*Copenhagen Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, section 4242, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark.*

Objective Deposition of immune complexes containing DNA and nuclear proteins, released during neutrophil extracellular trap (NET) formation, plays a key role in the pathogenesis of systemic lupus erythematosus (SLE) and lupus nephritis (LN). Histone citrullination, catalyzed by peptidylarginine deiminase 4 (PAD4), allows chromatin decondensation, and is thereby essential for NETosis. We sought to determine if selected single nucleotide polymorphisms (SNPs) in the encoding gene, *PADI4*, previously known to influence expression and functionality of the enzyme, affect risk of developing SLE and LN. **Methods**: 234 patients and 484 controls were genotyped for nine *PADI4*-SNPs using an in-house assay. Analyses were adjusted for age and gender. **Results**: Homozygosity and heterozygosity for rs1635564(T) were associated with increased SLE occurrence (P=0.02, OR 1.52, 95% CI 1.06-2.19 and P=0.03, OR 2.06, 95% CI 1.08-3.93, respectively), and homozygosity for rs1635564(T) was associated with increased LN occurrence (P=0.03, OR 3.35, 95% CI: 1.2-10.97). Notably, a gene dose effect for rs1635564(T) was observed for SLE and LN (P=0.005, OR 1.47, 95% CI 1.12-1-93 and P=0.01, OR 1.74, 95% CI 1.13-2.68, respectively). Additionally, minor allele carriage of five other SNPs (rs11203366, rs11203367, rs874881, rs2240340 and rs11203368) in high linkage disequilibrium, was associated with increased occurrence of LN and hypertension. **Conclusion**: We provide the first indications that the rs1635564 polymorphism of *PADI4* could be a risk factor for SLE, in general, and LN in particular. Additional *PADI4* polymorphisms may confer increased risk of LN. Overall, these findings support the notion of a role for citrullination in SLE and LN pathogenesis.

P.A3.01.15

Splenic CD4+CD39+ T lymphocyte frequencies are differentially altered in patients with leukemia and autoimmune thrompocytopenia

N. Nanava[1], *S. Metreveli*[1], *N. Kikodze*[2], *G. Giorgobiani*[3], *T. Chikovani*[1], *N. Janikashvili*[1];
[1]*Department of Immunology, Tbilisi State Medical University, Tbilisi, Georgia,* [2]*Institute of Medical Biotechnology, Tbilisi State Medical University, Tbilisi, Georgia,* [3]*Department of Surgery, Tbilisi State Medical University, Tbilisi, Georgia.*

Introduction: Accumulating evidence suggests that the expression of ectoenzime CD39 in CD4+ T lymphocytes indicates on their suppressive acitvities. In certain immune pathologies - blood cancer or autoimmune hematological disorders, there is a direct relationship between circulating and splenic T cell biomarkers reflecting the response to therapy. Our retrospective study aims to explore the differential expressions of CD39 and FoxP3 in blood and splenic CD4+ T cells of patients with chronic myelogenous leukmeia (CML) and immune thrombocytopenia (ITP). Individuals undergoing splenectomy due to other reason than cancer or autoimmune disease are used as controls.
Methods: Mononuclear cells from peripheral blood and dissociated spleen tissue are purified and the expressions of CD39 and FoxP3 are quantified within the CD4+ compartment of T lymphocytes. Data are acquired on a FacsCalibur flow cytometer and analyzed using FlowJo® v10 software.
Results: Our data suggest that the frequency of total circulating as well as splenic CD4+ T lymphocytes are comparable between CML and ITP patients and controls. However, CD39 expression is elevated in these T cells in patients with myelogenous leukemia and diminished in patients with ITP. Importantly, the differential expression of CD39 resembles FoxP3 levels in both groups of patients and is more evident in spleen compared to blood.
Conclusion: Expression of CD39 in splenic CD4+ T cells can be considered as a good biomarker and, respectively, a prospective therapeutic target in patients with CML and ITP undergoing therapeutic splenectomy.
This research was funded by Shota Rustaveli National Science Foundation (Grant №PhD_F_17_20).

Granzyme B induced by RV0140 antigen better classified latently infected from active tuberculosis patients

R. Ouni[1,2], *A. Braïek*[1,3], *V. Dirix*[4], *H. Gharsalli*[5], *A. Jarraya*[6], *N. Sendi*[1], *A. Baccouche*[1], *A. Akremi*[6], *L. Gharbi-Douik*[5], *R. Barbouche*[1], *C. Benabdessalem*[1];
[1]*Laboratory of Transmission control and immunobiology of infections, Institut Pasteur de Tunis, Tunis, Tunisia,* [2]*faculty of sciences of Bizerte, University of Carthage, Bizerte, Tunisia,* [3]*University of Tunis El Manar, Tunis, Tunisia,* [4]*Laboratory of vaccinology and mucosal immunity, Université Libre de Bruxelles, Brussels, Belgium,* [5]*Hospital of Abderrahman Mami, Ariana, Tunisia,* [6]*Dispensaire anti-TB Ariana, direction régionale de la santé de l'Ariana, Ariana, Tunisia.*

Nearly two billion people are latently infected with *M.tb* (LTBI). Detection of LTBI with high risk to develop active tuberculosis (aTB) is considered the corner stone to control the disease. The current challenge is to identify markers that better classified LTBI from aTB. It has been shown that Rv0140, a reactivation-associated antigen of Mtb, induced significantly higher IFNg in LTBI individuals as compared to aTB. Herein, we described that Rv0140 induces high GranzymeB level mainly by PBMC derived from LTBI (n=33) as compared to aTB (n=18). ROC curves were used to evaluate the capacity of Rv0140 specifically induced IFNg and GranzymeB levels to classify LTBI from aTB. Our results show that, in response to Rv0140, GranzymeB allowed better discrimination of LTBI from aTB with areas under the curve (AUC) of 0.88 (95% CI 0.77-0.98) as compared to IFNg, AUC of 0.85 (95% CI 0.74-0.96).When combining GranzymeB and IFNg the AUC reaches 0.96. In the current study, we show that GranzymeB could be considered as another biomarker of TB that could be used as an alternative or in adjunction of IFNg to better classified LTBI from aTB.

P.A3.01.17

Long-term immunologic effects of human endotoxemia: similarities and differences with sepsis

Y. Rodriguez Rosales[1], *M. Kox*[2], *E. van Rijssen*[1], *M. van Welie*[1], *P. Pikkers*[2], *I. Joosten*[1], *H. Koenen*[1];
[1]*Laboratory of medical immunology, Radboudumc, Nijmegen, Netherlands,* [2]*Intensive care unit, Radboudumc, Nijmegen, Netherlands.*

Introduction: Sepsis is the cause of more than 5.3 million deaths per year, and novel immunotherapeutic strategies are highly warranted. Human models that mirror sepsis immunology are instrumental to this aim. The response to endotoxin administration in humans during the first 24 hours, captures many hallmarks of the inflammatory response observed in early sepsis. However, the long-term immunologic effects of human experimental endotoxemia have been sparsely studied and could be determinant for the use of this human model in sepsis therapy research. Aim and methods: We studied the immune cell composition of healthy subjects challenged with a bolus of endotoxin (1 ng/kg) 4 hours, 2 days and 20 days' post-administration by flow cytometry to study the effects on the innate and adaptive immune system, and compared it with the immune cell composition in patients during the first 9 days after onset of septic shock. Results: As a result of experimental endotoxemia, an increase in absolute numbers of intermediate monocyte was observed, which also showed lower HLA-DR expression 20 days' post-endotoxin. These changes differed with those observed in septic shock patients. Another long-term effect of experimental endotoxemia was elevated numbers of effector CD8+ cells and an increased percentage of proliferating and cytokine expressing CD8+ cells, these phenomena were also present in sepsis patients. Conclusion: We propose that experimental endotoxemia can be used to study several aspects of adaptive immunity in sepsis, specifically the behavior of CD8+ T-cells, which may eventually aid the development of new therapies for sepsis patients.

P.A3.01.18

Clinical, demographic and laboratory data associated with the risk of progressive multifocal leukoencephalopaty risk in multiple sclerosis patients treated with natalizumab

I. Toboso, A. Tejeda, S. Saiz, R. Alvarez-Lafuente2 , R. Arroyo3 , H. Hegen4 , ,G. Izquierdo5 , D. Paramo5 , P. Oliva6 , B. Casan, J. Álvarez, ***L. Villar****;*
Ramón y Cajal Hospital, Madrid, Spain.

Introduction: Natalizumab is and effective treatment for relapsing-remitting multiple sclerosis (MS). However, the risk of progressive multifocal leukoencephalopathy (PML), a serious opportunistic infection by JC virus limits its use. Anti JC antibodies, prior immunosupresion and time on natalizumab are risk factors for PML onset. We aimed to identify new biomarkers predicting PML onset in MS patients treated with natalizumab. Patients: We studied 1240 MS patients treated with natalizumab. Thirty-five developed PML. Clinical and demographic variables were studied. Moreover, lipid-specific oligoclonal IgM bands (LS-OCMB) were explored in a subgroup of 277 patients by isoelectric focusing and western blot. Data were analyzed with the Stata statistical package. We used MannWhitney U tests, ROC curves, and uni and multi variate logistic regression analyses to study PML risk. Results: We confirmed that anti-JC antibodies predicted PML risk. However, no effect of prior immunosuppression or time on natalizumab were observed in this cohort. New variables were identified in our study. The strongest association with PML risk were a relapse rate below 0.5 prior to natalizumab ($p<0.0001$) and an age over 45 years (p=0,048). Those were the only variables that remained significant in the multivariate analysis of the total cohort (AUC=0.85). We also confirmed the association of LS-OCMB and lower PML risk ($p<0.0001$). In junction with relapse rate below 0.5 and age over 45 constituted an accurate model for PML risk stratification (AUC=0.92). Conclusion: We describe here an statistical model that can contribute to establish PML risk in individual MS patients treated with natalizumab.

P.A3.01.19

Mass cytometry and immune cell-specific gene expression analysis of matched psoriatic arthritis blood and synovial fluid

N. Yager[1], *S. Cole*[2], *A. Lledo Lara*[1], *A. Maroof*[2], *C. Simpson*[2], *P. Bowness*[1], *H. Al-Mossawi*[1];
[1]*University of Oxford, Oxford, United Kingdom,* [2]*UCB Pharma, Slough, United Kingdom.*

Introduction: Mass Cytometry (CyTOF) has revolutionised the way cell samples can be immunophenotyped, allowing simultaneous quantification of >30 parameters with minimal spillover. This study aims to use CyTOF to generate a high-dimensional data-set of immune populations in matched psoriatic arthritis (PsA) blood and synovial fluid directly *ex vivo*, followed by transcriptomic analysis of key expanded cell populations.
Materials and Methods: Paired blood and synovial fluid were taken from 10 PsA patients and fixed with formaldehyde within 30 min of venipuncture/aspiration. The cells were stained with a 34-channel CyTOF panel of surface markers. Analysis was performed using conventional biaxial manual gating and unbiased visualisation methods including PhenoGraph and SPADE. RNA was isolated from the core expanded populations of freshly cell sorted PBMC and synovial fluid samples (n = 3), and a 384-gene array was performed.
Results: Using only one staining panel and applying multiple clustering algorithms, we were able to observe distinct changes in cell population structure in the synovial fluid of PsA patients compared to the blood. While some populations diminished (i.e. B cells), others expanded, including memory T cells and CD14 myeloid populations. Gene expression analysis of these expanded populations demonstrated multiple significant differences between the blood and synovial fluid that was shared across PsA patients.
Conclusions: We have generated an in-depth map of the immune landscape in PsA blood and matched synovial fluid in combination with a cell-specific transcriptomic analysis of expanded synovial cell populations to reveal novel inflammatory modules in PsA pathogenesis.

P.A3.01.20

BATF Levels in Chronic Lymphocytic Leukemia Patients

M. GELMEZ[1], *S. Cinar*[1], *G. Ozcit*[1], *I. Yonal*[2], *A. Daglar-Aday*[1], *G. Deniz*[1], *M. Aktan*[3];
[1]*Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology,, Istanbul, Turkey,* [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Hematology,, Istanbul, Turkey,* [3]*Istanbul University, Istanbul Faculty of Medicine, Department of Hematology, Istanbul, Turkey.*

Chronic lymphocytic leukemia (CLL) is characterized by accumulation of $CD5^+CD19^+$ cells in the peripheral blood and lymphoid organs. BATF has an essential role in Tfol, Th17 cells and B cell expansion, isotype switching, AID expression and differentiation. The findings show increased AID expression, number of Tfol and Th17 cells in CLL patients, but the role of BATF is not known in CLL pathogenesis. In this study, *BATF* mRNA and protein expressions in CLL were investigated.
Peripheral blood samples were collected from 37 patients with CLL and 16 healthy subjects. Total RNA was isolated from whole blood samples and cDNA synthesis was done. *BATF* and a reference gene, *HPRT1,* were analyzed by real-time PCR. The relative expression levels were calculated by using ΔC_T method. CLL-B ($CD5^+CD19^+$) and Tfol ($CD3^+CD4^+CXCR5^+$) cells were evaluated after staining with anti-CD5, -CD19, -CD3, -CD4, -CXCR5, and intracytoplasmic BATF monoclonal antibodies using flow cytometry according to whole blood lysing protocol.
Compared to healthy controls, *BATF* mRNA levels (p= 0.05); $BATF^+$ and $BATF^+CD19^+$ cells (p= 0.0013 and p< 0.0001, respectively); BATF expression in both $CD19^+$ and $CD3^+$ cells (p=0.0011 and p=0.003, respectively); $CD3^+CD4^+CXCR5^+$ cells (p=0.007) were increased in patients with CLL and also high BATF expression of $CD3^+CD4^+CXCR5^+$ Tfol cells (p<0.001) were found.
Increased BATF expression of different lymphocyte subtypes in patients with CLL was observed. Given the current role of BATF with some molecules associated with the pathogenesis of CLL, our findings provide the impression that BATF could play a role in the biology of CLL.

Complement factor H increased and associated with elevated oxidative stress markers and IL-1β in Algerian Behçet's disease patients.

A. Chekaoui[1], ***H. Belguendouz***[1], *K. Lahmar*[1], *M. Terahi*[2], *F. Z. Mazari*[2], *F. Otmani*[3], *D. Hakem*[4], *C. Touil-Boukoffa*[1];
[1]*Cytokines and NO Synthases team, LBCM, USTHB, Algiers, Algeria,* [2]*Ophtalmology department, CHU Nafissa Hammoud, Algiers, Algeria,* [3]*Internal medicine department, CHU Mustapha Bacha, Algiers, Algeria,* [4]*Internal medicine department, CHU Bab ElOued, Algiers, Algeria.*

Background: Behçet's disease (BD) is a multisystem disease. It stands at the crossroad between autoimmunity and autoinflammatory disorders. In the present study, we aimed to assess the plasma level of complement factor H (CFH) and elucidate its possible correlation with oxidative stress markers and the proinflammatory cytokine IL-1β in Algerian BD patients.
Patients and methods: We investigated the CFH, stress oxidative markers (Nitric oxide (NO), Advanced oxidized proteins products (AOPP)) and IL-1β in Algerian BD patients (78: Active BD patients (ABP, 28) and Inactive BD patients (IBP, 50) referring to disease activity and clinical manifestations compared to healthy controls (HC, 41). Mann–Whitney U and Pearson correlation tests were used for statistical analyses.
Results: CFH levels significantly increased in ABP and IBP (p<0.0001) compared to HC, whereas there is no significant difference (p=0.05) between ABP and IBP. NO and AOPP levels significantly increased in ABP (p<0.001) compared to IBP and HC and in IBP (p<0.001) versus HC. ABP displayed higher plasma levels of IL-1β (p<0.05) versus IBP and HC (P<0.001), also IBP showed higher levels of IL-1β (p<0.01) versus HC.
CFH significantly and positively correlated with AOPP (r=0.414, p=0.0015) and (r=0.5858, p=0.0139) in BD patients and ABP respectively. Moreover, CFH positively correlated with NO (r=0.290, p=0.028) and with IL-1β (r=0.523, p<0.05) in BD patients.
Conclusion: Our study highlights an overexpression of CFH correlated with high levels of oxidative stress markers and IL-1β. We suggest to further study this relationship to illuminate alternative paths of therapeutics in BD.

P.A3.02.02

Analysis of the immune system in patients with hereditary hemochromatosis

V. Bönnemann*, M. Claus, P. Bröde, K. Golka, C. Watzl;*
IfaDo, Dortmund, Germany.

Hereditary Hemochromatosis (HH) is an autosomal recessive disorder of the iron metabolism. The typical systemic iron overload in this disease can cause dysfunction of several organs by iron accumulation. Iron is crucial for cell function, but on the other hand, it produces reactive oxygen species (ROS) by the catalysis of important chemical reactions. Since ROS are known to cause oxidative stress and cellular damage, a precise regulation of iron within cells is necessary. The identification of the HFE gene was a major breakthrough for the understanding of HH. This gene encodes for a novel major histocompatibility complex class 1-related molecule, which play important roles in the immune system. Due to the fact that some HH patients showed aberrant NK cell functionalities in preliminary studies, we wanted to examine whether NK cells could be influenced by iron overload in HH patients.In order to investigate the properties of HH NK cells, PBMC of hemochromatosis patients and age-matched controls were used for immunophenotyping and functional assays such as degranulation and chromium-release assay. In addition, a cytometric bead array and a ferritin ELISA were performed. We observed increased basal and stimulated production of pro-inflammatory cytokines, assuming a distinct functionality of HH PBMC compared to controls. In addition we did not find aberrant NK cell phenotypes, but a general decrease of total granulocyte numbers. These data underline the complexity and sensitivity of the immune system to systemic influences.

The TNF and IFN-γ-inducible ubiquitin-like modifier HLA-F adjacent transcript 10 (FAT10) is most prominently expressed in immunological tissues but information regarding basal expression and inducibility of FAT10 in the different types of immune cells is still lacking. Hence, we investigated FAT10 mRNA expression in the major human and murine immune cell subsets, and FAT10 protein expression in human leukocytes. We isolated the different human leukocytes from peripheral blood and the murine immune cell subsets from spleen. The purified leukocytes were left untreated or stimulated with TNF and INF-γ or LPS to induce FAT10 followed by quantitative real-time PCR or western blot analysis. Basal expression of FAT10 mRNA and protein was generally low but strongly up- regulated by IFN-γ and TNF in all immune cell subsets. LPS treatment induced FAT10 expression marginally in human CD8 + T cells and murine granulocytes, but it increased Fat10 expression significantly in murine regulatory T cells. Yet, in human CD8 + T cells, natural killer cells, natural killer T cells, and dendritic cells, the FAT10 mRNAwas expressed without induction. Similarly, murine macrophages, monocytes, and regulatory T cells expressed Fat10 in the absence of stimulation. In summary, our findings suggest particular functions of FAT10 in these cell types. Furthermore, we observed not only a cell type-specific but also a species-specific basal FAT10 expression profile. Our data will serve as a guideline for future investigations to further elucidate FAT10's role in the immune system.

P.A3.02.04

Personalized monitoring of immune system from undifferentiated arthritis to rheumatoid arthritis in humans and during treatment - a possible practical usage of cytokine profile

E. Bryl[1], *E. Brzustewicz*[1], *I. Bzoma*[1], *M. Bykowska*[2], *M. Szarecka*[2], *A. Daca*[1], *J. M. Witkowski*[3];
[1]*Department of Pathology and Experimental Rheumatology, Medial University of Gdańsk, Gdańsk, Poland,* [2]*Pomeranian Center of Rheumatology, Sopot, Poland,* [3]*Department of Pathophysiology, Medial University of Gdańsk, Gdańsk, Poland.*

Introduction. Undifferentiated arthritis (UA) being usually the first clinical representation of many forms of specific arthritis mostly progresses to rheumatoid arthritis (RA). The immunological studies in established RA showed the profound changes in peripheral blood $CD4^+$ T cells and changed the paradigm of RA being a joint disease only. Our goal was to monitor the cytokine profile in patients progressing from early UA to RA and being monitored during treatment.
Patients and methods: The group of UA patients developing RA (UA→RA) was identified from a total of 121 people with arthralgia. All subjects underwent clinical and laboratory evaluation, including acute phase reactants (APRs) and autoantibodies (anti-CCP, RF, ANA-HEp-2). Cytokines IFN-γ, IL-10, TNF, IL-17A, IL-6, IL-1β, and IL-2 in sera and mononuclear cell supernatants were assayed using BD™ CBA Flex Sets. UA→RA patients were followed up for six months since the final RA diagnosis and DMARDs treatment.
Results: 34.5% of patients with UA developed RA. We observed specific cytokine patterns characterizing each patient, which altered during course of disease. We distinguished three UA→RA cohorts with different cytokine profiles: the group of patients susceptible to the therapy, the group refractory to the therapy and the group with variable responses to the therapy.
Conclusions: The serum cytokine profiles change in the course of RA and may be potentially used for optimization of RA monitoring. The personal profile including multiplexed cytokine patterns in serum and supernatant may be likely utilized for optimization of therapy introduction and monitoring.

P.A3.02.05

T_{FH}2 and T_{FH}17-Polarized Cells Contribute Highly to Circulating Follicular Help T Cell Response following Measles, Mumps, and Rubella (MMR) Vaccination

G. Elias[1], *E. Bartholomeus*[2], *P. Meysman*[3], *N. De Neuter*[3], *A. Suls*[2], *N. Keersmaekers*[1], *H. Jansens*[4], *S. van der Heijden*[1], *E. Smits*[1], *N. Hens*[1], *K. Laukens*[3], *P. Beutels*[1], *P. Van Damme*[1], *G. Mortier*[2], *V. Van Tendeloo*[1], *B. Ogunjimi*[1];

[1]*Vaccine and Infectious Disease Institute, University of Antwerp, Antwerp, Belgium,* [2]*Centre of Medical Genetics, University of Antwerp, Antwerp, Belgium,* [3]*Advanced Database Research and Modelling (ADReM), Department of Mathematics and Computer Science, University of Antwerp, Antwerp, Belgium,* [4]*Department of Microbiology , Antwerp University Hospital, Antwerp, Belgium.*

The sequence of immunological pathways that cooperate in the successful induction of protective antibody response is not completely understood in humans. T follicular helper (T_{FH}) cells provide help to B cells in germinal centres, in which class switching, affinity maturation, and generation of long-lived plasma cells and memory B cells occur. However, studying T_{FH} in humans is difficult since secondary lymphoid tissues are only accessible through invasive techniques.
Recently, circulatory $CXCR5^+$ $CD4^+$ T cells have been shown to represent memory counterparts of bona fide T_{FH} cells in peripheral blood. Circulatory T_{FH} (cT_{FH}) were further shown to be constituted of three major subsets based on the expression of two chemokine receptors, CXCR3 and CCR6. In this paradigm, T_{FH}2 and T_{FH}17- polarized responses ($CXCR3^-$ $CCR6^-$ and $CXCR3^-CCR6^+$, respectively) proved to be superior to T_{FH}1- polarized responses ($CXCR3^+CCR6^-$) in helping B cells. Interestingly, in longitudinal studies following influenza vaccination, activated cT_{FH} were shown to be T_{FH}1-polarized but not T_{FH}2 or T_{FH}17-polarized. Here, we show that following administration of a measles/mumps/rubella (MMR) vaccine, cT_{FH} are more diversely polarized, in which T_{FH}2 and T_{FH}17-polarized responses accompany the inferior T_{FH}1-polarized response. We observed a peak of cT_{FH} activation at day 3, decreasing at day 7 and returning to the initial level of activation at day 21. These data provide insights into the cT_{FH} cell biology and dynamics and further support the notion that vaccine strategies that promote superior cT_{FH} cell responses may improve vaccine efficacy.

P.A3.02.06

Tracking dye-independent approach to identify and sort viable antigen-specific T cells

G. Elias*, B. Ogunjimi, V. Van Tendeloo;*
Vaccine and Infectious Disease Institute, University of Antwerp, Antwerp, Belgium.

Proliferation after antigen encounter is a key feature of T cells contributing to the robust recall immune responses that form the basis of vaccination. Proliferation assays are used to study T cell function and for immune monitoring. Proliferative capacity of T cells is routinely assessed *in vitro* using tracking dyes such as carboxyfluorescein succinimidyl ester (CFSE) or through detecting intracellular upregulation of the nuclear protein, Ki-67. However, labelling with tracking dyes is cumbersome, toxic to cells and demands extensive washing, resulting in a substantial loss of cells, while nuclear Ki-67 staining cannot be used when sorting viable cells, thereby limiting its applicability.
Here we introduce a flow cytometric technique for identification of proliferating T cells that is dye-independent and allows for sorting of viable cells. CD71, a transferrin receptor, and CD98, an amino acid transporter, have been described as surface markers of T-cell activation. We show here that CD71 and CD98 upregulation plateaued 24 and 48 hours after stimulation, respectively, and that CD71 expression peaked on the more recent progeny T cells while CD98 upregulation was more stable on dividing cells up to 6 days of expansion. We further demonstrate that αβ T cells and γδ T cells bearing upregulated expression of CD71 and CD98 were also $CFSE_{low}$ and Ki-67^{high} T cells.
In conclusion, we show that CD71 and CD98 can be used to identify and sort viable antigen-specific T cells following *in vitro* expansion and provides a valid alternative to assays based on tracking dyes or Ki-67 upregulation.

P.A3.02.07

The measurement of IP-10 release in the Bovigam PC-EC and PC-HP assays for the optimal diagnosis of Bovine tuberculosis in African buffaloes (*Syncerus caffer*).

W. J. Goosen*;*
Stellenbosch University, Cape Town, South Africa.

Background: African buffaloes (*Syncerus caffer*) are a maintenance host of *Mycobacterium bovis*, the cause of bovine tuberculosis (bTB). The control of bTB in buffaloes relies on use of the single intradermal comparative tuberculin test (SICTT) and interferon gamma (IFN-γ) release assays (IGRAs) such as commercial Bovigam assays. However, the diagnostic sensitivities of these IGRAs are still believed to be sub-optimal. We aimed to evaluate the diagnostic utility of measuring antigen-dependent interferon gamma-induced protein 10 (IP-10) release as an alternative to measuring IFN-γ levels.
Materials and Methods: *M. bovis*-exposed buffaloes were tested using the SICTT and Bovigam assays, i.e. purified protein derivative (PPD) assay, PC-EC assay and PC-HP assay, and a modification of the PPD assay. Animals positive on any IGRA were slaughtered (n = 63) and classified as *M. bovis*-infected to culture (n = 35) or both culture and bTB pathological findings (n = 41). The relative sensitivity of the SICTT, each IGRA and IP-10 release assay were calculated as the proportion of *M. bovis*-infected testing positive and the diagnostic agreement between assays.
Results: Confirmed *M. bovis*-infected animals: the IP-10(HP) assay showed greatest test sensitivity and the best agreement with the IP-10(EC) assay. The Bovigam PPD assay in combination with either the IP-10(HP)- or the IP-10(EC) assay resulted in the optimal diagnostic sensitivity for both cohorts.
Conclusion: The IP-10(HP) assay had the highest individual relative sensitivity and combining the Bovigam PPD assay with any IP-10 assay produced an optimal combination of blood tests that successfully detected all *M. bovis*-infected animals.

P.A3.02.08

Sample aging profoundly reduces monocyte-, but not T-cell-driven innate immune responses in human whole blood cultures

W. Grievink*, M. Moerland;*
Centre for Human Drug Research, Leiden, Netherlands.

Human whole blood cultures are widely used for investigation of physiological pathways and drug effects *in vitro*. Detailed information on the effect of 'sample aging' (the time-span between blood collection and experimental start) on the experimental outcome is not readily available in the public domain. We studied the effect of sample aging on the ability of immune cells to respond to cell-specific immune triggers (LPS, PMA/ionomycin, SEB). Sample aging at room temperature profoundly inhibited the LPS-induced monocytic cytokine release in minimally diluted whole blood cultures. The reduction ranged from 20-50% after 30 minutes to 80-100% after 10 hours, and differed between cytokines (IL-1β, IL-2, IL-6, IFNγ, TNFα). Sample storage at 4ºC or 37ºC even worsened this. In contrast, PMA/ionomycin- and SEB-induced cytokine release, both mainly T-cell-driven, remained much more stable during sample storage. Intracellular cytokine staining revealed that the number of LPS-responding cells was not impacted by sample aging, and reduced LPS responsivity could also not be explained by apoptosis or downregulated TLR4 expression. Addition of culture medium during aging did not result in a more stable monocyte response to LPS during aging. Thus, we speculate that sample aging induces an inhibitory pathway downstream from TLR4 in monocytes. These results underline the importance of quick sample handling when investigating innate immune responses in whole blood, especially for monocyte responses.

P.A3.02.09

IL-7 induces an epitope masking of common gamma chain protein in IL-7 receptor signaling complex

Y. Jo, B. Lee, G. Kim, ***C. Hong****;*
Pusan National University, Yangsan, Korea, Republic of.

IL-7 signaling via IL-7Rα and common γ-chain (γc) is necessary for the development and homeostasis of T cells. Although the delicate mechanism in which IL-7Rα downregulation allows the homeostasis of T cell with limited IL-7 has been well known, the exact mechanism behind the interaction between IL-7Rα and γc in the absence or presence of IL-7 remains unclear. Additionally, we are still uncertain as to how only IL-7Rα is separately downregulated by the binding of IL-7 from their IL-7Rα/γc complex. We demonstrate here that 4G3, TUGm2, and 3E12 epitope masking of γc protein is induced in the presence of IL-7, indicating that the epitope alteration is induced by IL-7 binding to the preassembled receptor core. Moreover, the epitope masking of γc protein is inversely correlated with the expression of IL-7Rα upon IL-7 binding, implying that the structural alteration of γc might be involved in the regulation of IL-7Rα expression. The conformational change in γc upon IL-7 binding may not contribute only to form the functional IL-7 signaling complex but also to optimally regulate the expression of IL-7Rα.

P.A3.02.10

Fecal galectin-3 - new promising biomarker for severity and progression of colorectal carcinoma

M. Jurisevic*, N. Gajovic, N. Zdravkovic, M. Jovanovic, M. Jovanovic, D. Vojvodic, I. Jovanovic;*
Center for Molecular Medicine and Stem Cell Research, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia.

The aim of study was to determine systemic and fecal values of Galectin-3, pro- and anti-inflammatory cytokines, in patients with CRC and the relationship with clinicopathological aspects. Concentrations of Galectin-3, TNF-α, TGF-β, IL-10 and IL-1β were analyzed in samples of blood and stool of 60 patients with CRC. Systemic concentration of TNF-α was significantly lower in patients with severe disease (advanced TNM stage, nuclear grade and poor histological differentiation) as in patients with more progressive CRC (lymph and blood vessels invasion, presence of metastasis). Fecal values of anti-inflammatory cytokines TGF-β and IL-10 were increased in patients with severe stadium of CRC.

Fecal concentration of Gal-3 was enhanced in CRC patients with higher nuclear grade, poor tumor tissue differentiation, advanced TNM stage and metastatic disease. Gal-3/TNF-α ratio in sera and feces had a higher trend in patients with severe and advanced disease. Positive correlation between fecal Gal-3 and disease severity, tumor progression and biomarkers AFP and CEA, respectively was also observed. Predomination of Gal-3 in patients with advanced disease may implicate on its role in limiting ongoing proinflammatory processes. The fecal values of Gal-3 can be used as valuable marker for CRC severity and progression.

P.A3.02.12

Complement component C1q as serum biomarker to detect active tuberculosis

R. Lubbers[1], *J. Sutherland*[2], *D. Goletti*[3], *F. A. Verreck*[4], *A. Geluk*[1], *T. H. Ottenhoff*[1], *S. A. Joosten*[1], *L. A. Trouw*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Medical Research Council Unit, Banjul, Gambia,* [3]*National Institute for Infectious Diseases, Rome, Italy,* [4]*Biomedical Primate Research Centre, Rijswijk, Netherlands.*

Introduction: Tuberculosis (TB) remains a major threat to global health. Currently, diagnosis of active TB is hampered by the lack of specific biomarkers that discriminate active TB from other (lung) diseases or latent TB infection (LTBI). The complement system is an important part of the innate immune system and integrated gene expression analyses have revealed that complement genes, in particular the C1q genes, were expressed at higher levels in active TB compared to LTBI.
Methods: C1q protein levels were determined using ELISA in sera from patients, from geographically distinct populations, with active TB, LTBI as well as disease controls.
Results: Serum levels of C1q were increased in active TB compared to LTBI in four independent cohorts and discriminated with an AUC of 0.77 [0.70 ; 0.83]. After six months of TB treatment, levels of C1q had normalized to those of endemic controls, indicating an association with disease rather than individual genetic predisposition. Importantly, C1q levels in sera of TB patients were significantly higher as compared to patients with sarcoidosis or pneumonia, clinically differential diagnoses. Moreover, exposure to other mycobacteria such as *M. leprae* (leprosy patients) or BCG (vaccinees) did not present with elevated levels of serum C1q. In agreement with the human data, in non-human primates challenged with *Mycobacterium tuberculosis*, increased serum C1q levels were detected in animals that developed progressive disease.
Conclusions: Circulating C1q is a novel TB biomarker, which discriminates active TB from most other conditions, including other lung diseases, and could have added value in diagnosing TB.

Cellular immune response to T3SS proteins in humans vaccinated with live bacterial vaccine

A. M. Lyapina[1], *V. A. Feodorova*[1,2], *S. S. Zaitsev*[1], *M. A. Khizhnyakova*[1,2], *L. V. Sayapina*[3], *M. V. Telepnev*[4], *O. V. Ulianova*[1], *E. P. Lyapina*[5], *S. S. Ulyanov*[1,6], *V. L. Motin*[4];
[1]*Laboratory for Molecular Biology and NanoBiotechnology, Federal Research Center for Virology and Microbiology (FRCViM), Branch in Saratov, Saratov, Russian Federation,* [2]*Department for Microbiology, Biotechnology and Chemistry, Saratov State Agrarian University named after N.I. Vavilov, Saratov, Russian Federation,* [3]*Department of Vaccine Control, Scientific Center on Expertise of Medical Application Products, Moscow, Russian Federation,* [4]*Department of Pathology, Department of Microbiology & Immunology, University of Texas Medical Branch, Galveston, United States,* [5]*Department for Infectious Diseases, Saratov State Medical University named after V.I. Razumovsky, Saratov, Russian Federation,* [6]*Department for Medical Optics, Saratov State University, Saratov, Russian Federation.*

Type III Secretion System (T3SS) is a special “nanomachine” widely used by Gram-negative bacteria for the delivery of effector proteins to mammalian target cells. In fact, T3SS components may participate in eliciting effective adaptive response. In this study we investigated human cellular immune response to the live plague vaccine (LPV), an attenuated *Y. pestis* EV strain line NIIEG possessing T3SS. Highly pure T3SS recombinant proteins, LcrV and YopM, were used for the *in vitro* stimulation of PBMCs collected from multiply immunized donors (n=18) and naïve control individuals (n=6) to assess lymphocyte proliferation and Th1/Th2/Th17 polarization. We found that although there was no significant difference between vaccinated and control groups in proliferative responses to all antigens, re-stimulation with YopM induced a high proliferative reaction of lymphocytes from vaccinees exceeding those with control F1 antigen ($p>0.05$) and LcrV ($p<0.001$) 2.1-fold and 3.3-fold respectively. Marked proliferative response to YopM was accompanied by high production of IFN-γ and TNF-α, which was specific for vaccinees ($p<0.05$). On the contrary, F1 stimulus specifically induced mixed Th1/Th2 response with IFN-γ, TNF-α and IL-4 secretion in vaccinees ($p<0.01$). *In vitro* stimulation with LcrV induced an increased secretion of IL-10 exclusively in vaccinated persons ($p<0.05$), while the similar response to YopM and F1 was nonspecific ($p>0.05$). In conclusion, we have shown that T3SS effector protein YopM, but not LcrV, is likely to be strongly involved in the cellular response elicited by LPV in humans. This antigen-specific response was Th1-polarized. This study was supported by the RFBR #18-016-00159.

P.A3.02.14

IL-10 and IL-17 chronic low grade inflammation marker in colorectal cancer patients and healthy elderly

I. Pantsulaia[1], *A. Aladashvili*[1], *M. Iobadze*[1], *N. Kikodze*[1], *T. Atamashvili*[1], *T. Chikovani*[2];
[1]*Vl.Bakhutashvili Institute of Medical Biotechnology, Tbilisi State Medical University, Tbilisi, Georgia,* [2]*Tbilisi State Medical University, Tbilisi, Georgia.*

Background: Permanent exposure of environmental factors and numerous interactions with pathogen leads to a chronic inflammatory state in older individuals. In fact, acute inflammation is a beneficial process but with ageing it becomes chronic and leads to tissues dysfunction or degeneration. Recently, many studies have been demonstrated that chronic inflammation is associated with all stages of cancer development increasing its risk, supporting and promoting cancer progression. Moreover preventive treatment with anti-inflammatory drugs like aspirin reduces the incidence and mortality for colorectal cancer. Consequently, evaluation inflammatory state in different tumors and age matched individuals is essential for designing new personalized treatments. **Aim:** The main aim of our study was to evaluate the alterations of cytokine (IL-17, IL-10, IL-22, TNF-a, IL-6, IL-4 and IFN gamma) plasma levels in colorectal (n=50) and elderly population (n=150). Plasma specimens from studied individuals were obtained in the morning after fasting. The samples were analyzed using ELISA kits. **Results:** The IL-10, IL-17, IL-22 levels was higher in colorectal cancer patients than healthy individuals. IL-10 concentrations were significantly ($P<0.01$) decreased in elderly group comparing to young people. On the contrary to IL-10, IL-17 levels were higher in aged persons than young population. The correlations among studied cytokines were strong and significant in both groups. **Conclusion:** The outcomes of study suggest a shift the inflammatory status in elderly population, however, could not prove a clear and strong polarization. The ratio of IL-10/IL-17 concentrations should be used as indicator of declining health in aged individuals.

P.A3.02.15

Utility of serum levels of interleukin 13 in patients with sarcoidosis.

P. Sohal[1], *K. Upadhyay*[1], *A. Ali*[1], *H. Aggarwal*[2], *M. Goel*[1], *V. Singh*[3], *K. Madan*[1], *A. Mohan*[1], *R. Guleria*[1];
[1]*Pulmonary Medicine and Sleep Disorders, AIIMS, New delhi, India,* [2]*Biochemistry, AIIMS, New delhi, India,* [3]*Biostatistics, AIIMS, New delhi, India.*

Introduction: Cytokines are inflammatory mediators which play an important part in immunopathognesis of sarcoidosis. Cytokine IL-13 produced by type 2 helper T cells (TH2), mast cells, eosinophils and basophils, is the key mediator during effector phase of allergic inflammation. Our study aimed to describe the variations of serum levels of IL-13 among patients with sarcoidosis and healthy controls. **Methods:** In this study 57 newly diagnosed sarcoidosis patients and 32 healthy controls were enrolled. A total of 27 sarcoidosis patients were followed up for six months after initiation of treatment. Serum levels of IL-13 were measured using Enzyme-linked Immunosorbent Assay (ELISA) among sarcoidosis patients at baseline, post six months of treatment and healthy controls. **Results:** Median (range) of serum IL-13 levels in patients with sarcoidosis at baseline, after treatment and in healthy controls were 16.12 (7.289-93.90)pg/ml, 14.81 (7.77-29.51)pg/ml and 11.59 (4.265-31.24) pg/ml respectively. The IL-13 levels were higher among patients at baseline compared to healthy controls ($p=0.01$). IL-13 levels were significantly reduced among patients after six months of treatment as compared to baseline ($p=0.03$). There was no significant difference in IL-13 levels after follow up when compared to healthy controls. **Conclusion:** The data shows the involvement of IL-13 in inflammation of sarcoidosis and can be a useful marker of disease activity. Serum IL- 13 levels at baseline may significantly aid in diagnosis of sarcoidosis. To confirm this, large population study is warranted.

P.A3.02.16

Amniotic fluid complement component C3 and complement factor I levels in pregnancies complicated by the preterm prelabor rupture of membranes

O. Soucek[1], *I. Musilova*[2], *C. Andrys*[1], *J. Krejsek*[1], *M. Kacerovsky*[2,3];
[1]*Department of Clinical Immunology and Allergy, University Hospital, Hradec Kralove, Czech Republic,* [2]*Department of Obstetrics and Gynecology, University Hospital, Hradec Kralove, Czech Republic,* [3]*Biomedical Research Center, University Hospital, Hradec Kralove, Czech Republic.*

Introduction: Preterm prelabor rupture of membranes (PPROM) is characterized by the rupture of fetal membranes and leakage of amniotic fluid before onset of regular labor activity prior to gestational age 37 weeks. It is a significant public health problem because it complicates about 3% of all pregnancies (about one-half of spontaneous preterm deliveries) and has a significant health, social and economic impact on society. Etiology of PPROM is not yet fully elucidated, but it is known that is commonly accompanied by microbial invasion of the amniotic cavity (MIAC) and/or intra-amniotic inflammation (IAI). **Objective:** The aim of this study was to determine the amniotic fluid complement component C3 and complement factor I concentrations in women with PPROM based on MIAC, IAI and microbial-associated IAI. **Methods**: One hundred fifty-nine women with singleton pregnancies complicated by PPROM were included in the study. Amniotic fluid samples were obtained by transabdominal amniocentesis and were assayed for complement component C3 and complement factor I concentrations by ELISA tests. **Conclusion:** The presence of IAI and microbial-associated IAI is connected with higher concentrations of complement component C3 and lower concentrations of complement factor I. MIAC alone had no impact on C3 or complement factor I levels in amniotic fluid. The results show that complement may be involved in etiology of PPROM. **Acknowledgments:** This work was supported by the Faculty Hospital in Hradec Kralove and by Charles University in Prague, Faculty of Medicine in Hradec Kralove, Czech Republic, project “PROGRES Q40/10”

P.A3.02.17

Serum levels of BAFF and IL17 induces tissue damage in pauci immune small vessel vasculits and glomerulonephritis

M. Stangou[1], *A. Fylaktou*[2], *D. Daikidou*[1], *C. Nikolaidou*[3], *C. Stamos*[4], *E. Sampani*[1], *E. Moraiti*[1], *A. Papagianni*[1];
[1]*Department of Nephrology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*Department of Immunology, National Peripheral Histocompatibility Center, Hippokration Hospital, Thessaloniki, Greece,* [3]*Department of Pathology, Thessaloniki, Greece,* [4]*Department of Pathology, General University Hospital of Alexandroupolis, Alexandroupolis, Greece.*

Introduction: Renal impairment in small vessel vasculitis (SVV) is characterised by inflammation, proliferation and necrosis. B cell activating or B lymphocyte stimulating factor (BAFF/BLyS) and Interleukin 17 (IL-17) may be involved in the pathogenesis of tissue damage. **Patients-Methods.** BAFF and IL17 levels were measured by ELISA, in serum from 60patients with SVV and glomerulonephritis [33 female, age 57.7yrs (25-80)] collected at the day of renal biopsy, before any treatment was applied, and results were correlated with renal pathology and urinary excretion of INF-γ, IL-10 and G-CSF. Treatment protocol consisted of prednisolone+cyclophosphamide as induction, with or without plasmapheresis, followed by prednisolone+azathioprine for at least 2yrs. Follow up of the patients was 28.8±30months. **Results.** Serum levels of BAFF and IL-17 were significantly increased in SVV patients compared to controls (1601.45±1.34 vs. 960.33±305.24mg/dl, p=0.001 and 21.7±25.9 vs. 12.4±3.8mg/dl, p=0.009 respectively). Both serum BAFF and IL-17 levels were significantly increased in ANCA(+) compared to ANCA(-) patients (1663.5±1309mg/dl vs.1073.8±521.8mg/dl, p=0.02 and 24.9±30mg/dl vs. 15.2±2.8mg/dl, p=0.05, respectively). Serum BAFF levels correlated significantly with urinary IL-10 (p=0.04) and INF-γ (p=0.03), percentage of cellular crescents (p=0.04), while serum IL-17 was correlated with urinary IL-17 levels (p=0.04), degree of interstitial fibrosis (p=0.04) and renal function outcome (p=0.02). **Conclusions.** BAFF and IL-17 are increased in the serum of patients with glomerulonephritis secondary to SVV, especially in the presence of ANCA(+). BAFF at early stages may be implicated in inflammation, through the production of IL-10 and INF-γ, while IL-17 in more advanced stages, induces fibrosis and deterioration of renal function.

P.A3.02.18

Epidermal Growth Factor (EGF) as biomarker of renal function outcome in different forms of primary glomerular diseases.

M. Stangou[1], *A. Fylaktou*[2], *E. Sampani*[1], *C. Nikolaidou*[3], *C. Stamos*[4], *D. Daikidou*[1], *E. Moraiti*[1], *A. Papagianni*[1];
[1]*Department of Nephrology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*Department of Immunology, National Peripheral Histocompatibility Center, Hippokration Hospital, Thessaloniki, Greece,* [3]*Department of Pathology, Hippokration Hospital, Thessaloniki, Greece,* [4]*Department of Pathology, General University Hospital of Alexandroupolis, Thessaloniki, Greece.*

Introduction and aims: EGF acts through EGF receptor and facilitates regeneration of tubular epithelial cells after injury. We investigated the role of urinary EGF excretion as biomarker for pathology and renal function outcome in glomerulonephritis.
Msthods: EGF urinary levels were estimated in 3 forms of glomerular diseases: (1) IgA nephropathy (IgAN), as chronic glomerulonephritis, [n=50, 21female, age 39.8yrs(18-65)], (2) pauci immune rapidly progressive glomerulonephritis (RPGN), as acute glomerulonephritis, [n=38, 17 female, age 59.5yrs(25-80)] and, (3) Nephrotic syndrome (NS) due to focal segmental glomerulosclerosis (FSGS) [n=23, 9 female, age 47.5yrs(19-79)] and minimal change disease (MCD) [n=12, 7female, age 45.5yrs(37-62)]. Ten healthy volunteers were used as controls. First morning urine samples were collected on the day of renal biopsy. Patients were followed up for 7.5±2.1yrs.
Results: EGF urinary levels were: IgAN 0.13±0.2, FSGS 0.19±0.2, MCD 0.7±0.4, RPGN 0.15±0.3, controls 0.14±0.07pg/mgUcr. EGF urinary levels had significant negative correlation with severity of interstitial fibrosis, r=-0.6, p=0.02, in IgAN, with the percentage of fibrous crescents, r=-0.6, p=0.01 in RPGN, and finally, with the percentage of global sclerosed glomeruli, r=-0,5, p=0,04, degree of fibrosis, r=-0.6, p=0.005 and interstitial infiltration, r=-0.6, p=0.01 in patients with NS.
Declining renal function was associated with reduced urinary EGF levels in IgAN (0.04±0.04 vs. 0.2±0.2pg/mgUcr, p=0.01), and FSGS (0.007±0.004 vs. 0.6±0.04pg/mgUcr, p=0.009), but not in RPGN (0.05±0.1 vs. 0.2±0.4pg/mg cr, p=NS).
Conclusions: Reduction of EGF urinary levels in patients with glomerulonephritis is associated with "chronic" histological changes, and can predict renal function outcome mainly in patients with chronic forms of glomerulonephrits.

P.A3.02.19

Circulating cytokines predict response to anti-PD1 therapy in NSCLC

I. Zizzari, *M. Dionisi, A. Botticelli, A. Di Filippo, F. Di Pietro, C. Scopelliti, A. Ugolini, C. Napoletano, A. Rughetti, P. Marchetti, M. Nuti;
Sapienza University of Rome, Rome, Italy.*

Background: Despite the recent successes of immunotherapy in the treatment of non small cell lung cancer (NSCLC), only 20-30% of patients have a long-term benefit from immunotherapy, while the remaining 70-80% result resistant. The identification of responder patients represents the open issue of immunoncology. In the context of several biomarkers the study of cytokine profile represents a promising approach. Chemokines, such as CXCL10 and sICAM, can facilitate chemotactic recruitment of TILs thus favouring their intratumoral trafficking accumulation and increasing the immune response against tumor. In the present study, we explored the prognostic impact of circulating cytokines in 18 NSCLC patients undergoing anti-PD-1 treatment.**Methods**: Sera from 18 NSCLC patients in treatment with nivolumab, were analysed using the ProcartaPlex Human Inflammation Panel. Samples were measured by BioPlex Magpix Multiplex Reader and data analysis was performed using Bioplex Manager MP software.**Results:** Seven out of 18 patients presented early progression, defined as progression of disease within 6 months from the beginning of nivolumab treatment. The median value of CXCL10 and sICAM in early progressor patients were 1339 pg/ml and 255202 pg/ml respectively, while in no progressor patients were 2334 pg/ml for CXCL10 and 370000 pg/ml for sICAM. We found a significant association between the circulating levels of the chemokine CXCL10 and sICAM and early progression (p<0.05).**Conclusions:** CXCL10 and sICAM seem to be associated with response to immunotherapy and could predict resistance to anti-PD-1 treatment. These preliminary results suggest the possibility of design and select alternative strategies to overcome the resistance in progressor patients

P.A3.02.20

Methods for whole blood immunomonitoring of clinical samples for flow and mass cytometry studies.

P. Rybakowska[1], *C. Burbano*[1], *R. Aguilar Quesada*[2], *C. Marañón*[1], *M. E. Alarcón Riquelme*[1,3];
[1]*Genyo. Centre for Genomics and Oncological Research: Pfizer / University of Granada / Andalusian Reg, Granada, Spain,* [2]*Biobanco del Sistema Sanitario Público de Andalucía, Andalusian Public Health System Biobank, Granada, Spain,* [3]*Institute for Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

The multicentric PRECISESADS project aims at the molecular re-classification of the systemic autoimmune diseases combining molecular and cellular -omics, including flow and mass cytometry. Therefore to avoid center bias and technical variations we considered the preservation of collected samples until the time of analysis. Herein we compare two buffers for whole blood fixation and cryopreservation: Smart Tube Proteomic Stabilizer (PROT1) and BD phosphoflow lyse/fix buffer (BD). Eight surface markers were verified using flow cytometry, and 15 surface and 8 intracellular markers were verified for mass cytometry upon R848 stimulation in fresh blood, and compared with the results obtained after fixation and freezing. The verified storage time was 1 and 6 months for flow and 1 month for mass cytometry. Our data show that whole blood can be preserved and stored until acquisition; however care needs to be taken when designing the antibody panel. In flow cytometry BD buffer allows monocyte/granulocyte discrimination based on FSC/SSC, while with PROT1 granulocytes or monocytes marker is needed. In both technologies similar percentages of major leucocytes and their subpopulations were observed when comparing the two fixation methods to the unfixed condition. A cytokine response study can be done using both buffers, as we did not observe significant differences between the two products. We consider blood preservation as a good method for immunomonitoring of samples that minimizes center bias and technical variation in both flow and mass cytometry studies. Financial support: IMI-JU, GA [115565], with financial contribution from the EU FP7, EFPIA & SANOFI.

Maximizing human immune monitoring studies with mass cytometry

C. Loh[1], *T. Selvanantham*[1], *L. Fung*[1], *M. P. Poulin*[1], *C. B. Bagwell*[2], *M. Inokuma*[2], ***C. E. Rogers***[1], *S. T. Lott*[1];
[1]*Fluidigm, South San Francisco, United States,* [2]*Verity Software House, Topsham, United States.*

Immune monitoring is an essential method for quantifying changes in immune cell populations in chronic inflammation, infectious disease, autoimmune disease and cancer studies. The extreme heterogeneity of immune cells demands a high-parameter approach to more fully and efficiently quantify the immune response in health and disease. Mass cytometry is an ideal solution, enabling the simultaneous detection of over 40 phenotypic and functional markers in a single tube of sample. We report development of a 29-marker panel for mass cytometry based on the Human ImmunoPhenotyping Consortium (HIPC) consensus panel [Maecker et al. *Nature Reviews Immunology* (2012)], expanded to allow identification of additional leukocyte subsets, particularly T cells. Automated data analysis with Verity Software House GemStone™ software has been developed specifically for data collected with the panel. Extensive panel testing for repeatability, reproducibility and agreement of full versus partial panel population identification was performed. Repeatability was tested with a single PBMC sample stained by a single technician in two technical replicates and acquired in triplicate on two Helios™ mass cytometers. SDs for percent of parent were 1% or less for 16 identified populations. Reproducibility was tested by determining the variability in measurements of five PBMC lots stained by five technicians and collected on two Helios instruments. CVs on mean percent of 13 populations were under 15% for all but three of 130 measurements. Lastly, R^2 values for agreement of percent parent populations using the full 29marker panel compared to a 10marker panel for T cell populations were 0.94 or higher.

In depth analysis of antibody reactivities directed against numerous citrullinated peptides derived from the human proteome

H. Thiesen[1], *F. Steinbeck*[2], *E. Schade*[2], *S. Drynda*[3], *J. Kekow*[4];
[1]*Institute of Immunology, Rostock, Germany,* [2]*Gesellschaft für Individualisierte Medizin, Rostock, Germany,* [3]*Helios Fachklinik Vogelsang-Gommern, Gommerrn, Germany,* [4]*Helios Fachklinik Vogelsang-Gommern, Gommern, Germany.*

Introduction: Our analysis is driven by the interest to select citrullinated peptides whose sequences are derived from the human proteome. Panels of peptides were determined that show differential epitope-antibody-reactivities (EAR) as initially found in intravenous immunglobulin preparations, see PMID: 27059896 and PMID: 24244326. Method: Highdensity peptide microarrays representing pairs of peptides were incubated with sera of patients suffering from CCP positive versus CCP negative rheumatoid arthritis (RA). The paired peptides carry either an arginine, whereas the other the same sequence but the arginine replaced by a citrulline The most informative citrullinated peptides were then comparatively evaluated by applying MSD multi-array analysis. Ten different peptides placed per well were either incubated with sera of blood donors or of substratified RA patients. Results: In total, 96 different citrulinated peptides were finally characterized of which 63 were further studied in multi-array analysis, leading to distinct subsets of human derived citrullinated peptides. One peptide panel has the potential to replace the commerical CCP assay, the other panel stratifies CCP negative RA patients and the third one is suitable to determine putative preClinical RA within blood donors. Conclusion: Our comparative computational analysis of the most informative citrullinated peptides specifies proteins that play major roles in conducting and elicitating immune responses as well as in performing cellular functions of intercellular communication. Our data set represent putative candicate peptides whose antibody reactivity profiles might have great values in determining clinical features being causative in initiation and progression of CCP positive RA disease.

The IgG4:IgG RNA ratio differentiates active disease from remission in granulomatosis with polyangiitis: A new disease activity marker?

A. Al-Soudi[1], *M. Doorenspleet*[1], *R. Esveldt*[1], *L. Burgemeister*[1], *L. Hak*[1], *B. Van den Born*[2], *S. Tas*[1], *R. van Vollenhoven*[1], *P. Klarenbeek*[1], *N. de Vries*[1];
[1]*Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands.*

Objectives: An important limitation in Granulomatosis with Polyangiitis (GPA) is the lack of disease activity markers. Immunoglobulin G4 positive (IgG4+) B-cells and plasma cells are implicated in the pathogenesis of GPA. We hypothesized that the presence of these cells in peripheral blood could serve as biomarker in GPA.
Methods: We included 32 PR3-ANCA positive GPA patients in a cross-sectional study. Active disease was defined as BVAS≥3 (n=14), remission as BVAS of 0 (n=15) and low disease activity (LDA) as BVAS 1-2 and clinical remission (n=3). Healthy subjects (n=10), patients with systemic lupus erythematosus (n=24), and patients with rheumatoid arthritis (n=19) functioned as controls. An additional longitudinal study was performed in 9 GPA patients. Using a validated qPCR test, we measured the IgG4:IgG RNA ratio in all groups and compared the results to known biomarkers.
Results: The median qPCR score was higher in active GPA (20.7; IQR 12.1-29.3) compared with remission/LDA (3.8; IQR 1.9-5.8) (Mann-Whitney U, p<0.0001) and outperformed other known disease activity parameters in detecting activity. A cut-off qPCR score of 11.2% differentiated active disease from remission/LDA accurately (AUC 0.992). The qPCR test correlated well with the BVAS (Spearman r=0.75, p<0.0001). In the longitudinal study, a decrease in BVAS was associated with a qPCR score reduction.
Conclusions: The IgG4:IgG RNA ratio in GPA accurately distinguishes active disease from remission and correlates well with disease activity in these single-center studies. If these results are confirmed in larger and longitudinal studies, this test might help steering treatment decisions in GPA patients.

Research of Anti-GAD and Anti-IA2 autoantibodies by ELISA test in a series of Moroccan pediatric patient with diabetes type 1

O. BELHIBA[1,2], *B. Ahmed Aziz*[3,4], *F. Jennane*[2,3];
[1]*Faculty of Medicine and Pharmacy Hassan II University- Casablanca, Morocco., Casablanca, Morocco,* [2]*Pediatric Endocrinology Unit, Hopital d'Enfant Abderrahim Harouchi Chu Ibn Rochd, Casablanca, Morocco., Casablanca, Morocco,* [3]*Laboratory of Clinical Immunology, Allergy and Inflammation LICIA, Faculty of Medicine and Pharmacy Hassan II University-Casablanca, Morocco., Casablanca, Morocco,* [4]*Clinical Immunology Unit, Infectious Department, Hopital d'Enfant Abderrahim Harouchi, CHU Ibn Rochd, Morocco., Casablanca, Morocco.*

Introduction : Type I diabetes (T1D) is an autoimmune disease with a asymptomatic period characterized by the destruction of insulin-producing β cells. This preclinical phase is of a variable duration during which various autoantibodies are generated against several beta cell antigens such as : Anti Glutamate Acid Decarboxylase (Anti-GAD), Anti Tyrosine Phosphatase (Anti-IA2). **Objectives :** In this work, we want to evaluate the diagnostic value of Anti-GAD and Anti-IA2 antibodies in a series based on 78 Moroccan subjects initially under 16, suspected T1D. **Patients and Methods :** Our study concerns 78 children aged from 1 to 16 years followed for an evocative table of T1D. Samples of patients were analyzed by ELISA tests using Anti GAD and Anti-IA2 commercial kits (EUROIMMUN). **Results and Discussion :** Our series consists mainly of 74% of newly diagnosed patients for T1D and 26% of confirmed diagnostic patients, of whom 52% are females. The mean age of diagnosis is 7 ± 4 years, the mean of HbA1c at the time of diagnosis is 11.63 ± 2.16%, and the percentage of family history in our series is 69%. The proportion of positive results for Anti-IA2 antibodies and Anti-GAD antibodies are respectively 76.92% and 62.82%, and 52.56% of patients are positive for both autoantibodies. **Conclusion :** This study confirmed the diagnosis and the classification of T1D (type 1A) in 87.18% of patients, and we reported that the prevalence of Anti-GAD and Anti-IA2 is higher in girls than in boys.

P.A3.03.03

Analysis of B cell lymphocyte subpopulations in pre and post dialysis end stage renal disease patients

D. Daikidou[1], *A. Fylaktou*[2], *M. Stangou*[1], *D. Asouchidou*[2], *V. Nikolaidou*[2], *E. Sampani*[1], *F. Markovasili*[2], *T. Chronis*[2], *C. Dimitriadis*[1], *A. Papagianni*[1];
[1]*Department of Nephrology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*Department of Immunology, National Peripheral Histocompatibility Center, Hippokration Hospital, Thessaloniki, Greece.*

Introduction and aims: End-stage renal disease (ESRD) is associated with immunodeficiency, which makes a significant contribution to morbidity and mortality. The present study aimed at analysis of B lymphocyte subpopulations in pre- and six months post-dialysis ESRD patients. **Methods:** B cells (CD45+ CD19+) and their subsets B1a (CD19+CD5+), naive (CD19+ CD27−), memory (CD19+ CD27+), CD19+ BAFF+ and CD19+ IgM+, were quantified using flow cytometry in the peripheral blood of 27pre-dialysis and 11 post-dialysis patients.The results were compared to healthy control group. **Results:** ESRD patients had reduced lymphocyte count (1606±655μ/L vs.2459±520μ/L, p<0.001)and B cell (CD19+) count (82.7±54.9μ/L vs.177.6±73.8μ/L, p<0.001)compared to controls. Likewise, whereas the percentages of B cell subsets were not particularly affected, except for B1a subset which presented a significant increase (4.1±3.8% vs. 0.7±0.7% p<0.001), the absolute number of almost all subsets was significantly smaller in ESRD patients (CD19+: 81.3±60.4μ/Lvs. 162.1 ±64.5μ/L, p=0.005, Naive:55.6±46.6μ/Lvs.97.2±46.6μ/L, p=0.004, Memory: 27.1±15.6μ/L vs.83.5±56.8μ/L, p<0.001,CD19+BAFF+:69.5±47.5μ/Lvs. 154.7±74.6μ/L, p<0.001, CD19+IgM+: 58.1±42.7μ/Lvs.117.9±58.94μ/L, p=0.001). In 11 patients who had a follow-up 6 months after starting on renal replacement treatment no differences were found, apart from CD19+IgM+ (74.7±7.4μ/Lvs.post 66.9±14.7μ/L, p=0.041) and B1a percentage (3.0±2.4% vs. 1.0±0.8% p=0.038), which further decreased. **Conclusions:** Significant reduction was noticed in B cells subpopulations in patients with ESRD on pre-dialysis stage, and in some of them further reduction was noticed in post-dialysis stage, and these changes may be implicated in clinical manifestations, such as frequent infections or impaired response to vaccination.

P.A3.03.04

The introduction of*N*-linked glycans in the variable domain of Anti-Citrullinated Protein Antibodies marks the development of Rheumatoid Arthritis.

L. Hafkenscheid[1], *E. de Moel*[1], *I. Smolik*[2], *B. Jansen*[3], *A. Bondt*[1], *M. Wuhrer*[1], *T. Huizinga*[1], *R. Toes*[1], *H. Scherer*[1], *H. El-Gabalawy*[2];
[1]*LUMC, Leiden, Netherlands,* [2]*University of Manitoba, Winnipeg, Manitoba, Canada,* [3]*Ludger Ltd., Culham Science Centre, Oxfordshire, United Kingdom.*

The most prominent biomarker implicated in disease pathogenesis in Rheumatoid arthritis (RA) are anti-citrullinated protein autoantibodies (ACPA). Intriguingly, ACPA can be present years before the disease onset. Therefore it is thought that the development of ACPA-positive disease is a multistep process. The possible sequence of events starts with an environmental event (first hit) that initiates a break of tolerance against citrullinated antigens leading to ACPA production. Upon a certain trigger (second hit) ACPA-B cells receive T-cell help inducing an autoimmune responses resulting in RA. We recently showed that ACPA-IgG display a unique feature by harbouring *N*-linked glycans in the antigen-binding fragment (Fab) and the *N*-glycosylation sites were not germ-line encoded but introduced upon SHM, indicating T-cell help. Therefore we aimed to investigate if the presence of ACPA-Fab-glycosylation is an indicator of the second hit. We analysed the ACPA-IgG Fab-glycosylation in indigenous North-American first-degree relatives (FDR) that developed RA overtime and in ACPA-positive FDR that did not. The data showed that ACPA-positive individuals that stayed healthy had indeed lower levels of ACPA-Fab-glycosylation compared to ACPA-positive FDR that developed RA. This indicates that glycans are involved in the disease progression and could predict when an ACPA-positive individual is at risk to develop disease.

P.A3.03.05

Clinical usefulness of autoantibodies to M-type phospholipase A2 receptor for diagnostic and monitoring disease activity in idiopathic membranous nephropathy

***d. khelifi touhami**, y. lounici, s. Amoura, M. Benhalima;*
Mustapha bacha teaching hospital, Algiers, Algeria.

Objectives PLA2R is the major target antigen in adult idiopathic membranous nephropathy (iMN). This study aimed to assess these antibodies (Abs) prevalence and specificity in a cohort of iMN Algerian patients and to correlate this Abs with clinical parameters reflecting the disease activity. **Patients and methods** We measured anti-PLA2R Abs using an immuno-enzymatic assay in the serum of 40 patients with iMN, 09 with secondary MN and 10 with other forms of primary glomerular diseases.
Anti-PLA2R Abs levels were correlated with proteinuria, serum albumin and serum creatinine in IMN patients. In 6 anti-PLA2R positive iMN patients, Abs levels were assessed at various stages of clinical disease and correlated with disease activity. **Results** Anti-PLA2R Abs were detected in 57,5% of iMN patients, but not in secondary MN or other forms of primary glomerular diseases. In 24 iMN patienst, proteinuria was >3g/24h at the time Abs measurement. 23 (91,66%) of them were positive for PLA2R Abs, while in 14 patients, proteinuria was < 3g/24h. Among them, only 1 patient was positive for Abs. In iMN patients, Abs levels correlated positively with proteinuria and negatively with serum albumin. No correlation was found between Abs and serum creatinine. During the clinical course of the 6 anti-PLA2R positive patients, Abs levels correlated with clinical status, which were high at the active phase disease and decreased during remission. **Conclusions** anti-PLA2R Abs is a sensitive and specific test for iMN. Abs levels correlate with clinical disease activity, there measurement may provide a tool for monitoring disease activity.

P.A3.03.06

Gene expression profile of tolerogenic dendritic cells differentiated with vitamin D3, dexamethasone and rapamycin

***J. Navarro-Barriuso**[1], M. Mansilla[1], B. Quirant-Sánchez[1], A. Teniente-Serra[1], Á. Sánchez-Pla[2], M. Naranjo-Gómez[1], C. Ramo-Tello[3], E. Martínez-Cáceres[1];*
[1]Germans Trias i Pujol University Hospital and Research Institute, Campus Can Ruti, Badalona, Spain, [2]Department of Statistics. University of Barcelona, Barcelona, Spain, [3]Germans Trias i Pujol University Hospital, Campus Can Ruti, Badalona, Spain.

Background: Tolerogenic dendritic cell (tolDC)-based therapies have become promising approaches for the treatment of autoimmune diseases by their potential ability to restore immune tolerance in an antigen-specific manner. There is a broad variety of protocols to generate tolDC *in vitro*, being their differentiation in the presence of vitamin D3 (vitD3-tolDC), dexamethasone (dexa-tolDC) or rapamycin (rapa-tolDC) three of the most frequent. However, the characteristics of these cells are very heterogeneous, thus making the need to find common genetic pathways and biomarkers of high relevance.
Objective: To compare the transcriptomic profile of vitD3-tolDC, dexa-tolDC and rapa-tolDC in order to find common induced pathways and biomarkers.
Methods: Monocyte-derived dendritic cell differentiations of immature (iDC), mature (mDC), vitD3-tolDC, dexa-tolDC and rapa-tolDC from 5 healthy donors were generated, and a microarray analysis was performed (Affymetrix). Results were normalized and filtered, and differentially expressed genes (DEG) were selected. A Gene Set Enrichment Analysis (GSEA) was performed to select common enriched pathways. Statistical analyses were performed using R software.
Results: Common DEG could not be found for the three tolDC, although 14 genes (many of them immune-related) appeared up-regulated in at least one condition. GSEA revealed 11 common protein sets differentially expressed in tolDC. However, all of them were induced for vitD3-tolDC and dexa-tolDC, while down-regulated in rapa-tolDC.
Conclusions: The analysis revealed that, despite not sharing potential common biomarkers, vitD3-tolDC and dexa-tolDC presented similar transcriptomic profiles, suggesting an induction of immune tolerance through common pathways, while rapa-tolDC seem to develop their function through different ones.

P.A3.03.07

Higher responsiveness of CLL cells to B-cell receptor stimulation is associated with reduced expression of inhibitory molecules of the NF-κB pathway

***R. W. J. Meijers**[1], A. F. Muggen[1], L. G. Leon[1], O. B. Corneth[2], R. W. Hendriks[2], J. J. van Dongen[1], A. W. Langerak[1];*
[1]Dept. of Immunology, Erasmus MC, Rotterdam, Netherlands, [2]Dept. of Pulmonary Medicine, Erasmus MC, Rotterdam, Netherlands.

Background Chronic lymphocytic leukemia (CLL) is a heterogeneous disease based on both clinical and biological characteristics. We previously described (Muggen et al, Leukemia, 2015) differences in Ca^{2+}-levels among CLL cases (both basal and upon B-cell receptor (BCR) stimulation). Such differences in BCR responsiveness could reflect a heterogeneity in CLL pathogenesis due to cell-intrinsic factors.
Aim To elucidate cell-intrinsic differences between BCR-unresponsive and BCR-responsive CLL patients.
Methods From 52 CLL cases, the BCR-responsiveness was determined *ex vivo* based on Ca^{2+}-influx upon α-IgM stimulation. Phosphorylation levels of various BCR-signaling molecules, as well as the expression of activation markers were assessed by flow cytometry. Transcription profiling of BCR-responsive (n=6) and BCR-unresponsive CLL cases (n=6) was performed by RNA sequencing. RQ-PCR was used to validate transcript level differences.
Results The increase in Ca^{2+} after α-IgM stimulation was accompanied by higher phosphorylation of PLCγ2, Akt and higher surface expression levels of CD21, CD38, CD80 and CD27. RNA sequencing revealed differences between the two groups, especially in expression of NF-κB pathway genes. RQ-PCR validation in additional CLL cases confirmed the lower expression of the critical NF-κB inhibitors *NFKBIB* (p=0.021) and *NFKBIE* (p=0.009) genes in BCR-responsive CLL. Likewise, expression of the potential NF-κB inhibitors *NFKB1* (p=0.017) and *NFKB2* (p=0.009) was reduced.
Conclusion From our data we conclude that BCR-responsive CLL cells have a more activated cell surface phenotype and reduced expression of components that are associated with inhibition of NF-κB signaling. These findings illustrate that enhanced NF-κB activation is critical for the BCR responsiveness of CLL cells.

P.A3.03.08

Circulating Dendritic cells and monocyte subsets in multiple sclerosis patients

***A. Monteiro**[1,2], C. Cruto[3], P. Rosado[3], L. Rosado[3], M. Fonseca[1], A. Paiva[4];*
[1]CICS-UBI- Centro de Investigação em Ciências da Saúde, Covilhã, Portugal, [2]Serviço Patologia Clínica, Centro Hospitalar Cova da Beira, Covilhã, Portugal, [3]Serviço Neurologia, Centro Hospitalar Cova da Beira, Covilhã, Portugal, [4]Unidade de Gestão Operacional de Citometria, Serviço de Patologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Dendritic cells (DCs) and monocyte have been considered key players in multiple sclerosis (MS), an autoimmune demyelinating disease of the central nervous system. We propose to characterize phenotypically circulating DCs and monocytes subsets in remission and relapsing RR (relapsing-remitting)MS patients treated with interferon beta (IFN-β) comparing with healthy controls. 38 patients with RRMS, 30 of them in remission and 8 in relapse were included in this study, as well as, 20 healthy age- and gender-matched volunteers. The study was approved by Centro Hospitalar Cova da Beira Ethics Committee. By flow cytometry, and based on the expression of CD123, HLA-DR, CD14, CD16 and CD33, were identified and characterized: plasmacytoid DC (pDC), myeloid DC (mDC), classical monocytes, intermediate monocytes (HLA-DR^{dim+} or HLA-$DR^{bright+}$) and non-classical monocytes. Moreover, the expression of CD11c, CD54 and CD123 was evaluated in all subsets. The ratio mDC/pDC was significantly decreased in remission when compared to relapsing patients and healthy controls. Concerning monocytes subpopulations, we observed a decrease in the frequency and absolute number of non-classical monocytes in both disease stages. Interestingly, a bimodal expression of CD54 on pDCs, decreasing in remission and increasing in relapse RRMS, was observed. In the two groups of patients, intermediate monocytes HLA-$DR^{bright+}$ exhibit an increased expression of CD11c, and in relapsing phase a decreased expression of CD123. Alterations in the homeostasis of circulating DCs and monocyte subsets in RRMS patients supports the idea that these cells participate in the pathophysiology of MS and, at least in part, were regulated by the IFN-β treatment.

P.A3.03.09

Chronic Lymphocytic Leukaemia: Increased IL-10 and STAT3 Levels in B cells

***Ö. ÖZCAN**[1], M. GELMEZ[1], S. CİNAR[1], G. DENIZ[1], M. AKTAN[2];*
[1]Istanbul University Aziz Sancar Institute of Experimental Medicine, İstanbul, Turkey, [2]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, İstanbul, Turkey.

Chronic Lymphocytic Leukaemia **(**CLL) is characterized by the accumulation of $CD5^+CD19^+$ B cells in the bone marrow and peripheral blood. Recent studies indicated that expression of IL-10, AID and mir-155 that are regulated by STAT3 are increased in CLL patients. $CD5^+CD19^+$ regulator B (B_{reg}) cells secrete IL-10 and suppress the immune system. While the CLL cells show similar immunophenotypic properties to Breg cells, they are also thought to be functionally similar. In this study, levels of STAT3 and IL-10 in CLL patients were investigated. Peripheral blood samples obtained from patients (n: 24) and healthy subjects (n: 14). Peripheral blood mononuclear cells (PBMCs) were isolated by Ficoll gradient method. PBMCs ($1x10^6$ cell/ml) were cultured for 48 hours in the presence and absence of CpG (1 ug/ml) for IL-10 expression and for STAT3 expression cultured with and without PMA (1 ug/ml) for 15 min. IL-10 and STAT3 expressions were analysed using anti-CD5, anti-CD19, anti-CD38, anti-STAT3 and anti-IL-10 monoclonal antibodies by flow cytometry. Compared to healthy subjects, in lymphocyte population increased $IL\text{-}10^+$, $IL\text{-}10^+CD19^+$ and $STAT3^+CD19^+$ cells were obtained ($p<0.0001$, $p<0.0001$ and $p<0.0001$, respectively). $CD19^+$ B cells showed elevated IL-10 content in CLL patients ($p<0.0001$). Similarly, increased IL-10 levels ($p<0.0001$) were also found in $CD5^+CD19^+$ cells, whereas STAT3 levels were diminished ($p<0.0074$). These results support that for the levels of IL-10 and STAT3 in CLL patients, B cells are clearly different from normal B-lymphocytes might have a role in the biology of CLL.

P.A3.03.10

The role of Natural Killer cells in B cell Acute Lymphoblastic Leukemia

***G. Ozcit**, G. Deniz, Adın-Cınar Suzan, Gelmez M. Yusuf, Yılmaz Abdullah, Aydoğan Gonul;*
Aziz Sancar Institute of Experimental Medicine, Istanbul, Turkey.

In ALL lymphocyte progenitor cells' maturation process break down and proliferation become uncontrollable. Studies suggesting the use of NK cells capable of lysing tumor cells in the treatment of ALL. In this study, the response of NK cells to cytokines in B-ALL cases and the correlation with assessment of minimal residual disease (MRD) by flow cytometry according to International BFM Study Group protocol were investigated. CD7, CD10, CD19, CD34, CD45 cell surface expressions were evaluated to detect B-ALL blast phenotypes. CD3, CD16 and CD56 cell surface expressions were detected in BM and peripheral blood (PB) samples of B-ALL. Mononuclear cells, isolated from PB and BM obtained from B-ALL patients at day of diagnosis, were stimulated with IL-2 for 24 hours and PMA+IO for 5 hours. Intracellular IFN-γ and IL-10 levels in NK cell subsets were determined by flow cytometry. PB $CD3^-CD56^{dim}CD16^-$ and $CD3^-CD56^{bright}CD16^+$ NK cell frequencies were found to be higher than those from BM. Although IL-10 content of $CD3^-CD56^{dim}CD16^+$ and $CD3^-CD56^{bright}CD16^+$ NK cell subsets were decreased, IFN-γ content of both subsets of NK cells were diminished after stimulation both with IL-2 and PMA-IO. After treatment on day 15, IFN-γ levels of $CD3^-CD56^{dim}CD16^+$ NK cells were elevated by IL-2 stimulation only in patients detected as low risk. . Our findings support that increased IFN-γ secreting $CD3^-CD56^{dim}CD16^+$ NK cell subset in FLR patients, after treatment of B-ALL according to the International BFM Study Group protocol, might have an indicator for the following of MRD-ALL at FLR patient.

P.A3.03.11

The Role of Phagocytic Cells in Acute Respiratory Distress Syndrome

***A. Petre**[1], A. Ohradanova-Repic[1], K. Krenn[2], R. Ullrich[2], K. Markstaller[2], H. Stockinger[1];*
[1]Center for Pathophysiology, Infectiology and Immunology, MUW, Vienna, Austria, [2]Department of Anesthesia, General Intensive Care and Pain Medicine, MUW, Vienna, Austria.

Acute respiratory distress syndrome (ARDS) remains a disputed clinical entity in terms of definition, pathophysiological understanding and therapeutic approach. Due to high heterogeneity, ARDS subgroups are best studied individually. Our focus lies on a) ARDS associated with pneumonia and b) ARDS in trauma patients. By means of multicolor flow cytometry, we provide a comprehensive analysis of surface markers in sputum, tracheal aspirate and bronchoalveolar lavage (BAL) cells. Sputum is obtained from lung-healthy volunteers, whereas tracheal aspirate and BAL are collected from lung-heathy intubated patients, as well as from patients diagnosed with ARDS. By comparing samples obtained from lung-healthy controls to those of ARDS patients, we aim to pinpoint cell populations that undergo significant changes in pathological states, with a focus on phagocytic cells (especially granulocytes and macrophages). Once we identify the populations most relevant for the studied condition, we proceed to performing mRNA-Sequencing of the fluorescence-activated cell-sorted phagocytes. By characterizing the expression patterns in ARDS patients depending on the underlying pathology and by discriminating these changes from those induced by mechanical ventilation, this study will provide a basis for identifying individual risk factors and biomarkers of lung disease on the intensive care unit.

P.A3.03.12

Determination of quantity and biological activity of platelet-bound antibodies using Fc-receptors in a single assay using surface plasmon resonance

***Z. Szittner**[1], R. Temming[1], D. Schmidt[1], A. Bentlage[1], R. Visser[1], S. Lissenberg-Thunnissen[1], J. Mok[1], W. J. van Esch[1], M. Sonneveld[1], E. de Graaf[1], M. Wuhrer[2], L. Porcelijn[1], M. de Haas[1], E. van der Schoot[1], G. Vidarsson[1];*
[1]Sanquin, Amsterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands.

Here we describe how surface plasmon resonance biosensor array can be utilized to characterize and determine the biological activity of platelet-bound antibodies. Current methods applying anti-human IgG using whole platelets measure both antibodies targeting the platelets and those bound to platelet FcγRIIa. We hypothesized that this can be overcome using a human FcγR for detection of only Fab-bound antibodies targeting platelets. At the same time this can provide an evaluation reflecting the biological activity of the platelet-bound antibodies. This would improve the diagnostic work up both in fetal and neonatal alloimmune thrombocytopenia (FNAIT) and in immune thrombocytopenia (ITP). To test our hypothesis we compared the binding of chloroquine-treated platelets (removing HLA antigens), opsonized with serum samples from 166 women with anti-HPA-1a antibodies causing FNAIT, to anti-IgG and to FcγR coupled onto the biosensor surface. Our results show that compared to anti-IgG, the binding by FcγR of these opsonized platelets shows a stronger correlation (Pearson's r=0.56 and 0.67, respectively) to the anti-HPA-1a antibody levels measured by monoclonal-antibody immobilization of platelet antigens (MAIPA). In addition, we have combined this technique with anti-complement (C3) and anti-IgA and anti-IgM and show that these features can also be evaluated simultaneously and directly on primary material from patients with ITP (n> 50). These methods show that SPR technology can be applied to get reliable clinically relevant data that go beyond what is possible with current diagnostic techniques.

P.A3.03.13

Heavy/light chain (HLC) ratio measurements in intact immunoglobulin multiple myeloma (IIMM) patients-a single center experience

*I. Kakkas[1], I. Konstantellos[2], S. Delimbasi[2], K. Papageorgiou[1], N. Harhalakis[2], **A. Tsirogianni**[1];*
[1]Immunology-Histocompatibility Dept. "Evaggelismos" General Hospital, Athens, Greece, [2]Hematology & Lymphoma Dept. "Evaggelismos" General Hospital, Athens, Greece.

Aim: The investigation for existence of any prognostic significance of HLC measurements for symptomatic IIMM patients (before treatment initiation) diagnosed and treated in our Hospital.
Patients-Methods: Forty-one newly diagnosed symptomatic IIMM patients were studied. Twenty-five of them were men and 16 women. Their median age was 68 years (range: 43-83). The isotype of paraprotein was in 31 cases IgG and in 10 cases IgA. Patients median follow-up was 16 months (range: 6-24). HLC ratio was determined in all patients before treatment initiation. HLC measurements were performed by using the Hevylite™ assays (The Binding Site Group Ltd, UK) on a SPA PLUS turbidometer.
Results: Statistical analysis was done by using the x^2 test. At the time of last evaluation, 36 patients were alive. Five patients had died due to disease progression and their median survival was seven months (range: 2-14). Extreme HLC ratios (<0.01 or >200) emerged in 14 patients (7/31 IgG and 7/10 IgA, $p < 0.05$). Two out of five deceased patients were IgG and three IgA. Also, four out of the five deceased patients had extreme HLC ratios ($p < 0.05$). It is noted that all three IgA deceased patients emerged extreme HLC ratios ($p < 0.01$).
Conclusions: Despite the limited number of patients in our study, it is clear from the above-mentioned that there is a statistically significant correlation between IgA isotype of paraprotein and HLC ratio extreme values (<0.01 or >200). Also, there is a statistically significant correlation between mortality and HLC ratio extreme values, especially for IgA patients.

P.A3.03.14

Study of soluble vascular endothelial cell adhesion molecules sICAM-1 and sVCAM-1 in hemodialysis patients

*C. Tsigalou[1], T. Konstantinidis[1], **A. Tsirogianni**[2], G. Romanidou[3], K. Kantartzi[3], A. Grapsa[1], M. Panopoulou[1], P. Pasadakis[3];*
[1]Laboratory of Microbiology-Democritus University of Thrace, ALEXANDROUPOLIS, Greece, [2]Immumology-Histocompatibility Dept. Evangelismos General Hospital, Athens, Greece, ATHENS, Greece, [3]Division of Nephrology, Democritus University of Thrace, Alexandroupolis, Greece, ALEXANDROUPOLIS, Greece.

Aim: Cardiovascular complications are the leading cause of mortality and morbidity in patients with end-stage renal disease undergoing chronic hemodialysis (ESRD-HD). Intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) are involved as markers of the atherosclerotic burden.The aim of the study was to determine the level of sICAM 1 and sVCAM-1 in patients with ESRD-HD.
Materials and Methods: The study enrolled 60 patients, mean age 64±13 yrs, ♀ 39(65%) and ♂ 21(35%). The levels of sICAM-1and sVCAM-1 were measured at the beginning and after 6 months by elisa kit (Bender MedSystem, Austria).
Statistical analysis was performed with OriginPro version 8. Student t-test and one way ANOVA were used for data that followed Gaussian distribution, while the Kruskal-Wallis tests were used for data that did not follow the Gaussian distribution. For all measurements, a two-tailed p value ≤0.05 was considered as significant.
Results: The mean value of sICAM-1and sVCAM-1at the start of dialysis was 442.01±215.5ng/mland 11704,83 ±421,4ng/ml respectively. The levels of sICAM-1 after 6 months increased significantly (442.01±215.5ng/ml vs 835,08 ±339ng/ml p<0.0001), but not the levels of sVCAM-1(11704,83 ±421,4ng/ml vs 10461,31±314.7ng/ml p=0,072). Moreover,sICAM-1 was elevated significantly in dialysis patients with co-morbidity of coronary artery disease and diabetes mellitus type II (442.01±215.5ng/ml vs 631,28±134ng/ml =0,089).
Conclusions: A significant increase sICAM-1 at 6 months compared with baseline was observed as evidence for chronic inflammatory/immune system involvement. The role of sVCAM-1 and sICAM-1 as markers of atherosclerosis in chronic renal disease may implicate an upregulation of inflammatory/immune response and may facilitate possible therapeutic interventions.

P.A3.03.15
Incidence of CMV infection in childhood

N. Zotos[1], *P. Christodoulou*[1], *E. Tatsina*[2], *N. Varsamis*[1], *A. Zotou*[3], *F. Adam*[1], *G. Katagis*[1], *L. Papageorgiou*[1], *M. Gianniki*[4], *N. Tsifetaki*[1];
[1]*General Hospital of Ioannina, Greece, Ioannina, Greece,* [2]*Papageorgiou Hospital, Thessaloniki, Greece,* [3]*University Hospital of Ioannina, Ioannina, Greece,* [4]*Agia Sofia Hospital, Athens, Greece.*

Aim: To determine the incidence of CMV infection in children during a two-year period (2016-2017) Method: 980 children of 1-14 years of age who presented to the outpatient department of the hospital with symptoms of the disease or hospitalized from January 2016 until December 2017, were the material of the study. The samples were tested for IgG and IgM antibodies against CMV by ELISA (AxSYM,Abbott).The diagnosis was set either by detecting both IgG and IgM antibodies or by detecting a fourfold elevation of the titer of IgG antibodies in the second serum sample Results: No antibodies were detected in 520 (53%) out of 980 children that were tested for CMV antibodies, while 460 (47%) were positive. 232 (50.4%) were suffering from CMV infection.
139 (59.9%) out of 232 were initially positive only for IgM antibodies, 73 (31.5%) were positive for IgG and IgM antibodies while 20 (8.6%) were positive only for IgG antibodies and presented a fourfold increase of their titer in the second sample. The remaining 228 patients (49.6%) presented a low titer of IgG antibodies in both serum samples. There was no significant difference in two sexes. Epidemiological factors, such as social-economic status, follow-up in daily care centers and cohabitation in large numbers don't correlate with CMV serum-positivity. Conclusion: The study revealed that CMV infection is not rare. Due two severe complications in infancy, it is important to diagnose the disease quickly and efficiently so that proper personalized care is delivered.

P.A3.03.16
Estimation of two serological markers in the diagnosis of rheumatoid arthritis

N. Zotos[1], *P. Christodoulou*[1], *E. Tatsina*[2], *N. Varsamis*[1], *A. Zotou*[3], *G. Katagis*[1], *F. Adam*[1], *A. Pournou*[1], *M. Gianniki*[4], *N. Tsifetaki*[1];
[1]*General Hospital of Ioannina, Greece, Ioannina, Greece,* [2]*Papageorgiou Hospital, Thessaloniki, Greece,* [3]*University Hospital of Ioannina, Greece, Ioannina, Greece,* [4]*Agia Sofia Hospital, Athens, Greece.*

Rheumatoid arthritis (RA) is a systemic autoimmune disease of unknown etiology Aim: To determine the frequency of antibodies against synthetic circular citrullinyl peptides (anti-CCP) and to compare them with rheumatoid factor (RF) in a group of patients with rheumatoid arthritis symptoms. Material-Method: 74 sera that were referred to the Laboratory with symptoms of mild to very severe rheumatoid arthritis were tested for the presence of anti-CCP and IgM RF antibodies. Control of the first was performed with enzyme immunoassay anti-RA / CCP τ and of the second with the method of nebulometry. Results: In 44 out of 74 patients the titles of both antibodies ranged in normal levels. Of the others, 18 had elevated titles of both antibodies while IgM were detected in 12. The 44 patients with negative antibody titles and 12 with only RF antibodies positive, showed mild and non-specific symptoms of the disease whereas the 18 patients with elevated anti-CCP and IgM RF titles had clinical picture consistant with rheumatoid arthritis. Conclusions: Anti-CCP antibodies are an important and specific indicator in the diagnosis of rheumatoid arthritis. Rheumatoid factor, although a sensitive marker for RA, lags behind in its specificity because it is detected in small percentages in a healthy population and other autoimmune diseases.

P.A3.03.17
Incidence of antibodies against Toxoplasma gondii,Rubella virus,cytomegalovirus and herpes simplex virus in greek and foreign women

N. Zotos[1], *E. Tatsina*[2], *L. Papageorgiou*[1], *E. Chrysostomou*[1], *P. Christodoulou*[1], *A. Zotou*[3], *N. Varsamis*[1], *A. Pournou*[1];
[1]*General Hospital of Ioannina, Greece, Ioannina, Greece,* [2]*Papageorgiou Hospital, Thessaloniki, Greece,* [3]*University Hospital of Ioannina, Ioannina, Greece.*

Aim: To determine the incidence of infections caused by Toxoplasma.gondii, Rubella Virus, Cytomegalovirus (CMV) and Herpes Virus Simplex (HSV) in Greek and foreign women, presenting in a tertiary hospital of North-Western Greece. Material and Methods: 382 women (278 Greeks and 104 Foreigners leaving in Greece) were tested for antibodies against T.gondii ,Rubella Virus,CMV, HSV during one year (January 2017 to December 2017).327 were tested for antibodies against T.gondii, 238 were tested for antibodies against Rubella Virus,302 were tested for anti-CMV antibodies and 124 for anti-HSV antibodies.92 of the women were tested for antibodies against all of the pathogens (TORCH). An enzyme-linked immunoassay was employed for the detection of all antibodies. Results: It is important to note that there was a statistically significant difference in the seropositivity against anti-Toxoplasma IgG and anti-CMV IgG antibodies in foreign women in comparison to Greek women (19.8% and 10.2%, 88.6% and 71.8%,) .There was no difference as far as positivity to the remaining types of antibodies tested in foreign and Greek women is concerned. Conclusion: An elevated seropositivity against T.gondii, Rubella Virus, CMV and HSV detected in women, both Greek and Foreign, makes the evaluation of the population inevitable. In this way infection prevention and control can be accomplished.

P.A3.03.18
Rapid Target Identification for T-Cell Immune Responses with SpotMix™ Peptide Pools

U. Reimer, *M. Eckey, P. Holenya, T. A. Teck, J. Zerweck, T. Knaute, H. Wenschuh, T. Kaan, F. Kern;*
JPT Peptide Technologies, Berlin, Germany.

Introduction: Vaccinations inducing or boosting T-cell immunity are successfully used in the infectious diseases and cancer fields. Suitable vaccine target proteins must contain T-cell stimulating peptides providing good epitopes. However, to date, algorithms for T-cell epitope prediction cannot reliably identify the most promising target proteins. Protein-spanning, overlapping pools of conventional synthetic peptides (PepMix™) represent all possible stimulating peptides in a target protein and are, therefore, ideally suited for this purpose. However, they are too costly for testing multiple potential target proteins.
Methods: Based on a method for the highly parallel synthesis of multiple peptides in low quantities, referred to as SPOT synthesis, we developed a novel protocol for synthesizing multiple peptides, which includes QC and quantification by LC-MS and permits the production of equimolar pools of SPOT peptides (SpotMix™). Our new protocol features consistent quality control of thousands of peptides.
Results: Comparisons between T-cell stimulation assays (ELISPOT, flow cytometry/intracellular cytokine staining) performed with the classic PepMix™ peptide pools and SpotMix™ pools demonstrated similar performance of these preparations.
Conclusions: SpotMix reagents will significantly facilitate T-cell protein target discovery by permitting the synthesis of protein-spanning, overlapping peptide pools for many potential target antigens in parallel. These can be tested experimentally and the most promising target proteins can be selected for further investigation. Since SPOT peptides are unpurified and produced in small quantities (approx. 10nmol) they are unsuitable for T-cell expansions or other therapeutic applications, however, represent ideal tools for T-cell target discovery.

P.A3.03.19
Fine characterization of healthy Conjunctiva: Main differences when comparing IELs and peripheral blood lymphocyte subsets.

Z. José Carlos, *C. Alfredo;*
Universidad de Valladolid, Valladolid, Spain.

Introduction: As occurs in other mucosal tissues —for example gut, bronchi and nose—, ocular mucosa holds a conjunctiva- associated lymphoid tissue (CALT). It is well-known that MALT (Mucosa Associated Lymphoid Tissue) has morphological and functional variations across tissues. Therefore, a thorough analysis of lymphoid populations might render useful information on ocular surface conditions. **Objectives:** The aim of this study is to improve the knowledge of human immune system within the conjunctiva in different ocular surface conditions. **Material and methods:** Twenty-five healthy volunteers were recruited. Peripheral blood lymphocytes were obtained by venipuncture while intraepithelial lymphocytes (IELs) from conjunctival mucosa were obtained by brush cytology. Major and fine subsets were characterized by flow cytometry. Memory, naïve, γδ T cells, $CD8^+$ (**Tc, NKT subtypes**), $CD4^+$ (**Th0, Th1, Th2, Th17, Th1/Th17, Th22** and **Treg** subsets), B cells (B_1 and B_2) and **NK cells** —regulatory and cytotoxic— subsets were analyzed in both conjunctival mucosa and peripheral blood. **Results:** Age and sex seemed to determine few differences in some lymphocyte subsets: Th1 cells might be age-influenced whereas Th22 might be sex-influenced. As expected, no strong correlations between peripheral and conjunctival lymphocytes were found. Conjunctival T cells seemed to be mainly CD8+ and TCRγδ+, while they were only a minor population in peripheral blood. Memory CD4+ T cells, NKT, B1, Tregs and regulatory NK cells had higher values in conjunctiva. **Conclusions:** Some well-known differences (increased TCRγδ cells) whereas others are apparently new in our knowledge (increased B1, NKT, Tregs and regulatory NK lymphocytes) were found. These features provide an extra effect and regulatory function to the conjunctiva.

P.A3.03.20

Cell-free tumoral DNA (ctDNA) based *EGFR* mutation analysis in a cohort of Indian non-small cell lung carcinoma (NSCLC) patients.

***S. Verma Kumar**, R. Katara, V. Kumar, J. Kandpal, S. Pandey, S. Sharma, L. Kini;*
CORE Diagnostics, Gurugram, Haryana 122016, India., Gurugram, India.

Patients with lung cancer show poor prognosis, with a five-year survival rate of about 17.8%. Epidermal Growth Factor Receptor (*EGFR*) mutation analysis is critical for patient selection for targeted tyrosine kinase inhibitor (TKI) therapy, and immunotherapy. Mutations such as exon 19 deletions and L858R point mutation confer sensitivity to EGFR TKIs; while mutations such as T790M confer decreased sensitivity to first- and second-generation *EGFR* TKIs.
The study population comprised of 627 (male: female ratio of 1.18: 1) patients with primary NSCLC. The patients ranged in clinical presentation from Stages I to IV of lung cancer, and most had previously tested positive in *EGFR* mutation analysis on tissue biopsy. The ctDNA was tested for "hotspot mutations" in *EGFR* c.2573T>G (L858R); *EGFR* Deletion E746-A750; and *EGFR* c.2369C>T (T790M) using ddPCR.
We report a 45.15% positivity for *EGFR* mutations in this cohort of NSCLC patients. Further, 26.63% tested positive for Deletion E746-A750; 21.37% for T790M; and 13.87% for L858R mutations. 11.16% cases showed concomitant positivity for Deletion E746-A750 and T790M, and 4.62% for L858R and T790M. As the sensitivity of ctDNA based *EGFR* testing ranged from 71-74% (as against tissue-based mutation analysis), we recommend testing all negative cases by a repeat tissue biopsy. We are currently carrying out a retrospective correlation of these test results with patients' clinical data, especially with reference to disease progression.

P.A3.03.21

Distinct cytokine patterns may regulate the severity of perinatal asphyxia

***A. Bajnok**, L. Berta, C. Orban, G. Toldi;*
Semmelweis University, Budapest, Hungary.

Neuroinflammation following perinatal asphyxia may have dual aspects being a hindrance, but also a necessity in the recovery of the CNS. We aimed to assess intracellular cytokine levels of T-lymphocytes and plasma cytokine levels in moderate and severe asphyxia in order to identify factors that may influence patient outcome. We analyzed data of neonates with moderate (n = 17) and a severe (n = 11) asphyxia. Grouping was based on neuroradiological and aEEG characteristics. Blood samples were collected at 6 h, at 24 h, 72 h, 1 week and 1 month of life. Blood samples were stimulated for 6 h, then intracellular cytokine levels were determined using flow cytometry. Cytokine plasma levels were measured using Bioplex immunoassays. The prevalence of IL-1b+ CD4 cells was higher in severe than in moderate asphyxia at 6 h and the prevalence of CD4+ IL-1β+ and CD4+ IL-1β+ CD49d+ cells appears to be able to predict severity of the insult at an early stage in asphyxia. At 1 mo, intracellular levels of TNF-α were higher in the severe group. Plasma IL-6 levels were higher at 1 wk in the severe group and decreased by 1 mo in the moderate group. Intracellular TGF-β levels were increased from 24 h onwards in the moderate group only. IL-1β and IL-6 appear to play a key role in the early events of the inflammatory response, while TNF-α seems to be responsible for prolonged neuroinflammation, potentially contributing to a worse outcome. TGF-β has a compensatory role in decreasing inflammation.

P.A3.03.22

Immunobiogram as a diagnostic assay for detection of resistance to immunomodulatory treatment in patients with chronic inflammatory diseases.

***Á. Ortega**, M. Di Scala, T. Yebra, T. Diez, J. Richter, I. Portero;*
BIOHOPE Scientific SL, Madrid, Spain.

Introduction: The immune system is very complex, dynamic and with self-learning capacity. The response of patients with chronic inflammatory diseases treated with immunomodulatory drugs can change over time.
Resistance arise during immunomodulator treatment and is particularly problematic during long-term treatment regimens. Nowadays, there are no biomarkers or pharmacovigilance tools to monitor drug resistance development.
Methods: Biohope has designed the Immunobiogram to be a "final point" immunoassay using a pharmacodynamic approach. We studied a cohort of transplant recipients treated with different immunosuppressants. The Immunobiogram allows to stablish an individualized pattern of sensitivity/resistance for each patient.
Results: We verified the existence of different patterns of sensitivity/resistance as response to immunosuppressive treatment in 70 patients. We detected that patients who had not been treated with a specific immunosuppressant are more sensitive to such treatment than patients already treated. Moreover, we determined the existence of a correlation between the dose supplied of a certain drug during the treatment and the decrease of the sensitivity. This decrease dose-dependent sensitivity is determined at least in part by the establishment of resistance to drug, which entails to an increase in the ID50 (half-maximal inhibitory dose) necessary for the maintenance of immunosuppression.
Conclusions: When evaluating the immunological status of the patient treated with immunosuppressants, it should be considered two antagonistic variables: the loss of synergistic activation networks of the immune system due to drug effect and the generation of molecular mechanisms of resistance to treatment. The Immunobiogram will allow us monitor appearance, or not, of these resistances.

P.A3.04.01

A study of hs-CRPas cardiovascular risk marker in pre-hypertension

***S. Das**;*
School of Medical Sciences and Research, Greater Noida, India.

Background: Hypertension has turned into a leading cause of non-communicable disease associated with mortality and morbidity in both developing as well as developed world. The concept of pre-hypertension, defined as a systolic blood pressure of 120-139 mmHg and/or a diastolic blood pressure of 80-89 mmHg was introduced as the new guideline for the management of blood pressure. Hs-CRP has been studied extensively as marker of cardiovascular risk, however its role as a marker of cardiovascular risk in pre-hypertension is not well defined. The aim of this study was to explore the role hs-CRP cardiovascular risk marker in patients of pre-hypertension.
Methods: 50 adult patients, above 19 years of age ,with diagnosed pre-hypertension and 50 age and sex matched healthy controls were studied in a tertiary health care center in Uttar Pradesh India, over a period of 6 months. The serum levels of hs-CRP was measured by ELISA and routine lipid profile was measured by automated analyzer. Framingham Risk scoring scoring was also done for all the patients. Data is presented as Mean±S.D. and relationships were determined by Pearson correlations.
Results : The mean age of the patients was 51±6.5 years (72% men, 28%women). The mean serum Hs-CRP levels [5.40±2.51 mg/l] for pre-hypertension were significantly higher than in controls [0.91±0.76 mg/l] [p<0.001]. Framingham Risk score was higher for patients with
pre-hypertension than controls. Higher hs-CRP values correlated with higher Framingham risk score.
Conclusion: Our results suggest that hs-CRP is a marker of Cardiovascular Risk in patients of pre-hypertension.

P.A3.04.02

Serum uromodulin, a new biomarker of renal function?

***C. Esteve Cols**[1,2], F. Graterol Torres[3], M. Navarro Díaz[3], À. Soriano Martínez[1], J. Ara del Rey[3], E. Martínez Cáceres[1,2], B. Quirant Sánchez[1,2];*
[1]Immunology Deparment Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [2]Department of Cell Biology, Physiology and immunology, Universitat Autònoma de Barcelona, Bellaterra, Spain, [3]Nephrology Deparment Hospital Universitari Germans Trias i Pujol, Badalona, Spain.

Membranous GlomeruloNephritis (MGN) and IgA Nephropathy (IgAN) are the leading forms of primary glomerulonephritis. MGN is caused by autoantibodies against PhospholipaseA-2 receptor, and IgAN by partially degalactosilated IgA1 (Gd-IgA1) that induces the generation of immunocomplexes of soluble IgA receptor (CD89) and Gd-IgA1.
The glycoprotein uromodulin is synthesized exclusively in the ascending limb of loop of Henle. A decrease in serum values is a sensitive marker of low renal function.
We aim, to evaluate serum uromodulin as a biomarker of renal function in comparison to serum creatinine, renal glomerular filtrate (eGFR) and proteinuria.
A retrospective study of 46 MGN, 22 IgAN patients diagnosed by renal biopsy and 9 Healthy Subjects (HS) was performed. Clinical and pathological features were collected and analyzed according to serum uromodulin levels. Analysis of serum uromodulin was performed with uromodulin-*ELISA* kit *(Euroimmun®)*.
MGN and IgAN patients had lower levels of serum uromodulin than HD (MGN: 131 ± 74,31; IgAN: 91,79 ± 57,12; HS 224,9 ± 74,70 ng/mL). There were no differences between uromodulin levels and patients age or gender.
We stratified the patients according to histopathological features of renal biopsy. MGN patients with positive biopsy for IgG4 deposits, showed a correlation between serum uromodulin-eGFR ($p<0.0007$, $r=0.62$) and serum uromodulin-creatinine ($p<0.0565$, $r=-0.38$). The same results were observed in those IgAN patients with more severe renal biopsy ($p<0.0037$, $r=0.76$; $p<0.0002$, $r=-0.87$), respectively.
The inverse correlation observed between uromodulin levels and severity of renal biopsy suggests that uromodulin might be a prognostic biomarker of renal function, especially in IgAN patients.

P.A3.04.03

Immunological characterization of IgA Nephropathy patients

C. Esteve Cols[1,2], *F. Graterol Torres*[3], *A. Teniente Serra*[1,2], *B. Quirant Sánchez*[1,2], *J. Ara del Rey*[3], *E. Martínez Cáceres*[1,2];
[1]*Immunology Deparment Hospital Universitari Germans Trias i Pujol, Badalona, Spain,* [2]*Department of Cell Biology, Physiology and immunology, Universitat Autònoma de Barcelona, Bellaterra, Spain,* [3]*Nephrology Deparment Hospital Universitari Germans Trias i Pujol, Badalona, Spain.*

IgA Nephroapthy (IgAN) is the leading form of primary glomerulonephritis affecting glomerular mesangium, with proteinuria, hematuria, hypertension and reduction of renal glomerular filtrate. Approximately 40% of cases are related to end-stage renal failure, requiring either dialysis or renal tranplantation. The gold-standard technique for IgAN diagnosis is renal biopsy. In the last years, the better knowledge of the disease, has led several authors to describe serum biomarkers that may be useful for diagnosis and prognosis, such as levels of partially degalactosilated IgA1 (Gd-IgA1), of specific IgG against Gd-IgA1, as well as sCD89 and Gd-IgA1 immune complexes. Until now, it has not been performed and exhaustive analysis of peripheral leukocyte subpopulations and CD89 expression on monocytes.
A prospective study of 22 patients diagnosed of IgAN by renal biopsy was performed. Immunophenotype of leukocyte subpopulations and CD89 expression on three monocyte subpopulations was characterized by flow cytometry.
The immunophenotype showed that patients had a higher percentage of activated and effector memory $CD4^+$ and $CD8^+$ lymphocytes, lower percentages of B transitional lymphocytes and plasmablasts, and higher percentages of NK lymphocytes $CD56^{dim}CD16^+$and myeloid dendritic cells, than healthy subjects. In parallel, those patients with poor renal function and more sever renal biopsy had lower Mean Fluorescence Intensity (MFI) of CD89 on non-classical monocytes.
This preliminary study shows that MFI of CD89 on non-classical monocytes could be used as a prognostic biomarker of IgAN. In parallel, activated leukocyte subpopulations predominate on peripheral blood of IgAN patients, which may contribute to renal damage.

P.A3.04.04

Impaired T cell metabolism in patients with major depressive disorder

H. Hasselmann[1], ***S. Gamradt***[1], *A. Taenzer*[1], *J. Nowacki*[1], *K. Patas*[2], *C. Ramien*[2], *K. Wingenfeld*[1], *C. Otte*[1], *S. M. Gold*[1];
[1]*Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Klinik für Psychiatrie und Psychotherapie, Campus Benjamin Franklin, Berlin, Germany,* [2]*Institut für Neuroimmunologie und Multiple Sklerose (INIMS), Zentrum für Molekulare Neurobiologie, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany.*

Introduction: Major depressive disorder (MDD) is associated with an increased risk of metabolic illness and immune dysregulation. This includes an impaired cellular immunity as well as a higher risk of infections such as Epstein-Barr virus (EBV). However, the underlying pathways for this association remain poorly understood.
Material and Methods: To investigate a potential link between cellular metabolism, immune dysfunction and infections in MDD, we employed T cell metabolic phenotyping and antigen-reactive T cell enrichment (ARTE) in a cohort of 28 well-characterized, antidepressant-free MDD patients and 28 carefully matched healthy controls.
Results: Basal mitochondrial respiration, spare respiratory capacity and ATP-production were significantly reduced in T cells of MDD patients compared to matched controls. Frequency and function of antigen-specific (EBV) $CD4^+$ T cells was unaltered and no increase in immune exhaustion markers (PD-1, LAG-3, CTLA-4, Tim-3) could be detected in EBV-specific or total T cells. However, we observed a small but significant increase in the expression of KLRG1 in total $CD4^+$ T cells of MDD patients.
Conclusion: Results indicate that an impaired bioenergetic profile in T cells suggestive of mitochondrial dysfunction is associated with MDD. These alterations are unlikely to simply reflect an epiphenomenon of general immune exhaustion and may be linked to early manifestations of immune senescence.
Funding: Deutsche Forschungsgemeinschaft and National MS Society

P.A3.04.07

Evaluation of matrix metalloproteinase-3 (MMP-3) as a candidate biomarker in assessment of disease activity in Algerian rheumatoid arthritis patients.

T. Hadjout[1], *S. Salah*[1], *M. Benidir*[1], *N. Klouche*[1], *M. Djennane*[2], *A. Hamdi*[1], *H. Balaouane*[1], *N. Attal*[1];
[1]*Institut Pasteur of Algeria, Algiers, Algeria,* [2]*Tizi Ouzou Hospital, Tizi Ouzou, Algeria.*

Introduction: Matrix metalloproteinase-3 (MMP-3) is a protease induced by inflammatory cytokines in rheumatoid arthritis (RA) synovium and degrade a number of extracellular matrix components of cartilage and bone. Considering its central role in RA joint destruction, serum MMP-3 level could be a clinically useful maker for disease activity assessment. The aim of our study is to evaluate serum MMP-3 levels in RA patients compared to controls and to assess whether MMP-3 levels reflect disease activity in RA patients in correlation with inflammatory markers, erosion and autoantibodies status. **Methods:** Our study groups consisted of 116 RA patients (86% women, mean age 50±13years, mean disease duration 7±9years), 66 healthy controls and 47 control patients [33 undifferentiated connective tissue disease (UCTD) and 14 Chronic Inflammatory diseases (CID)]. MMP-3 serum measurement was based on a quantitative ELISA assay (Aeskulisa MMP-3, Aesku.Diagnostics, Germany). **Results:** Serum MMP-3 was significantly higher in sera of RA patients (49±46ng/ml) compared to healthy controls (18±14ng/ml) ($p<0.001$) and UCTD patients (17±16ng/ml) (p=0,004). There was no statistical difference with CID patients (43±58ng/ml). MMP-3 levels were increased in 56% of RA patients. This statistical increasing values were found also with positivity of CRP (p=0,02), RF (p=0,03), ACPA (p=0,02) and erosive status (p=0,009). Finally, MMP-3 levels correlated positively only with RF ($p<0,0001$; r=0,35) and ACPA rates (p=0,004, r=0,26) but not with DAS28 in RA patients. **Conclusion:** Measurement of serum MMP-3 provides a particularly useful marker of inflammatory activity in RA patients and may have a particular value in predicting the progression of erosive disease.

P.A3.04.09

Immunological effects of dimethyl fumarate in multiple sclerosis patients

M. Mansilla[1], *J. Navarro-Barriuso*[1], *S. Presas-Rodríguez*[2], *A. Teniente-Serra*[1], *B. Quirant-Sánchez*[1], *C. Ramo-Tello*[2], ***E. Martínez-Cáceres***[1];
[1]*Germans Trias i Pujol Hospital and Research Institute. Campus Can Ruti, Badalona, Spain,* [2]*Germans Trias i Pujol Hospital, Badalona, Spain.*

Dimethyl fumarate (DMF) is an oral drug for the treatment of relapsing-remitting multiple sclerosis (RRMS), with an anti-inflammatory effect. It is relatively well tolerated, but it has an important impact over several leukocyte subpopulations. Consequently, immune monitorization becomes necessary to understand the effect of DMF on the immune system and to relate these changes to the clinical outcome and potential adverse effects. **Objective:** To analyze the immunological changes induced by DMF in samples of whole blood of RRMS patients. **Methods:** Longitudinal prospective study of peripheral blood T, B, NK, monocyte and DC subpopulations using multiparametric flow cytometry in whole blood from 12 RRMS patients under DMF treatment at baseline and after 1, 3, 6 and 12 months of follow up. **Results:** The study evidenced a selective reduction of T effector, T central and B memory cells in a 52.3±14.1%, 37.3±16.1% and 54.3±20.3%, respectively, was evidenced after 12 months. In contrast, the relative prevalence of both T and B naïve subpopulations increased in a 58.4±25.6% and 47.1±31.6%, respectively. Additionally, a switch in the central memory Th2/Th1 ratio from 0.8±0.3 to 1.4±0.6 and an increase of transitional B cells in absolute number (from 5±3 to 10±5 cells/µL) were spotted. All these changes were progressive from month 1, and already significant by month 6. All results were statistically significant ($p<0.05$). **Conclusions:** The beneficial effect of DMF reducing the number of clinical relapses in MS patients seems to be related with the effect of DMF depleting effector T cells and increasing transitional B cells.

P.A3.04.10

Single nucleotide polymorphisms in relapsing-remitting multiple sclerosis in Serbian patients: no association with disease susceptibility and interferon-beta treatment response

E. Milosevic[1], *M. Markovic*[1], *V. Perovic*[1], *I. Vukovic Petrovic*[1], *V. Pravica*[1], *I. Dujmovic*[2], *S. Mesaros*[2], *J. Drulovic*[2], *M. Mostarica Stojkovic*[1], *D. Popadic*[1];
[1]*Institute of Microbiology and Immunology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia,* [2]*Clinic of Neurology, Clinical Center of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.*

Therapy response varies in multiple sclerosis (MS) patients and still cannot be predicted. Interferon (IFN)-β, a first-line drug for relapsing-remitting (RR) MS is not efficient in up to 50% of treated patients. Considering autoimmune etiology of MS in prone genetic background, our objective was to analyze selected single nucleotide polymorphisms (SNPs) in genes with assumed pathogenic role as potential biomarkers of disease susceptibility and response to IFN-β therapy.
SNPs in *CSF2* (rs25882), *IL10* (rs1800871, rs3024505), *CD86* (rs1129055), *CTLA-4* (rs5742909), *IL6* (rs1800795), *TNFA* (rs361525) and *IL23R* (rs11209026) were assessed in 121 consecutive patients with RRMS starting IFN-β therapy and 250 healthy controls. Response to IFN-β was defined after two-year follow-up: patients without relapses and no progression in the Expanded Disability Status Scale (EDSS) score were considered responders (R, n= 69), while those with relapses and/or progression in disability were considered nonresponders (NR, n=52). SNPs were determined by TaqMan® SNP qPCR genotyping assays.
Genotype and allele distribution was similar in MS patients compared to healthy controls. Likewise, no significant disparity in genotype and allele frequencies between R and NR patients was found for any of the explored SNPs.
Although these SNPs are thought to affect protein function, we did not found association of their variants with susceptibility to MS and IFN-β therapy outcome, including the ones whose role in MS pathogenesis has not been addressed thus far (*CSF2* (rs25882) and *IL10* (rs3024505)).

P.A3.04.11

Determination of monocytes, dendritic cells, NK cells and T regulatory cells in patients with type 1 diabetes and healthy children

***A. Oras**, R. Uibo;*
University of Tartu, Tartu, Estonia.

Introduction: Type 1 diabetes (T1D) is an autoimmune disease characterized by immune-mediated destruction of the insulin-producing β-cells in pancreatic islets. Altered numbers of innate immune cells such as dendritic cells (DC), natural killer (NK) cells and monocytes as well as adaptive immune cells such as T regulatory (Treg) cells have been demonstrated in previous studies. The aim of this ongoing study is to compare the numbers of aforementioned cell populations in children with T1D and healthy controls. **Material and Methods:** We investigated whole blood samples from patients with recent onset of T1D and healthy children. Relative numbers of DC, plasmacytoid DC, myeloid DC, monocytes, NK cells, Tregs and their subpopulations were determined based on differential expression of HLA-DR, CD16, CD56, CD14, CD123, CD11c, CD4, CD25, CD127 and CD194. For calculating the absolute cell counts BD TruCOUNT Beads were used. The data was analyzed according to the COST-ENTIRE HIP-C version 3.3 protocol and immunophenotyping of whole blood was performed on the BD LSRFortessa™. Mann-Whitney U test was employed to assess the difference in study groups. **Results:** Our studies revealed statistically significant differences in dendritic cells subsets between patients with T1D and healthy controls. **Conclusions:** Our results confirm the suitability of HIP-C 3.3 protocol for testing peripheral blood innate immunity and Treg cell subpopulations; and support the possible involvement of some of these subsets in T1D pathogenesis.

Tapasin edits HLA-Imolecules and hence plays a crucial role in immunological surveillance. Our novel data shows that recombinant tapasin dissolves abberant conformations of HLA-I when added to the cell surface. During inflammation and in tumours pH is decreased. To study the effect on tapasin secondary structure at different pH and temperature we here used Synchrotron Radiation Circular Dichroism (SRCD) spectroscopy and Small Angle X-ray Scattering (SAXS) to study the dynamic solution structure of tapasin under physiological conditions. Contrary to crystal structure data, which was performed at room temperature, we found that tapasin undergoes structural transition and acquires a characteristic fold at physiological temperature i.e at 37C. Interestingly, decreased pH also resulted in the same conformational change of structure. These results show a conformational change in tapasin at low pH as well as at physiological temperature, which is highly relevant to consider when e.g, developing new peptide based vaccines or studying HLA-I antigen presentation at physiological temperature and in inflamed tissue with lower pH.

P.A3.04.13

Relationship between serum protein pattern and disease activity in patients with systemic sclerosis

***A. Petrackova**, A. Smrzova, T. Dyskova, R. Fillerova, G. Gabcova, M. Schubertova, M. Skacelova, F. Mrazek, P. Horak, E. Kriegova;*
Faculty of Medicine and Dentistry, Palacky University and Hospital Olomouc, Olomouc, Czech Republic.

Introduction: Systemic sclerosis (SSc) is a complex autoimmune connective tissue disorder with varying manifestations and clinical outcomes. There is still limited information of serum biomarkers suitable for effective monitoring of disease activity.
Methods: We investigated the serum levels of 92 inflammation-related proteins in 52 Czech patients with SSc and 24 age/gender-matched healthy control subjects using a highly sensitive innovative multiplex PEA (Olink Bioscience, Sweden). Subgroups were formed based on the disease activity (non-active SSc, n=14; active SSc, n=38), where revised EUSTAR activity index of >2.25 was taken as active SSc. Statistics were performed using GenEx (Sweden).
Results: Top-ranked proteins distinguishing SSc and healthy controls (P_{corr}<0.00001) were sTNFSF14, axin 1, sulfotransferase 1A1, CCL7, caspase 8, sTGFα, FGF23, and CXCL10. When comparing SSc patients with active and non-active disease, upregulation of IL-6, CCL7, IL-10, sTGFα, FGF21, CCL23, oncostatin M, EN-RAGE, CSF1, sHGF, GDNF, CCL11, and downregulation of sTNFβ was observed to be associated with disease activity (P<0.05). Moreover, serum levels of IL-6, CCL7, IL-10, CSF1, sHGF positively correlated (r>0.353, P<0.009) and sTNFβ negatively correlated (r=-0.374, P<0.006) with levels of C-reactive protein. Further multivariate analysis is needed to identify pattern associated with high disease activity.
Conclusions: This study nominated novel serum markers IL-6, CCL7, IL-10, CSF1, sHGF, and sTNFβ for evaluation of the disease activity of patients with SSc. Larger cohorts and multivariate analysis will be needed to prove their usefulness as biomarkers for active SSc.

P.A3.04.14

Phagocyte metabolic profile in different models of Parkinson's disease in rats

***M. P. Rudyk**[1], Y. Hurmach[1], V. Svyatetska[1], A. Prysiazhniuk[1], K. Stepura[1], A. Shuliak[1], Y. Maiboroda[1], T. Dovbynchuk[1], N. Khranovska[2], O. Skachkova[2], G. Tolstanova[1], L. Skivka[1];*
[1]Institute of biology and medicine, Kyiv, Ukraine, [2]National Cancer Institute, Kyiv, Ukraine.

Introduction: The local inflammation in CNS during Parkinson's disease (PD) is associated with phenotypic and functional changes not only in local microglia but also in peripheral phagocytes. The aim of this study was to compare the functional state of phagocytes from different locations in rats with MPTP-induced and 6-OHDA-induced PD. **Methods:** PD in rats was induced with subcutaneous injection of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) or unilateral stereotaxic injection of 6-Hydroxydopamine (6-OHDA) into the striatum. Reactive oxygen species (ROS) generation and phagocytosis activity, as well as CD14, CD69, CD80/86 and CD206 expression by microglia, circulating phagocytes and peritoneal macrophages were evaluated by flow cytometry. NO production and arginase activity of the cells were examined in colorimetric assays. **Results:** MPTP-induced PD in rats was associated with increase in highly phagocytic $CD14^{high}$ CD 69+ microglia fraction. $CD14^{high}$ $CD69^{high}$ peritoneal macrophages were characterised by increased NO production. Circulating phagocytes showed upregulated CD69, while their ROS production and phagocytosis were decreased. In rats with 6-OHDA-induced PD, sharply decreased phagocytosis along with increased ROS and NO production by microglia were detected. Decreased CD14 and CD80/86 expression, along with high CD206 expression were observed on microglia of these animals. Progressive neuronal damage led to monocytosis. Circulating phagocytes and peritoneal macrophages showed pro-inflammatory activation. **Conclusion:** Inflammatory process in CNS of rats with PD was characterised by their microglia strong activation, more pronounced in case of 6-OHDA-induced PD. Peripheral phagocyte metabolic changes in rats with different PD models have different activation patterns indicating distinct disease immunopathogenesis.

Immunomonitoring of Treg heterogenity in Multiple Sclerosis

***M. Sambucci**[1,2], F. Gargano[1], V. De Rosa[2], M. De Bardi[1], M. Picozza[1], R. Placido[1], S. Ruggieri[3,4], A. Capone[1,5], C. Gasperini[3], G. Matarese[6,2], L. Battistini[1], G. Borsellino[1];*
[1]Laboratory of Neuroimmunology, Fondazione Santa Lucia, Rome, Italy, [2]Institute of Experimental Oncology and Endocrinology, National Research Council (IEOS-CNR), Immunology Lab, Naples, Italy, [3]Department of Neurosciences, San Camillo Forlanini Hospital, Rome, Italy, [4]Department of Neurology and Psychiatry, Sapienza University of Rome, Rome, Italy, [5]Laboratory of Neuroembryology, Fondazione Santa Lucia, Rome, Italy, [6]Department of Molecular Medicine and Biotechnologies, University of Naples "Federico II", Naples, Italy.

Introduction: Regulatory T cells (Treg) are a fundamental component for immune regulation and homeostasis. In humans, Tregs are a heterogeneous population for gene expression, phenotype, and suppressive functions. While there is a general consensus regarding the surface markers required for their identification, several studies have identified distinct subsets within this cell population based on the evidence that several FoxP3 isoforms exist. The two most relevant FoxP3 isoforms are the full length isoform (FoxP3fl) and the isoform lacking exon 2. Since FoxP3 regulates the development and function of Treg cells, different FoxP3 isoforms lead to different Treg cells.
Material and Methods: Fresh PBMC (ex-vivo) from MS patients and healthy controls (HD) were stained to define the phenotype of Treg cells, using antibody clones that detect different FoxP3 isoforms. Total cell lysates were used to perform Western Blots. When the amount of cells was very low total RNA was isolated and PCR was performed.
Results: We find that Treg cells from MS patients preferentially express the Foxp3 isoform lacking exon 2. This isoform confers reduced suppressive abilities. We also find that in patients T reg cells express markers of cellular exhaustion. These findings may explain the the less effective immune regulation found in patients with autoimmune disease.
Conclusion: This study underlines the importance of studying T regulatory cells taking in consideration the existence of distinct FoxP3 isoforms which identify cells with potentially diverse suppressive abilities and which may be differently expressed in health and in disease.

P.A3.04.16

Analysis of relationship of functional activity of peripheral immune cells with the course of Parkinson's disease

J. Teterina[1], *A. Boyko*[1], *N. Troyanova*[1], *M. Grechikhina*[1], *N. Ponomareva*[2], *V. Fokin*[2], *E. Fedotova*[2], *T. Azhikina*[1], *E. Kovalenko*[1], *A. Sapozhnikov*[1];

Parkinson's disease (PD) is one of the most common neurodegenerative diseases. In recent years, there is growing evidence that the pathogenesis of this disease is connected with regional and peripheral immune processes. Currently, the association of clinical signs of PD with different characteristics of patient immune status is actively being searched. In the framework of this problem we perform an investigation of functional state of immune cells, in particular, activity of their chaperone-associated system of protein homeostasis, in patients with PD. 26 healthy donors and 21 patients with PD were examined during the first stage of the study. Flow cytometric analysis of intracellular HSP70 in populations of granulocytes (PMN) and mononuclear cells (PBMC) in normal and heat shock conditions did not reveal significant distinctions between the groups of healthy volunteers and the patients. However, analysis of basal transcription activity of different HSPA genes demonstrated a considerable increased expression of minor stress-induced HSPA6 gene in PBMC fractions of the patients with PD as compared to the healthy donors. The data suggest that PD dose not associate with essential alterations of HSP70 synthesis in peripheral blood leukocytes. However, the course of PD might be accompanied by increased transcription of some stress-induced HSPA genes in peripheral immunocompetent cells. This work was supported by Russian Science Foundation, grant No. 16-15-10404.

P.A3.04.17

Serum cytokines and chemokines in newly diagnosed Ulcerative Colitis patients predicting the effect on treatment and disease course.

E. G. van Lochem[1], *B. Roosenboom*[1], *C. Smids*[1], *P. Wahab*[1], *M. Groenen*[1], *S. Nierkens*[2], *E. van Koolwijk*[1], *C. Horjus Talabur Horje*[1];
[1]*Rijnstate Hospital, Velp, Netherlands,* [2]*Utrecht Medical Center, Utrecht, Netherlands.*

Predicting disease course and treatment response remains difficult in patients with Ulcerative colitis (UC). Based on our previous study on Crohns disease and new insights in UC pathophysiology, we identified distinctive serum analytes associated with disease activity and course in newly diagnosed, untreated patients at presentation and during follow-up. Multiplex-immunoassay analysis for 21 cytokines, chemokines and receptors was performed on blood samples from 45 UC patients at diagnosis and follow-up (n=20) and compared to healthy controls (n=18, HC). Results: Compared to HC, baseline UC patients had significant higher levels of IL-6, IL-7, IL-17, Oncostatin, CCL-11, CCL-19, CXCL-1, CXCL-13, MMP-10, sTNF-R2 and sIL2RsCD25. Comparing mild endoscopic disease (Mayo 1, N=14) with severe endoscopic disease (Mayo 3, N=9), higher serum levels of IL-6 (p=0.001), IL-17 (p=0.019), OncostatinM (p=0.002), CXCL-1 (p=0.011), GCSF (p=0.001) and sTNFR-2 (p=0.009) were found in patients with severe disease.
The levels of IL-6 (p=0.038), IL-7 (p=0.028) and MMP-10 (p=0.038) in UC patients during remission, dropped significantly to the level of HC (n=9) after follow-up. Patients who did not respond on corticosteroids (n=5) had higher levels of IL-10 (p=0.001) and IL-13 (p=0.005) at baseline; non-responders on anti-TNF treatment (n=3) had higher IL-10 (p=0.006) levels. Patients with an exacerbation within one year had significant higher IL-10, OncostatinM, CXCL-8, GCSF and sTNFR-2 levels at baseline compared to patients without exacerbation. In this cohort of newly diagnosed UC patients we identified IL-6 as a possible predictor of endoscopic disease severity. Higher IL-10 and IL-13 levels at baseline were associated with non-responding on corticosteroids.

P.A3.04.18

SERUM ANGIOGENESIS MARKERS PREDICT DISEASE OUTCOME IN GIANT CELL ARTERITIS

Y. van Sleen, *M. Sandovici, W. H. Abdulahad, J. Bijzet, A. M. Boots, E. Brouwer;*
University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Giant cell arteritis (GCA) is an inflammatory large vessel disease requiring long-term treatment with glucocorticoids. Relapses occur often and the high cumulative glucocorticoid dose has detrimental effects on patient's quality of life. Therefore, new biomarkers are needed for diagnosis and disease course prediction. As the majority of infiltrating cells in GCA vessels are macrophages, the aim of this project was to evaluate levels of macrophage serum products in GCA patients as candidate disease course predictors.
Forty-one newly diagnosed GCA patients were recruited before start of glucocorticoids. Disease course was monitored and time to glucocorticoid treatment-free remission was prospectively documented. Also, thirty age- and sex-matched healthy controls (HCs) were included. Serum concentrations of IL-6, SAA, sCD163, calprotectin, YKL-40, and angiopoietin-1 and 2 were determined by ELISA or Luminex assay at baseline, during treatment and in treatment-free remission.
IL-6, SAA, sCD163, calprotectin, YKL-40, VEGF and angiopoietin-2 levels were elevated in GCA compared to HCs. High VEGF and angiopoietin-1, but low YKL40 and angiopoietin-2 levels, at baseline predicted a shorter time to treatment-free remission. Other markers had no predictive value. In patients on treatment, angiopoietin-2 levels were increased shortly before relapse. Patients in treatment-free remission still showed increased levels of angiopoietin-1 and 2, sCD163, IL-6 and calprotectin compared to healthy controls. Markers of angiogenesis hold promise as predictors of disease outcome at baseline and during treatment. Validation of this angiogenesis signature in independent cohorts is required. Whether patients in treatment-free remission may still suffer from smouldering vessel wall inflammation needs further investigation.

P.A3.04.20

Circadian rhythm of immune cells in healthy individuals and patients with rheumatoid arthritis

S. Wilantri[1,2], *C. Strehl*[1,2], *D. Abdirama*[1,2], *T. Gaber*[1,2], *F. Buttgereit*[1,2];
[1]*Charité Universitätsmedizin Berlin, Berlin, Germany,* [2]*Deutsches Rheuma Forschungszentrum, Berlin, Germany.*

Circadian rhythms have been appreciated as important regulators of various biological processes. Disrupted circadian rhythms were observed in patients suffered from cancer, tumor and inflammatory diseases. Our previous 24-hour pilot study suggested that immunological circadian rhythms in patients with rheumatoid arthritis (RA) were altered compared to the healthy individuals. Fourteen eligible female patients with RA aged 45-75 and twelve eligible healthy individuals were recruited to join the study. The circadian rhythms were synchronized by scheduled food and water intake and sleeping period a week prior to study day. On the study day, the blood was drawn in two hours interval throughout 24 hours. The absolute number of circulating immune cells was determined by TruCount. RNA was isolated from CD14+ monocytes and analyzed by qPCR.We investigated major immune populations and found striking differences in the circadian rhythm of NK T cells, NK cells, CD8 T cells, CD3 T cells, CD4 T cells and regulatory T cells of healthy individuals and patients with RA. Phase shifting, reduction of amplitude, attenuation and new establishment of circadian rhythms were observed in patients with RA. In addition, the qPCR data also indicated a disrupted circadian rhythm in RNA level. Among ten clock genes that were examined, REVERBα, PER1, and PER3 showed altered rhythmic expression in patients with RA. We will continue to investigate the circadian rhythms using mass cytometry and multiplex immunoassay. Identification of circadian rhythm in healthy individuals and patients with RA may provide an outlook for future implication, such as in chronotherapy.

P.A3.04.21

The Structure and Functional regulation of CD36 and Its Role in Atherosclerosis

K. Zhang, *L. Peng, H. Wei;*
Department of Laboratory Medicine, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing University, Nanjing, PR China, Nanjing, China.

CD36 is a multifunctional transmembrane glycoprotein that binds to oxidized low density lipoprotein to induce monocyte transformation into foam cells and promotes the formation of atherosclerosis through inflammatory response, oxidative stress, platelet activation, macrophage trapping. Inhibition of CD36 expression or interference with its associated signaling pathways can significantly alleviate the severity of atherosclerosis. In addition, the highly expression of CD36 in the tongue, nasal cavity, small intestine and brain promotes the body's intake and absorption of lipids, and increases the risk factors of metabolic diseases. Serum soluble CD36 is found as a component of circulating microparticles (MPs) and may be as a predictor for atherosclerotic disease.

Introduction: Positive anti-nuclear antibodies are detected with high frequency in systemic rheumatic diseases, infections, inflammations, neoplasms as well as in normal individuals. Detection and identification of autoantibodies significantly help in accurate diagnosis, prognosis, treatment regulation, and clinical follow-up of patients. Aim: The analysis of the antinuclear antibody (ANA) detection results and the association of positive ANAs with the occurrence of specific antinuclear antibodies: anti-double stranded DNA (anti-dsDNA) and anti-extrapolated core antigens (ENA) in patients both internals and externals. Material-Method: A total of 383 patients (126 internal and 257 external) were examined over a 12-month period from January 2017 to December 2017. The measurement of autoantibodies was performed by indirect immunofluorescence. Results: A total of 28 subjects (7.31%) with positive anti-nuclear antibody titles, 25 women and 3 men were found. Among the negative results, 29 serum boundary sera were found. Of the 28 ANA-positive sera, 9 were found with anti-ENA (+), 2 showed anti-dsDNA (+), and 6 subjects were found positive with anti-ENA and anti-dsDNA. The remaining 11 individuals (2.87%) with ANA positive had specific anti-nuclear antibodies negative. Of the 29 marginal activity sera, 6 showed anti-ENA (+) and one sample with a known SLE history showed a high anti-dsDNA title. Conclusions: ANAs were detected in 7.31% of patients, while 2.87% of the total number of patients had ANA (+) without specific individual antibodies. The evaluation of both a negative and a positive result should be done with great care.

Electrochemical biosensing of cancer exosomes in human serum based on magnetic separation

*S. Lima de Moura[1], M. Pividori[1], **M. Martí**[2];*
[1]Grup Sensors i Biosensors. Dpt Química. Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain, [2]Institut de Biotecnologia i Biomedicina, Bellaterra (Barcelona), Spain.

The identification of novel biomarkers represents a worldwide challenge not only for the improvement of early diagnostics, but also for patient monitoring and for the evaluation of the efficiency of a therapeutic strategy. Exosomes are nano-sized and cup-shaped vesicles, which are currently under intensive study as potential diagnostic biomarkers for many health disorders, including cancer. Therefore, this is a growing need for sensitive methods capable of accurately and specifically determining the concentration of exosomes. This work addresses the study of different receptor by flow cytometry as well as the design of a quantitative and rapid method for total exosome counting based on magneto-actuated platforms with electrochemical readout. Two different strategies were explored for the magnetic separation of exosomes. Briefly, based on i) the direct covalent immobilization on tosyl-activated magnetic particles or, instead, by ii) immunomagnetic separation based on different receptors. The magneto electrochemical biosensor for the exosomes counting was successfully achieved in human serum. This proof-of-concept device represents a rapid, cost-effective, and high-sample-throughput detection of exosomes and can be potentially established as promising approach for cancer diagnostics based on liquid biopsy.

P.A3.04.24

Magneto-actuated rapid test for the detection of circulating tumor cells

*A. Pallarès[1], S. Lima de Moura[1], M. Mesas[1], **M. Martí**[2], M. Pividori[1];*
[1]Grup Sensors i Biosensors. Dpt Química. Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain, [2]Institut de Biotecnologia i Biomedicina, Bellaterra (Barcelona), Spain.

According to WHO, breast cancer is the top cancer in women both in the developed and the developing world, and the number of new cases is expected to rise by about 70% over the next two decades. The early and accurate detection of breast cancer as well as the risk of metastasis in small healthcare centers remains as the cornerstone of breast cancer control. This work is intended to contribute in the development of Rapid Diagnostic Test (RDTs) for cancer diagnosis at point-of-care in low resource settings, taking breast cancer circulating tumor cells from MCF7 cellular line as a model. Two different strategies were designed: a magneto-actuated immunosensor for the quantification of the breast cancer cells and a magnetic genosensor for the detection of the PCR-amplified genetic material from the cells. For that purpose, different commercial antibodies against specific epitopes of the cellular membrane were firstly studied by flow cytometry and confocal microscopy.
Such antibodies were then covalently immobilized on magnetic particles to capture the tumor cells by immunomagnetic separation for the preconcentration of the cells from complex samples and immunosensing with an specific antibody. The magneto genosensing approach is based on a double-tagging RT-PCR amplification of the transcripts from the cells and the quantification of the amplicon by amperometry technique or visual readout based on lateral flow. Finally, the results of these strategies are compared in terms of the analytical performance, showing promising features for being used as RDTs.

Innate immune recovery predicts CD4+ T-cell reconstitution after hematopoietic cell transplantation

***C. de Koning**[1], J. Langenhorst[1], C. van Kesteren[1], C. A. Lindemans[2], A. Huitema[1], S. Nierkens[1], J. J. Boelens[2,1];*
[1]University Medical Centre Utrecht, Utrecht, Netherlands, [2]Wilhemina Children's Hospital, Utrecht, Netherlands.

Innate immune cells are the first to recover after allogeneic hematopoietic cell transplantation (HCT). Nevertheless, reports of innate immune cell recovery and their relation to adaptive recovery after HCT, are largely lacking. Especially predicting CD4+ T-cell reconstitution is of clinical interest, as this parameter directly associates with survival chances after HCT.
We developed a multivariate, combined non-linear mixed-effects model for monocytes, neutrophils and NK-cell recovery after transplantation. We evaluated whether innate recovery relates to CD4+ T-cell reconstitution probability, and investigated differences between innate recovery after cord blood transplantation (CBT) and bone marrow transplantation (BMT).
205 Patients, undergoing a first HCT (76 BMT, 129 CBT) between 2007-2016, were included. The median age was 7.3 years (range 0.16-23). Innate recovery was highly associated with CD4+ T-cell reconstitution probability (p<0.001) in multivariate analysis correcting for covariates. Monocyte (p<0.001), neutrophil (p<0.001), and NK-cell (p<0.001) recovery reached higher levels during the first 200 days after CBT compared to BMT. The higher innate recovery after CBT may be explained by increased proliferation capacity (measured by Ki-67 expression) of innate cells in CB-grafts compared to BM-grafts (p=0.041), and of innate cells in vivo after CBT compared to BMT (p=0.048). At an individual level, patients with increased innate recovery after either CBT or BMT had received grafts with higher proliferating innate cells (CB; p=0.004, BM; p=0.01, respectively).
Our findings implicate the use of early innate immune monitoring to predict the chance of CD4+ T-cell reconstitution after HCT, with respect to higher innate recovery after CBT compared to BMT.

P.A3.05.02

Effects of adalimumab on T-helper-17 lymphocyte and neutrophil related inflammatory serum markers in patients with moderate to severe hidradenitis suppurativa

***R. de la Varga Martínez**[1,2], D. Jiménez Gallo[3], L. Ossorio García[3], M. Linares Barrios[3], C. Rodríguez[2];*
[1]Servicio de Inmunología, UGC de Laboratorios Clínicos. Hospital Universitario Virgen del Rocío, Sevilla, Spain, [2]Servicio de Inmunología, UGC de Hematología, Inmunología y Genética. Hospital Universitario Puerta del Mar, Cádiz, Spain, [3]UGC de Dermatología. Hospital Universitario Puerta del Mar, Cádiz, Spain.

Introduction: T-helper (Th)-17 lymphocytes and neutrophils are the main sources of the proinflammatory cytokines involved in the pathogenesis of hidradenitis suppurativa (HS). Objective: This study aims to evaluate the improvement of the inflammatory serum markers (ISM) levels in patients with moderate-to-severe HS who receive adalimumab. Methods: Nineteen moderate-to-severe HS patients were prospectively recruited. Each of the patients received 40 mg of adalimumab weekly. The ISM levels and modified Hidradenitis Suppurativa Score (mHSS) scores were assessed at baseline and at week 36. Nineteen healthy volunteers (HC) constituted the control group. Results: Before adalimumab treatment, the HS patients showed significantly increased levels of interleukin (IL)-6, IL-8, IL-10, IL-17A, soluble TNF receptor II (sTNF-RII), and C-reactive protein (CRP) as well as an increased erythrocyte sedimentation rate (ESR) (all p<0.01). At week 36, the circulating levels of IL-1β, IL-6, IL-8, IL-10, IL-17A, soluble TNF receptor I (sTNF-RI), sTNF-RII, and CRP, as well as the ESR (all p<0.05), decreased significantly in the HS patients who received adalimumab. The decrease in levels of IL-6 (r=0.65, p=0.003), IL-8 (r=0.52, p=0.024), sTNF-RI (r=0.55, p=0.015), and CRP (r=0.47, p<0.040) and the ESR (r=0.60, p<0.006) were significantly well correlated with clinical improvements according to the mHSS. Conclusions: Adalimumab improves the ISM-based systemic inflammatory burden in patients with moderate-to severe HS. IL-6, IL-8, sTNF-RI and CRP and the ESR may serve as novel biomarkers for a therapeutic response.

P.A3.05.03

Characterization and enumeration of immune phenotypes in individuals from different age groups

***M. de Zeeuw-Brouwer**[1], L. de Rond[1], L. Samson[1], D. van Baarle[1,2], F. van der Klis[1], A. M. Buisman[1];*
[1]National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, [2]University of Utrecht, University Medical Centre Utrecht (UMCU), Utrecht, Netherlands.

Background Ageing is accompanied by alterations of the immune system and often leads to a decline in immune function. To assess the level of variation in immune phenotype of individuals with age, different lymphocyte subsets were analysed in a cross-sectional population study, performed in 2016/2017. Method Extensive whole blood immunophenotyping of absolute numbers of several immune subsets and their activation markers, was performed in 4 age groups (5-8 yr, 18-25 yr, 40-45 yr and 65-70 yr, n=60-90) Results No differences in the absolute numbers of lymphocytes, monocytes and granulocytes among the age groups were observed. Not surprisingly, children (5-8 yr) had significantly more (naïve) B-cells than other age groups. The numbers of $CD56^{bright}CD16^{dim/-}$ NK cells and CD4+HLADR-CD38+ cells were also elevated in children, while numbers of $CD56^{dim}CD16^{+}$ NK cells were lower. No differences were observed in numbers of CD4 cells, while a decline in those of CD8 cells was seen with increasing age. Also the amount of CD4+HLADR+CD38- T-cells increased during ageing. Conclusion Most differences in numbers of lymphocyte subsets were seen in children (5-8 yr), compared to other age groups. Especially numbers of CD4+HLADR-CD38+ and $CD56^{bright}CD16^{dim/-}$ cells were high in children, which indicates more naïve/immature T- and NK cells in this age group. A higher level of CD4+HLADR+CD38- cells in the older groups suggests the presence of more activated memory T-cells with ageing. These data will be combined with functional immunological assays, to get more insight in alterations of the various immune subsets during ageing.

P.A3.05.04

T helper cell subsets and related cytokines in infertile women undergoing in vitro fertilization before and after seminal plasma exposure

*M. Azad[1], S. Keshtgar[2], Z. Kanannejad[1], B. Namavar-Jahromi[3,4], **B. Gharesi-Fard**[1,4];*
[1]Department of immunology, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [2]Department of Physiology, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [3]Department of Obstetrics and Gynecology, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [4]Infertility Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of.

In vitro fertilization (IVF) is a well-known method for the treatment of infertility. The present study aimed to compare the differences between infertile women with successful and unsuccessful IVF outcomes regarding the expression of T helper (Th) cell transcription factors and a group of related cytokines before and after exposure to their husbands' seminal plasma. This study was performed on 19 couples with unexplained infertility undergoing IVF treatment. Among the studied group, nine and 10 couples had successful and unsuccessful IVF outcomes, respectively. This study was carried out using real-time polymerase chain reaction. Before seminal plasma exposure, the expression levels of T-bet (p<0.007), interferon-γ (p=0.013), and TNF-α (p=0.017) were higher in the infertile women with IVF failure than in those with successful IVF outcomes, while those of GATA3 (p<0.001), Foxp3 (p=0.001), and interleukin (IL)-35 (p<0.003) were lower. After seminal exposure, the expression of T-bet (p=0.02), Rorc (p<0.001), TNF-α (p=0.001), Foxp3 (p=0.02), and interferon-γ (p=0.001) increased in the unsuccessful IVF group, while the expression of Foxp3 (p=0.02), Rorc (p<0.001), IL-23 (p=0.04), IL-17 (p=0.02), IL-6 (p<0.001), transforming growth factor-β (p=0.01), and IL-35 (p<0.001) increased in the successful IVF group. In summary, IVF failure was associated with imbalanced Th1/Th2/Th17/Treg responses. Moreover, our results show that seminal plasma might have a positive effect on IVF outcomes via changes in peripheral blood T cell subsets.

P.A3.05.05

Difference in protein expression of the peripheral blood CD4+ T lymphocytes between polycystic ovary syndrome and healthy women

***B. Gharesi-Fard**[1,2], F. Nasri[1];*
[1]Department of Immunology, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [2]Infertility Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of.

Proteome profile analysis of CD4+ T lymphocytes in polycystic ovary syndrome (PCOS) may represent the proteins involved in the pathogenesis of the disease. The present study aimed to compare the protein expression profiles of the peripheral blood CD4+ T lymphocytes between PCOS patients and healthy women. We used two-dimensional gel electrophoresis (2-DE) followed by mass spectrometry (MS) of selected protein spots. Moreover, identified protein spots were confirmed by western blot technique. Despite the overall proteome similarities between patients and healthy women, the analysis of protein spots revealed that at least seven spots were differently expressed (P< 0.05). Protein identification was successfully achieved for 3 out of 7 spots by Mass technique and confirmed by western blot. All 3 identified proteins including Phosphatidyl ethanolamine-binding protein 1(PEBP1), Proteasome activator complex subunit 1 (PSME1), and Triosephosphate isomerase 1 (TPI) showed over-expression in PCOS patients compared with the healthy subjects. These deferentially expressed proteins might be involved in oxidative processes and cardiac pathology. This evidence highlights T lymphocytes competence as a living biosensor system to record the alteration of metabolism and gene expression and would be a good substitution for tissue biopsies.

P.A3.05.06

Expression levels of serum lncRNA HOTAIR in patients with rheumatoid arthritis

***X. Li**, S. Song, J. Yu, A. Li, F. Chen, N. Sun, Y. Yang;*
Department of Clinical Laboratory Science,Jinling Hospital, School of Medicine, Nanjing University, Nanjing, China.

Objective To investigate the different expression levels of lncRNA HOTAIR in serum of patients with rheumatoid arthritis (RA) . **Methods** 205 serum samples were selected from 95 patients with RA, 50 patients with Systemic lupus erythematosus (SLE) and 60 healthy controls. The total RNAs from serum were extracted,and the expressions of lncRNA HOTAIR, XIST and H19 were detected by the method of RT-qPCR. Pearson correlation analysis was used to explore the correlation between disease activity index(DAS28)of RA and the Expression level of HOTAIR. **Results** Compared with control and SLE groups, the expression level of HOTAIR in RA group is obviously increased(P<0.05). There were no any significant different expressions of XIST and H19 between RA and control groups. Furthermore, the serum level of HOTAIR has a positive correlation with DAS28 score (P<0.02,R^2=0.2438) and the serum level of HOTAIR in the higher activity of RA group whose DAS28 score is greater than 5.1 is higher than the activity of RA group whose DAS28 score is greater than 3.2. No significant correlations were found between levels of HOTAIR and other laboratory parameters including rheumatoid factor (RF), anti-cyclic citrullinated peptide autoantibodies, C-reactive protein (CRP), and erythrocyte sedimentation rate(ESR). **Conclusion:**Expression level of lncRNA HOTAIR in the serum of RA patients was significantly higher than healthy donors and SLE patients. HOTAIR in the serum may serve as a novel and valuable biomarker for the diagnosis of RA.

P.A3.05.07

Ligands for inhibitory and activating NK cell receptors in childhood B- and T-ALL

***M. V. Martinez-Sanchez**[1,2], L. Gimeno-Arias[1,2], J. F. Pascual-Gázquez[3,2], A. M. Fita[3,2], E. Ramos-Elbal[3,2], A. M. Galera-Miñarro[3,2], M. M. Bermúdez-Cortés[3,2], M. E. Llinares-Riestra[3,2], M. Blanquer-Blanquer[4,2], J. L. Fuster-Soler[3,2], A. Minguela-Puras[1,2];*
[1]Immunology Service, Virgen Arrixaca Clinical University Hospital, El Palmar-Murcia, Spain, [2]Murcia BioHealth Research Institute (IMIB), Murcia, Spain, [3]Pediatric Oncohematology Department, Pediatric Service, Virgen Arrixaca Clinical University Hospital, El Palmar-Murcia, Spain, [4]Hematology and Hemotherapy Department, Virgen Arrixaca Clinical University Hospital, El Palmar-Murcia, Spain.

The level of HLA-I molecules expressed by leukemic cells is one of the most important factors influencing NK-mediated lysis. Efficient lysis requires interaction of additional activating receptors with their ligands on tumour cells such as CD112 and CD155 for DNAM-1, and MICA/B and ULBPs for NKG2D. It has been described that HLA-I down regulation is more frequent in myeloid than in lymphoblastic leukaemias and that expression of CD112 and CD155 is consistent in myeloid leukaemias but MICA/B and ULBPs were either absent or weakly expressed.
The expression of ligands for inhibitory (total HLA-I and HLA-C) and for activating (CD112, CD155, MICA/B and ULBP-1) receptors was evaluated in 45 paediatric patients at diagnosis by flow cytometry, both on bone marrow tumour cells and on normal lymphocytes as a control.
Higher expression of CD112 as percentage and as mean fluorescence intensity (MFI) was detected for B-ALL blast cells than for normal lymphocytes and higher number of CD155+ cells was observed in T-ALL blast cells than in normal lymphocytes. No differences in the expression of HLA-I and slight reduction in HLA-C were detected for B ALL blast cells compared to normal lymphocytes. A lower percentage of HLA-C cells was detected in T-ALL and lower expression of both HLA-I and HLA-C were observed in T-ALL blasts cells than in normal lymphocytes.
Differential expression of ligands for NK cells activating and inhibitory receptors in B- and T-ALL childhood blast could condition NK cell antitumor response and should be taken in consideration in NK immunotherapy protocols.

P.A3.05.08

Ligands for inhibitory and activating NK cell receptors in childhood M7 and non-M7 AML

***M. V. Martínez-Sánchez**[1,2], L. Gimeno-Arias[1,2], J. F. Pascual-Gázquez[3,4], A. M. Fita[3,2], E. Ramos-Elbal[3,2], A. M. Galera-Miñarro[3,2], M. M. Bermúdez-Cortés[3,2], M. E. Llinares-Riestra[3,2], M. Blanquer-Blanquer[5,2], J. L. Fuster-Soler[3,2], A. Minguela-Puras[1,2];*
[1]Immunology Service. Virgen Arrixaca Clinical University Hospital, El Palmar-Murcia, Spain, [2]Murcia BioHealth Research Institute (IMIB), Murcia, Spain, [3]Pediatric Oncohematology Department, Pediatric Service, Virgen Arrixaca Clinical University Hospital, El Palmar-Murcia, Spain, [4]Murcia BioHealth Research Institute (IMIB), Murcia, Saint Martin, [5]Hematology and Hemotherapy Department, Virgen Arrixaca Clinical University Hospital, El Palmar-Murcia, Spain.

The level of HLA-I molecules expressed by leukemic cells is one of the most important factors influencing NK-mediated lysis. Efficient lysis requires interaction of additional activating receptors with their ligands on tumour cells such as CD112 and CD155 for DNAM-1, and MICA/B and ULBPs for NKG2D. It has been described that HLA-I down regulation is more frequent in myeloid than in lymphoblastic leukaemias and that expression of CD112 and CD155 is consistent in myeloid leukaemias but MICA/B and ULBPs were either absent or weakly expressed. The expression of ligands for inhibitory (total HLA-I and HLA-C) and for activating (CD112, CD155, MICA/B and ULBP-1) receptors was evaluated in 9 paediatric patients at diagnosis (4 AML-M7 not related to Down syndrome and 5 AML-non-M7) by flow cytometry, both on bone marrow tumour cells and on normal granulocytes as a control. The expression of CD112 was significantly higher in AML blasts both as percentage as MFI in M7-AMLs and non-M7-AMLs compared to normal granulocytes. Increased no-significant expression for CD155 was observed in blasts compared to granulocytes. In contrast, MICA/B and ULBP were weakly expressed in blast cells and normal granulocytes. Higher expression of HLA-I in M7-AML blasts but not in non-M7-AML blasts than in normal granulocytes was observed. No significant differences were observed for HLA-C expression. Differential expression of ligands for NK cells activating and inhibitory receptors in M7 and non-M7 childhood AML blast could condition NK cell antitumor response and should be taken in consideration in NK immunotherapy protocols.

NK cells activity and extracellular microvesicles at healthy pregnancy and preeclampsia

***V. A. Mikhailova**, K. L. Belyakova, D. O. Bazhenov, A. R. Sheveleva, E. V. Khokhlova, O. N. Arzhanova, S. A. Selkov, D. I. Sokolov;*
FSBSI "The Research Institute of Obstetrics, Gynecology and Reproductology named after D.O.Ott", Saint-Petersburg, Russian Federation.

Introduction: Pregnancy is associated with alterations in leucocytes functional characteristics. The aim was to assess functional activity of NK cells at healthy pregnancy and preeclampsia. Materials and methods: The groups included nonpregnant women, healthy pregnant women, pregnant women with preeclampsia. For assessment of NK cells cytotoxic activity we used peripheral blood mononuclear cells. For analysis of microvesicles content we used blood plasma. For confirmation the ability of NK cells to form microvesicles cell line NK-92 was used. For analysis of microvesicles influence on cells we used monocytes of cell line THP-1 and blood plasma microvesicles. The methods included cell culturing, conventional flow cytometry, high-precision flow cytometry. Results: Preeclampsia comparing with healthy pregnancy was associated with less amount of CD107a+NK cells but higher content of TRAIL+NK cells. NK cells of NK-92 line were able to form microvesicles different in phenotype. Higher counts of NK cells microvesicles with phenotype CD45+CD16+CD56+ and lower counts of CD45+CD16-CD56+NK cells microvesicles were detected in pregnant women comparing with nonpregnant. At preeclampsia there was higher content of CD45+CD16+CD56-microvesicles comparing to healthy pregnancy. The expression of CD18 and CD54 by THP-1 cells was higher after treatment with microvesicles of healthy pregnant women comparing to nonpregnant and lower after treatment with microvesicles of women with preeclampsia comparing to heathy pregnant. Conclusions: The mechanism of cytotoxity induction of NK cells, the content of NK cells microvesicles and their influence on cells differs at preeclampsia comparing to healthy pregnancy. NK cells cytotoxity towards trophoblast cells at healthy pregnancy and recurrent pregnancy loss

***V. A. Mikhailova**, D. O. Bazhenov, L. P. Viazmina, E. V. Khokhlova, K. L. Belyakova, A. R. Sheveleva, S. A. Selkov, D. I. Sokolov;*
FSBSI "The Research Institute of Obstetrics, Gynecology and Reproductology named after D.O.Ott", Saint-Petersburg, Russian Federation.

Introduction: NK cells are present in decidua during pregnancy and can interact with trophoblast cells. The aim was to assess cytotoxic activity of NK cells towards trophoblast cells at heathy pregnancy and recurrent pregnancy loss (RPL). Materials and methods: The groups included healthy nonpregnant fertile women at proliferative (PrPh) and secretory (SecPh) phases of menstrual cycle, healthy pregnant women at 6-7 weeks of gestation (wg), nonpregnant women with RPL at PrPh and SecPh. Trophoblast cells of JEG-3 cell line were treated with CFSE (4μM). Peripheral blood mononuclear cells which contained NK cells were incubated with trophoblast cells for 4 hours. Then cell mixtures were treated with propidium iodide (0,01mg/ml). Dead trophoblast cells were detected using flow cytometer. Results: The cytotoxic activity of NK cells of fertile women in PrPh towards trophoblast cells was higher than of fertile women in SecPh and at healthy pregnancy. There was no difference in NK cells activity of fertile women in SecPh and at healthy pregnancy. The cytotoxic activity of NK cells of nonpregnant women with RPL in SecPh was higher than in PrPh and was higher than activity of NK cells of fertile women in SecPh. Conclusions: The cytotoxic activity of NK cells of fertile women towards trophoblast cells is low in SecPh that contributes occurrence of blastocyst implantation and promotes healthy pregnancy. In RPL NK cells cytotoxic activity in SecPh is high that contributes pregnancy loss in case of possible blastocyst implantation. Funding: President's grant NSh-2873.2018.7, President's scholarship SP-2836.2018.4, State program № AAAA-A18-118011020016-9

P.A3.05.11

T helper cells profile and $CD4^+CD25^+Foxp3^+$ regulatory T cells in Polycystic Ovary Syndrome (PCOS)

***F. Nasri**[1], M. Doroudchi[1], B. Namavar-Jahromi[2,3], B. Gharesi-Fard[1,3];*
[1]Department of Immunology, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [2]Department of Obstetrics and Gynecology, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [3]Infertility Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of.

Polycystic ovary syndrome (PCOS) is considered as the most common cause of female infertility that affects 4-10% of women in the reproductive ages. Previous studies showed that T helper cell balances play an important role in successful pregnancy. Therefore, the aim of this study was to investigate the Th1/Th2/Th17/Treg paradigms in peripheral blood of infertile women with PCOS compared with healthy fertile women.
Peripheral blood mononuclear cells (PBMCs) were isolated at the late follicular phase from 10 women complicated with PCOS and 10 healthy fertile women. PBMCs were stimulated with PMA and Ionomycin in the presence of Berefeldin A as Golgi stop agent to detect intracellular cytokine production (IFN-γ, Il-17, and IL-4) from $CD3^+CD4^+$T cells population indicating T helper (Th) cells subsets by flowcytometry technique. Moreover, regulatory T cells were checked using CD25 and Foxp3 markers.
Results indicated that T helper cells type 1 (Th1) were statistically increased over Th2 in infertile PCOS groups when considering Th1/Th2 ratio (P=0.05) Moreover analysis of Th17/Th2 ratio showed a significant difference with a bias toward Th17 dominancy (P=0.02) for PCOS women. Finally the proportion of $CD4^+CD25^+Foxp3^+$ regulatory T cells significantly was decreased in PCOS patients as compared with that of healthy fertile women (P=0.02).
In summary results of the present study showed that over-activation of Th1 and Th17, as inflammatory subsets, and reduction of Treg and Th2, as regulators of inflammation, might be one of the underlying mechanisms in the pathogenesis of PCOS patients.

P.A3.05.13

Development of frailty is associated with elevated CRP trajectories and increased numbers of innate immune cells

***L. D. Samson**[1,2,3], P. Engelfriet[1], W. M. Verschuren[1], A. M. Boots[3], A. Buisman[2];*
[1]Center for Nutrition, Prevention and Health Services, National Institute of Public Health and the Environment, Bilthoven, Netherlands, [2]Center for Infectious Disease Control, National Institute of Public Health and the Environment, Bilthoven, Netherlands, [3]Department of Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

With age, the immune system undergoes several changes such as shift from naive to memory T cells, thymic involution and increase in inflammatory cytokines. However, clinical relevance of these changes is relatively unknown. The longitudinal Doetinchem Cohort Study (DCS) (n=±3700), wherein health parameters and blood samples have been collected every five years since 1987, provides a unique framework to investigate the immune system in terms of healthy and unhealthy aging. Health status was defined by combining 34 health deficits into a frailty index. A subcohort (n=289, 60-85 yr.) was selected from DCS participants by random sampling, equally stratified by age, sex and health status. Absolute numbers of leukocyte subsets were characterized by multicolor flow cytometry. In addition, cytomegalovirus (CMV) serostatus and c-reactive protein (CRP) concentrations were measured. Our results revealed elevated numbers of neutrophils and monocytes in the frail population compared to the non-frail population. Furthermore, CRP trajectories (15 yr.) were higher in the frail population, consistent with inflammation and skewing of hematopoietic stem cells towards myeloid progenitors. Elevated memory (CD8) T cells were observed with age and CMV serostatus but not with frailty and could be part of a normal aging pathway. These differences in aging patterns of frail and non-frail populations make DCS subcohort promising for future research towards aging of the immune system. Identifying cellular immune markers and immune biomarker trajectories related to health status and age might help to predict future health problems and to explore intervention strategies to target immunological decline in the future.

P.A3.05.14

Analysis of alterations of HSP70 expression in peripheral immune cells of patients with obliterating arteriosclerosis

*A. Bornusova[1], E. Dzyubinskaya[2], **A. Sapozhnikov**[1,2];*
[1]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation, [2]Lomonosov Moscow State University, Moscow, Russian Federation.

In recent years, the role of humoral and cellular immunity in processes of atherosclerotic damages of vessels is being actively investigated. It was demonstrated that heat shock proteins HSP70 translocated on the surface of endothelial cells play an important role in development of autoimmune reactions peculiar to arteriosclerosis. It was also shown a considerable increase of extracellular pool of HSP70 and level of antibody to the protein in serum of peripheral blood obtained from patients with arteriosclerosis. In this work we investigated alterations of HSP70 expression in peripheral immune cells of patients with obliterating arteriosclerosis. The obtained results testify to significant differences between healthy donors and patients in a number of parameters connected with HSP70. In particular, our data demonstrated an increased content of inducible Hsp70 in lymphocytes isolated from peripheral blood of the patients as compared with healthy donors. Our preliminary results indicated also the presence of considerable level of surface HSP70 on lymphocytes obtained from a number of patients in contrast to healthy donor lymphocytes having no surface HSP70. Additionally our data confirm the results of other authors concerning an increased serum level of extracellular HSP70 and antibody to the protein in the blood of the patients. An essential addition to the literature data is connected with demonstrated in our study a significant positive correlation of the measured parameters mentioned above with the level of vessel calcification that reflects the development of arteriosclerosis. This work was partly supported by Russian Science Foundation, grant No. 16-15-10404.

Analysing human peripheral B cell repertoire to predict rheumatoid arthritis

B. Szikora[1], *A. Marx*[1], *K. Kovács*[1], *O. Pipek*[2], *I. Csabai*[2], *I. Kacskovics*[1];
[1]*Department of Immunology, Eötvös Loránd University, Budapest, Hungary,* [2]*Department of Physics of Complex Systems, Eötvös Loránd University, Budapest, Hungary.*

B cells and the antibodies they produce are the most important elements of the humoral immune response. At the end of the B cell development, naïve B cells produce unique immunoglobulins, which are the basic elements of the immune repertoire. The diversity of these immunoglobulins (Ig) comes mainly from the various gene segments (V(D)J), randomly built-in nucleotides and somatic hypermutation during germinal center reaction. The healthy repertoire consists of many different Ig sequences with a relatively even distribution that can be altered due to infections or other disorders such as autoimmunity. In these diseases some B cells are activated, their numbers are increased and these clonal changes can be detected in peripheral blood. Current studies suggest that such alterations can be discovered and followed by analysing the Ig repertoire with the help of next-generation sequencing and bioinformatical evaluation. Rheumatoid arthritis (RA) is a common autoimmune disease, manifesting in synovial inflammation. Before the onset of RA, typical disease markers can be detected from blood: autoantibodies of given specificity, typically anti-citrullinated protein antibodies and/or IgM rheumatoid factors. However, these markers are not entirely reliable. Our aim is to establish a sensitive and accurate diagnostic marker that can detect highly expanded clones from the blood of RA patients to predict disease progression and follow treatment efficiency. Acknowledgments: Project no. FIEK_16-1-2016-0005 has been implemented with the support provided from the National Research, Development and Innovation Fund of Hungary, financed under the FIEK_16 funding scheme.

Anti-atherosclerotic study of the macrophages polarization mediated by salidroside in atherosclerosis mice

X. Tong[1], *F. Huang*[2];
[1]*The First Affiliated Hospital, Kunming, China,* [2]*Yunnan University of Traditional Chinese Medicine, Kunming, China.*

The polarization of M1 and M2 macrophages has been proven to be closely related to Atherosclerosis (ATH). The purpose of this study was to investigate the role and potential mechanism of salidroside in the treatment of ATH mice.
ApoE-/- mice were fed with Western high-fat diet 12 weeks for the ATH models and devided into model group, positive group, salidroside group at random. Intragastric saline were given to model group. Atorvastatin (10mg/kg) was given to positive group. The salidroside group were administrated with salidroside of 100mg/kg daily for 8 weeks. The levels of serum lipids were checked and the aorta plaques were observed with Oil-red-O staining and Movat staining. Immunohistochemistry for F4/80, iNOS and CD206 were performed and the levels of cytokines MCP-1, IL-12p70, IL-6, L-1β, IL-10 and IL-13 were detected by ELISA.
The levels of TG, TC, and LDL-C in salidroside group were significantly lower ($P<0.01$) while the level of HDL-C was increased ($P<0.05$) when compared with model group. In histological changes less plaque areas were observed in positive group and salidroside group in comparison to model group. The expression of F4/80, iNOS, IL-6,IL-1β in positive group and salidroside group were significantly reduced ($P<0.05$) while the expression of CD206, IL-1β, IL-10, IL-13, IL-12p70 and MCP-1 were significantly increased when compared with model group ($P<0.01$).
Blood lipids might be regulated and ATh plaques might be stabilized by salidroside which might exert anti-inflammatory reactions by regulating the macrophages polarization.

P.A3.05.17

Immunological signatures of influenza vaccine responders and non-responders in the elderly

S. Trittel[1,2], *P. Riese*[1,2], *M. Akmatov*[3,2], *M. May*[4], *J. Prokein*[5], *T. Illig*[5,2], *C. Schindler*[4,2], *J. Huehn*[1,6], *F. Pessler*[3,2], *C. A. Guzmán*[1,2];

Seasonal influenza outbreaks represent a serious public health problem leading to a significant economic burden and high mortality rates especially in risk groups, e.g. the elderly (≥ 65 years). Compared to younger vaccinees, the elderly show considerably reduced vaccine-induced protective immune responses. Although vaccines adapted to the needs of the elderly immune system are available (Fluad®), vaccine non-responsiveness is still a critical issue. The development of new or improved vaccination strategies and the identification of biomarkers predicting vaccine efficacy are thus urgently needed. Therefore, a clinical study was performed aimed at elucidating immunological mechanisms underlying influenza vaccine non-responsiveness in the elderly (n=234). Volunteers aged ≥ 65 years were vaccinated in the season 2014/15 or 2015/16 and blood samples (serum/plasma, PBMCs, whole blood) were collected before and at specific time points after vaccination. The stratification of the vaccinees by their increase in the hemagglutination inhibition titre against the three vaccine antigens allowed the identification of triple responders and triple non-responders. The immunophenotyping of PBMCs derived from these two distinct extreme groups revealed specific immunological signatures. Triple responders displayed enhanced functionality of T cell populations and NK cells whereas triple non-responders showed enhanced frequencies of suppressive regulatory T and B cells and reduced plasma levels of IL-8/IL-18 as compared to triple responders already before vaccination. These differences shed light on the mechanism underlying vaccine non-responsiveness and thus will contribute to the improvement of vaccination strategies. In addition, plasma cytokine levels might serve as putative biomarkers for the early stratification of vaccinees.

Ageing is a complex process occuring in every living organism. One of the most recognized consequences of ageing is a decline in immune function. Although the causes of ageing are still poorly understood, the link between DNA methylation and ageing has been very meticulously characterized in past decades. Changes in DNA methylation patterns occur gradually throughout an individual's lifespan and result in the age-related phenotypes. The accumulation of epigenetic modifications is part of normal ageing process. The aim of our study is to evaluate the changes in the numbers of different immune cells from whole blood using only site-specific DNA methylation analysis. We have chosen several distinctive CpG sites for different immune cell subpopulations and carried out sequencing to evaluate the methylation levels in young and elderly individuals. We correlated methylation values of specific CpG sites and cell numbers for different immune cells and created models for cellular quantification using only DNA methylation values. For example, we have created a model to calculate the number of $CD8^+$ TEMRA cells, that are considered to be the hallmark of ageing. The number of TEMRA cells increases in pro-inflammatory conditions of elderly and can therefore be used as a marker for inflammatory conditions. Our goal is to create cellular quantification models for different immune cell subpopulations and to use them as a potential biomarkers in different disease and health conditions.

Bratanov", Bulgarian Academy of Sciences, Sofia, Bulgaria,* [2]*Medical University, University Obstetrics and Gynecology Hospital "Mother House", Sofia, Bulgaria, Sofia, Bulgaria,* [3]*Institute of Microbiology "Acad. St. Angelov", Bulgarian Academy of Sciences, Sofia, Bulgaria.*

Introduction: During pregnancy the plasticity of maternal immune system is challenged by the requirement to tolerate a semi-allogeneic fetus while remaining vigilant against pathogen invasion. Lack of immune balance in the uterus can lead to excessive inflammation and pregnancy failure. Gamma/delta T cells are dual face fast-acting cells that bridge innate and adaptive immune system and have a role in the protection against infections, in tumor surveillance and in tissue repair in both inflammatory and metabolic stress. Our aim was to investigate the profile of maternal gamma/delta T cells during the establishment of successful pregnancy. Materials and methods: Decidual and blood samples from healthy pregnant women in early and term pregnancy and from non-pregnant women were examined by immunohistochemistry, flow cytometry and CDR3 size spectratyping to assess *in situ* distribution, differentiation, activation and migration potential of gamma/delta T cells as well as overall TCR repertoire diversity. Results: Our findings showed that 1) human early pregnancy decidua was enriched for activated, fully differentiated and pro-inflammatory γαμμα/δελτα T cells; 2) the expansion of gamma/delta T cells at materno-fetal interface was restricted to Vdelta1 subset; 3) CDR3delta's and CDR3gamma's repertoires were polyclonal except CDR3gamma9 which was oligoclonal regardless gamma/delta T cells location. Conclusions: Early pregnancy triggeres an influx of terminally differentiated and pro-inflammatory gamma/delta T cells with diverse TCR repertoires. **Acknowledgments:** This study is funded by Bulgarian National Science Fund, project DN 03/5.

A peptide targeting inflammatory CNS lesions in the EAE rat model of multiple sclerosis

C. BOIZIAU;
INSERM U1026, Bordeaux, France.

Multiple sclerosis is characterized by inflammatory lesions dispersed throughout the central nervous system (CNS) leading to severe neurological handicap. Demyelination, axonal damage, and blood brain barrier alterations are hallmarks of this pathology, whose precise processes are not fully understood. In the experimental autoimmune encephalomyelitis (EAE) rat model that mimics many features of human multiple sclerosis, the phage display strategy was applied to select peptide ligands targeting inflammatory sites in CNS. Due to the large diversity of sequences after phage display selection, a bioinformatics procedure called PepTeam designed to identify peptides mimicking naturally occurring proteins was used, with the goal to predict peptides that were not background noise. We identified a circular peptide CLSTASNSC called Ph48 as an efficient binder of inflammatory regions of EAE CNS sections including small inflammatory lesions of both white and gray matter. Tested on human brain endothelial cells hCMEC/D3, Ph48 was able to bind efficiently when these cells were activated with IL1β to mimic inflammatory conditions. The peptide is therefore a candidate for further analyses of the molecular alterations in inflammatory lesions. This work was supported by grants from ANR, ARSEP, and Conseil Régional d'Aquitaine (France). KVS received a doctoral fellowship from the European Network Council ENC-Network.

P.A3.06.01

Investigating the correlations between single nucleotide polymorphisms of immunity-related genes and cell surface markers of immune cells in porcine stocks in Taiwan

***A. Chen**, A. Liu, S. Liu, M. Wu, Y. Lien, H. Chaung;*
Research Center of Animal Biologics, Pingtung, Taiwan.

Single nucleotide polymorphism (SNP) is a genetic variation controlled gene expressions on transcriptional level. It has been reported that SNPs in immune-relevant genes influence the susceptibility of individuals to pathogens and diseases. The aims of this study are to investigate the distribution of SNP sites in immunity-related genes and its correlations to cell surface markers of immune cells within purebred and crossbred pigs in Taiwan. In this study, 39 SNPs of porcine immune-related genes (IFN-α, IFN-γ, TNF-α, GM-CSF, MCP-1, TLR3, TLR4, TLR7, TLR8 and TLR9) were identified and percentages of positive cells with cell surface markers of CD4, CD8, CD80/86, MHCI, and MHCII were analyzed from blood samples collected from 187 piglets at the age of 8 weeks (Landrace, Yorkshire, Landrace-Yorkshire hybrid, Duroc and Taiwan Black). The results showed that genotype distribution of 28 SNPs were significant associated with breeds, especially between Landrace and Taiwan Black. For instance, frequency of AG genotype of SNP-1 in Taiwan Black and Landrace were 1.6% and 13.4%, respectively. Among them, 18 SNPs significantly had impacts on the expressions of cell surface markers of CD4, CD8, CD80/86, MHCI and MHC II. Interestingly, CD4% (35.42±4.17) in AA genotype of SNP-28 was significantly higher than those in GG genotype (26.65±1.93) in all breeds. An understanding of these SNPs and their correlations with immunity parameters may be beneficial on establishing high pathogen-resistant breeding parameters. This genomic information aids in the discovery of SNPs in genes controlling disease resistance.

P.A3.06.02

Rapid and robust CD4+ and CD8+ T-, NK-, B-cell, and monocyte reconstitution after nicotinamide-expanded cord blood (NiCord) transplantation

***C. de Koning**[1], K. van Veghel[1], A. Lacna[1], L. Ebskamp-van Raaij[1], J. J. Boelens[2,1], S. Nierkens[1];*
[1]University Medical Centre Utrecht, Utrecht, Netherlands, [2]Wilhemina Children's Hospital, Utrecht, Netherlands.

Nicotinamide-expanded cord blood (NiCord) is a promising alternative source for allogeneic hematopoietic cell transplantation (HCT) when an appropriate donor is lacking.
We evaluated early immune reconstitution (IR) after NiCord HCT, in which especially CD4+ T-cell reconstitution is related for successful outcome.
In this phase1/2 multicenter trial, patients with hematologic malignancies received a NiCord-HCT after myeloablative conditioning. IR monitoring was performed in a random subgroup. Primary endpoint was CD4+-IR (>50*10 /L within 100 days). Secondary endpoints were IR of T-, natural killer (NK), B-cells, and monocytes during the first 6 months after HCT. Data were compared with cohorts of adolescent and young adult (AYA) patients at the UMC Utrecht receiving either unmanipulated cord blood transplantation (unCBT) or bone marrow transplantation (BMT) for hematological malignancy. Linear-mixed effects modelling in LOESS-regression curves and two-sided log-rank test for univariate comparisons in cumulative incidence plots were used.
36 NiCord recipients (median 41.5; 13.4-61.7yrs) were included, IR data was available from 22 patients. Of these patients, 91% achieved successful CD4+ IR; comparable to 27 unCBT (median 15.4; 12.2-22.1yrs) and 20 BMT (median 14.3; 12.1-19.7yrs) recipients (p=0.98). Overall T-cell IR was similar (p=0.53), while IR of NK-cells (p<0.001), B-cells (p=0.017) and monocytes (p<0.001), was faster after NiCord transplantation.
NiCord recipients had rapid and robust IR despite the younger age of the AYA cohorts receiving unCBT and BMT (expected to reconstitute faster). These data show the high proliferative capacity of the NiCord- expanded product in vivo, which will be further evaluated in an ongoing phase III multi-center trial.

P.A3.06.03

Identification of immune biomarkers in Tuberculosis patients and their contacts

***O. Estévez-Martínez**[1], E. Garet-Fernández[1], A. Martínez-Pérez[1], N. Fonseca[2], D. González-Peña[1], A. Pena[3], L. Barcia[3], Á. Pallares[4], L. Anibarro[3], Á. González-Fernández[1];*
[1]Cinbio (University of Vigo), Vigo, Spain, [2]European Bioinformatics Institute (EMBL-EBI), Cambridge, United Kingdom, [3]Tuberculosis Unit-Hospital Provincial Pontevedra, Pontevedra, Spain, [4]Microbiology Unit-Hospital Provincial Pontevedra, Pontevedra, Spain.

INTRODUCTION: The immunological mechanisms behind Tuberculosis (TB) infection or resistance are not yet fully characterized. A better understanding of these mechanisms could provide new biomarkers of the infection status. This would not only improve the diagnosis of new TB cases but also help on the identification of a different spectrum of contacts with latent infection. OBJECTIVE: Identification of a set of Tuberculosis biomarkers in blood, saliva and sputum samples. METHODOLOGY: We have recruited a Galician cohort of 28 newly diagnosed TB patients and 71 contacts exposed to the infection (44 uninfected -*NoTBI*- and 27 with latent infection -*LTBI*-). We have measured different cytokines and chemokines in serum, saliva and sputum by multiplex and studied the gene expression profile by RNAseq. Candidate biomarkers were selected based on the differential expression between groups (padj<0.05) and the fold change, and were used to create classification models. RESULTS: We have identified 6 protein markers in saliva and 4 in serum. Sputum did not allow us to select biomarkers. A set of genes differentiate TB patients from NoTBI contacts that partially overlap with a set of differentially expressed genes between TB patients and LTBI contacts. Genes differentiating NoTBI from TB were used to create a classification model that identifies different subsets of LTBI based on their similarity to infected patients. CONCLUSIONS: A group of biomarkers detected by different techniques characterizes the different status of TB infection and the different profiles of the latent infection.

Anti-PD-1 Immunotherapy Modulates PD-L1 Expression on Neutrophil Subsets and Monocytes from Advanced Melanoma Patients

***M. R. Galdiero**[1,2,3], L. Cristinziano[1,2,3], M. Capone[4], G. Madonna[4], D. Mallardo[4], S. Loffredo[1,2,3], A. Ferrara[1,2,3], M. Braile[1,2,3], V. Vanella[4], L. Festino[4], P. Ascierto[4], G. Marone[1,2,3];*
[1]Department of Translational Medical Sciences (DiSMeT), Naples, Italy, [2]Center for Basic and Clinical Immunology Research (CISI), Naples, Italy, [3]WAO Center of Excellence, University of Naples Federico II, Naples, Italy, [4]Melanoma Cancer Immunotherapy and Innovative Therapy Unit, Istituto Nazionale Tumori Fondazione "G. Pascale, Naples, Italy.

Introduction: Advanced melanoma is a life-threatening cancer with a median survival of 6-9 months. Monoclonal antibodies (mAbs) that disrupt programmed death (PD-1) and PD-Ligand 1 (PD-L1) have revolutioned cancer immunotherapy. PD-L1 is expressed on several immune cells and recent evidence indicates that can be also expressed on human neutrophils. In addition to Normal Density Neutrophils (NDNs), a population of "Low Density" neutrophils (LDNs) increases in chronic inflammatory conditions and correlates with cancer progression. The role of peripheral blood neutrophils and monocytes as predictive biomarkers in anti-PD-1 therapy response is largely unknown. **Methods:** 39 Patients with advanced melanoma were prospectively recruited. PMNs and mononuclear cells were isolated from peripheral blood of healthy controls (HC) and melanoma patients, before and during anti-PD-1 therapy, to evaluate activation markers, PD-L1 expression, morphology, ROS production. **Results:** NDNs from melanoma patients displayed increased activation markers and PD-L1 levels compared to HC, which reverted during anti-PD-1 immunotherapy. Melanoma patients presented increased number of LDNs compared to HC but their percentages did not change during immunotherapy. Patients LDNs displayed increased PD-L1 expression compared to autologous NDNs which dropped after 3 months of therapy. PD-L1 expressing monocytes were increased in patients and decreased after 3 months of therapy. Patients NDNs showed reduced ROS production and peculiar morphological aspects. **Conclusions:** we found increased PD-L1 expression on peripheral blood NDNs, LDNs and monocytes in advanced melanoma patients, which was modulated by anti-PD-1 immunotherapy. Ongoing investigations are evaluating whether PD-L1 expressing myeloid cells can be associated with patient clinical outcome.

P.A3.06.05

Indoleamine 2,3 dioxygenase expression pattern in the tumor microenvironment predicts clinical outcome in early stage cervical cancer

***A. Heeren**, I. van Dijk, D. R. Berry, M. Khelil, D. Ferns, J. Kole, R. J. Musters, V. L. Thijssen, C. H. Mom, G. G. Kenter, M. C. Bleeker, T. D. de Gruijl, E. S. Jordanova;*
VUMC-CCA, Amsterdam, Netherlands.

Indoleamine 2,3-dioxygenase (IDO) can act as immunoregulator by inhibiting T cells via the degradation of tryptophan (trp) into kynurenine (kyn). The kyn/trp-ratio in serum is a prognostic factor for cervical cancer patients, however, information about the relationship between serum levels and IDO expression in the tumor microenvironment is lacking. IDO expression was studied in 71 cervical cancer samples by immunohistochemistry, and the link between kyn/trp-ratio in serum, clinicopathological characteristics, and the presence of T cells (CD8, Ki67, and FoxP3) in tumors were examined. In addition, we studied *IDO1* and *IFNG* gene expression using RNAseq data from 144 cervical tumor samples published by The Cancer Genome Atlas (TCGA). We demonstrate that patchy tumor IDO expression is associated with an increased systemic kyn/trp ratio in cervical cancer (P=0.009), whereas marginal tumor expression at the interface with the stroma is linked to improved disease-free and disease-specific survival (DFS: P=0.017, DSS: P=0.043). The latter may be related to T cell infiltration and localized IFNγ-release inducing IDO expression. Indeed, TCGA analysis revealed a positive correlation between *IDO1* and *IFNG* mRNA expression levels (P<0.001) and a significant association with improved DFS for high *IDO1* and *IFNG* levels. Our data indicate that the serum kyn/trp-ratio and IDO expression in primary tumors are not clear-cut biomarkers for prognosis and stratification of patients with cervical cancer for clinical trials implementing IDO inhibitors. Rather, a marginal IDO expression pattern in the tumor dominantly predicts favorable outcome, which appears to be related to IFNγ-release in the cervical tumor microenvironment.

P.A3.06.06

Observationally and genetically elevated plasma YKL-40 and risk of infectious disease in general population

***A. D. Kjaergaard**[1], J. Helby[2], J. S. Johansen[2], S. E. Bojesen[2], B. G. Nordestgaard[2];*
[1]Regionshospitalet Randers, Randers, Denmark, [2]Herlev and Gentofte University Hospital, Copenhagen, Denmark.

Background: YKL-40 is an acute phase protein elevated in patients with infectious and inflammatory diseases. We tested the hypothesis that baseline elevated YKL-40 is associated with increased risk of future infectious disease in the general population.
Methods: We performed prospective cohort and Mendelian randomization studies on 82,976 participants from the Danish general population followed for up to 23 years. We analyzed plasma YKL-40 levels (N=21,643) and *CHI3L1* (gene for YKL-40*)* rs4950928 genotype (N=82,375). Endpoints were any infection, bacterial pneumonia, diarrhoeal disease, sepsis, skin infection, urinary tract infection, and other infection.
Results: Multifactorially and CRP adjusted hazard ratio (HR) for any infection was 1.60 (95% CI: 1.40-1.83) for 91-100% versus 0-33% YKL-40 percentile category. Corresponding HRs were 1.80 (1.49-2.18) for bacterial pneumonia, 1.60 (1.08-2.37) for diarrhoeal disease, 1.63 (1.16-2.29) for sepsis, 1.64 (1.23-2.48) for skin infection, 1.54 (1.17-2.02) for urinary tract infection and 2.35 (1.18-4.70) for other infection. There was no difference between YKL-40 and CRP in the ability to predict risk of any infection (both area under the receiver operating characteristic (ROC) curve was 0.70). *CHI3L1* genotype was associated with plasma YKL-40 levels, but not with risk of any endpoint. Mendelian randomization did not support causality.
Conclusions: In the general population, elevated plasma YKL-40 levels were associated with increased risk of future infectious disease. The association was robust to extensive stratification as well as adjustment for confounders, including plasma CRP levels, but with no evidence to support causality.

P.A3.06.07

Impact of Radiofrequency ablation on plasma cytokines in patients with unresectable liver cancer

***K. Mazmishvili**[1], N. Kikodze[1], I. Pantsulaia[1], M. Iobadze[2], M. Mizandari[3], N. Janikashvili[1], T. Chikovani[1];*
[1]Department of Immunology, Tbilisi state medical university, Tbilisi, Georgia, [2]V.Bakhutashvili Institute of Medical Biotechnology, Tbilisi state medical university, Tbilisi, Georgia, [3]Department of Interventional Radiology, Tbilisi State Medical University, Tbilisi, Georgia.

Introduction: Radiofrequency ablation (RFA) is widely accepted interventional approach for liver cancer and has the advantages of high treatment efficacy and low complication risk. The various studies, including ours, have reported the immunomodulatory effects of RFA procedure on primary and metastatic liver cancer. The aim of this study was to explore the influence of RFA on the factors of tumor microenvironment including plasma cytokines.
Material and Methods: 10 patients aged 39 to 72 years (mean 55.1±11.2 years) with unresectable primary and metastatic hepatic tumors underwent RFA. Blood samples were collected from each patient and plasma cytokines (TGF-β, IL-10, IL-17, INFγ) were measured before and after 1 and 3 month of RFA treatment. Healthy age-matched volunteers were used for group comparison. The Mann-Whitney U test, Mc Nemar test and Wilcoxon rank test were applied for intergroup comparisons as appropriate.
Results: Serum IL-17, IL-10 and TGF-β and IL-17 levels were elevated in the patients with liver cancer compared to healthy volunteers. Decreased IL-10 and INF γ levels were reported after 1 and 3 month of RFA procedure, whilst there were not a significant changes in TGF-β and IL-17 levels after RFA treatment.
Conclusion. Changes in plasma cytokine levels in patients treated with RFA further edits the evidence on the immunomodulatory effects of RFA on tumor microenvironment.

P.A3.06.08

Analysis of the specific T cell repertoire against polyomavirus BKV

***A. Mohr**, A. Moosmann;*
DZIF Research Group "Host Control of Viral Latency and Reactivation" (HOCOVLAR), Helmholtz Center Munich, Munich, Germany.

BKV is a persistent virus, widespread in the population, and an important pathogen in immunocompromised persons. No specific treatment is currently available.
BKV-specific T cells are believed to be important mediators of antiviral protection, especially after transplantation. Previously, T cell epitopes of BKV antigens were identified, but mostly limited to a subset of BKV antigens and HLAs. Antiviral protection appears associated with certain HLAs, but candidates for protective epitopes have not been identified.
A more complete picture of BKV-specific T cell immunity covering all antigens and ranking epitopes for immunodominance would help understand immune protection and improve immunomonitoring and immunotherapy.
Therefore, we are studying the BKV-specific T cell response at the level of antigens, epitopes and HLA restriction in healthy donors. We use CD40-activated B cells loaded with peptide libraries to establish T cell clones and consecutively analyze function and phenotype of the T cells.
Our preliminary results indicate that individual BKV carriers recognize multiple epitopes per antigen. Analyses of ex vivo reactivity in ELISPOT (n=27) indicated that most donors recognize 2-5 antigens (out of 5). Specific T cell clones have been established, and their exact specificity and HLA restriction is being investigated.
We will proceed to determine the minimal epitopes and analyze the endogenous presentation and recognition of identified epitopes. The results of these studies will allow to identify the T cell repertoire at the level of antigen, epitope, and HLA in order to optimize monitoring and therapy of patients.

P.A3.06.09

Binding Immunoglobulin Protein as a potential target for immunotherapy during TB disease

***B. Motaung**, A. Loxton;*
Stellenbosch University, Cape Town, South Africa.

Background: Mycobacterium *tuberculosis* (M.*tb*) infection is one of the leading causes of mortality worldwide. Recent studies have highlighted the importance of BiP in cells, which can become a target in many diagnostic settings as it has been implicated in conditions including arthritis, cancer, bacterial infection and autoimmune diseases. In our studies, we are aiming to understand the expression differences of BiP in different M.*tb* infection stages to help us understand the change of function in immune cells in relation to infection stress. **Method:** Absolute BiP secretion levels were assessed in plasma samples using ELISA. This included participants at TB diagnosis (TBDx), TB Treatment group (Week 1, Month 2 and Month 6) and Healthy (unexposed) participants. BiP concentration results were analyzed using GraphPad Prism 7. **Results:** Secretion of BiP was comparable between newly diagnosed untreated pulmonary TB cases and healthy unexposed controls, with levels obtained in healthy group (42.64 µg/ml) and in TBDx (40.88 µg/ml). Highest levels of plasma BiP during treated TB was observed by W1 (mean 68.57 µg/ml) and declined by M2 with 60.92 µg/ml and M6 with 51.40 µg/ml. **Conclusion:** Detection of BiP in plasma samples indicated metabolic change in immune cells due to stress posed onto cells by M.*tb* burden. Even though not significant, we observed a decrease in the mean levels of BiP over the course of TB treatment which correlates with a reduction in the accumulation of unfolded polypeptides in the ER. This observation requires further testing in larger prospective studies.

P.A3.06.10

Association of the natural killer cells with the clinical complications in patients with common variable immunodeficiency: a new risk marker

***S. Padure**, M. Di Natale;*
Hospital General Universitario Gregorio Marañón, Madrid, Spain.

The common variable immunodeficiency (CVID) is a pimary immunodeficiency that consists of hypogammaglobulinemia IgG and IgM or IgA, associated to recurrent infeccions and poor response to vaccines. In this study we will evaluate the association between the NK cell levels and the complications developed in patients with CVID.Methods: A retrospective study of 50 patients with CVID. Quantifications of NK cells were made by flow cytometry of 4 colours with the phenotypic definition CD3-CD56 + / CD16 +. T de Student, Chi-cuadrado and logistic regression statistical tests were used to analyze the data. Results: Demographic variables - 23 men and 27 women. We observed levels significantly lower of NK cells in patients hospitalyzed with infections (75±83 vs 170±129 cells/uL, p = 0.03) especially pneumonia (104±90 vs 163±133 cells/uL, p = 0.19), also with lymphoproliferation (76±70 vs 163±130 cells/uL, p = 0.019) and autoimmunity (93±91 vs 162±130 cells/uL p = 0.16). We observed that 50% of patients with severe infections had NK levels < 50 cells/uL compared to only 15% of patients without this event (p = 0.017). The logistic regression analysis confirmed that patients with levels of NK cells < 50 cells/uL were more exposed at risk of developing severe infection or death. Conclusion: Based on the results, we can conclude that levels of NK cells < 50 cells/uL can be considered as a risk factor for poor evolution in patients with CVID. This could be useful in the process of selection of patients who need more frequent controls.

P.A3.06.11

The influence of lithium and valproic acid on proliferation and apoptosis of T lymphocytes in patients with bipolar disorder.

***K. Pietruczuk**[1], K. Lisowska[1], K. Grabowski[2], J. Landowski[2], J. Witkowski[1];*
[1]Department of Pathophysiology, Gdansk, Poland, [2]Clinic of Adult Psychiatry, Gdansk, Poland.

Bipolar disorder (BD) is a serious mental illness with cyclic alternations of mood. It is not only affecting patients' mood and behavior but also influences their immune system. Therefore, we evaluated the efficiency of the immune system of BD patients treated with two different mood stabilizers (lithium or valproic acid).
We investigated proliferation of T cells stimulated with anti-CD3 antibody using cytometric dividing cell tracking (DCT) method. We also assessed their susceptibility to apoptosis using staining with annexin-V and measuring intracellulary amount of protein Bax and Bcl-2. Expression of Bax and Bcl-2 was also analyzed with quantitative RT-PCR. Additionally, we investigated *in vitro* influence of lithium or valproic acid on these parameters of T lymphocytes.
T lymphocytes of BD patients, especially those treated with lithium, had reduced proliferation capacity compared to healthy people. *In vitro*, valproic acid in very high dose reduced the number of cell divisions and percentages of proliferating cells regardless of health status. Meanwhile lithium had no significant influence on proliferation parameters of patients' lymphocytes. Lymphocytes of BD patients were also more prone to apoptosis compared with healthy individuals, which was related to high expression of Bax. *In vitro*, both lithium and valproic acid protected patients' lymphocytes from apoptosis.
To conclude, these results showed that mood stabilizers used to prevent relapses of BD have strong anti-apoptotic effect on patients' T lymphocytes but they are not able to improve their proliferation.

P.A3.06.12

Deciphering the role of Macrophages in pituitary tumours development

***M. Principe**[1], M. Chanal[1], A. Vasiljevic[2], E. Jouanneau[3], A. Hennino[1], G. Raverot[1,4,5], P. Bertolino[1];*
[1]Centre de Recherche en Cancérologie de Lyon, Inserm U1052, CNRS UMR5286, Université Lyon 1, Lyon, France, [2]Centre de Pathologie Est, Groupment Hospitalier Est, Hospices Civils de Lyon, Bron, France, [3]Universite Lyon 1, Service de Neurochirurgie, Hopital Neurologique, Hospices Civils de Lyon, Bron, France, [4]Féderation d'Endocrinologie, Groupement Hospitalier Est, Hospices Civils de Lyon, Bron, France, [5]Faculté de Médecine Lyon Est, Université Lyon 1, Lyon, France.

INTRODUCTION: Pituitary tumours (PiTs)- the second intracranial neoplasm- present heterogenic characteristics based on hormonal expression and secretion. Even if most of the PiTs have slow progression, a subset of these exhibits an aggressive clinical course with recurrences despite surgery, radio- and chemotherapy. Our project aims at cartographing the immune landscape of PiT Microenvironment (PiTME) in order to identified new immune-therapeutic targets. METHODS: Cytofluorimetric and immunohistochemical (IHC) analysis on fresh resected human PiTs are used. *In vivo* transplantation of fresh human PiTs has been performed in in Rag2KO mice. RESULTS: Firstly, we report the presence of T, B, NK cells and Macrophages in PiTME in a cohort of 42 patients screened by cytofluometry. Gonadotroph tumours have a peculiar infiltration of $CD68^+$ Macrophages in comparison to Somatotroph tumors that instead show a T cells infiltrate (activated $CD44^+/CD8^+$ T cells). Secondly, we confirm our data on human tissue sections showing a significant increase in $CD163^+$ staining in Gonadotroph compared to Somatotroph tumors, and this positively correlates with local invasion, but not with the tumour size. Thirdly, *in vivo* injection of fresh human PiT shows a sustained recruitment of mouse Macrophages, suggesting their importance in supporting tumour growth. CONCLUSION: We identified different TME landscapes in PiTs (Somatotroph and Gonadotroph). Our work pinpoints the crucial role of CD68+/CD163+ macrophages in tumoral progression and invasion. Future experiments will aim to find out if the re-education of these Macrophages (e.g. anti-CSF1R) can affects the PiTME and slow down tumour growth.

P.A3.06.13

A longitudinal investigative study of dengue-specific B cell responses during natural infection.

***A. Rouers**, K. Kaur, Y. Toh, D. Sathiakumar, R. Appanna, G. Au, K. Fink;*
*Singapore Immunology Network, A*STAR, Singapore, Singapore, Singapore.*

Dengue is a viral disease for which the immune response can be both protective and detrimental. T and B cells are highly activated in patients with severe disease, and this massive activation inevitably affects the immune repertoire. T and B cells are also important for the generation of immune memory and subsequent protection against re-infection. However, this anti-dengue adaptive immune response is not well characterized. To this end, we deeply investigated the cellular and molecular phenotype of dengue-specific B cell responses in a longitudinal cohort of 68 individuals infected by dengue virus for the first time or the second time.
We identified plasmablasts and observed a dramatic increase of their frequency 1 week after fever and a diminution by the early convalescent phase (1month after fever). In addition, secondary infected subjects had higher percentages of plasmablasts than primary infected subjects. Interestingly, study of anti-dengue antibodies in the serum of patients showed that titers drop rapidly between 1 and 6 months after fever. By investigating the neutralization ability of these antibodies, we observed a peak of neutralization at 1 month after fever, which is even higher in secondary-infected subjects. B-cell Elispot assays have been performed to assess the long-lasting B cell memory responses against dengue and highlight a maintenance of anti-dengue memory B cell responses at least 6 months after fever.
This work, completed by deep sequencing of B cell populations and investigation of T cell responses, will lead to important insights in the field of dengue immunology and vaccinology.

P.A3.06.15

Influence of DCF on peripheralimmune responses in HPV+ Squamous Cell Carcinoma of the anus (SCCA)

***L. Spehner**[1], M. Jary[1,2], S. Kim[2], M. Kroemer[1,2], O. Adotevi[1,2], V. Westeel[1,2], C. Borg[1,2];*
[1]UMR1098/BFC/EFS, Besançon, France, [2]CHRU, Besançon, France.

Purpose: To investigate the influence of Docetaxel-Cisplatine and 5-Fluorouracil (DCF) systemic chemotherapy on the peripheral immune responses in HPV+ Squamous Cell carcinoma of the anus (SCCA). Experimental Design: The presence of T-cell responses after a short term T-cell assay (7 days) against HPV16 E6/E7 derived-peptivator and Telomerase derived-peptides was monitored in 17 healthy donors (HD) and 59 patients with SCCA using IFN-g ELISPOT assay, before (n=59) and after (n=51) DCF treatment. Expression of TIGIT and Foxp3 on T-cells collected from peripheral blood both in HD and SCCA-cancer patients was determined using flow cytometry. Results: A HPV16 E6/E7 specific T-cell repertoire was present in HD (2/17 and 1/17 respectively) and SCCA-cancer patients before (21/59 and 7/59 respectively) and after (17/51 and 10/51 respectively) DCF treatment. A Telomerase specific T-cell repertoire was present in HD (5/17) and patients before (21/59) and after (16/51) DCF treatment. TIGIT expression on CD4 T-cells was higher in patients (8.3% and 8.2% respectively before and after DCF treatment) compared to HD (4.8%) ($p<0.001$). Similarly, CD4+FoxP3+CD25+ T-cells were higher in patients before (5.2%) and after (5.1%) DCF treatment compared to HD ($p<0.05$). DCF treatment did not modify TIGIT and Foxp3 expression. Conclusion: These results confirmed the immunogenicity of HPV16 E6/E7 and Telomerase derived peptides in HPV+SCCA. Our results show for the first time that the intensity of HPV16 E6/E7 and Telomerase specific responses are increased in HPV+SCCA patients after DCF treatment. Expression of TIGIT and Foxp3 were higher in patients and were not modify by DCF treatment.

P.A3.06.16

Are CD163-macrophages related with BRAF-mutation and progression of papillary thyroid carcinoma?

O. Sulaieva[1], *O. Chernenko*[2], *O. Larin*[2];
[1]*Laboratory of Pathology CSD Health Care, Kyiv, Ukraine,* [2]*Ukrainian Research and Practical Centre for Endocrine Surgery, Kyiv, Ukraine.*

The aim of this study was to assess relationship between *BRAF*-mutation status and papillary thyroid carcinoma (PTC) immune microenvironment with focus on CD163 macrophages. 60 patients with histopathologically confirmed PTC (48 females and 12 males, 43.2±0,9 years old) were enrolled in the study. *BRAF* V600E mutation was detected by PCR-RT prior to surgery using fine needle aspiration biopsy. There were 28 patients with BRAF mutation (46.7%). Tumor size, histological type of PTC, extra thyroidal extension (ETE) and intrathyroid invasion (ITI) and regional lymph nodes metastases were considered. In addition, immunohistochemistry with antibodies against CD163, COX-2 and VEGF was performed. *BRAF* mutation was detected in 28 patients (46,7%) with PTC. We did not find a significant association between *BRAF* V600E mutation and PTC clinicopathological features such as tumor size, ETE, ITI and lymph node metastasis. However, it was the significant difference in count of tumor associated CD163 macrophages in patients with different BRAF-mutation status (P=0.02). Most of PTC with high CD163 cells number was conventional rather than follicular type. CD163 cells number tightly correlated with VEGF (r=0.825, p<0.0001) and COX-2 expression (r=0.798, P<0.0001) and was related with high microvascular density (P=0.006) and ITI features (P=0.03). High number of tumor infiltrating CD163 cells was also associated with increase of CD163+ cells number in lymph nodes (P=0.002) and PTC metastasis (OR 13.3; 95% CI 3.1-57.2; P=0.0005). Thus, count of tumor associated CD163-macrophages, rather than BRAF-mutation, is associated with PTC lymph node metastasis.

P.A3.06.17

Varicella Zoster Virus-IgG antibody avidity in dialysis and kidney transplant patients

L. Wang[1], *C. Rondaan*[2], *E. Eelsing*[1], *A. A. de Joode*[3], *J. Westra*[1], *N. A. Bos*[1];
[1]*Department of Rheumatology and Clinical Immunology, University Medical Center Groningen and University of Groningen, Groningen, Netherlands,* [2]*Department of Medical Microbiology, University Medical Center Groningen and University of Groningen, Groningen, Netherlands,* [3]*Department of Internal Medicine, Division of Nephrology, University Medical Center Groningen and University of Groningen, Groningen, Netherlands.*

Introduction: Varicella zoster virus (VZV) infection usually occurs during childhood causing chickenpox establishing a lifelong latency, but can reactivate resulting in herpes zoster (HZ). Older persons and immunocompromised patients are at increased risk for developing HZ and related complications. The relation between functional affinity (avidity) of VZV-IgG and immunity against VZV reactivation has not been fully understood in immunocompromised patients. **Materials and Methods**: Serum samples and PBMCs were collected from 60 kidney transplant patients (KTx, median age: 55.6 years) approximately 3 years after transplantation, 63 patients on renal dialysis (RDs, 71.1 years) and 30 matched healthy controls (HC, 55.3 years). VZV-IgG level and relative avidity index (RAI) were assessed by glycoprotein (gp)VZV-ELISA with a denaturing agent (urea) incubation step. Cellular immunity (CMI) to VZV was measured by IFN-γ Elispot and expressed in spotforming units (SFU) per $5x10^5$ PBMCs. **Results**: There were no significant differences in IgG anti-VZV levels and RAI between the groups. CMI was higher in HC (128 SFU/$5x10^5$ PBMCs) compared to KTx (69 SFU/$5x10^5$ PBMCs, p=0.011) and RDs (82 SFU/$5x10^5$ PBMCs, p=0.094). In KTx, CMI correlated negatively to age (R^2=0.146, p=0.003). In KTx there was also a negative correlation between RAI and level of anti-VZV antibodies (R^2=0.189, p=0.0005) and age (R^2=0.088, p=0.021). No such correlations were found in HC and RDs. **Conclusion:** In kidney transplant patients both VZV- CMI and avidity of IgG anti-VZV antibodies decrease with age, while higher levels of VZV antibodies do not compensate for this. Especially older KTx are therefore at risk of HZ.

P.A3.06.18

Rotavirus antigen detection in children with gastroenteritis

N. Zotos[1], *P. Christodoulou*[1], *E. Tatsina*[2], *C. Mitsis*[1], *C. Briasoulis*[1], *K. Tolis*[1], *A. Zotou*[3], *G. Katagis*[1], *A. Pournou*[1];
[1]*General Hospital of Ioannina, Greece, Ioannina, Greece,* [2]*Papageorgiou Hospital, Thessaloniki, Greece,* [3]*University Hospital of Ioannina, Ioannina, Greece.*

Aim: The present study aims to record the frequency of detection of soluble Rotavirus antigen in stools of children with gastroenteritis. Method**:** During the 2016-2017 period, 198 stools of children with gastroenteritis were sent to the Microbiology Laboratory of our hospital. In the context of the laboratory investigation to identify the causative agent of the disease, feces were tested for the presence of a Rotavirus protein antigen by immunochromatographic method. Results: In a total of 198 diarrheal faeces tested, 82 (41.41%) were found positive for the presence of Rotavirus antigen, 116 (58.58%) negative Conclusions**:** Rotavirus immunochromatographic methods for detecting stools are methods that can be used to search for the virus and give a fairly reliable result. Rotaviruses are a very common cause of gastroenteritis in children. Their valid and timely detection in the stools can help in the immediate application of the appropriate treatment and avoid the unnecessary use of antibiotics.

P.A3.06.19

Rubella antibody incidence in children

N. Zotos[1], *E. Tatsina*[2], *L. Papageorgiou*[1], *M. Gianniki*[3], *P. Christodoulou*[1], *F. Adam*[1], *A. Zotou*[4], *E. Chrisostomou*[1], *A. Pournou*[1], *N. Tsifetaki*[1];
[1]*General Hospital of Ioannina, Greece, Ioannina, Greece,* [2]*Papageorgiou Hospital, Thessaloniki, Greece,* [3]*Agia Sofia Hospital, Athens, Greece,* [4]*University Hospital of Ioannina, Ioannina, Greece.*

Infection by Rubella Virus occurs mainly during childhood. However vaccination against Rubella Virus is part of the vaccination program. Rubella infection during pregnancy may result in the birth of a child suffering from Congenital Rubella Syndrome (CRS) Aim: To determine the incidence of antibodies against Rubella Virus in children during a two-year study Method: 394 serum samples from children (Greek and Immigrants) were tested for the presence of IgG and IgM antibodies against rubella virus from January 2015 until December 2017. They were 1 - 14 years old. ELISA (AxSYM , Abbott) was employed for the detection of the specific antibodies. Results: 394 children (48% boys and 52% girls) were tested.79% of the children tested were positive to IgG antibodies while 21% of the children were negative. Acute infection (positive IgM antibodies) was detected in 1% of the children. Immune deficiency was discovered more frequently in girls (57%) as well as in Greek children (67.5%) Conclusion: A high rate of IgG antibodies against Rubella Virus was detected. To note, more Greek girls were immune compromised. It is important to note that the high rate of immunity against rubella among immigrants is not attributed to the actual incidence of rubella but it reveals the fact that they have adapted successfully to Greek society. Moreover, a strong social approach is important, so as to increase the rate of immunized people, especially women of the reproductive age.

P.A3.06.20

Serological indication of acute infection by CMV and EBV in patients of a thirdgrade hospital

N. Zotos[1], *E. Tatsina*[2], *P. Christodoulou*[1], *M. Gerasimou*[1], *G. Katagis*[1], *N. Varsamis*[1], *A. Zotou*[3], *M. Gianniki*[4], *A. Pournou*[1], *N. Tsifetaki*[1];
[1]*General Hospital of Ioannina, Greece, Ioannina, Greece,* [2]*Papageorgiou Hospital, Ioannina, Greece,* [3]*University Hospital of Ioannina, Ioannina, Greece,* [4]*Agia Sofia Hospital, Athens, Greece.*

Aim: The aim of this study was to find positive IgM antibodies for CMV and EBV the simultaneously in patients with mononuclear syndrome. Material / Method: 2611 sera of patients for IgM antibodies against Epstein-Barr virus were examined. The tests were performed with ELISA. Also, 3558 patients' sera for IgM antibodies against CMV were tested by ELISA. Patients, whose sera were tested, were hospitalized in a hospital of Northwestern Greece during the last six years (2012-2017). Results: Of the 2611 sera tested for EBV, the following results were obtained: 128 (4.9%) positive, 75 (2.9%) marginal positive and 2408 (92.2%) negative for ANTI-VCA IgM. Of the 3558 sera tested for CMV, 94 (2.6%) positive, 35 (1%) marginal positive and 3429 (96.4%) negative for CMV IgM were obtained. All positive or marginal positive CMV IgM results were crossed with the corresponding results of EBV, in order to investigate the current IgM antibody positivity. All 129 positive sera for CMV IgM were tested for IgM against EBV. So it emerged that 37/129 (28.7%) had a simultaneous positivity. Of the 37 sera, 22 had high transaminases, leading to EBV infection, and positive IgM antibodies to CMV probably due to P62. Conclusions: Contemporary serological evidence of EBV and CMV co-infection has not been adequately explained whereas it is co-infection or endogenous reinfection. It appears, however, that EBV or CMV infection can lead to the synthesis of identical or approximately identical IgM antibodies.

P.A3.06.21

Interferon gamma transcript detection on T cells by combining three types of magnetic separation

S. Carinelli[1], *C. Xufre*[2], *M. Pividori*[1], ***M. Marti***[2];
[1]*Grup Sensors i Biosensors. Dpt Química. Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain,* [2]*Institut de Biotecnologia i Biomedicina. Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain.*

Interferon-γ is a proinflammatory cytokine, and its production is related with effective host defense against intracellular pathogens. Therefore, the level of interferon-γ is considered a good biomarker for intracellular infections. Beside this, it is also useful for the assessment, treatment progression and follow-up of non-communicable diseases, including cancer and autoimmune disorders, among others. This work addresses the development of a new strategy to evaluate the expression of interferon-γ transcripts produced by stimulated T lymphocytes cells as biomarker. The method sequentially combined three different types of magnetic separation, including the immunomagnetic separation of the T lymphocytes performed with antiCD3 magnetic particles. After that, the isolation and preconcentration of polyadenylated mRNA followed by the multiplex double-tagging RT-PCR amplification of the interferon-γ and glyceraldehyde 3-phosphate dehydrogenase (GAPDH) genes (as a housekeeping control) were performed on polydT magnetic particles. Finally, the multiplex electrochemical genosensing is performed on streptavidin magnetic particles as a support. This approach is able to quantify the levels of cellular interferon-γ produced by as low as 150 T cells with outstanding analytical features to be considered as a promising strategy for the quantification of this important biomarker for several clinical applications.

P.A3.07.01
Folate deficiency exacerbates the elevation of inflammatory cytokines in a sodium fluoride-induced renal inflammatory murine model

***C. Chan**, B. Lin;*
Department of Biochemical Science and Technology, College of Life Science, National Taiwan University, Taipei, Taiwan.

Introduction: Inflammation, as well as nutritional status, is associated with chronic diseases. Folate deficiency impairs immune cells function and differentiation. Whether folate deficiency exaggerates inflammatory responses still need to be clarified. It has been shown that sodium fluoride (NaF) induced renal inflammatory responses. Therefore, in the present study, we investigate the effect of folate status on the NaF-induced renal inflammatory responses in mice.
Materials and Methods: Twelve-week-old C57BL/6 mice fed with AIN93 diet were randomly divided into four groups: without or with folic acid for 10 weeks, and further orally gavaged with NaF (48 mg/kg body weight, F0-NaF, F1-NaF), or PBS as the vehicle groups (F0-PBS, F1-PBS), respectively, for 4 weeks.
Results: Feed efficiency, initial and final body weight did not differ among groups, but lower food intake and serum folate under folate deficient (F0) diet. Although urine protein, urea and BUN did not differ among groups during 4 weeks' induction, the significantly highest serum creatinine level was found in the F0-NaF mice. Serum TGF-β1 level and inflammatory mediators IL-6, MCP-1, but not TNF-α, were significantly higher in folate-deficient mice, and further increased by NaF induction.
Conclusions: Folate deficiency and NaF are independent factors that enhanced inflammatory cytokines levels in mice.

P.A3.07.02
Isoelectrofocusing as a high-resolution tool for the characterization of monoclonal gammopathies

***J. I. Fernández**, P. E. Walo, A. Roncancio, E. Roldán, L. M. Villar, M. Espiño;*
Immunology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain.

Introduction: Immunofixation electrophoresis (IFE) is considered the gold standard for characterization of monoclonal (M) proteins. However, IFE is not always easy to interpret. The presence of oligoclonal pattern or single diffuse M protein bands could generate confusion about the nature of M bands or their clonality. Isoelectric focusing followed by immunoblotting (IEF/IB) allows a greater analytical sensitivity and band resolution. We report a case that show the usefulness of this technique in charaterization of M components.
Materials and Methods: IFE was performed on the Hydrasys 2 Scan Focusing system using Sebia antisera. IEF were carried out following a method previously developed in our laboratory. In this procedure, ampholytes in the range pH 3–10 were used; proteins were transferred to PVDF membrane and revealed with anti-human IgM conjugated with alkaline phosphatase and anti-human kappa and lambda light chain antibodies conjugated with HRP.
Results: A 65-year-old male patient presented with anaemia, thalamic hemorrhage and IgM levels of 5.2 g/dl. Serum protein electrophoresis revealed a wide M speak in gamma region. A single monoclonal IgM band was characterized by IFE. This band was reactive with lambda and kappa light chain antisera. Pre-IFE reduction with DTT did not change double recognition of the IgM band by anti-kappa and lambda antibodies. However, IEF revealed the presence of two distinct separate bands: IgM kappa and IgM lambda indicating IgM biclonal gammopathy.
Conclusion: IEF/IB could be useful in the clinical setting to detect the clonality of M protein bands in problematic cases.

P.A3.07.03
Effect of chronic physical stress on immune system

***A. S. Hamada**, M. S. Shorbagy;*
Al Azhar university hospital, Cairo, Egypt.

Background: Physical stress affects most people in some way. During short-term stress, multiple physiological systems are activated to enable survival. Short-term stress response prepares the cardiovascular, musculoskeletal, and neuroendocrine and immune systems for fight-or-flight. On the contrary, stress can be harmful when it is chronic or long lasting as prolonged exposure to physical stress can negatively affect all body systems including immune system.
Objective: Investigating the effect of chronic physical stress on some parameters of immune system.
Patients and Methods: This study has been carried out on 50 truck drivers who work more than 72 hours per week, and 20 healthy persons of matched age and sex as a control group. Serum cortisol level (fasting, morning), IgG, IgM, IgA, C3 and C4 were measured, in addition to CBC and leucocyte differential count.
Results: Comparing results of patients group to normal control group, The patients group showed significant increase in cortisol(p=0.0024) , decrease in IgG and IgA levels (p=0.0122 and p=0.0089; respecively) and statistical significant increase in WBCs count in the case group(p=0.017). While C3,C4 and IgM levels showed insignificant change(p=0.0916, p=0.153 and p=0.111; respectively) .
Conclusions: Chronic physical stress suppresses the immune system and its function, subsequently, our study recommends adequate sleeping, healthy diet, reasonable exercise and to minimize physical stress as a life style to stay away from infections ,cancers and autoimmune disorders.

P.A3.07.04
T-Cell outcomes of HIV/AIDS treated patients with either EFAVIRENZ or NEVIRAPINE regimens in Yaoundé, Cameroon

***G. M. Ikomey**[1], B. Hycenta[1], G. Jacobs[2], M. Mesembe[1], E. Lyonga[1], A. Eyoh[1], M. Okomo Assoumou[1];*
[1]Virus Immunology Unit, Yaounde, Cameroon, [2]Division of Medical Virology, University of Stellenbosch, South Africa.

Introduction: T-cells responses provide information on immune failure or successes. Our study aimed to evaluate T-cell outcomes of patients on either Efavirenz (EFV) or Nevirapine (NVP) regimens after six months on therapy.
Method: A longitudinal study was conducted from May through December 2016. HIV-1 positive participants were enrolled. T-cell counts were done using standard methods.
Results: Of the 256 there were 108 (56%) females and 84 (44%) males, mean age of 39.3 ± 7.9 years. There were no significant increases in CD4 T-cell with p=0.3676 and 0.5662, respectively. Immunological failure rate of EFV and NVP were 37.0%, and 61.9% respectively. There was a significant change in CD4:CD8 with p=0.0444.
Conclusion: EFV regimen showed a better immunological failure compared to NVP. There was a significant change in CD4:CD8 ratio ranging from < 1 to >1.CD4/CD8 ratio could serve as a marker to monitor immune restitution of HIV/AIDS patients on ARV than CD4 absolute.

P.A3.07.05
Mechanismof Wenyangjianpi Prescription on The Treatment of Recurrent Spontaneous Abortion Caused by Maternal-FetalImmune Tolerance Based on Its Effects on The Balance of Th17/Treg Cells

***L. Jiang**;*
Gynecology, Kunming, China.

object:Recurrent Spontaneous Abortion(RSA) is a complicated disease in women of reproductive age, and its morbidity rate is on rising year by year.This article was explored Wenyangjianpi prescription possess a satisfactory effect in treating RSA may mediate by regulation of Th17/Treg cells balance. In this study, in vivo CBA/J×DBA/2 mice RSA model was established. The balance of Th17/Treg cells and their specific transcription factor and protein expressions are investigated. The theory that Wenyangjianpi prescription affects Th17/Treg cells balance to prevent RSA caused by maternal-fetal immune tolerance will be tested. Method: The CBA/J×BALB/C mice was established . Mice were divided into five groups including, Model group,control group and Wenyangjianpi prescription high, middle and lowdosage group.After 56 days which record Embryo absorption rate by flow cytometry. We tested Th17/Treg ratio in the peripheral blood each group. And also IL-6,CD130,p-STAT3,VEGF,VEGF Receptor,IL-27,IL-23 were tested with western blotting approach. Results: 1.Embryo absorption rate, Th17/ Treg cells ratio, CD130 and IL-23 of model group is higher than control group; the expression of IL-6,p-STAT3,VEGF, VEGF-Receptor, IL-27 of model group was lower than control group. 2. Th17/Treg ratio, CD130, and IL-23 of the three different dosage groups were lower than model group. IL-6,p-STAT3, VEGF, VEGFReceptor, IL-27 of the three different dosage groups were higher thanmodel group.
Conclusion: Wenyangjianpi prescription decreased Embryo loss rate through adjusting Th17/Treg cells balance.

P.A3.07.06
Comparison of mitogen induced proliferation levels of pediatric and adult healthy control groups by CFSE dilution assay

***U. C. Kucuksezer**[1], Z. Shoub F Elshari[1], I. Tahrali[1], S. Nepesov[2], G. Deniz[1], Y. Camcioglu[2];*
[1]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Dept. of Immunology, Istanbul, Turkey, [2]Istanbul University, Cerrahpaşa Faculty of Medicine, Dept. of Pediatrics, Istanbul, Turkey.

Introduction: Proliferation of antigen-responsive lymphocyte clones is the first-step in acquired immunity, which is important for development of effector functions. Tests investigating lymphocyte proliferation gains attendance both for immunology research and clinical diagnose. Proliferation tests requested from pediatric clinics for diagnose and follow-up of primary immune deficiency patients require healthy controls for comparison, however due to multiple reasons, it is hard to obtain blood samples from pediatric age groups. Concordance with adult healthy controls is a question.
This study aims to compare mitogen-induced proliferation values of pediatric and adult healthy control groups.

Materials and methods: Peripheral blood mononuclear cells (PBMC) isolated from freshly heparinized blood samples of pediatric (n=15) and adult (n=15) healthy control groups were stained with CFSE and stimulated with polyclonal activators; anti-CD2, -CD3 and -CD28 (CD-mix) and phytohemaglutinin (PHA). Proliferation levels of total lymphocytes were investigated on day +5 of cell culture. Independent samples T test was utilized for comparison of proliferation values of pediatric and adult healthy control groups.
Results: No comparable differences were observed for proliferation values of unstimulated (3.46±1.22% vs 3.70±2.12%), PHA stimulated (82.66±7.42% vs 75.59±9.12%) and CD-mix stimulated (82.96±7.15% vs 84.95±3.85%) proliferation values between pediatric and adult healthy control groups, respectively.
Discussion: The preliminary results of this study revealed similarity between pediatric and adult healthy controls. These findings may suggest the possible utilization of adult controls for comparison with pediatrics. More number of pediatric controls are needed, which will let the formation of specific pediatric age groups for more powerful comparisons.

P.A3.07.07
Mitogen-triggered proliferation responses of pediatric thalassemia major patients treated with bone marrow transplantation

U. C. Kucuksezer[1], *I. Tahrali*[1], *S. Nepesov*[2], *A. Yesilipek*[3], *G. Deniz*[1], *Y. Camcioglu*[2];
[1]*Istanbul University, Aziz Sancar Institute of Experimental Medicine, Dept. of Immunology, Istanbul, Turkey,* [2]*Istanbul University, Cerrahpaşa Faculty of Medicine, Dept. of Pediatrics, Istanbul, Turkey,* [3]*Bahcesehir University, Faculty of Medicine, Dept. of Pediatrics, Istanbul, Turkey.*

Introduction: Thalassemia major (TM), a disorder caused by gene mutations encoding globin chains of the hemoglobin molecule present with severe hemolytic anemia, impaired organs and have increased risk for infections due to deficient immune responses. The main way of permanent treatment for TM is bone marrow transplantation. Determination of cellular responses are required for vaccination timing after bone marrow transplantation. CFSE dilution is a flow cytometric approach for estimation of proliferative capacity.
Aim: This study aims to investigate mitogen-triggered proliferative responses of pediatric bone marrow transplant recipients with TM.
Methods: Peripheral blood mononuclear cells (PBMC) were isolated from freshly heparinized blood samples of TM patients after 1 year of bone marrow transplantation, and also from healthy subjects. PBMCs stained with CFSE were stimulated with polyclonal activators; anti-CD2, -CD3 and -CD28 (CD-mix) and phytohemaglutinin (PHA), and total, $CD4^+$ and $CD19^+$ lymphocyte proliferation levels were investigated on day +5 of cell culture.
Results: Cut-off values evaluated from healthy controls (n=20) were used for comparative evaluation of proliferative capacities of bone marrow recipients (n=23). 20 patients had normal proliferation values of total PBMCs, $CD4^+$ T cells and $CD19^+$ B cells, with no statistical significance in comparison with healthy controls. 3 patients were non-responsive to mitogens at various degrees.
Discussion: Our results reveal re-gained proliferative capacity in TM patients 1 year following bone marrow transplantation, which may be adequate for determination of vaccination time points. CFSE dilution can be a suitable tool for determining success of bone marrow transplant in immunological aspect.

P.A3.07.08
Identification of very early inflammatory markers in a porcine myocardial infarction model

E. López*, V. Álvarez, R. Blázquez, F. Marinaro, V. Crisóstomo, C. Báez, V. Blanco, A. Abad, J. García-Casado, F. Sánchez-Margallo;*
Centro de Cirugía de Mínima Invasión, Cáceres, Spain.

Introduction: The porcine model has been widely used to understand the pathophysiological mechanisms involved in cardiovascular disorders. The porcine myocardial infarction model is associated to an inflammatory response which includes elevation of circulating inflammatory cytokines, chemokines and activation of immune cells. This study aimed to identify which are the very early immune-related biomarkers that can be used as predictors of myocardial infarction severity.
Materials and Methods: Myocardial infarction model was created by 90 minutes temporary occlusion of the mid-left anterior descending artery. Peripheral blood samples were collected before and 1 hour after model creation. Peripheral blood leukocytes subpopulations were isolated by gradient density and analysed by flow cytometry. IL2, IFNγ, TNFα, IL12, IL10, IL4 and IL5 cytokines gene expression was analysed by RT-PCR.
Results: The analysis of lymphocyte subsets revealed a significant increase of CD4+/CD8+ ratio at 1 hour post-myocardial infarction. Regarding to the activation/differentiation status of T lymphocytes, the percentages of naïve, effector and effector/memory T cells did not show any significant change. Interestingly, CD4+ FoxP3+ cells were slightly increased after myocardial infarction. Concerning TH1/TH2 cytokines, a decrease in IL2, IFNγ, IL4 and IL5 gene expression was observed in peripheral blood cells.
Conclusions: The experimentally induced myocardial infarction modifies the distribution of T-cells and TH1/TH2 cytokines which is probably the consequence of lymphocyte recruitment to the inflammatory focus. Here we suggest that, the identification early biomarkers for myocardial infarction may provide very useful information for the diagnosis and treatment of this disease.

P.A3.07.09
Ubiquitin signalling in T cell activation: mapping the dynamic ubiquitylome

S. Matthews*, D. Kwasna, D. Pathak, Y. Kulathu;*
University of Dundee, Dundee, United Kingdom.

Precise control of T cell activation and differentiation is essential for competent adaptive immunity and deregulation of these processes can lead to lymphomas, autoimmunity and inflammation. The biochemical events regulating these processes have therefore long been a topic of intense research, which has been focussed predominantly on protein phosphorylation. It is now emerging that ubiquitin (Ub) and Ub-like protein (UBL) systems have important functions in regulating immune responses. The importance of ubiquitylation in adaptive immunity is underscored by the severe immunological disorders that arise when components of the ubiquitin system are disrupted in lymphocytes. However, we have a poor understanding of the pathways and mechanisms by which ubiquitin signalling regulates T cell function. This is largely due to the complexity of the ubiquitin system which makes it challenging to study this posttranslational modification. We here combine recently developed tools and quantitative proteomics to analyse dynamic changes in the Ub and UBL-modified proteome of activated T cells. Further, by analysing deubiquitinating enzymes, I will present our recent work that provides novel insights into the regulation of T cell function.

P.A3.07.10
TNF-Luc mouse: A Novel Model to Screen Anti-Inflammatory Drugs

F. MINSHAWI*, MIKE WHITE, WERNER MULLER, NEIL HUMPHREYS, DEAN JACKSON, ANTONY ADAMSON, AND STAMATIA PAPOUTSOPOULOU;*
University of Manchester, Manchester, United Kingdom.

In order to screen new potential anti-inflammatory drugs, it is vital to have an accurate and quantitative physiological model to measure inflammation and changes in inflammation. Tumor necrosis factor alpha (TNFalpha) is a major pro-inflammatory cytokine expressed at high levels in the immune response. We have generated a bacterial artificial chromosome that encompasses the human TNFalpha genomic region, and have engineered it to express luciferase under the control of natural human TNFalpha genomic sequences and generated a novel transgenic mouse line using this construct, we call the TNF-luc mouse.
We show that macrophages from TNF-luc mice have low resting levels of luminescence that is rapidly turned on in response to Lipopolysaccharide (LPS) stimulation *in vitro*. The luminescence response closely minics the production of soluble endogenous mouse TNF secretion indicating that the reporter gene expression from the human *Tnf* promoter in this transgenic mouse strain is similar to the regulation of the endogenous murine promoter. Several known NF-kb pathway inhibitors, but not a MAP pathway inhibitor, were able to suppress the luciferase expression. Moreover, Interleukin 10 (IL-10), a known anti-inflammatory cytokine inhibits luciferase expression in a dose dependent fashion. In conclusion, the TNF-Luc reporter mouse and cells derived from this mouse line is a valuable tool for screening of pro and anti-inflammatory compounds *in vitro*.

Recent findings on NK cell activation in cancer patients indicate that several important parameters, such as tumour capacity to modulate NK function and phenotype of NK cells require consideration for the choice of a NK-based therapy. In this study, we show in a melanoma-bearing mouse model that NK cells from the spleen are reduced as percentage and have different phenotypic characteristics than NK cells from the healthy controls. Methods. C57BL/6 mice, 8-10 weeks old were subjected to subcutaneous inoculation of B16F10 cells for developing cutaneous melanoma. Controls were sex and age-matched mice. After 21 days spleens were harvested and immediately assessed using flow cytometry analyses for NK cells populations (FACSCanto II flow cytometer with DIVA software). Results. Experimental data show a statistically significant reduction of the percentage of NK cells in melanoma-bearing mice compared to control animals. Analysis of NK cell subsets, defined by the differential expression CD27 and CD11b combination, indicated a significant difference in the distribution of NK cell subsets, namely the mature subset being dominant in control mice. Also, we found decreased CD43 and KLRG1 markers (commonly used for terminally mature NK cells), down-regulation of activating receptor NKp46 and up-regulation of inhibitory receptor Tim-3 in tumor-bearing mice. Our study has provided new insights into NK cell phenotype as future new approaches to cancer immunotherapy.Acknowledgement.This work was partially supported by Core Program, implemented with the support NASR, project no. 18.21.02.01.

Virus-specific TH2 cells grow out following addition of IL-4 in cell culture

S. Pollastro[1], *M. De Bourayne*[2], *B. van Schaik*[1], *A. Jongejan*[1], *A. van Kampen*[1], *B. Maillère*[2], *N. de Vries*[1];
[1]*AMC, Amsterdam, Netherlands,* [2]*SIMOPRO, CEA, Saclay, France.*

Introduction: Virus-specific Th2 T cells show lower frequency and lower capacity to expand compared to their Th1 counterparts. This makes their identification and characterization challenging when using *in vitro* T cells assays. **Methods:** Here, using a quantitative sequencing-based T-cell receptor (TCR) fingerprinting of clones, we studied expansion of virus-specific T cell clones after *in vitro* stimulation with virus-derived peptides in different cytokine milieus (addition of IL-2 + IL-4, IL-2 alone or no cytokines). **Results:** Significantly higher clonal expansion occurred in IL-2 + IL-4 milieu compared to IL-2 alone, and in IL-2 alone compared to no cytokines. Specificity for the peptides was confirmed by sorting and sequencing of CD40L-expressing T-cells. Analysis of the expanded TCR clonotypes revealed that addition of IL-4 induces expansion of different TCR clones when compared to IL-2 alone or no cytokines. Finally, three-color fluorospot assay showed that increased production of IL-5 and IL-10 could be detected only in the presence of IL-4 + IL-2 milieu. **Conclusion:** Taken together these data validate sequencing-based TCR analysis of clonal proliferation, and indicate that addition of IL-4 is necessary to induced clonal expansion of antigen-specific T cell clones with a Th2 functional phenotype.

As a consequence of cell activation or death, adenosine triphosphate (ATP) is released from cells into the extracellular space, inducing autocrine and paracrine purinergic signaling and inflammation. The ectonucleotidases CD39 and CD73 sequentially hydrolyze pro-inflammatory ATP to anti-inflammatory adenosine (ADO) and therefore play a key role in the generation of an anti-inflammatory environment. Under steady-state conditions human T cells express low levels of CD39. Upon activation cell surface CD39 is upregulated and contributes to local ATP degradation. In contrast to CD39, CD73 is mostly expressed on naïve CD8 T cells, while effector and memory T cells are mostly devoid. Upon *in vitro* activation, CD8 T cells upregulated CD73 in the first 24 hours, followed by loss of CD73 expression on the cell surface. *NT5E* RNA increased during the first hours and returns to initial levels two days after activation. Notably, only the cells which were primordially $CD73^-$ or that lost CD73 upon activation upregulated activation markers and underwent proliferation. CD73 was not re-expressed up to three weeks after activation. This $CD39^+CD73^-$ phenotype was observed at sites of inflammation, *i.e.* in the synovial fluid of children with juvenile idiopathic arthritis, where a large fraction of CD8 T cells were $CD39^+$ and lacked CD73 expression. Interestingly, cell culture supernatants from *in vitro* activated T cells displayed CD73-specific AMPase activity, indicating that T cell-derived extracellular CD73 is functional and may contribute to the mitigation of the immune response in the context of acute and chronic inflammation.

P.A3.07.14

The effect of end stage renal disease of T lymphocyte subpopulations in pre and post dialysis patients

E. Sampani[1], *A. Fylaktou*[2], *M. Stangou*[1], *V. Nikolaidou*[2], *D. Asouchidou*[2], *D. Daikidou*[1], *A. Anastasiou*[2], *M. Chalkia*[3], *C. Dimitriadis*[1], *P. Giamalis*[1], *A. Papagianni*[1];
[1]*Department of Nephrology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*Department of Immunology, National Peripheral Histocompatibility Center, Hippokration Hospital, Thessaloniki, Greece,* [3]*Department of Radiology, Hippokration Hospital, Thessaloniki, Greece.*

Introduction: End stage renal disease (ESRD) is associated with alterations in immune response The aim of this study was to assess changes in the T cell repertoire within ESRD patients on pre-and six-months post-dialysis state.
Methods: T cells subpopulations, namely CD3+CD4+, CD3+CD8+, Natural Killer cells (CD4+CD16+56+), Tregs (CD4+CD25+FoxP3+),CD8+CD28+,CD8+CD28- and CD4+CD28- cells, were isolated from whole blood samples using flow cytometry in 27 predialysis and 12 post-dialysis patients. The results were compared to 13 healthy controls.
Results: ESRD patients had reduced total lymphocyte number (1606±655μ/L vs. 2459±520μ/L, p<0.001). Furthermore the total numbersof CD4+ and CD8+ Tcells were significantly decreased (701.5±360.9μ/L vs. 1052.5±301.1μ/L, p=0.005) and (419.8±256μ/L vs. 478.8±194.7μ/L) respectively compared to healthy controls. Reduced total number of NK cells (238.3±141.2μ/L vs. 277.3±83.8μ/L) and Tregs (47.0±25.5μ/L vs. 58.9±24.4μ/L) was also noticed.
The frequencies of CD3+CD8+CD28+Tcells were decreased (48.5±22.1% vs. 58.2±17.0%), p=0.067), while the percentage of CD3+CD8+CD28- (55.2±21.9% vs. 37.4±15.4%p=0.022) was significantly increased. In 12 patients who had a follow up sample 6 months after renal replacement treatment, no differences were found except for Tregs subpopulation which decreased post-dialysis (5.0±2.9%vs. 7.5±1.3%, p=0.093). In 4/12 who commenced on peritoneal dialysis, CD3+CD4+CD28- subpopulations reduced (from 8.0±3.5% to 4.2±3.2%, p=0.068), in contrast to hemodialysis patients, who showed no difference.
Conclusions: Significant alterations within ESRD patients were noticed, with a reduction in CD4+, NK and Tregs and increased expression of CD8+CD28-cells. After dialysis a further reduction in Tregs happened while the changes in CD28 expression on CD4 T cells tended to return to normal in peritoneal dialysis.

P.A3.07.15

Immunophenotypic and clinical characterization of acute lymphoblastic leukemia at a public oncology reference center in Maranhão, Brazil

A. SERPA[1], *L. Pontes*[1], *E. Noronha*[2], *A. Azevedo-Santos*[1], *R. Oliveira*[3];
[1]*Federal University of Maranhão, São Luís, Brazil,* [2]*National Institute of Cancer, Rio de Janeiro, Brazil,* [3]*Centre of Clinical Research - HUUFMA, São Luís, Brazil.*

Introduction: Acutel ymphoid leukemias (ALL) are characterized by the exaggerated proliferation of precursor cells of the lymphoid lineage, caused by successive mutations in this maturative phase. ALL are immunophenotypically classified as B: B-I or pro-B, B-II or common LLAB, B-III or pre-B and B-IV or mature; and T-1 or pro-T, T-II or pre-T, TIII or cortical-T and T-IV or mature lineage ALL; and ALL with expression of one or two myeloid markers. Materials and Methods: the present study analyzed clinical and immunophenotypic data from 52 patients assisted by the State referral center. Results: stratification showed a higher frequency between 1 and 10 years (63,5%), males (53,8%) and subtype B (88,5%). In abhorrent phenotype analysis, CD33 expression was 31,8% (n = 7) in 22 patients diagnosed with ALL B, 33% (n = 1) in 3 patients diagnosed with ALL. CD13 positivity was evaluated in 34 patients with B-ALL testing positive in 29.4% (n = 10), in 5 patients with T-ALL had no positivity. Regarding the evolution of patients from the day of diagnosis to day 8 of the treatment, there wasn't a statistical difference in the variation of the global leukocyte count in diagnosis and on the eighth day of treatment in all subgroups of ALL. Conclusion: the study showed that the frequencies of ALL in the state of Maranhão are relatively similar to those seen in literature, they present abhorrent phenotypes and respond to the treatment used.

P.A3.07.16

Memory-like CD8+ T cells show contradictory functional properties under lymphopenic conditions

Y. Y. Silaeva[1], *A. A. Kalinina*[2], *L. M. Khromykh*[2], *D. B. Kazansky*[2];
[1]*Federal State Budget Institution of Sciences Institute of Gene Biology, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Federal State Budgetary Institution "N.N. Blokhin Medical Research Center of Oncology" of the Ministry of Health of the Russian Federation, Moscow, Russian Federation.*

Introduction: One of the major surface markers that allow to define different populations of T cells are CD44 and CD62L. Expression of these markers on a surface of T-lymphocytes defines their migration pathways and functional status. It is known, that in lymphopenic conditions peripheral T cells undergo homeostatic proliferation and acquire the memory like surface phenotype $CD44^{hi}CD62L^{hi}$, but data about functional activity of these cells remain controversial. We studied relationship between surface expression of the markers CD44 and CD62L and functional properties of CD8+ T cells under lymphopenic conditions. Materials and Methods: First of all, we investigated allogenic immune response of memory cells in sublethally irradiated immunized and unimmunized mice. Secondly, we studied the allogeneic immune response of splenocytes of sublethally irradiated mice after adoptive transfer of syngeneic splenocytes from intact or immune mice. Results: In spite of the practically identical ratio of cells with the surface phenotype of naive and activated T-lymphocytes in spleens of intact and immune sublethally irradiated animals, the antigen-specific response of the memory cells was observed only in immunized animals. Although splenocytes of both intact and immunized mice after adoptive transfer to sublethally irradiated animals acquired the surface phenotype of activated T cells their primary and secondary immune responses in vitro and in vivo are significantly suppressed. Conclusion: Thus, we proved that surface expression of CD44 in not the only condition for T lymphocyte to acquire the functional properties of memory T-cell.

P.A3.07.17

Effect of the levels of vitamin D upon CD161 positives T cells in healthy Bulgarian women

E. S. Slavov[1], *K. G. Nancheva*[1], *V. N. Mateva*[1], *R. B. Lokova*[1], *A. V. Avramova*[2];
[1]*Trakia University, Stara Zagora, Bulgaria,* [2]*"Medical Center SELENA-L", Stara Zagora, Bulgaria.*

A pandemic of decreased vitamin D serum levels in humans could disrupt the immune tolerance via activation of autoreactive lymphocyte subpopulations. We studied the effect of vitamin D levels upon the distribution of CD4+CD161+, and CD8+CD161+ T-cells in healthy Bulgarian women. We also surveyed the effect of the working environment on these parameters. 62 women (age 47,7±9,6) were evaluated. They were divided in three groups, according to their working place: 23 industrial workers in shift work, 16 office workers, and 23 teachers. The percentage of CD4+CD161+ and CD8+CD161+ cells was analysed by flow cytometry. Total vitamin D level was evaluated by electrochemiluminescence.
We found that only 4,8% of the women had normal vitamin D levels (>30ng/ml), 22,2% had insufficiency (20-30ng/ml), 63,5% had deficiency (10-20ng/ml) and 9,5% had severe deficiency (<10ng/ml). A moderate inverse correlation (r=-0,3, p=0,037) between vitamin D levels and the percentage of CD8+CD161+ cells was calculated. We found no statistically significant differences in vitamin D levels, and the percentage of CD4+CD161+ T-lymphocytes according to the type of work. A statistically significant decreased percentage of CD8+CD161+ T-lymphocytes was found in the industrial workers group (4,7±2,6) compared to office workers (7,9±2,6 p=0,0001) and teachers (7,8±3,5 p=0,002).We may conclude that the majority of the cohort of Bulgarian women had vitamin D deficiency. Vitamin D exerts specific dose dependent regulation on CD4+161+ and CD8+CD161+ T-lymphocytes. Further studies are needed to clarify the impact of the epigenetic effects of working conditions on vitamin D mediated regulation of CD161 positives T-lymphocytes.

P.A3.07.18

Virus-associated subpopulations of T-lymphocytes forming antiviral immune response to tick-borne encephalitis vaccine

A. L. Sycheva*, M. V. Pogorelyy, E. A. Komech, I. V. Zvyagin, I. Z. Mamedov, Y. B. Lebedev;*
Shemyakin–Ovchinnikov Institute of bioorganic chemistry RAS, Moscow, Russian Federation.

For tick-borne encephalitis (TBE), as for many other viral diseases, the most promising approach to reduce morbidity and mortality is preventive immunization. Vaccination efficiency is evaluated by antibody titers as standard, whereas T-cells form antiviral response as well. Therefore, study of T-cell response to immunization could give new insight in antiviral defense and be useful for new vaccine developing.
For this purpose we took PBMC from 5 donors and isolated pairs of full, $CD4^+$, $CD8^+$, and $CD45RO^+$ leukocyte fractions at each of the six timepoints during immunization with TBE vaccine. At several timepoints small vaccine-associated populations (IFNγ or IL-2 producers and $CD38^+HLA\text{-}DR^{hi}$ T-cells) were collected. Total RNA was isolated, T-cell receptor (TCR) β-chain cDNA libraries were prepared and sequenced on Illumina HiSeq.
Deep TCR repertoire profiling was performed for all collected fractions. By implementing mathematical models we found hundreds of significantly expanded T-cell clonotypes. Many of these clonotypes was detected in repertoire of small vaccine-associated fractions. Single preferential peak of the expansion was observed for $CD4^+$ T-cell clonotypes, while $CD8^+$ clonotypes had several comparable peaks at different timepoints. The last evidence allows us hypothesize recruitment of distinct $CD8^+$ T-cell clones at various stages of immune response. Also in TCR repertoire of each donor we found clonotype clusters (with similar amino acid TCR sequence reflecting in presumably similar specificity) that had maximal concentration at the same timepoint. These new data will help deeper understand T-cell clonotypes behavior during immunization with inactivated vaccines.
The work was supported by RSF grant 15-15-00178.

P.A3.07.19

Using commercially available antibodies for flow cytometry of *Panthera* species lymphocytes: A pilot study

T. T. Sylvester*, S. D. Parsons, P. D. van Helden, M. A. Miller, A. G. Loxton;*
DST/NRF Centre of Excellence for Biomedical Tuberculosis Research/SAMRC Centre for TB Research, Cape Town, South Africa.

The immune response against tuberculosis in lions is still poorly defined and our understanding is hampered by the lack of lion specific reagents. The process for producing antibodies against a specific antigen is laborious and not available to many research laboratories. As the search for antibody cross-reactivity is an important strategy for immunological studies in veterinary medicine, we have investigated the use of commercially available antibodies to characterize T cell subsets in African lions (*Panthera leo)*. We screened commercially available antibodies and investigated the influence of two different sample processing methods, as well as the effect of time delay on cell surface marker expression on lion lymphocytes. Using commercially available antibodies, we were able to identify CD4+, CD5+, CD8+, CD14+, CD25+, CD44+ and CD45+ T lymphocytes in samples obtained by density gradient centrifugation as well as red cell lysis of lion whole blood. Two distinct lymphocyte populations, which differed in size and phenotype, were observed in the samples processed by density gradient centrifugation. In this study we demonstrate the utility of commercially available antibodies to differentiate between T lymphocyte subsets including immune effector cells in African lion whole blood.

Streptococcus pneumoniae antigen detection in urines of pneumoniae patients

N. Zotos[1], *P. Christodoulou*[1], *E. Tatsina*[2], *L. Papageorgiou*[1], *E. Chrisostomou*[1], *G. Katagis*[1], *A. Zotou*[1], *N. Varsamis*[1], *M. Gianniki*[3], *A. Pournou*[1], *N. Tsifetaki*[1];
[1]*General Hospital of Ioannina, Greece, Ioannina, Greece,* [2]*Papageorgiou Hospital, Thessaloniki, Greece,* [3]*Agia Sofia Hospital, Athens, Greece.*

Aim: The goal of this study is to record the frequency of detection of soluble pneumococcal antigen in human urine. Material and Methods: During the years 2014-2017, 505 samples of patients' (treated with pneumonia symptoms) urine were examined at the hospital's Microbiology Laboratory. Urine was tested for pneumococcal antigen detection by immunochromatographic method. The method detects the 23 serological types of streptococcal pneumonia that cause at least 90% of serious pneumococcal infections worldwide. With this method, it is possible to detect pneumococcal antigens when they are secreted at concentrations $>10^5$ cells / ml of urine. Results: A total of 505 urine specimens tested, positive for pneumococcal antigen present were 89 (17.62%), while 416 (82.37%) were negative. Conclusions: The immunochromatographic method of detecting urinary pneumococcal antigen is a fairly reliable laboratory method that contributes to the immediate identification of the pneumococcal agent. However, both a negative and a positive result should always be confirmed by sputum or bronchial secretion cultures.

Distinct subsets of isotype-switched memory B cells in murine bone marrow and spleen

R. K. Addo[1], *R. Riedel*[1,2], *P. Durek*[1], *J. Kummer*[1], *G. A. Heinz*[1], *V. Greiff*[1], *D. Schulz*[1], *C. Klaeden*[1], *F. Heinrich*[1], *U. Menzel*[2], *S. Kröger*[3], *U. Stervbo*[1], *R. Köhler*[1], *C. Haftmann*[4], *S. Kühnel*[1], *K. Lehmann*[1], *P. Maschmeyer*[1], *M. McGrath*[1], *S. Naundorf*[1], *S. Hahne*[1], *S. T. Reddy*[2], *A. E. Hauser*[1], *M. Mashreghi*[1], *H. Chang*[1], *A. Radbruch*[1];
[1]*Deutsches Rheuma-Forschungszentrum, Berlin, Germany,* [2]*Eidgenössische Technische Hochschule (ETH Zürich), Basel, Switzerland,* [3]*Humboldt-Universität zu Berlin, Berlin, Germany,* [4]*Universitätsspital Zürich, Switzerland, Zürich, Switzerland.*

It is known that bone marrow contains resident memory T lymphocytes and longlived memory plasma cells, in niches organized by mesenchymal stromal cells. Here we demonstrate that bone marrow also maintains a distinct population of isotype-switched memory B lymphocytes. These cells differ from memory B lymphocytes of the spleen expressing the same isotype, in terms of phenotype and B cell receptor repertoire. Switched memory B cells from spleen and bone marrow show a significant fraction of exclusive B cell receptors. While all cells of the spleen express CD62L and CD21, only about 50% of switched memory B cells of bone marrow express CD62L, and 50% have downregulated CD21, pointing to functional differences in recall responses. More than 90% of the switched memory B lymphocytes of bone marrow and spleen rest in terms of proliferation, according to staining with Ki-67 and resistance to Cyclophosphamide treatment. In the bone marrow, switched memory B cells localize individually to VCAM-1+ and fibronectin+ stromal cells, similar to bone marrow-resident memory T and plasma cells. Like those, resident and resting switched memory B cells of the bone marrow, as a distinct compartment of B cell memory, probably provide longterm memory to systemic antigens.

P.A4.01.02
Toll-like receptor 9 signaling antagonizes cognate B cell-helper T cell interactions

***M. Akkaya**, B. Akkaya, A. S. Kim, P. Miozzo, H. Sohn, S. K. Pierce;*
National Institutes of Health, Rockville, United States.

Ability of B cells to capture antigens in order to process and present to follicular helper T cells plays an important role in T cell dependent antibody responses such as germinal center formation and affinity maturation. However, our understanding of the regulation of these key events is incomplete. Here we show that stimulation of B cells through TLR9, while enhancing cytokine production, proliferation and IgM secretion, blocked the ability of B cells to capture, process and present antigens. In the presence of TLR9 agonist CpG, B cells were less able to pull antigens from membranes, and to deliver captured antigens to MHC loading compartments which in turn resulted in less peptide MHC complexes on cell surface. This decreased the duration of B-T interaction and caused a less efficient activation of antigen specific T cells. RNA seq experiment of B cells stimulated through BCR and/or TLR9 generated a non-overlapping principle component analysis indicating that TLR9 dependent inhibition of BCR mediated activities are through a novel transcriptomal program. Using a chimeric mouse model and serum samples from a human clinical trial, we showed that CpG, enhanced the magnitude of the antibody response to a protein vaccine but failed to promote affinity maturation. Thus, TLR9 signaling may enhance the level of antibody response at the expense of the ability of B cells to engage in germinal center events that are highly dependent on antigen capture and presentation.

P.A4.01.03
Antigen stimulated B cells require a second signal to maintain their initial metabolic boost and avoid activation induced mitochondrial dysfunction.

***M. Akkaya**, J. Traba, A. S. Roesler, P. Miozzo, B. Akkaya, H. Sohn, B. P. Theall, M. N. Sack, S. K. Pierce;*
National Institutes of Health, Rockville, United States.

Events that follow B cell activation and lead to proliferation and differentiation into antibody secreting cells are tightly controlled in order to prevent unwanted immune responses. Requirement for two temporally distinct stimuli, first provided by BCR stimulation and second by either T helper cells or TLRs is the key to this control mechanism. However, our knowledge on the interplay between these two signals is incomplete. Here, using in vitro and in vivo models, we showed that antigen binding to BCR rapidly increases both oxidative phosphorylation and glycolysis, however most of the early events following BCR stimulation such as spreading and contraction of antigen bound BCR and internalization of the bound antigen are performed entirely by using the energy produced by oxidative phosphorylation. Changes in gene expression and cellular remodeling resulting in increased glucose uptake and mitochondrial performance follow the initial activation, preparing the cells to respond to a second signal. However, if the second signal is not received in a timely manner, B cells undergo progressive loss of mitochondria function ultimately leading to apoptosis. Mitochondria dysfunction is a result of the gradual accumulation of intracellular calcium which leads to inefficient oxidative phosphorylation and increased ROS production and eventually swollen patches of mitochondria. Receiving a secondary signal within 9 hours of initial BCR signaling can prevent these pathological changes. Thus, antigen binding activates a metabolic program that imposes a short time window in which B cells either receive a second signal and survive or alternatively face elimination.

P.A4.01.04
Type I interferon remodels the lung to promote ectopic GC formation during influenza A virus infection

***A. E. Denton**[1], S. Innocentin[1], E. J. Carr[1], B. Bradford[2], F. Lafouresse[3], M. A. Neil[2], B. Ludewig[4], J. R. Groom[3], K. L. Good-Jacobson[5], M. A. Linterman[1];*
[1]Lymphocyte Signalling and Development, Babraham Institute, Cambridge, United Kingdom, [2]The Roslin Institute and the Royal (Dick) School of Veterinary Sciences, University of Edinburgh, Edinburgh, United Kingdom, [3]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [4]Institute of Immunobiology,, St Gallen, Switzerland, [5]Infection and Immunity Program, Biomedicine Discovery Institute, Monash University, Melbourne, Australia.

Ectopic lymphoid structures form in a wide range of inflammatory conditions, including infection, autoimmune disease and cancer. Despite their relative ubiquity, little is known about the mechanism(s) through which inflammation is able to convert a peripheral tissue into one that resembles a secondary lymphoid organ. Here we show that type I interferon produced after pulmonary viral infection induces CXCL13 in lung fibroblasts, driving CXCR5-dependent recruitment of B cells and initiating ectopic germinal centre formation. This identifies type I IFN signalling as a novel inducer of CXCL13 and demonstrates that this cytokine can promote lung remodelling, converting a non-lymphoid tissue to one capable of supporting a highly ordered functional tertiary lymphoid structure.

P.A4.01.05
Unfolded protein response triggers metalloprotease-mediated processing of BAFFR and TACI in B cells

*C. R. Smulski[1], P. Odermatt[1], L. M. Seidel[1], S. Herr[1], P. Schneider[2], **H. Eibel**[1];*
[1]University Medical Center Freiburg, Freiburg, Germany, [2]University of Lausanne, Lausanne, Switzerland.

BAFF-receptor and TACI are members of the TNF-receptor superfamily. They are expressed specifically by B cells. Binding of BAFF as a common ligand for both receptors initiates pro-survival signals by BAFFR and class-switch recombination by TACI. Processing of BAFFR and TACI modulates the survival of resting and of germinal center B cells as well as the levels of circulating BAFF. We recently have shown that the membrane metalloproteases ADAM10 and ADAM17 can both process BAFFR and TACI at the plasma membrane and that the proteolytic cleavage of both receptors is regulated by the degree of BAFF oligomerization. Now we report that different signaling pathways can activate selectively the processing of BAFFR and TACI by ADAM10 and by ADAM17 in a ligand-independent manner. Inhibition of proteasomal activity by compounds like bortezomib induces the unfolded protein response, generates reactive oxygen species (ROS) and activates the TRAF2-ASK1 pathway. The newly produced ROS then selectively enhance the constitutive processing of TACI by ADAM10, whereas ASK1 induces processing of BAFFR by ADAM17. This unexpected role of the unfolded protein response and of ROS production affects the ability of primary human B cells to survive in response to BAFF but not to CD40L. Our results provide new insight into the treatment of autoimmunity and multiple myeloma

P.A4.01.06
A molecular signature of human regulatory B cells

***A. Grasseau**, M. Boudigou, Q. Simon, D. Cornec, J. Pers, S. Hillion;*
INSERM UMR 1227, Brest, France.

Regulatory B cell (Breg) in human is a large group of B cell subpopulations with a large heterogeneity in phenotypes and suppressor mechanisms. This variability leads to a high difficulty to characterize Bregs. It is now possible to define a molecular signature identifying a cell function using high throughput sequencing approach. One aim of our work is to better characterize a molecular signature of Breg in order to better understand their characteristics and functions in human physiology.Our laboratory has developed an in vitro model to polarize B cells in Breg and effector B cell. We have performed RNA-sequencing on these opposed polarized cell and underlined 225 significantly differentially expressed genes (DEG) in Breg related to effector B cells.A “DAVID” analysis shows that upregulated DEGs are linked to cytokine production and immune regulation, such as IL-10 . PCA analysis performed on co-culture supernatants confirms the important modification of cytokine production between the two conditions. Moreover, downregulated DEGs are related to the interferon type-I pathway. Furthermore, several genes from DEGs are related to plasmablast/plasma cell differentiation pathways, such as PRDM1. We thus have confirmed that Breg function is dependent of a unique differentiation process through a “GSEA” analysis using public data. In conclusion, we demonstrated that B-cell functions could be modulated by a specific microenvironment and cellular interactions. Overall, Bregs could be seen as a continuum of various phenotypes that associates distinct cell surface markers, cytokine secretion and transcriptional regulator expression driving by a specific differentiation program.

P.A4.01.07
Characterization of distinct functional domains of Pax5 *in vivo*

***S. Gruenbacher**, L. Hill, D. Kostanova Poliakova, M. Busslinger;*
Research Institute of Molecular Pathology, Vienna, Austria.

B lymphocytes express a vast diversity of antigen receptors on their cell surface, which provide immunity against foreign pathogens. During B cell development, the transcription factor Pax5 tailors the gene expression profile in favor of B cells by both activating B cell-specific genes and inhibiting B-lineage inappropriate genes. By doing so, Pax5 induces B cell commitment at the pro-B cell stage and controls the maintenance of B cell identity throughout B cell development. Consistent with this, B-lymphopoiesis is arrested at an early uncommitted progenitor stage in the absence of Pax5.
The Pax5 protein consists of different evolutionarily conserved domains, some of which have been mutated by amino acid substitutions or truncations in B-cell acute lymphoblastic leukemia. For instance, the introduction of a premature stop codon has eliminated the C-terminal transactivation domain and adjacent inhibitory region, suggesting that these domains are crucial for the function of Pax5. So far, the different domains have been functionally characterized only *in vitro* in cell lines. To elucidate the function of the different Pax5 domains *in vivo*, we generated several *Pax5* mutant mice lacking individual domains. Interestingly, mice harboring a C-terminal truncation of Pax5 showed a developmental arrest at the onset of B-lymphopoiesis, similar to what has been observed in *Pax5* knockout mice. However, another mutant containing the first few amino acids of the transactivation domain could facilitate transcriptional activation of selected Pax5 target genes, while B cell development was still arrested at an early pro-B cell-like stage.

Early emergence of the B cell lineage in developing zebrafish

***P. GUGLIELMI**, N. Abdellaoui, K. Kissa, G. Lutfalla, M. Nguyen Chi;*
DIMNP, UMR5235, Montpellier, France.

Our IGBP1 fluorescent transgenic zebrafish line identifies B lymphocytes throughout all maturation stages. B lymphocyte precursors are present on the yolk sac starting 2.5 dpf. Subsequently B lineage cells populate kidney, skin and gut. Use of double transgenic fish with IGBP1- and either *runx1*-, *kdr*- or *itga2b* (CD41)- reporters delineates two types of early B lymphocytes in embryos and larvae: 1/ a B cell population bearing the hallmarks of HSC progeny (*runx1*$^+$, *kdr*$^+$ and *itga2b*$^+$); 2/ an independent B cell lineage originating from yolk sac derived progenitors. After inhibition of HSC formation with a *runx1* morpholino, we still observed the yolk sack progenitor lineage. Functional transcripts for μ and ζ heavy chains were first detected in 11-12 dpf larvae with a limited repertoire. At 19 dpf and subsequently, H chain mRNAs pertaining to all VH subgroups were consistently present. Functional L chain transcripts were only found after 30 dpf. However, a germline transcription of the chromosome 19 L chain locus occurred starting 7 dpf. The resulting transcripts were processed using several cryptic splice sites present within the VL exons and upstream of the JL exon. Taken together, these results point to the existence of two separate developmental pathways for zebrafish B lymphocytes that could be reminiscent of the B1 and B2 type of differentiation in mammals. In addition, the existence of B cell precursors without Ig chain expression and the asynchronous appearance of H and L chain transcripts suggest respectively the existence of pro-B and pre-B cell maturation stages.

P.A4.01.09

The KDM4A/KDM4C/NF-κB and WDR5 epigenetic cascade regulates the activation of B cells

***K. Hung**[1], Y. Woo[2], I. Lin[1], C. Liu[1,3], L. Wang[4], H. Chen[1], B. Chiang[4,5], K. Lin[1];*
[1]Genomics Research Center, Academia Sinica, Taipei, Taiwan, [2]Division of Biological Sciences, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, [3]PhD Program in Translational Medicine, Kaohsiung Medical University and Academia Sinica, Division of Allergy, Immunology and Rheumatology, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, New Taipei City, Taiwan, [4]Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan, [5]Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.

How epigenetic regulation participates in the function of transcription factors during the activation and differentiation of B cells is largely unknown. Here, we demonstrated that the histone demethylases KDM4A and KDM4C are up-regulated in stimulated mouse splenic B cells, concomitantly linked with the global down-regulation of histone modification of their substrates H3K9me3/me2. KDM4A and KDM4C are important for the coordinated regulation of activation and proliferation of stimulated B cells. Upon chromatin immunoprecipitation sequencing (ChIP-Seq) and *de novo* motif analysis, we identified NF-κB p65 as the binding partner of KDM4A and KDM4C. Their co-targeting to *Wdr5*, a MLL complex member promoting H3K4 methylation, results in the up-regulation of cell cycle inhibitors, including *Cdkn2c* and *Cdkn3*. Thus, B cell activation is accompanied by KDM4A and KDM4C induction that initiates a stepwise epigenetic cascade for the proper control of the proliferation of activated B cells. We also assess whether the regulation of KDM4A/KDM4C/NF-κB/WDR5-mediated CDKN2C and CDKN3 gene regulatory cascades is disturbed in stimulated B cells of systemic lupus erythematosus (SLE) patients and found that the up-regulation of KDM4A and KDM4C as well as the induction of WDR5 are impaired in stimulated SLE B cells, as compared those in stimulated B cells from healthy donors. Together, in this study, we uncovered a stepwise epigenetic regulatory cascade that regulates B cell proliferation and activation.

P.A4.01.10

B cell-intrinsic role of DOCK2 inT cell-dependent humoral immunity

***Y. Kamikaseda**[1], M. Ushijima[1], Y. Fukui[1,2];*
[1]Medical Institute of Bioregulation Kyushu University, fukuoka city, Japan, [2], Reseach Center for Advanced Immunology, Kyushu University, Fukuoka city, Japan.

Introduction: Although activation of the small GTPase Rac has been implicated in BCR-mediated antigen recognition, its precise role in humoral immunity and the upstream regulator remain elusive. In this study, we examined B cell-intrinsic roleof DOCK2 in plasma cell (PC) differentiation and antibody production.Material and methods: We took the following three approaches: 1) B cells from conventional DOCK2 KO mice and control mice were used for biochemical analyses and in vitro functional assays. 2) DOCK2-deficient and control B cells expressing HEL-specific BCR were adoptively transferred into mice for in vivo functional assays. 3) The conditional KO mice lacking DOCK2 in B-cell lineage were developed and used to examine antigen-specific antibody production.Results:BCR-mediated Rac activation was almost completely lost in DOCK2-deficient B cells, resulting in defects in B cell spreading over the target cell-membrane and sustained growth of BCR microclusters at the interface. When wild-type B cells were stimulated in vitro with anti-IgM $F(ab')_2$antibody in the presence of cytokines, they differentiated efficiently into PCs. However, BCR-mediated PC differentiation was severely impaired in the case of DOCK2-deficient B cells. Similar results were obtained in vivo when DOCK2-deficient B cells expressing HEL-specific BCR were adoptively transferred into mice and challenged with the HEL antigen. In addition, by generating the conditional knockout mice, we found that DOCK2 expression in B-cell lineage was required to mount antigen-specific IgG antibody. Conclusion: The Rac activator DOCK2 regulates PC differentiation and antigen-specific IgG production.

P.A4.01.11

Transcription of the Ets1 gene is diminished in response to BCR signaling in an IKK2-dependent manner

***A. Kearly**, L. Garrett-Sinha;*
State University of New York at Buffalo, Buffalo, United States.

Introduction: The transcription factor Ets1 is required to retain B cells in a quiescent state. In response to BCR stimulation, Ets1 is downregulated in a manner dependent upon the kinase IKK2. However, whether this downregulation is due to changes in Ets1 gene transcription, Ets1 mRNA stability, and/or Ets1 protein stability is not known. It is also not clear whether NFκB is involved in downregulation of Ets1.
Methods: To determine whether Ets1 gene transcription is altered by activation, we measured newly-transcribed Ets1 precursor mRNA (pre-mRNA) by qPCR. This was complemented by assessing RNA polymerase II (Pol II) occupancy at the Ets1 promoter by ChIP-qPCR. To determine the role of NFκB in the downregulation of Ets1, we tested the effects of RelA (p65) loss using both B cell-specific RelA knockout mice and RelA siRNA knockdown.
Results: Levels of Ets1 pre-mRNA diminish in response to BCR stimulation in an IKK2-dependent manner. Pol II binding at the Ets1 promoter is also decreased with stimulation. Preliminary results further suggest that RelA is not required for this effect.
Conclusions: Control of Ets1 levels in B cells seems to be at the level of Ets1 gene transcription. Although the kinase IKK2 is required for this effect, RelA may not be a required downstream effector. Our studies are important because Ets1 is a key regulator of B cell quiescence and understanding how its expression is controlled may help develop therapies that can regulate B cell activation during immune responses.

P.A4.01.12

Temperature regulation of B cell activation

***M. LE BORGNE**[1,2], E. Procopio[1,2], B. Gachet[1,2], A. Loste[1,2], O. Thaunat[3,4], G. Caligiuri[1,2,5], A. Nicoletti[1,2];*
[1]INSERM U1148 "Laboratory for Vascular Translational Science", Paris, France, [2]Université Paris Diderot, Université Sorbonne Paris Cité, DHU FIRE, Paris, France, [3]INSERM U851, Lyon, France, [4]Hospices Civils de Lyon, Hôpital Edouard Herriot, Université de Lyon, Lyon, France, [5]Assistance Publique-Hôpitaux de Paris, Hôpital Bichat, Paris, France.

Elevated temperatures are often associated with the induction of immune responses: global elevation of body temperature in the case of fever, or local heat in the case of inflammation. It is known that elevated temperature impact the activation and functions of innate immune cells and T cells. However, the impact of temperature on B cell responses has been barely addressed.
In order to study if the activation and function of B cells are dependent on temperature, we stimulated B cells *in vitro* at different temperatures, and looked at the survival and activation of B cells by flow cytometry. We also analysed if activation of B cells with antigen-coated synthetic particulate antigens (SPAg) at different temperatures impacted their ability to later present antigens to antigen-specific T cells. We observed that elevated temperatures decreased the survival of B cells, and increased the internalization of CD19 (a member of the BCR co-receptor) and the upregulation of the costimulatory molecule CD86. B cells activated with SPAg at fever-like temperatures induced more proliferation of antigen-specific T cells in subsequent co-culture assays.
Altogether, our data show that activation of B cells depends on temperature. Further experiments are ongoing to decipher if temperature controls other aspects of B cell function *in vitro*, such as antibody production, and B cell activation *in vivo* in the context of vaccination.

P.A4.01.13

Size of CD40L signalling domain regulates efficacy of human naïve B cell differentiation and IgG class-switch recombination

C. Marsman[1], *P. Unger*[1], *N. Verstegen*[1,2], *T. Jorritsma*[1], *A. ten Brinke*[1], *M. van Ham*[1,3];
[1]*Sanquin Research, Dept Immunopathology, Amsterdam, Netherlands,* [2]*Synthetic Systems Biology and Nuclear Organization, Swammerdam Institute for Life Sciences, University of Amsterdam, Amsterdam, Netherlands,* [3]*Swammerdam Institute for Life Sciences, University of Amsterdam, Amsterdam, Netherlands.*

Human naïve B cells are notoriously difficult to differentiate into antibody-secreting cells (ASCs) *in vitro* due to unknown regulatory mechanisms involved in this process. Insights in factors controlling differentiation of B cells into antibody-secreting plasmablasts (PB) and plasma cells (PC) however, are not only important to generate effective humoral immunity against invading pathogens, but also to prevent undesired antibody formation in autoimmunity and blood transfusion. After uptake of antigens *in vivo*, B cells require co-stimulatory signals, like CD40L, and cytokines, like IL-4 and IL-21, from cognate T follicular helper (T_{FH}) cells during the germinal center response to undergo PB/PC differentiation. Here we elucidated that the size of the CD40L signalling domain is key in inducing significant naïve B cell to ASC differentiation *in vitro.* Our data, using different sizes of fractionated CD40L-expressing cell membranes, show that the efficacy of *in vitro* IgG class-switch and differentiation of naïve B cells into ASCs are highly dependent on the size of the CD40L signalling domain and can be dramatically induced in the appropriate cytokine environment. We have unravelled how T_{FH} cytokines IL-21 and IL-4 and variation of CD40L co-stimulation regulate the kinetics of phosphorylation of various signal transducers and activators of transcription (STAT1, STAT3, STAT5 and STAT6) involved in PB/PC differentiation. Our data are the first steps to provide much needed insight in the process of human naïve B cell differentiation to ASCs. This is not only crucial in improving vaccination strategies but will also aid in the prevention and treatment of auto-immunity.

P.A4.01.14

DGKζ dependent PA production at the B cell immune synapse regulates antigen presentation and the B cell response.

S. Merino Cortes[1], *S. Gardeta Castillo*[1], *S. Roman Garcia*[1], *A. Martínez-Riaño*[2], *B. Alarcon*[2], *Y. R.Carrasco*[1];
[1]*Centro Nacional de Biotecnolgia, Madrid, Spain,* [2]*Centro de Biologia Molecular Severo Ochoa, Madrid, Spain.*

BCR recognition of antigen at the APC surface leads to immune synapse (IS) formation. Vinculin and Rac GEFs regulate actin cytoskeleton during IS assembly. Vinculin and Rac GEFs are recruited to the B cell IS. These events lead to Rac activation and F-actin polymerization. DGKζ(diacylglycerol kinase ζ) metabolizes the DAG generated following antigen recognition to produce PA (phosphatidic acid). In non-immune cells, DGKζ is involved in controlling PIP_2 levels, by PA-dependent allosteric modulation of PIP5KI, and Rac recruitment. A proper synapse assembly is necessary for antigen acquisition and B cell activation; the DGKζ role on these molecular and activation events is unknown. We used primary B cells from wild type and DGKζ-/- mice, non-treated or treated with the pan-DGK inhibitor R59. Our results suggest that DGKζ-dependent PA production regulates Vinculin and Rac GEFs recruitment as well as F-actin polymerization at the B cell IS. DGKζ also controls MTOC polarization to the synapse. The impaired IS structure of DGKζ-/- and R59-B cells contrasts with increased B cell activation, suggesting that DGKζ exerts a balance between DAG consumption and PA production. Analysis *in vitro* of the antigen presentation of DGKζ-/- and R59-B cells showed reduced T cell proliferation and IL-2 production, suggesting defects in B cell antigen acquisition. Moreover, adoptive transfer revealed a decrease in B cell differentiation to plasma cells and IgG1+ cells for DGKζ-deficient mice. Our studies highlight an important role for DGKζ in B cell IS structure that controls antigen up-take and presentation to T cells.

P.A4.01.15

microRNA-148a: regulator of plasma cell differentiation and maintenance

K. Pracht, *J. Meinzinger, P. Daum, J. Côrte-Real, M. Hauke, S. Schulz, E. Roth, J. Wittmann, H. Jäck;*
Division of Molecular Immunology, Department of Internal Medicine III, Nikolaus-Fiebiger Center, Uni, Erlangen, Germany.

microRNAs (miRNAs) are critical regulators of central and Ag-driven B cell development. In addition, several plasma cell (PC) associated-diseases and a variety of cancer types are caused by deregulated miRNA-expression. However, it is still unclear how single miRNAs regulate the formation and survival of healthy or malignant PCs. We showed that miR-148a, the most abundantly expressed miRNA in PCs, is upregulated in activated B cells and promotes *in vitro* plasmablast differentiation and viability by targeting Bach2, MiTF, PTEN and Bim. To determine wether miR-148a is involved in the maintenance of PCs we estalished a tamoxifen-inducile miR-148a deficient mouseline. Deletion of miR-148a, 4 weeks after boost imunisation, resulted in reduced numbers of mature PCs and dividing plasmabasts in the spleen. While the number of mature PCs was also reduced in the BM, their frequency was significantly elevated in the blood. Moreover, *in vitro* deletion of miR-148a, 3 days after stimulation, revealed diminished numbers of viable LPS blasts. ELISpot analysis of isolated miR-148a deficient PCs showed altered isotype composition in the spleen and the bone marrow. These findings support the hypothesis that miR-148a controls the formation of plasma blasts as well as the maintenance of long-lived PCs and could be a potential target for the treatment of PC-associated diseases. Supported by DFG grants GRK1660 and TRR130 to H.-M.J.

A closer look at tissue-specific B cell regulation

J. H. Y. Siu[1], *Y. Zhao*[2], *T. J. Tull*[2], *K. T. Mahbubani*[1], *C. Pararasa*[2], *R. Ellis*[3], *N. Petrov*[3], *J. Spencer*[2];
[1]*University of Cambridge, Cambridge, United Kingdom,* [2]*King's College London, London, United Kingdom,* [3]*Biomedical Research Centre, Guy's and St Thomas' NHS Trust, London, United Kingdom.*

Lymphoid tissue is essential for normal B cell maturation and activation. Whilst B cell subsets in peripheral blood are well characterized, human tissue B cells and the differences that exist between blood and tissue are poorly understood.
We use mass cytometry (CyTOF) to perform a phenotypic analysis of B cell subsets in paired healthy human peripheral blood and gut-associated lymphoid tissue (GALT) (n=8). Spleen (n=6) and tonsil (n=5) were included for comparison. Using a panel of 34 antibodies to identify markers of B cell lineage, migration and activation, we assess their relative surface expression by B cell subsets across blood and tissue compartments.
We observe B cell surface phenotype alters dramatically as B cells enter tissues. In addition to changes in expression of chemokine receptors and homing markers, reduced expression of CD19 and IgD by naive B cells was observed in tissues compared to blood. This was confirmed in paired samples of blood and GALT by flow cytometry. Interestingly some differences that were observed between blood and GALT were not shared with other tissues. An example of this was reduced expression of CD40 by B cells in GALT compared to blood and other tissues suggesting that B cells may have reduced potential for CD40L dependent interactions with T cells in GALT. This study highlights that different tissues may regulate and modulate the potential for B cell responses in distinct ways.

P.A4.01.17

Quantitative assays to measure human B lymphocyte health

J. C. Tempany[1,2], *V. L. Bryant*[1,2,3], *P. D. Hodgkin*[1,2];
[1]*The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia,* [2]*Department of Medical Biology, University of Melbourne, Melbourne, Australia,* [3]*Department of Clinical Immunology and Allergy, The Royal Melbourne Hospital, Melbourne, Australia.*

We have developed standardised, quantitative functional assays for human B-lymphocyte responses to T-dependent (CD40L+IL-21) and T-independent (anti-Ig±CpG) stimuli. These assays measure division, death, differentiation and isotype switching, to reveal the innate programming of B lymphocytes in response to these conditions.
Here, we observed, for the first time, regulation of the size of the division burst (division destiny) in human B cells, a phenomena shown to be essential for appropriate regulation of murine T- and B-lymphocyte responses. We also determined that human B lymphocytes regulate survival, independently of both division rate and division destiny. Thus, we propose that standardised quantitative assays, and accompanying parametric models, can provide a sensitive measure of the 'health' of B cells, and may reveal underlying B cell dysfunction in patients with monogenic or complex immune disorders.
As a first test of this hypothesis we focused on patients with Common Variable Immunodeficiency (CVID), the most prevalent primary immunodeficiency. CVID is a clinically heterogenous disorder, united by antibody deficiency, where most cases are sporadic and, presumably, polygenic. We hypothesised that for many CVID cases, the sum of multiple small changes in cellular functions are responsible for an antibody deficit when combined in an immunodeficient individual. In a preliminary screen of 12 patients, we have identified defects in various parameters of B cell responses including survival, division, differentiation, isotype switching and immunoglobulin production. We are now using this approach to test B cell responses in patients from multiplex families to investigate combinatorial changes in cellular functions in affected individuals.

A novel multidisciplinary approach to elucidate disease causing processes in the germinal center

P. A. van Schouwenburg[1], *S. Unger*[2,3], *I. Pico-Knijnenburg*[1], *F. N. Kaiser*[1], *J. Pfeiffer*[4], *O. Hausmann*[5], *D. van Zessen*[6], *A. P. Stubbs*[6], *M. van der Burg*[1], *K. Warnatz*[2];
[1]*Department of Immunology, Erasmus MC University Medical Center, Rotterdam, Netherlands,* [2]*Center for Chronic Immunodeficiency (CCI), Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany,* [3]*University of Freiburg, Faculty of Biology, Freiburg, Germany,* [4]*Department of Otorhinolaryngology- Head and Neck Surgery, University of Freiburg, Freiburg, Germany,* [5]*Löwenpraxis and Klinik St. Anna, Zürichstrasse12, 6004, Luzern, Switzerland,* [6]*Clinical Bioinformatics Unit, Department of Pathology, Erasmus MC University Medical Center, Rotterdam, Netherlands.*

Here, we present a novel multidisciplinary approach to analyse patient germinal center (GC) material to further elucidate disease causing processes in individual patients. By combining histology, flow cytometry and B-cell receptor repertoire analysis of sorted GC B-cell populations we are able to model the disturbances in different patients.
Currently we have analysed three patients suffering from Common Variable Immune Deficiency disorder (CVID), a highly diverse disease characterized by recurrent infections, low IgG levels with low IgA and/or IgM and poor vaccination responses. We have previously found that CVID patients often have a defect in the GC.
Our data show that all three patients have different defects in the GC. In one patient both quantitative and qualitative B-cell development is normal in the GC, but only little memory B-cells are present in the periphery. In both other patients, GCs are non-polarised and abnormally shaped. Analysis in the second patient suggests impaired induction of SHM, poor antigen selection and impaired class-switching. IgM plasmablasts and IgM and IgG memory B-cells are formed but qualitative defective, while IgG plasmablasts are qualitatively normal but reduced in numbers. Results in the final patient indicate increased cycling of cells in the GC producing plasmablasts with increased SHM in the GC, and in very limited numbers in the periphery. Antigen selection and CSR are also impaired.
In addition to giving new insights in the GC reaction in CVID, this approach can also be applied to other immunological diseases with presumed GC defects.

P.A4.01.19

Do neonates benefit from influenza vaccination in the presence of high levels of maternal antibodies?

M. Vono[1], *C. Eberhardt*[1], *M. Schmolke*[2], *D. Christensen*[3], *P. Andersen*[3], *P. Lambert*[1], *C. Siegrist*[1];
[1]*WHO Collaborative Center for Vaccine Immunology, Department of Pathology and Immunology,University of Geneva, Geneva, Switzerland,* [2]*Department of Microbiology and Molecular Medicine, University of Geneva, Geneva, Switzerland,* [3]*Vaccine Adjuvant Research, Department of Infectious Disease Immunology, Statens Serum Institut, Copenhagen, Denmark.*

Influenza causes severe illness and death in high risk populations, including neonates and young infants, and remains a major public health issue. No influenza vaccine is currently licensed for use below 6 months of age. Maternal vaccination and transfer of vaccine-induced antibodies is an effective alternative - but with a transient efficacy. In our murine model, naïve pups from immunized mothers born with high levels of influenza-specific maternal antibodies (5 log10) loose protection against challenge when their antibody titers reach 3 log10 or less. Vaccination is the best way to prevent infection and we recently identified the adjuvant CAF01 as the first adjuvant able to induce germinal centers and protective primary responses to influenza hemagglutinin (HA) in neonatal mice. Here, we asked whether HA/CAF01 immunization at the age of 1-week remains effective in presence of maternal antibodies. Unexpectedly, total $CD4^+$ T cell, T follicular helper cell and even Germinal Center (GC) B cell responses to HA/CAF01 in neonates were preserved in the presence of maternal antibodies. Organized GC structures were observed even in the presence of high levels of maternal antibodies. However, these GCs did not generate effector functions: plasma cells, antibody and memory B cell responses to HA/CAF01 were fully inhibited. Although present, HA-specific T cell responses failed to protect mice against a lethal influenza virus challenge when maternal antibodies were no longer sufficient. Thus, the protective efficacy of neonatal HA/CAF01 vaccination is lost in the presence of high levels of maternal antibodies and alternative vaccination strategies are needed.

P.A4.01.20

$CD4^+$ T cell-released exosomes potentiate the HBsAg Vaccine by enhancing B cells respons

J. Lu[1,2], *J. Wu*[3], *H. Xu*[3], ***S. WANG***[1,2];
[1]*Department of Laboratory Medicine, The Affiliated People's Hospital, Jiangsu University, ZHENJIANG, China,* [2]*Department of Immunology, School of Medicine, Jiangsu University, Zhenjiang, China,* [3]*Department of Immunology, School of Medicine, Jiangsu University, ZHENJIANG, China.*

Introduction: $CD4^+$ T cells excrete bioactive exosomes, but the potential biological effect of CD4+T-cell exosomes is still unclear. The principal objective of this research was to investigate the role of the CD4+T-cell exosomes on antibody production and B cells activation when challenged with HbsAg.
Materials and Methods: In this study, $CD4^+$T-cell exosomes were purified from in vitro activated $CD4^+$ T cells. The role of $CD4^+$T-cell exosomes were administrated in HBsAg vaccinated mice, and B cells responses were evaluated in vitro.
Results: After immunized with commercial HBsAg, $CD4^+$T-cell exosomes treated mice showed a stronger humoral immune response, as reflected by higher specific antibody levels in serum and higher proportion of plasma cells in bone marrow. In vitro experiment, we found that exosomes derived from activated $CD4^+$T cells both promoted B cells activation and proliferation. In addition, antigen-specific exosomes shows stronger biological function than normal exosomes. Using mouse T cell line EL-4, we showed that CD40L plays a significant role in $CD4^+$T-cell exosomes mediated B cells responses.
Conclusions: Taken together, CD4+T-cell exosomes can promote B cell activation in vitro and be served as a novel adjuvant to promote mouse antigen-specific humoral immune responses.

P.A4.01.21

Galectin-9 Compromised T-dependent Antibody Production

Y. Wu[1], *F. Liu*[2], *K. Lin*[1];
[1]*Genomics Research Center, Academia Sinica, Taipei, Taiwan,* [2]*Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.*

Galectins are Ca^{2+}-independent animal lectins with binding specificity for β-galactosides. Galectin-9 is a tandem repeat-type galectin with two carbohydrate binding sites and a linker peptide. Previous studies demonstrated various regulatory roles of galectin-9 in the immune responses. Especially, it has been shown that galectin-9 might bind to Tim-3 and trigger the apoptosis of T helper type 1 cells. On the other hand, the role of galectin-9 in B cells remains elusive. Here, we observe normal B cell development in galactin-9 deficient mice. We found that the expression of galectin-9 was decreased in germinal center B cells (GC B cells) as compared with naïve B cells in either mice immunized with a T-dependent antigen, NP-KLH, or splenic B cells given T follicular helper (Tfh) derived stimuli *ex vivo*. The basal serum levels of IgA and IgG3 in galectin-9 deficient mice were also reduced. We then examined the immune responses following NP-KLH immunization in mice and found that NP-specific IgG production was reduced in galactin-9 deficient mice as compared with littermate control mice. Further, the population of GC B cells in immunized mice was significantly decreased in galactin-9 deficient mice. Given that the activation of B cells from galectin-9 deficient mice was comparable with that of wild type B cells, we suspect that galectin-9 might serve as a pivotal regulator in adaptive immunity via affecting T cell activation. We are examining the effect of lack of galectin-9 on T cell activation.

P.A4.01.22

T cell regulation of gut IgA responses

I. Gribonika, *K. Schön, N. Lycke;*
Depatment of Microbiology and Immunology, Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden.

Understanding how gut IgA is induced is critical for the development of oral vaccines. We made the unexpected observation that adjuvant is not required for ovalbumin (OVA) -specific TCR-transgenic (Tg) mice to respond strongly with IgA plasma cells in the *lamina propria* (LP) after oral immunization. Adoptive transfer of TCR Tg CD4 T-cells into nu/nu mice in the absence of adjuvant demonstrated that the IgA response in this context is T cell dependent. Importantly, we revealed the transferred CD4 T-cells exhibited a rearranged α-chain and expressed a dual TCR phenotype. We identified that microbiota recognition via second TCR was an important inducer of the response.
Interestingly, TGFβ1 signalling was required not only for authentic IgA class-switch recombination, but also for control of suppressive T follicular regulatory cells. We speculate that TGFβ1 was thymic T regulatory cell (tTreg) derived as regulatory cell depletion from total CD4 T cell pool prior to adoptive transfer in athymic mice resulted in the absence of OVA-specific IgA, but not IgG antibodies. This suggests that follicular helper function can be distinguished from class-switching in Peyer's patches by T follicular helper cells and tTregs respectively. Together these findings illustrate the complex nature of T-dependent IgA induction at mucosal sites.

P.A4.01.23
Role of Grail in B cell activation and tolerance

*S. Bieerkehazhi[1], T. C. Waseem[2], A. Alekseev[1], E. V. Galkina[2], **R. Nurieva**[1];*
[1]MD Anderson Cancer Center, Houston, United States, [2]Eastern Virginia Medical School, Norfolk, United States.

To date, B cells are believed to play a central role in the pathogenesis of various autoimmune diseases. Loss of B-cell tolerance with emergence of autoreactive B cells and pathogenic autoantibodies are the hallmark features of autoimmune disorders. However, the intrinsic mechanisms that underlie initial disruptions in B cell tolerance have not been completely defined. Grail, gene related to anergy in lymphocytes (encoded by Rnf128) is an E3 ubiquitin ligase associated with $CD4^+$ and $CD8^+$ T cell tolerance. Our data for first time show Grail expression in both mouse and human B cells, with higher expression particularly in anergic B cells.
Grail deficiency in B cells lead to impaired B cell peripheral tolerance induction and greater susceptibility to autoimmune diseases. Grail deficient B cells were hyperresponsiveness in terms of proliferation and antibody production upon antigen stimulation *in vitro* and *in vivo*. Concomitantly, Grail-deficient B cells were less efficient in downregulation of IgM after B cell receptor (BCR) crosslinking and exhibited elevated activation/expression of BCR-signaling components and Ca^{2+} mobilization. Thus, our results indicate that Grail is a crucial intrinsic factor controlling B cell activation and tolerance by targeting of BCR signaling components.

Different epigenetic marks on *PRDM1* gene promoters determine the expression of the isoforms in human myeloma cells

*R. Romero García, L. Gomez-Jaramillo, F. Mora-Lopez, **A. Campos-Caro**;*
Hospital Universitario Puerta del Mar, Cádiz, Spain.

The human positive regulatory domain I (PRDM1) transcription factor, is considered the main regulator of terminal differentiation process from B-cells towards PCs. It is considered, in general, as a transcriptional repressor that silences several genes related to B-cell phenotype. In malignant PCs *PRDM1* gene has been described to originate two isoforms, PRDM1α and PRDM1β, by alternative transcriptional promoters. PRDM1β, which lacks the amino-terminal 101 amino acids compared to the normal PRDM1α, shows a loss of repressive function on multiple targeted genes, acting as a competitive dominant negative. Here we assessed if the methylation status as well as the histone modifications of the *PRDM1* gene promoters in myeloma PCs (MM-PCs) are related to the expression of the PRDM1α and PRDM1β isoforms. Normal-PCs and malignant MM-PCs were isolated from bone marrow samples. Human cell lines were also used. Methylation status of the PRDM1α and PRDM1β promoters was evaluated by bisulfite sequencing. Cell cultures were also treated with 5-dAza and ChIP assays were performed in order to investigate changes in transcriptional activity of *PRDM1* gene. Specific CpGs positions into the of the PRDM1α and PRDM1β promoters probably determine the turn-on/off transcriptional activity isoforms of the PRDM1 gene. On this way, 5´Aza treatment augmented the expression level of PRDM1 transcripts. On the other hand, ChIPs assays showed different histone marks when we compare the PRDM1 promoters. The loss/gain of epigenetic marks in the PRDM1 promoters contributes to modify the expression level ratio between PRDM1α and PRDM1β and this, consequently, might contribute to myeloma progression.

P.A4.02.02
The transcriptional profiling of human in vivo-generated plasma cells identifies selective imbalances in monoclonal gammopathies

*L. M. Valor, B. Rodríguez-Bayona, A. B. Ramos-Amaya, J. A. Brieva, **A. Campos-Caro**;*
Hospital Universitario Puerta del Mar, Cádiz, Spain.

Plasma cells (PC) represent the heterogeneous final stage of the B cells (BC) differentiation process. To characterize the transition of BC into PC, transcriptomes from human naïve BC were compared to those of three functionally-different subsets of human in vivo-generated PC: i) tonsil PC, mainly consisting of early PC; ii) PC released to the blood after a potent booster-immunization (mostly cycling plasmablasts); and, iii) bone marrow CD138+ PC that represent highly mature PC and include the long-lived PC compartment. This transcriptional transition involves subsets of genes related to key processes for PC maturation: the already known protein processing, apoptosis and homeostasis, and of new discovery including histones, macromolecule assembly, zinc-finger transcription factors and neuromodulation. This human PC signature is partially reproduced in vitro and is conserved in mouse. Moreover, the present study identifies genes that define PC subtypes (e.g., proliferation-associated genes for circulating PC and transcriptional-related genes for tonsil and bone marrow PC) and proposes some putative transcriptional regulators of the human PC signatures (e.g., OCT/POU, XBP1/CREB, E2F, among others). Finally, we also identified a restricted imbalance of the present PC transcriptional program in monoclonal gammopathies that correlated with PC malignancy.

P.A4.02.03
Stromal cell contact-induced PI3K signaling and BCMA-induced NF-κB signaling synergize to maintain plasma cells alive in the bone marrow

***R. Cornelis**, S. Hahne, H. D. Chang, A. Radbruch;*
German Rheumatism Research Centre (DRFZ Berlin), a Leibniz Institute, Berlin, Germany.

Long-lived memory plasma cells (mPC) can survive for years in niches organized by mesenchymal stromal cells in the bone marrow. We have developed an *in vitro* niche using ST2 stromal cells and the cytokine APRIL, under hypoxic conditions, to maintain mPC alive *ex vivo*. Here we show for the first time that direct cell contact between stromal cells and mPC is required for the mPC to survive. Apparently, cell contact induces PI3K signaling, while APRIL is known to induce NF-κB signaling. Both, cell-contact dependent PI3K and APRIL-induced NF-κB signaling are required and sufficient for mPC survival. Inhibition of either pathway kills mPC in the *in vitro* niche, as well as *in vivo*, in the bone marrow. PI3K and NF-κB signaling in synergy upregulate IRF4, a transcription factor critical for mPC survival, and the ratio of MCL1 to NOXA, and of BCL2 to BIM, critical for the prevention of caspase-dependent apoptosis. PI3K signaling downregulates expression of all four BCL2-family members. NF-κB signaling rescues the expression of the anti-apoptotic proteins BCL2 and MCL1, shifting the ratio of pro- versus anti-apoptotic proteins in favor of the latter. PI3K signaling also downregulates FoxO1 and FoxO3, probably mediating survival by downregulating expression of the pro-apoptotic proteins NOXA and BIM. The stromal cell contact dependent survival of memory plasma cells in the bone marrow may serve as a paradigm for maintenance of tissue-resident memory cells in general, since inhibition of PI3K also ablates memory T and memory B cells of the bone marrow.

P.A4.02.04
IgG4-related disease of the skull base in two patients with normal serum IgG4

***S. E. Detiger**[1], A. F. Karim[2,3], J. van Laar[2];*
[1]The Rotterdam Eye Hospital, Rotterdam, Netherlands, [2]Departments of Internal Medicine and Immunology, section Clinical Immunology, Erasmus Medical Center, Rotterdam, Netherlands, [3]Department of Internal Medicine, Groene Hart Hospital, Gouda, Netherlands.

Introduction: IgG4-related disease (IgG4-RD) is an immune-mediated systemic fibro-inflammatory disease, which may mimic a variety of disorders. The pathogenesis is mostly unclear, but B cells, IgG4 positive plasma cells, IgG4 antibodies, as well as the oligoclonal expansion of T cells seem to play an important role in the immunopathophysiology of IgG4-RD. IgG4-RD may manifest in almost every part of the human body. Here, we describe two patients with skull base manifestation of IgG4-RD that mimicked nasopharyngeal cancer. Case presentations: Patient 1, a 73-year-old male, with a history of smoking, diabetes mellitus type 1 and vascular disease, presented with a mass in the left nasopharynx extending to the cavernous sinus. Patient 2 was a 74-year-old male with a history of chronic obstructive pulmonary disease (COPD) and colon cancer who presented with a mass extending from the left nasopharynx into the inner ear with involvement of the left jaw joint. Both patients complained of pain and hearing loss. In both cases, serum IgG4 was normal and imaging did not show systemic manifestation of the disease. However, histology confirmed the diagnosis of IgG4-RD. Patients are currently treated successfully. Discussion: The described cases emphasize the broad clinical spectrum of IgG4-RD. The diagnostic workup may be challenging and serum IgG4 may be normal, as demonstrated in these cases. Careful histopathological examination of the tissues remains essential. Timely diagnosis of IgG4-RD is important to prevent secondary organ damage. Conclusion: IgG4-RD is a systemic disease and may present with normal serum IgG4.

P.A4.02.05

T cells modulate B cell receptor signaling in mature antigen-naive B cells via CD40L

***R. W. Hendriks**, J. Rip, M. Appelman, M. De Bruijn, H. Hau, O. Corneth;*
Erasmus MC Rotterdam, Rotterdam, Netherlands.

Survival of mature peripheral B lymphocytes requires B cell receptor (BCR) signaling in the absence of exogenous antigen-binding. However, the relationship between tonic BCR signals and antigen-triggered signals is currently unknown. Also, the mechanisms by which T-cell derived signals contribute to B cell survival remain unexplored. B-cell-specific overexpression of the BCR signaling molecule Bruton's tyrosine kinase (BTK) induces spontaneous germinal center formation, autoantibodies and systemic autoimmunity. In aging BTK-transgenic mice naive B cells manifest increased IFNγ, IL-6, IL-10 and surface CD86 expression. Except for increased IL-10, this phenotype of naive B cells was dependent on B-T cell interaction, because it was lost in CD40L-deficient BTK-transgenic mice. To further investigate the role of CD40-CD40L interaction on B cell responsiveness, we compared BCR signaling in naive splenic B cell subsets from CD40L-deficient and wild-type mice. We used intracellular flowcytometry to study phosphorylation of various BCR signaling proteins including PLCγ, as well as rS6, which is downstream of the AKT pathway. Consistent with the *in vivo* pre-activated state of marginal zone (MZ) B cells, we found that in the absence of antigen-stimulation the levels of phospho-PLCγ and phospho-rS6 were higher in MZ B cells than in immature or follicular B cells. Hereby, no differences between CD40L-deficient and wild-type mice were observed. Upon BCR stimulation phospho-PLCgamma and phospho-rS6 increased in wild-type follicular B cells and particularly in MZ B cells, but these responses were lower in CD40L-deficient mice. Therefore, we conclude that CD40 signaling modulates BCR responsiveness in mature antigen-naive splenic B cells.

P.A4.02.06

Functional consequence of atypical B cells for*in vivo*development of antiviral B cell responses in patients with hemorrhagic fever with renal syndrome

***P. F. Kerkman**[1], A. Håglin Dernstedt[1], R. Jangra[2], A. Tuiskunen-Bäck[1], J. Wigren Byström[1], K. Maleki[3], J. Tauriainen[3], J. Klingström[3], K. Chandran[2], C. Ahlm[1], M. N. Forsell[1];*
[1]Umeå University, Umeå, Sweden, [2]Albert Einstein College of Medicine, New York, United States, [3]Karolinska Institutet, Stockholm, Sweden.

Circulating B cells in healthy individuals comprise a small fraction of CD27-IgD- atypical B cells (ABCs). These cells may accumulate in patients with Systemic Lupus Erythematosus (SLE) nephritis. *In vitro* studies imply that ABCs are dysfunctional or exhausted but their *in vivo* biological function remains poorly understood. Hantavirus infections that cause hemorrhagic fever with renal syndrome (HFRS) lead to transient kidney dysfunction in patients, as shown by increased serum creatinine levels. We hypothesized that development of ABCs is associated with reduced kidney function, and that studies of HFRS could be used to assess if accumulation of ABCs is detrimental to the development of antiviral humoral immunity.
Using longitudinal HFRS-patient samples stratified based on the median creatinine level, we demonstrate that ABCs accumulate in circulation of high creatinine patients but not in patients with lower serum creatinine levels. Phenotypical analysis showed that HFRS-induced ABCs have lower expression of activation markers and show reduced capacity for antigen presentation to T cells. Moreover, we found that ABCs have lower expression of a complement regulatory protein, indicative of complement deposition. To assess the impact of ABCs on functional immune responses, we are characterizing longitudinal capacity of patients to mount antibodies that bind specifically and/or neutralize the homologous Hantavirus strains.
Collectively, this study demonstrates an association between reduced kidney function and accumulation of ABCs in circulation. Moreover, our data shed light on the potential impact that accumulation of circulating ABCs may have on productive antiviral responses in HFRS-patients.

P.A4.02.08

A computational model of kinetic maturation in the germinal center

***D. Lashgari**[1], M. Meyer-Hermann[2], R. W. Sanders[3], M. J. van Gils[3], A. H. van Kampen[1];*
[1]Department of Clinical Epidemiology, Biostatistics and Bioinformatics, Academic Medical Center, Amsterdam, Netherlands, [2]Department of Systems Immunology and Braunschweig Integrated Centre of Systems Biology, Helmholtz Centre for Infection Research, Braunschweig, Germany, [3]Department of Medical Microbiology, Academic Medical Center, Amsterdam, Netherlands.

Germinal centres (GC) are sites of affinity maturation, an evolutionary process in which B lymphocytes proliferate, undergo somatic hypermutations (SHM) and positive selection to produce high-affinity antibodies (Ab) eventually. Ab affinity (K_A) is defined as the ratio of kinetic constants k_{on} and k_{off} which determine the kinetics of the bond between B-cell receptors (BCR) and antigens (Ag) and between peptide-MHCs (pMHC) and T follicular helper (T_{FH}) cells. We aim to investigate the dependency of spatiotemporal dynamics, affinity maturation, and output of the GC on individual contributions of kinetic
constants. The model will be based on experimentally measured kinetic constants and affinities. We will extend a pre-existing agent-based model (ABM) of the GC (Meyer-Hermann et al., 2012) that comprises of the primary cellular mechanisms of the GC reaction (e.g., cell movement, B-cell proliferation, differentiation and apoptosis, SHM, Ag binding, positive B-cell selection). Binding kinetics will replace affinity representation in this model. We are currently implementing kinetics maturation in the ABM. We use three different scenarios to modify BCR-Ag binding kinetics since it is still not clear how k_{on} and k_{off} change during a GC reaction. It is assumed that k_{off} is altered through SHM in all scenarios while k_{on} is considered constant, affected by cell motility or affected only by SHM in separate scenarios. By comparing the output of these models to in-house generated experimental data and data from published studies, we aim to define the kinetics of GC reaction in more details.

Multiscale modeling of plasma cell differentiation in germinal centers

***E. Merino Tejero**[1], X. Gao[2], P. A. Robert[3], M. R. Martinez[4], F. Crauste[5], O. Gandrillon[5], M. M. Hermann[6], H. C. Hoefsloot[7], J. Guikema[8], A. V. Kampen[9];*
[1]Amsterdam Medical Center, Amsterdam, Netherlands, [2]Chinese Academy of Sciences, Beijing, China, [3]Department of Systems Immunology and Braunschweig Integrated Centre of Systems Biology, Helmholtz Centre for Infection Research, Braunschweig, Germany, [4]IBM Zurich Research Laboratory, Zurich, Swaziland, [5]Inria team Dracula, Lyon, France, [6]Department of Systems Immunology and Braunschweig Integrated Centre of Systems Biology, Helmholtz Centre for Infection Research; Institute for Biochemistry, Biotechnology and Bioinformatics, Technische Universität Braunschweig, Braunschweig, Germany, [7]Swammerdam Institute for Life Sciences, University van Amsterdam, Netherlands, [8]Department of Pathology, Academic Medical Center, Amsterdam, Netherlands, [9]Bioinformatics Laboratory, Amsterdam Medical Center, Amsterdam, Netherlands.

B cells undergo affinity maturation within the GCs forming high affinity Ab producing plasma and memory cells. The GC comprises complex interacting temporal and spatial dynamic processes at the cellular level (e.g., moving and interacting cells) and molecular level (e.g., interacting proteins in gene regulatory networks; GRNs). To understand potential mechanisms involved in health and disease (e.g., B-cell lymphoma) novel methods are urgently needed, such as multiscale modeling (MSM), that integrate these levels (Gao, X. *et al.*, 2016). We aim to develop a MSM that integrates the GC cellular dynamics with a GRN representing plasma cell differentiation. The MSM contributes to a better understanding of plasma cells differentiation in GCs and the mechanisms involved in this process. Furthermore, we will be able to predict changes in cell populations originating from perturbations in the dynamics of GRNs. An existing agent-based model (ABM) of the GC is used to represent the cellular level (Meyer-Hermann *et al.*, 2012). It describes B-cell behaviours in the GC including proliferation, SHM, selection and differentiation. The GRN is based on an existing model comprising ordinary differential equations (ODE; Martinez *et al.*, 2012). In the MSM we effectively embed the GRN (ODEs) in each B-cell represented by the ABM. One of the main challenges is to link the parameters of the cell-based model (e.g., proliferation, differentiation, apoptosis rates) with parameters of the GRN (e.g., kinetic constants, BCR signal, CD40 signal). Currently, we are calibrating the model to experimental data to lay the basis for making realistic predictions.

Siglec-G deficiency leads to autoimmunity and earlier onset of chronic lymphatic leukemia

*L. Özgör, S. Mrotzek, M. Korn, H. Fahnenstiel, **L. Nitschke**;*
University of Erlangen, Erlangen, Germany.

Siglec-G is an inhibitory receptor on B cells. Siglec-G deficient mice show increased Ca2+ signalling particularly in B1 cells and a large B1 cell expansion. Furthermore, ageing Siglec-G deficient mice develop a lupus-like autoimmune disease. Higher activation of B cells as well as dendritic cells may contribute to this autoimmune disease. We have previously shown, that CD22 (Siglec-2) x Siglec-G double deficient mice develop a stronger autoimmune disease than Siglec-G deficient or CD22-deficient mice. One hypothesis to explain these data was that these two Siglecs bind to their ligands, sialic acids in specific linkages and this controls B cell tolerance, as sialic acids are abundantly expressed self ligands. However, we could show in a new mouse model in which both Siglecs are defective in ligand binding, that this is not the case, as these mice do not develop autoimmune disease.Chronic lymphatic leukemia (CLL) is derived from CD5+ B cells. CD5+ B1a cells are largely expanded in Siglec-G deficient mice. We could show that these mice develop much earlier and stronger CLL in the Tcl1-transgenic mouse model.

The Art2.2/P2X7-system differently affects functionality of murine CD4 T and iNKT subsets

***G. Papadogianni**, H. Georgiev, I. Ravens, G. Bernhardt;*
Hannover Medical School, Hannover, Germany.

Introduction: P2X7 represents an ATP-gated ion channel promoting inflammasome formation and T cell activation. P2X7 can be locked in an open stage following ADP-ribosylation by the ecto-enzyme ART2.2 thereby triggering induction of apoptosis. We investigated the impact of the ART2.2/P2X7-system on functionality of iNKT and CD4 T cell subsets isolated from various organs.
Materials and Methods: Cell suspensions of thymus, spleen, Peyer's Patches (PP) and peripheral lymph node (pLN) with or without prior immunization were prepared and incubated in presence or absence of the drug KN-62 blocking P2X7. Cells were then analyzed by flow cytometry to determine apoptosis and cytokine production.
Results: The expression patterns of P2X7 and ART2.2 correlated well with the observed degree of apoptosis. Whereas naïve CD4 T cells resisted induction of apoptosis, follicular T cells were rather sensitive yet regulators were less affected than helpers. CD4 cell subsets of PP origin were more sensitive than their corresponding counterparts from pLN. Moreover, thymic but not splenic iNKT cells resisted P2X7-triggered apoptosis. Presence of KN-62 during cell preparations and subsequent steps protected cells from apoptosis and also preserved their fitness to produce cytokines.
Conclusions: The highly diverging and organ dependent sensitivities of immune cells to apoptosis caused by P2X7 can warp readouts of experiments. This can be avoided by KN-62 application.

P.A4.02.12

Characterisation of the S1P receptor expression and of the functional role of S1P signalling in peritoneal B cells

*A. Kleinwort[1], F. Lührs[1], C. Heidecke[1], M. Lipp[2], **T. Schulze**[1];*
[1]Department of General Surgery, Visceral, Thoracic and Vascular Surgery, Greifswald, Germany, [2]Max-Delbrück-Centre for Molecular Medicine, Berlin, Germany.

Sphingosine-1-phosphate (S1P) regulates migration of follicular B cells (B2 cells) and directs the positioning of Marginal Zone B cells (MZ B cells) within the spleen. The function of S1P signalling in the third B cell lineage, B1 B cells, mainly present in the pleural and peritoneal cavity has not yet been analysed. Methods: S1P receptor expression was determined in peritoneal B cells by RT-PCR. The chemotactic response to S1P was studied in vitro. In order to assess the involvement of the individual S1P receptors expressed on peritoneal B cells, a specific S1P1 antagonist and/or cells from $s1p_4^{-/-}$ mice were used. Results: Peritoneal B cells expressed significant amounts of the S1P receptors 1 and 4 ($S1P_1$ and $S1P_4$, respectively). S1P1 showed differential expression. While B2 cells showed no chemotactic response to S1P, B1b B cells showed the most important migratory response. $s1p_4^{-/-}$ mice showed significant alterations of the composition of peritoneal B cell populations as well as a significant reduction of mucosal IgA in the gut. Interestingly, $s1p_4^{-/-}$ mice had significantly higher plasmatic IgA levels than wildtype animals, while IgM levels were similar. Discussion: S1P signalling influences peritoneal B1 B cell migration. $S1P_4$ deficiency alters the composition of peritoneal B cell populations and reduces secretory IgA levels. These findings suggest that S1P signalling may be a target to modulate B cell function in inflammatory intestinal pathologies.

P.A4.02.14

Signaling requirements for metabolic reprogramming of human B cells following TLR stimulation

***R. Steiner**, G. Bantug, S. Wiedemann, C. Kunz, C. Hess;*
Univ. Hospital Basel, Basel, Switzerland.

B cell intrinsic TLR signaling is important for successful control of invading microbes via generation of pathogen specific antibodies and in promoting immune tolerance by generation of regulatory B cells. The aberrant activation of TLRs on B cells can lead to various disorders from primary immune deficiencies to autoimmunity. TLR stimulation alone is sufficient in driving B cell activation and metabolic reprogramming. However, it remains unresolved, which signaling pathway drives metabolic rewiring in these cells. To examine TLR-dependent metabolic reprogramming in B cells, we sorted naïve (IgD^+CD27^{neg}) and memory ($CD27^+$) cells by and stimulated cells with the TLR9 agonist, CpG. Using a snapshot metabolomics and transcriptomics approach, we established that naïve and memory human B cells present distinct metabolic signatures following stimulation with CpG. To further examine metabolic changes in both B cell subsets, we monitored glycolysis and mitochondrial respiration by metabolic flux analysis. CpG was found to rapidly induced glycolysis in both subsets, whereas, mitochondrial respiration remained stable early after stimulation. Stimulation with CpG for 48 hours induced a marked enhancement of aerobic glycolysis and mitochondrial respiration in both B cell subsets. Early and late enhancements in glycolytic and mitochondrial respiration in naïve cells but not in memory B cells were primarily dependent on NF-kB signaling. Lastly, blockade of metabolic reprogramming using IKK1/2 inhibitors differentially impacted CpG induced cell activation, cytokine production, and early antibody production in both subsets. These results indicate that NF-kB dependent metabolic reprogramming and effector maturation are intricately linked in TLR stimulated B cells.

P.A4.02.15

Elucidation of the *in vitro* requirements for the generation of plasma cells from human naïve B cells

***P. Unger**[1], T. Jorritsma[1], M. Aalbers[1], A. ten Brinke[1], T. Rispens[1], M. van Ham[1,2];*
[1]Sanquin Research, Department of Immunopathology, Amsterdam, The Netherlands, and Landsteiner Laboratory, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands, [2]University of Amsterdam, Swammerdam Institute for Life Sciences, Amsterdam, Netherlands.

CD40 co-stimulation of B cells by CD40L-expressing follicular T helper (T_{FH}) cells and T_{FH} cytokines is crucial for the generation of high-affinity antibodies. Whereas human memory B cells easily differentiate into antibody-secreting plasmablasts ($CD27^+CD38^{hi}$) upon CD40 and IL-21 stimulation *in vitro,* naïve B cells do not. *In vivo* plasmablast differentiation occurs after repeated contact with T_{FH} cells in cyclic germinal centre reactions, but the mechanisms underlying these observations remain largely unknown. Progressive T_{FH} differentiation shows a switch from IL-21$^+$ T_{FH} cells into IL-4$^+$ T_{FH} cells in mice. Furthermore, CD40L expression on T_{FH} cells is subject to dynamic regulation. Here, we elucidated the minimal co-stimulation and cytokine requirements for human naïve B cell differentiation into plasmablasts (PBs) and plasma cells (PCs). We investigated *in vitro* whether strength of CD40 co-stimulation in the presence of IL-4 and/or IL-21 regulates naïve B cell differentiation into PBs and PCs and whether repeated co-stimulation is an intrinsic requirement for differentiation. Variation of CD40L stimulation by CD40L-expressing 3T3 fibroblasts showed that strength of CD40 co-stimulation in presence of IL-21 was decisive for induction of the PB/PC transcriptional program (i.e. strong expression of *Prdm1* mRNA), while repeated co-stimulation was a key requirement to allow full effector PB and PC differentiation. The elucidation of the requirements to induce human naïve B cell differentiation into PCs *in vitro* now allow the investigation of the various steps in the human PC differentiation process and the discovery of targets to modulate desired and undesired antibody responses in vaccination, auto-immunity and allergy.

P.A4.02.16

Secretome screening reveals novel B cell differentiation factors

***S. D. van Asten**[1,2], P. Unger[1,2], S. Bliss[1,2], T. Jorritsma[1,2], C. Marsman[1,2], N. Makazaji[1,2], S. M. van Ham[1,2], R. M. Spaapen[1,2];*
[1]Dept. of Immunopathology, Sanquin Research, Amsterdam, Netherlands, [2]Landsteiner Laboratory, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands.

The most important function of B cells is the production of pathogen-specific antibodies. B cells become activated upon antigen encounter and may differentiate into memory B cells or antibody secreting plasma cells. Known pro-survival and (co-)activation signals include CD40L co-stimulation and the cytokines IL-4 and IL-21. Since these signals are essential but not sufficient for full human B cell differentiation *in vitro*, we set up a secretome screen to identify novel factors for B cell differentiation. We tested the differentiating capacity of 756 secreted proteins on human naive or memory B cells supported by CD40L expressing cells and suboptimal amounts of IL-21. After 9 days we determined the B cell differentiation state by high-throughput flow cytometry. By screening 2 donors we identified 10 B cell differentiation factors that altered surface IgG, induced CD38/CD138 (plasmablasts/plasma cells), and/or CD27 (activated/memory B cells) expression. The most prominent hits included type I interferons which strongly induced CD38. A similar phenotype for type I interferons was previously reported in a different model system. Interestingly, both soluble FasL (sFasL) and MAp19 induced differentiation of B cells into plasmablasts and plasma cells. Moreover, sFASL and MAp19 increased the secretion of IgG1 and IgG4 isotypes, showing that both proteins augment the induction of functional plasma cells. Notably, FasR was upregulated on memory B cells upon CD40L-CD40 interaction, suggesting that cognate sFasL-FasR is important for the specific differentiation into plasma cells. Thus this first secretome screen for B cell differentiation identified new regulators of B cell differentiation.

P.A4.02.17

PI3K as the main driver of actin-dependent particulate antigen acquisition by human B cells

N. J. M. Verstegen[1,2], *P. A. Unger*[1], *J. Z. Walker*[1], *B. P. Nicolet*[1], *T. Jorritsma*[1], *J. van Rijssel*[3], *R. Spaapens*[1], *J. de Wit*[1], *J. D. van Buul*[3], *A. ten Brinke*[1], *M. van Ham*[1,2];
[1]*Department of Immunopathology, Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [2]*Department of Synthetic Systems Biology and Nuclear Organization, Swammerdam Institute for Life Sciences, University of Amsterdam, Amsterdam, Netherlands,* [3]*Department of Molecular Cell Biology, Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

To induce antibody production, B cells internalize foreign antigen during infection or self-particles, like cell remnants, in auto-immunity and alloimmunization after blood transfusion. This internalization requires antigen recognition by the B cell receptor (BCR) and is needed to present antigenic peptides via MHC II to attract the $CD4^+$ T cell help required for class switching, somatic hypermutation and plasma cell differentiation. Often antigen is of a particulate nature. Although well described that B cells internalize particulate antigen, the underlying molecular pathways remain undefined. Using a high-throughput quantitative image analysis approach, we demonstrate that BCR-mediated signaling to PI3K promotes actin-driven particulate antigen acquisition and $CD4^+$ T cell activation. According to current dogma, PI3K is recruited to the BCR via CD19, as part of the co-receptor. Strikingly, using the CRISPR-Cas9 technique, we demonstrate that CD19 is not required for BCR-mediated internalization of particulate antigen by human B cells. The redundancy in PI3K recruitment to facilitate particulate antigen internalization is mediated by the adaptor protein Nck. Human B cells thus employ the direct BCR-Nck-PI3K axis to modulate the actin cytoskeleton without clear CD19 co-receptor involvement for acquisition of particulate antigen. This knowledge may help to develop therapeutic agents to prevent auto- or alloantibody induction in auto-immune diseases and transfusion in which internalization of large cell fragments containing self-antigen by B cells play a central role.

P.A4.02.18

A splenic IgM memory subset harboring anti-bacterial specificities is sustained from persistent mucosal germinal center reactions.

S. WELLER*;*
INSERM U1151-CNRS UMR 8253, PARIS, France.

To what extent immune responses against the gut flora are compartmentalized within mucosal lymphoid tissues in the absence of inflammation or external aggressions, remains a much-debated issue. We describe here, based on an inducible AID fate mapping mouse model, that systemic memory B cell subsets, including mainly IgM^+ B cells, together with IgA^+ B and plasma cells in the spleen, and IgA^+ plasma cells in bone marrow, are generated in mice in the absence of deliberate immunization. While the IgA component appears dependent upon the gut flora, IgM memory B cells are still generated in germfree mice, albeit to a reduced extent and with reduced Ig gene diversification. Clonal relationships, renewal kinetics after anti-CD20 treatment, and BrdU labeling reveal that this long-lasting splenic population is to a large extent maintained by constant output of B cell clones persisting in Peyer's patch and mesenteric lymph node germinal centers.
IgM-secreting hybridomas established from splenic IgM memory B cells showed reactivity against gut luminal content, $Gram^+$ and $Gram^-$ bacterial isolates and endogenous retroviruses. Ongoing activation of B cells in gut-associated lymphoid tissues thus generates a large systemic compartment showing long-lasting clonal persistence and harboring cross-reactive antigenic specificities endowing them with a protective capacity against systemic bacterial infections. This study reveals a new layer of protection achieved by diversified IgM memory B cells generated in homeostatic conditions.

P.A4.02.19

The role of Krüppel-Like-Factor 2 (KLF2) transcription factor in plasma cell homeostasis

J. Wittner[1,2], *H. Jäck*[1,2], *W. Schuh*[1,2];
[1]*Division of Molecular Immunology, Department of Internal Medicine III, University Hospital Erlangen, FAU Erlangen/Nürnberg, Erlangen, Germany,* [2]*Transregional Collaborative Research Centre TRR130: B cells: Immunity and Autoimmunity, Erlangen, Germany.*

Krüppel-Like-Factor 2 (KLF2), as a key regulator of cell differentiation and organ development, is known to regulate quiescence, migration and homing of B cells, plasmablasts (PB) and plasma cells (PC). Upon boost immunization, KLF2-deficient mice show a striking reduction in the number of antigen-specific IgG plasma cells in the bone marrow.
To determine the effect of KLF2 on plasma cell homeostasis in more detail, we analyzed CD138+/TACI+ PB/PC subpopulations in various lymphatic organs such as spleen, bone marrow (BM) and gut associated lymphoid tissues (GALT) for their isotype expression and antibody secretion by flow cytometry and Elispot. We found that frequencies of IgM-, IgA- and IgG producing CD138+/TACI+ PBs and PCs are altered in BM and spleen of KLF2-deficient mice. The vast majority of PBs and PCs in spleen and BM of KLF2-deficient mice were IgM positive. In addition, lowered serum IgA as well as fecal (s)IgA levels indicate a crucial role of KLF2 for migration and/or survival of class switched plasma cells.
To unravel the role of KLF2 for PB/PC homeostasis, we are currently investigating KLF2-dependent target genes and signaling pathways by analyzing gene expression profiles of KLF2-deficient PBs and PCs in comparison to their wildtype counter parts. Furthermore, we are performing transfer experiments with KLF2-deficient PB/PC to analyze their migration and homing behavior.
This work was supported, in part, by the Deutsche Forschungsgemeinschaft (DFG) through research grant TRR130 (project P09).

Receptor signals in a MyD88 L265P mutation-driven murine model of diffuse large B cell lymphoma

O. Wolz[1], *G. Knittel*[2], *Y. Cardona*[1], *F. Herster*[1], *H. Kashkar*[3], *C. Reinhardt*[2], *A. Weber*[1];
[1]*Department of Immunology, Tübingen, Germany,* [2]*University Hospital of Cologne, Cologne, Germany,* [3]*Institute for Medical Microbiology, Immunology and Hygiene, CECAD, Cologne, Germany.*

Diffuse large B cell lymphoma (DLBCL) is one of the most abundant and aggressive tumors of the hematopoietic system and remains a clinical challenge. Especially, the activated B cell (ABC) subtype of DLBCL is characterized by a high relapse rate and poor five year survival of less than 40%. 30% of ABC DLBCL tumors have a recurrent leucine 265 to proline (*L265P*) mutation in the adaptor protein MyD88, which transmits signals of Toll-like receptors (TLR), the IL-1 receptor (IL-1R) and the BAFF/APRIL-sensing receptor TACI. MyD88 L265P stimulates lymphomagenesis by constitutively activating the transcription factor NF-κB. We showed previously, that the L265P mutant strongly binds wild type MyD88, which seeds signaling complexes of a high molecular weight, the so-called Myddosomes. Consequently, blocking of MyD88 dimerization sites killed L265P-mutated DLBCL cells better than wild type controls. Whether MyD88 L265P Myddosomes form spontaneously or are triggered by beforehand mentioned upstream receptors or in combination with B cell receptor (BCR) signals is not understood. In a novel mouse model, in which B cell-specific expression of a *Myd88p.L252P* allele (murine orthologue to human *MYD88 L265P*) causes an ABC DLBCL-like disease, we have begun to analyze *in vitro* the effects of stimulating or inhibiting TLRs, IL-1R and TACI on proliferation, cytokine secretion and Myddosome signaling. This is with a view to study the impact of these receptors on lymphomagenesis *in vivo*, which may add to the treatment of the many patients carrying the somatic *MYD88 L265P* mutation.

B cell specific interleukin 6 production plays a paradoxical role in B cell differentiation

M. AKKAYA*, S. K. Pierce;*
National Institutes of Health, Rockville, United States.

B cells secrete interleukin 6 (IL-6) in response to TLR agonists or CD40L stimulation yet the significance of B cell specific IL-6 secretion in the progression of immune response is largely unknown. Here we show on isolated mouse splenic B cells that, among different TLR agonists, TLR9 agonist CpG induces the highest magnitude of IL-6 secretion which is antagonized by B cell receptor signaling. However IL-6 KO B cells responded normally to CpG in terms of proliferation,prevention of activation induced cell death and activation marker expression *in vitro*. We then generated bone marrow chimeric mice by transferring bone marrow from B cell defficient mice mixed with bone marrow from either IL-6 KO or WT mice at 9:1 ratio and obtained B cell specific IL-6 KO mice and control mice respectively. Upon reconstitution, these mice were challenged with a T cell dependent antigen adjuvanted with either alum or TLR9 agonist CpG. We showed that B cell specific IL-6 deficiency resulted in weaker germinal center responses, lower number of antigens pecific plasma cells, lower titers of specific antibodies and less antibody affinity maturation upon immunization with alum adsorbed antigen. Paradoxically, the same responses enhanced when antigen is adjuvanted with CpG.These results suggest that, in the absence of CpG, B cell mediated IL-6 secretion is driven by B-T interactions and works in favor of T dependent responses. However, in the presence of CpG, B cell specific IL-6 production favors early commitment towards T independent plasma cell generation and thus plays role in dampening germinal center formation and affinity maturation.

P.A4.02.22

Regulation of B cell development and differentiation through Type I interferon signalling

M. AKKAYA[1], *B. Akkaya*[1], *A. Gangaplara*[2], *A. S. Roesler*[1], *B. P. Theall*[1], *S. K. Pierce*[1];
[1]*National Institutes of Health, Rockville, United States,* [2]*National Institutes of Health, Bethesda, United States.*

Type I interferons (IFNs) are among the soluble mediators of anti-viral immune response. Although innate immune cells are responsible for the majority of type I IFN production in the body, recently we showed that B cells, when stimulated with lipid conjugated CpG-A type TLR9 agonists produce Type-I IFNs. However, other pathways that can induce Type I IFN in B cells and the overall significance of B cell specific IFN production have yet to be characterized. Here, upon testing a range of stimulation conditions, we showed that dual stimulation of TLR3 and TLR4 is a potent inducer of type I IFNs in murine splenic B cells. Furthermore, by comparing WT and IFNAR KO mice, we identified that TLR induced upregulations of CD86 and CD317 on B cells are dependent on autocrine effects of IFNs. We then tested the extent to which B cell responses are mediated by IFNs by generating bone marrow chimeric mice using 1:1 ratio of WT and IFNAR KO bone marrow cells. Upon reconstitution, 1:1 ratio was conserved in total B cells and follicular cell compartments. However, majority of B1 and marginal zone cells came from WT mice while transitional cells showed IFNAR KO predominance indicating the differential effects of IFN signaling in B cell development. Once chimeric mice were infected with LCMV, we observed a significant increase in WT/IFNAR KO ratio in class switched B cells despite relatively unchanged ratios in germinal center and plasma cell compartments. These findings indicate that Type I IFNs play major roles at various stages of B cell development, activation and differentiation.

Comprehensive characterization of the human plasmablast response in dengue patients from India

C. Aggarwal[1], *K. Nayak*[1], *M. Singla*[2], *S. Gunisetty*[3], *E. Reddy*[1], *H. Panda*[1], *G. Medigeshi*[4], *R. Lodha*[2], *S. Kabra*[2], *R. Ahmed*[3], *A. Chandele*[1], *M. Kaja*[1];
[1]*International Centre for Genetic Enginnering and Biotechnology (ICGEB), New Delhi, India,* [2]*All India Institute of Medical Sciences (AIIMS), New Delhi, India,* [3]*Emory Vaccine Centre, ATLANTA, United States,* [4]*Translational Health Science and Technology Institute (THSTI), Faridabad, India.*

Humoral immune responses are thought to play a major role in dengue virus-induced immunopathology; however, little is known about the plasmablasts. Plasmablasts are terminally differentiated antibody secreting cells. The timing of their transient appearance in peripheral blood strikingly coincides with the presence of an infection /vaccination. Only a handful of studies from different parts of the world and none from India, have analyzed the B cell response in dengue infection. However, none of these studies were designed to comprehensively study the B cell response that includes phenotype and functionality.
Here, we characterize the magnitude, specificity, and kinetics of the plasmablast response in acute febrile Dengue patients from New Delhi, India. We observe a massive plasmablast response which is heterogeneous and varies from 1% to 85% of B cells and averages at 22.5%. Longitudinal analysis showed that the plasmablasts can expand dramatically with frequencies increasing by more than 10-fold within a short window of 24-48hrs. A vast majority of these plasmablast produces dengue specific IgG irrespective of whether the patient was primary or secondary infection. Also, the frequency of plasmablast was not significantly different in primary and secondary infection, but the rapidity of expansion was faster in secondary infection.
This study is the first detailed analysis of the plasmablast response in Dengue patients in India and seeks to address whether plasmablasts are associated with clinical outcome and understand the biological mechanisms that determine the balance between protection versus pathology in dengue, which is critical for devising rational prevention/ control measures.

P.A4.03.02

Impact of type-1 and type-2 adjuvants on T follicular helper, T follicular regulatory and germinal center B cell populations

A. P. Basto[1], *A. Maceiras*[1,2,3], *S. C. Almeida*[1,4], *P. Campos*[1], *F. Ribeiro*[1], *S. Kumar*[1], *M. Russo*[5], *L. Graca*[1,2];
[1]*Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, 1649-028 Lisboa, Portugal,* [2]*Instituto Gulbenkian de Ciência, 2780-156 Oeiras, Portugal,* [3]*Current affiliations: i3S – Instituto de Investigação e Inovação em Saúde, Universidade do Porto, 4200-135 Porto, Portugal; and IBMC – Instituto de Biologia Celular e Molecular, Universidade do Porto, 4200-135 Porto, Portugal,* [4]*Current affiliation: Núcleo de Doenças Infecciosas (NDI), Universidade Federal do Espírito Santo (UFES), Vitória - ES, 29047-100, Brazil,* [5]*Department of Immunology, Institute of Biomedical Sciences, University of São Paulo, São Paulo - SP, CEP 05508-900, Brazil.*

The generation of antibody responses is crucial for the protective immunity induced by most effective vaccines. The efficacy of those vaccines relies not only on the magnitude but also on the type, persistence and affinity of the antibodies elicited. These qualitative properties of the humoral immune response depend on appropriate germinal center (GC) reactions, which are supported by T follicular helper (Tfh) cells and regulated by T follicular regulatory (Tfr) cells. Although it is known that different adjuvants induce distinct subclasses of antibodies, their influence on GC reactions is yet poorly understood. Here we investigated the impact of a panel of type-1 and type-2 adjuvants on Tfh, Tfr and GC B cell populations. Mice were immunized with the same model antigen (ovalbumin) in combination with Th2-polarizing adjuvants (potassium alum or incomplete Freund's adjuvant) or with three different formulations containing a toll-like receptor (TLR)9 ligand with Th1-polarizing properties (CpG oligodeoxynucleotides). As expected, Th2-type adjuvants induced an IgG1 class-switch whether formulations containing the TLR9 ligand induced higher IgG2a responses. We found that Th2-adjuvants were more effective in inducing proliferation of GC B cells ($CD19^+Fas^+GL7^+$) but this effect could not be ascribed to quantitative differences in Tfh or Tfr populations, since $CD4^+CXCR5^+PD1^+$ cell levels and Tfh:Tfr ratios did not correlate with GC B cell expansion. Similar conclusions were obtained from Th1-prone (C57BL/6) and Th2-prone (Balb/c) mouse strains. Qualitative differences of Tfh populations generated under Th1- versus Th2-polarizing conditions are now being evaluated through differential gene expression analysis.

P.A4.03.03

Phenotypical and functional characterization of IL-10-producing regulatory B cell subsets

V. Duong, *N. Farimany, N. Föger, K. Lee;*
Inflammation Research Group,Institute of Clinical Chemistry,Hannover Medical School, Hannover, Germany.

Recent studies have recognized that B cells can negatively regulate pathogenic T cell responses in an antibody-independent manner, which has led to the concept of regulatory B cells. Regulatory B cells have been functionally defined in mice and humans by their ability to produce the anti-inflammatory cytokine IL-10 and have been suggested to exhibit immunosuppressive function in the context of autoimmune and inflammatory disease. However, the nature and origin of regulatory B cells is controversial and it is still unclear whether they represent a distinct B cell lineage or a dynamic cellular state. Our study reveals that regulatory B cells are not a predetermined novel B cell lineage, but are formed by a pool of innate-like 'classical' B cells. Our data show that the majority of IL-10-competent regulatory B cell subsets resides within both B1 and B2 B cell compartments and originates from B1a and marginal zone B cells. We directly demonstrate that these IL-10-producing B cell subsets exhibit suppressive function on the production of proinflammatory cytokines by $CD4^+$ and $CD8^+$ T cells. Moreover, these regulatory B cells exhibit a high degree of self-reactivity and produce autoreactive antibodies directed against dsDNA and ssDNA. Our study further suggests that regulatory B cell differentiation is guided by BCR-responsiveness and signaling thresholds. Thus, regulatory B cells act as an immunological double-edged sword: they exhibit potent immunoregulatory activity on inflammatory T cell responses, but, owing to a high degree of self-reactivity, can also turn into harmful autoantibody-producing plasma cells.

P.A4.03.04

Dissecting the T cell-extrinsic requirements for Tfh cell differentiation

J. Huber, *D. Baumjohann;*
Institute for Immunology, Planegg-Martinsried, Germany.

T follicular helper (Tfh) cells represent the primary CD4+ T cell subset that provides crucial help to B cells for potent antibody responses during infection and vaccination. While there is emerging evidence for the molecular mechanisms in T cells that drive Tfh cell differentiation, e.g. up-regulation of the Tfh cell-associated transcription factor Bcl6 and down-regulation of the Bcl6 antagonist Blimp-1, the T cell-extrinsic signals that induce the Tfh cell fate remain largely unknown. Dendritic cells (DCs) are potent inducers of the Tfh cell phenotype and this induction is independent of cognate interactions with B cells. Thus, DC-derived signals seem to instruct molecular programs in responding T cells. While a differential role of splenic CD8+ and CD8– DC subsets has been reported for the activation of CD8+ or CD4+ T cells, respectively, less is known about the DC subset(s) that induce(s) Tfh cells and which transcription factor networks and co-stimulatory pathways are involved in the DC-T cell interactions that drive Th cell fate decisions. Here, we tested how the Bcl6/Blimp-1 axis in DCs impacted their ability to induce Tfh cells. These data provide new insights into the mechanisms by which DCs induce Tfh cells and shape their identity.

P.A4.03.05

Contribution of amino acid micro-environment to the glycosylation status of N-glycosylation sites in antibody VH4 genes

***J. Koers**, N. Derksen, P. Ooijevaar-de Heer, T. Rispens;*
Sanquin Research, Amsterdam, Netherlands.

Approximately 15% of IgG antibodies acquire glycans in the Fab domain on consensus amino acid motifs (Asn-X-Thr/Ser, X ≠ Pro), so-called *N*-linked glycosylation sites. Once acquired, Fab glycans can affect antibody stability and affinity. The human naïve B cell repertoire is largely devoid of *N*-linked glycosylation sites with only a few germline-encoded alleles displaying such sites. IGHV4-34 is such an allele and besides having an germline-encoded *N*-linked glycosylation site (N_H57) it is also one of the more frequently used human V_H alleles. However, despite being a canonical N-glycosylation site, it usually remains non-glycosylated, most likely due to the surrounding amino acid micro-environment. It has been shown that charge and hydrophobicity of the core amino acid X of the consensus motif plays an important role in likelihood of glycosylation. Interestingly, the germline N_H57 core amino acid X is histidine which was shown to be favorable for glycosylation. This raises the question whether neighboring amino acids can also influence glycosylation status of the consensus motif. Furthermore, other VH4 family members have the potential to gain this site in the CDR2 upon somatic hypermutation. By introducing the N_H57 glycosylation site in multiple IGHV4 IgG clones from several VH4 family genes we can investigate its glycosylation status in the context of different neighboring amino acids. Thereby, we intend to demonstrate the contribution of adjacent and core amino acids in the glycosylation status of the canonical or potential SHM induced N_H57 glycosylation site in VH4 gene family members.

P.A4.03.06

Modeling transcriptomics of T follicular helper cells across different strains of mice.

***S. Kumar**[1], S. C. Almeida[2], P. Campos[1], A. Bastos[1], M. Russo[3], M. Carvalho[4], L. Graça[1];*
[1]Instituto de Medicina Molecular, Lisbon, Portugal, [2]Núcleo de Doenças Infecciosas (NDI), Universidade Federal do Espírito Santo (UFES), Vitoria, Brazil, [3]Instituto de Ciências Biomédicas,Departamento de Imunologia, Universidade de São Paulo, São Paulo, Brazil, [4]BioISI - Institute for Biosystems and Integrative Sciences, Faculdade de Ciências, Universidade de Lisboa, Lisbon, Portugal.

It has been known that different inbred mouse strains show highly varied immune responses as a consequence of mutations and polymorphisms. However, the impact of these variations leading to differing immune response is not only limited at genetic level. Previous studies have shown that transcriptome variance in different mouse strains also has significant impact on the phenotype of immune cells and as such it is essential to investigate how transcriptomic variations from different mouse strains impact the immune responses. In T-cell dependent immune responses, T follicular helper cells play an important role in antibody production. These cells drive germinal centre reactions by interacting with B cells and provide signals required for somatic hypermutation, affinity maturation, and thus the development of high affinity antibodies. In this project, we model the transcriptomics of T follicular helper (Tfh) cells in two different strains of mice. We have generated RNA-seq data from C57BL/6J and Balb/c.ByJ immunized against same antigen using type 1 and type 2 adjuvants. These two mouse strains are well known for their stronger preference towards type 1 and type 2 responses respectively. Here we discuss some results of transcriptomics differences in Tfh cells across BALB/c and B6 mice.

P.A4.03.07

The deciphering of phenotypic and functional B cell defects in IgA deficiency

***A. L. Lemarquis**[1,2], F. P. Theodors[1], S. H. Lund[3], I. Jonsdottir[1], H. K. Einarsdottir[1], B. R. Ludviksson[1];*
[1]University Hospital of Iceland, Reykjavík, Iceland, [2]Faculty of Medicine, University of Iceland, Reykjavík, Iceland, Iceland, [3]University of Iceland, Reykjavík, Iceland.

Selective IgA deficiency (IgAD) is the most common primary antibody deficiency in Caucasians with affected individuals suffering from an increased burden of autoimmunity with autoantibody positivity, atopy and infections. Our *ex vivo* analysis of lymphocyte populations in IgAD shows B cell defects with significantly lower numbers of transitional B cells ($CD19^+CD24^{hi}CD38^{hi}$) and class-switched memory B cells ($CD20^+CD27^+IgD^-$). A novel T cell independent defect was seen *in vitro* after CpG (ODN-2006) stimulation where it failed to induce IgA production and enhanced the defect in transitional B cells, especially within B regulatory cells expressing IL-10. Proportions of T cell populations *ex vivo* as well as *in vitro* induced T effector cells and T regulatory cells remained however normal. The signalling analysis of ERK was normal after CpG while pSTAT3 showed decreased signal in both total T and B cells following IL-21 stimulation. In serum from IgAD individuals a raised concentration of sCD40L was seen without stimulation, correlating inversely with IgA in IgAD but not IgG and IgM.
Pathway enrichment analysis of mRNA transcriptomics of isolated B cells from IgAD individuals before and after CpG stimulation points towards defects related to longevity and survival. Collectively, our data indicates a complex B cell defect with defects in both T cell dependent and independent responses and overproduction of CD40L pointing towards a compensatory B cell overstimulation which may be important to assess in the treatment with “personalised immunotherapies” of individuals affected by IgAD and concomitant immunodysregulation.

P.A4.03.08

The mutation patterns in B-cell immunoglobulin receptors reflect the influence of selection acting at multiple time-scales

***Y. Louzoun**[1], G. Yaari[1], s. kleinstein[2];*
[1]Bar Ilan, Ramat Gan, Israel, [2]Yale, New Haven, United States.

During the adaptive immune response, B cells undergo a processof clonal expansion, somatic hypermutation of the immunoglobulin (Ig) genes and affinity-dependent selection. Over a lifetime, each B cell may participate in multiple rounds of affinity maturation as part of different immune responses. These two time-scales for selection are apparent in the structure of B-cell lineage trees, which often contain a ‘trunk’ consisting of mutations that are shared across all members of a clone, and several branches that form a ‘canopy’ consisting of mutations that are shared by a subset of clone members. The influence of affinity maturation on the B-cell population can be inferred through the pattern of somatic mutations in the Ig. While global analysis of mutation patterns has shown evidence of strong selection pressures shaping the B-cell population, the effect of different time-scales of selection and diversification has not yet been studied. Analysis of B cells from blood samples of three healthy individuals identifies a range of clone sizes with lineage trees that can contain long trunks and canopies. We here show that observed mutation patterns in the framework regions (FWRs) are determined by an almost purely purifying selection on both short and long time-scales. By contrast, complementarity determining regions (CDRs) are affected by a combination of purifying and antigen-driven positive selection on the short term, which leads to a net positive selection in the long term. In both the FWRs and CDRs, long-term selection is strongly dependent on the heavy chain variable gene family.

P.A4.03.09

Converging Evolution Leads to Near Maximal junction diversity through parallel mechanisms in B and T cell receptors

***Y. Louzoun**, J. Benichou;*
Bar Ilan, Ramat Gan, Israel.

T and B cell receptor (TCR and BCR) complementarity determining region 3 (CDR3) genetic diversity is produced through multiple diversification and selection stages. Potential holes in the CDR3 repertoire were argued to be linked to immunodeficiencies and diseases. In contrast with BCRs, TCRs have practically no Dβ germline genetic diversity, and the question whether they can produce a diverse CDR3 repertoire emerges.
In order to address the genetic diversity of the adaptive immune system, appropriate quantitative measures for diversity and large scale sequencing are required. Such diversity method should incorporate the complex diversification mechanisms of the adaptive immune response and the BCR and TCR loci structure.
We combined large-scale sequencing and diversity measures to show that TCRs have a near maximal CDR3 genetic diversity. Specifically, TCR have a larger junctional and V germline diversity, which starts more 5’ in Vβ than BCRs. Selection decreases the TCR repertoire diversity, but does not affect BCR repertoire. As a result, TCR is as diverse as BCR repertoire, with a biased CDR3 length toward short TCRs and long BCRs. These differences suggest parallel converging evolutionary tracks to reach the required diversity to avoid holes in the CDR3 repertoire.

P.A4.03.10

Inflammation mediated by T-bet during blood-stage infection modulates the development of humoral immunity to malaria

***A. Ly**[1,2], L. Yang[1,2], W. Shi[1,2], V. Ryg-Cornejo[1,2], L. Ioannidis[1,2], K. L. Jacobson[3], G. T. Belz[1,2], A. Kallies[1,4,5], D. S. Hansen[1,2];*
[1]The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [2]The University of Melbourne, Department of Medical Biology, Parkville, Australia, [3]Monash University, Department of Biochemistry and Molecular Biology, Clayton, Australia, [4]The University of Melbourne, Peter Doherty Institute for Infection and Immunity, Parkville, Australia, [5]The University of Melbourne, Department of Microbiology and Immunology, Parkville, Australia.

Malaria is a preventable but serious infectious disease that burdens developing countries, in part because natural immunity to the malaria-causing *Plasmodium* parasites takes years of repeated infections to develop. The reasons for this are elusive; however, growing immuno-epidemiological evidence indicate that parasite-specific antibodies and memory B cells (MBCs) that mediate protection, are poorly generated and short-lived in endemic areas. In contrast, MBCs can be induced effectively in low transmission settings, suggesting that acute infection may undermine the acquisition of humoral immunity. Using a preclinical model of malaria, we demonstrated that infection-associated pro-inflammatory pathways hinder germinal centre (GC) and MBC development. To delineate the underlying molecular mechanisms, GC responses to blood-stage *P. berghei* ANKA was examined in mice deficient in the pro-inflammatory, T helper 1 transcription factor, T-bet. Genetic ablation of T-bet in CD4 T cells significantly improved the differentiation rates of T follicular helper cells, consequently boosting GC and antibody responses to infection.

T-bet not only affected T cell help, but also modulated intrinsic B cell activity. Deletion of T-bet in B cells enhanced the GC response to infection, and altered its dark and light zone dynamics, critical for high-affinity antibody production. RNA sequencing further revealed that T-bet significantly modulated the GC B cell transcriptional program during infection. We show that inflammation driven by T-bet during blood-stage malaria suppresses the acquisition of humoral immunity, by compromising T cell help and GC B cell differentiation. This knowledge will inform next generation vaccine and therapeutic strategies to elicit sustained protection against disease.

P.A4.03.12
Human Antibody Transgenic Rabbits

S. Offner, *F. Ros, E. Koenigsberger, S. Klostermann, H. Niersbach;*
Roche Diagnostics GmbH, Penzberg, Germany.

Antibodies generated in animal hosts make up the larger part of marketed therapeutic antibodies. Their generation undergoes positive and negative selection as well as affinity maturation in vivo, which lead to antibodies with robust therapeutic properties. Rabbits use a distinct diversity generation mechanism, which has been exploited since long to achieve very high specificity and affinity. However, antibodies derived from wild type animals such as mouse, hamster, rat or rabbit still have to undergo a process called "humanization" before being used as therapeutics in humans, limiting flexibility and adding time to the drug development process. Here, we report the development of rabbits transgenic for human immunoglobulin genes and the characterization of their B-cell compartment. Highly affine antibody candidates were yielded from these human antibody transgenic rabbits showing an excellent "humanness" and a specific therapeutic mode of action.

P.A4.03.13
Role of dendritic cells in antigen transport, transfer and B cell activation

M. Capitao, S. Borreill, H. El-barbry, F. Niedergang, ***F. OUAAZ****;*
Institut Cochin-INSERM U1016, Paris, France.

Dendritic cells (DCs) are phagocytic cells, which sample antigen (Ag) in the periphery and migrate to the lymph node (LN) where they activate T cells and potentially B cells. Previously, we reported that DCs can transfer Ag to B cells after an extracellular release that was called "regurgitation". The modes of B cell activation by DCs and the underlying mechanisms still remain unknown. We have investigated: 1)- Ag transport by DCs and distribution in the LN, 2)- the role of DCs in B-cell activation *in vivo* and in co-culture *in vitro*, 3)- the mechanisms of early B cell activation by analysing NF-κB pathway in B cells. Ag-carrying DCs migrated to LN within 18h after footpad mice injection allowing to Ag colocalization with both $CD11b^+$ and $CD8\alpha^+$ resident DCs. At 48h, we observed proximal positionning of Ag with follicular B cells. At 72h, Ag-loaded DCs were able to induce B cell activation and differentiation *in vivo*. In co-culture *in vitro*, Ag-loaded DCs activated anti-HEL B cells and importantly Ag release in DC supernatant by regurgitation induced also early B cell activation. BCR stimulation with soluble Ag and Ag released by DCs were able to activate NF-κB in particular cRel subunit nuclear mobilization. DCs are an important cell transporter of native Ag from the periphery and also activators of B cells *in vivo* and in co-cultures *in vitro.* We expect to provide new insights into Ag encounter by B cells *in vivo*, and novel approaches of DC targeting to elicit humoral immunity.

P.A4.03.14
CLASS SWITCH RECOMBINATION DEFICIENCIES MOROCCAN CASES SERIES

H. OUAIR*[1,2], I. Benhsaien[3], J. El Bakkouri[3], L. Jeddane[4], H. Salih Alj[5], A. Bousfiha[6], F. Ailal[4];*
[1]Biology Laboratory and Health/ Immune and Metabolic Pathology Team- Faculty of Sciences Ben M'Sik. Hassan II University, casablanca, Morocco, [2]University Hospital Casablanca-Children Hospital Abderrahim Harouchi, Casablanca, Morocco, [3]2- Laboratory of Clinical Immunology, Allergy and Inflammation- Faculty of Medicine and Pharmacy Hassan II University, casablanca, Morocco, [4]Laboratory of Clinical Immunology, Allergy and Inflammation- Faculty of Medicine and Pharmacy Hassan II University, casablanca, Morocco, [5]1- Biology Laboratory and Health/ Immune and Metabolic Pathology Team- Faculty of Sciences Ben M'Sik. Hassan II University, casablanca, Morocco, [6]Laboratory of Clinical Immunology, Allergy and Inflammation- Faculty of Medicine and Pharmacy Hassan II University, Casablanca, Morocco.

Class Switch Recombination Deficiencies (CSR-D) is characterized by a decrease serum IgA and IgG with normal or increased IgM. Several genetic mutations were defined that affects the interaction between T and B cells required to produce Ig A and G. There are two main forms: X-linked and autosomal recessive. Clinical manifestations are dominated by recurrent infections (pulmonary, ENT, digestive ...), especially with opportunistic pathogens. Our study reports 17 cases of hyper IgM followed in our department since 1995. There are 8 boys and 9 girls with 12 patients reporting a parental consanguinity. The mean age at diagnosis is 4.5 years (5 months to 12 years). The clinical manifestations were dominated by respiratory infections (13 cases), including 6 cases of bronchiectasia and two CMV pneumonia. Chronic diarrhea was observed in 4 patients with cryptosporidiosis. ENT infections were noted in 6 cases. One patient had three episodes of meningitis and another one BCGitis. All patients had low IgG and IgA and 11 patients had high levels of IgM. Five patients had thrombocytopenia.
Unlike Europe, where X-linked hyper-IgM syndrome (HIGM1) is the most common, this Moroccan series shows the frequency of autosomal recessive forms in our context as suggested by the inbreeding rate, the frequency of female and the predominance of phenotypes with lymphoproliferation.

P.A4.03.15
Transcriptional dysregulation of CVID patients harboring C104R *TNFRSF13B* mutation

N. J. Ramirez*[1,2,3], N. Langer[1], C. Bossen[1], B. Grimbacher[1];*
[1]Centre for Chronic Immunodeficiency (CCI), University Medical Centre Freiburg, Freiburg, Germany, [2]Integrated Research Training Group (IRTG) Medical Epigenetics, Collaborative Research Centre 992, Freiburg, Germany, [3]Faculty of Biology, Albert-Ludwigs-University of Freiburg, Freiburg, Germany.

Objective- To determine additional factors contributing to the development of common variable immunodeficiency (CVID), we investigated the perturbations of the transcription factor binding in CVID patients harboring the C104R *TNFRSF13B* mutation, encoding the protein TACI, compared to their healthy relatives harboring the same *TNFRSF13B* mutation and healthy donors tested negative for the mutation. **Methods-** Assay for transposase accessible chromatin-sequencing (ATAC-seq) was performed on naïve and class switched memory B cells of three heterozygous CVID patients, three healthy relatives carrying the same heterozygous C104R *TNFRSF13B* mutation, three homozygous CVID patients and four healthy donors, to determine open regions of chromatin. In addition, ATAC-seq was performed on $CD14^+$ monocytes and $CD4^+$ naïve T cells of two of the heterozygous CVID patients and their healthy controls. **Results-** Our analysis revealed 14 467 regions differentially regulated in B cell subtypes between naïve and class-switched memory. Comparison of TACI mutant carriers and healthy donors identified 1001 regions preferentially open in TACI mutant carriers with the most enriched TFBM for NF-κB (p-value 1×10^{-239}). Comparison of monocytes and T cell subpopulations from CVID patients and their healthy controls showed no NF-κB dysregulation. **Conclusion-** Here we could show transcriptional dysregulation in naïve and class-switched memory B cells of TACI C104R carriers compared to healthy individuals with the most enriched TFBM for NF-κB, which is essential for regulating immune response to infections. Thus, its changes can lead to variety of disease-causing differences. Furthermore, the data suggest NF-κB dysregulation is B cell intrinsic.

P.A4.03.16
Sequence representation in Germinal Centre simulations

P. A. Robert*[1], M. Meyer-Hermann[2];*
[1]Helmholtz Zentrum für Infektionsforschung, Braunschweig, Germany, [2]Helmholtz Zentrum für Infektionsforschung and Institute for Biochemistry, Biotechnology and Bioinformatics, Technische Universität Braunschweig, Braunschweig, Germany.

The process of affinity maturation in Germinal Centres is critical for the production of efficient antibodies and recall responses against pathogens. The dynamics of B cell movement, proliferation, selection and thus affinity maturation inside Germinal Centres can be successfully captured by mathematical modelling. These models rely on an abstract representation of protein-protein interactions to translate the effects of somatic hypermutation into a change in affinity to the antigen. In light of recent challenges for the development of broadly neutralizing vaccines, it would be of interest to study the effect of multiple antigens or epitopes driving Germinal Centre dynamics. The sequence representation used in silico so far has structural biases and potential effects onto the emerging cross-reactivity of receptors produced by the Germinal Centres. Here, we compare the consequences of different representations of sequences onto the properties of affinity maturation. The results help to understand the efficiency of different vaccination regimens, and to solve emerging contradictions regarding the vaccination strategies using cocktails of antigens at the same time or following sequential immunizations.

P.A4.03.17
The immunoglobulin tail tyrosine motif in transmembrane IgE is required for generation and/or survival of IgE-producing plasma cells

M. E. R. Schmitt*[1], N. Engels[2], J. Wienands[2], D. Vöhringer[1];*
[1]Department of Infection Biology, Institute for Clinical Microbiology, Immunology and Hygiene, University Hospital and Friedrich-Alexander University (FAU), Erlangen-Nürnberg, Germany, [2]Institute of Cellular and Molecular Immunology, Georg August University, Göttingen, Germany.

Introduction: Immunoglobulins of the IgE isotype are associated with allergic inflammation and immunity against helminths. Affinity-matured IgE-producing plasma cells (PCs) are thought to be mainly generated by sequential class switch recombination via an IgG1 intermediate step. However, the generation and homeostasis of IgE-producing plasma cells (PC) is still poorly understood.

Objectives and Methods: To investigate whether the cytoplasmic tail of mIgG1 or mIgE is important for the IgE response we analysed mutant mice after infection with the helminth *Nippostrongylus brasiliensis.* We compared IgG1YF and IgEYF mice in which the immunoglobulin tail tyrosine (ITT) motif in mIgG1 or mIgE is inactive. In addition we used IgEKVK mice with a truncated cytoplasmic IgE tail.
Results: Our results show a normal IgE memory response in IgG1YF mice. In contrast, IgE+ PCs in IgEYF mice were reduced after secondary infection. In IgEKVK mice the IgE+ PCs were diminished after first and second infection. Serum IgE levels were reduced in both IgE mutant mice.
Conclusion: Our results show that the ITT motif in mIgG1 is important for the IgG1, but not the IgE memory response. However the ITT motif in mIgE and the intracellular part of IgE are important for the IgE response. This led to the hypothesis that the ITT motif in mIgE is important for the generation or survival of IgE+ PCs and we will now investigate whether this hypothesis can be validated.

P.A4.03.18
Hyperimmunization with RhD generates a broad and persistent repertoire of IgM$^-$ and IgG$^-$ antigen-specific B cells

*M. Berkowska[1], **N. van der Bolt**[1], L. Della Valle[1], H. IJspeert[2], O. Verhagen[1], M. van der Burg[2], A. ten Brinke[1], M. van Ham[1], G. Vidarsson[1], E. van der Schoo[1];*
[1]Sanquin Research, Amsterdam, Netherlands, [2]Leiden UMC, Leiden, Netherlands.

RhD-negative women, pregnant with a RhD-positive child, receive anti-D immunoglobulins (Ig) from hyperimmunized donors to prevent alloimmunization. The characteristics of anti-D-Igs and evolution of the anti-D response remain poorly characterized.
RhD-specific CD27$^-$IgM$^+$, CD27$^+$IgM$^+$, CD27$^+$IgG$^+$ and CD27$^-$IgG$^+$ B cells from six anti-D donors were single cell sorted. Clones producing anti-D-Igs were subjected to Ig gene analysis to study clonal relationships. To investigate evolution of the anti-D response, known anti-D rearrangements from 3 donors from 3 time points (spanning up to 10 years) were identified using next-generation sequencing.
RhD-specific B cells, equally distributed between IgM$^+$ and IgG$^+$, were identified in all donors. Rearranged Ig genes in RhD-specific B cells carried somatic hypermutations, displayed long IgH-CDR3s and showed a broad repertoire skewed towards *IGHV4-34*, *IGHV3-33* and *IGHV3-30* genes. Frequently utilized *IGHV4-34* genes showed limited selection for replacement mutations in IgH-CDRs, implicating structural advantage in RhD recognition. ≥ 30% of identified anti-D rearrangements represented clonally related cells. The majority of clones spanned either the IgM$^+$ or IgG$^+$ B-cell subsets and clones can have life-spans of at least 10 years. Remarkably, recent time point B cells harbored less mutations then their clonally related B cells at earlier time points and the somatic hypermutations rate does not increase over time
In conclusion, the RhD response involves a broad, but restricted Ig gene repertoire, persisting over time. IgM$^+$ and IgG$^+$ B cells are important for the maintenance of a lasting alloimmune response and recruitment of IgM$^+$ memory B cells plays an important role in the memory response.

P.A4.03.19
Identification of follicular dendritic cells (FDCs) from human tonsils and binding of model complement complexes

*L. Rapley, E. Lekova, **M. SAISANA**, K. Nistala, C. Ellson;*
Glaxosmithkline R&D, Stevenage, United Kingdom.

Follicular dendritic cells (FDCs) are a cell type found in the germinal centre. Complement-opsonised antigen can traffic to the germinal centre where antigen is then colocalised with FDCs. FDCs are the only known cell type to retain whole native antigen. This intact antigen is re-presented on the FDC cell surface for periodic interaction with B cells, aiding antibody affinity maturation. This complement-binding function of FDCs has relevance to numerous diseases, including autoimmunity and HIV infection.
Published work using primary human FDCs is limited as they are low in frequency and difficult to isolate. Here we describe a method we have developed to isolate FDCs from human tonsil, obtaining 1000-3000 FDCs per donor. We have confirmed by flow cytometry, cell sorting and imaging of cell surface markers that these cells are indeed FDCs. We have found that these FDCs express the complement receptor 1 (CD35) and a subset also express complement receptor 2 (CD21). Through the antigen opsonisation process, C3 fragments are cleaved to leave C3dg which can bind to CD21 with high affinity. We have built a fluorescent model antigen incorporating C3dg and have generated robust data demonstrating binding of these complexes to FDCs.
The human biological samples were sourced ethically and their research use was in accord with the terms of the informed consents under an IRB/EC approved protocol.

P.A4.03.20
microRNA-155 is essential for the proliferation and survival of plasmablast B-cells

***R. Leyland**[1,2], G. Arbore[2], L. Biggins[2], T. Henley[2], S. Andrews[2], R. Brink[3], E. Vigorito[2], M. Turner[2];*
[1]Sheffield Hallam University, Sheffield, United Kingdom, [2]Babraham Institute, Cambridge, United Kingdom, [3]Garvan Institute of Medical Research, Sydney, Australia.

The differentiation of B cells after antigen exposure is essential for antibody production and clearance of invading pathogens. During the early B-cell response to T-cell dependent antigens, B-cells differentiate into B-cell blasts, plasmablasts and germinal centre cells. Plasmablast B-cells secrete unmutated low affinity antibodies and typically differentiate into short-lived plasma cells. Although this response is short lived, it can be critical for neutralisation of rapidly dividing pathogens. The posttranscriptional regulator microRNA-155 (miR-155) has been shown to be critical for the germinal centre response; however, the cellular and molecular mechanisms by which miR-155 regulates the plasmablast response are not well understood. We utilized SW_{HEL} mice, either sufficient or deficient for miR-155, to assess the contribution of miR-155 to the plasmablast response after immunisation with hen egg lysozyme (HEL) conjugated to sheep red blood cells (HEL-SRBCs). We show that miR-155 is required to sustain the extrafollicular plasmablast response and is essential for plasmablast survival and proliferation. MiR-155 deficient, HEL-specific plasmablast B-cells showed an increase in apoptosis and defects in cell cycle progression and DNA replication compared to wild type controls. Through transcriptome analysis of miR-155 sufficient and deficient SW_{HEL} B cells we determined that miR-155 indirectly regulates genes involved in cellular processes such as the DNA metabolic process, DNA nucleosome assembly, DNA replication initiation and the mitotic cell cycle process. Overall, our data demonstrate a complex mechanism of plasmablast regulation by a single microRNA, which provides new insight into antibody production during the early response to infection and vaccination.

P.A4.03.22
B cell development sans BCR responsiveness due to unfolded protein response-triggered Mef2c protein degradation

***Y. Chen**[1], Y. Su[2], J. T. Kung[1];*
[1]Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan, [2]National Laboratory Animal Center, National Applied Research Laboratories, Taipei, Taiwan.

BCR engagement leads to activation and clonal expansion of B cells. The I-$A^{12\%}$ mutant mouse possesses a branch site point mutation in the *H2-Aa* gene that causes highly reduced I-Aa protein expression. As I-A is a heterodimer made up of I-Aa and I-Ab, reduced I-Aa results not in reduced surface I-A expression but also in an excess of upaired I-Ab. B cells that develop in I-$A^{12\%}$ mice proliferated in response to LPS stimulation but failed to do so upon BCR stimulation. Developing I-$A^{12\%}$ B cells were engaged in unfolded protein response (UPR) due to an excess of unpaired I-Ab. BCR responsiveness was restored by transduced I-Aa expression and by BiP, the UPR sensor. Reducing the load of unpaired I-Ab also restored BCR responsiveness of I-$A^{12\%}$ B cells. Mef2c protein, a transcription factor required for BCR-stimulated proliferation, was missing in I-$A^{12\%}$ B cells and that transduced Mef2c expression restored BCR responsiveness. Mef2c protein appeared in I-$A^{12\%}$ B cells after addition of proteosome inhibitors. Mef2c degradation was mediated by Skp2 E3 ligase and that knock-down of Skp2 mRNA in I-$A^{12\%}$ B cells restored BCR responsiveness. Our results point to a generalized incompatibility between BCR responsiveness and increased Skp2 stability. They also imply the existence of regulatory mechanisms other than *Ig* gene rearrangement that govern Mef2c turnover in a specific, exquisite, and dynamic fashion.

P.A5.01 Initiation of immune responses - Part 1

P.A5.01.01
XCR1$^+$ Dendritic Cells are required for intestinal Th1 homeostasis

***F. Ahmadi**[1], K. Müller Luda[1], B. Malissen[2], W. W Agace[1,3];*
[1]Biomedical centre, Immunology section, Lund, Sweden, [2]Centre d'Immunologie de Marseille-Luminy, Aix Marseille Université, INSERM, CNRS UMR,, Marseille, France, [3]Division of Immunology and Vaccinology, National Veterinary Institute, Technical University of Denmark (DTU), Kongens Lyngby, Denmark.

The intestinal mucosa contains several classical dendritic cell (cDC) subsets each of which appear to play a non-redundant role in intestinal T cell homeostasis. Intestinal cDC1, similar to cDC1 in other tissues, are dependent on the transcription factor IRF8 for their development. Utilizing CD11c-cre.IRF8$^{fl/fl}$ mice, we have recently provided data to suggest that intestinal cDC1 are important for intestinal Th1 homeostasis and priming (**1**). CD11c is however expressed by multiple cell types, including intestinal macrophages, plasmacytoid DC and subsets of B and T cells. To determine whether intestinal Th1 responses are dependent on cDC1 we have generated XCR1-Cre.IRF8$^{fl/fl}$ mice, that specifically and selectively lack cDC1. Similar to CD11c-Cre.IRF8$^{fl/fl}$ mice, XCR1-Cre.IRF8$^{fl/fl}$ mice lack Th1 cells in the small intestinal LP and displayed markedly reduced numbers of Th1 cells in the colon. In preliminary experiments, we have observed that intestinal Th1 numbers are normal in IL-12p35 or IFN-α receptor (IFNAR) deficient mice indicating that cDC1 driven intestinal Th1 homeostasis is independent of IL-12 and interferon signalling. Current studies are thus focused on identifying the key cDC1 derived factors required for intestinal Th1 homeostasis as well as the environmental triggers that promote Th1 development in the intestine.

Toll-like receptor-dependent activation of dendritic cells in cattle

G. T. Barut[1,2,3], *S. C. Talker*[1,2], *A. Summerfield*[1,2];
[1]*Institute of Virology and Immunology, Bern and Mittelhäusern, Switzerland,* [2]*Department of Infectious Diseases and Pathobiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland,* [3]*Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland.*

Introduction: Signaling via toll-like receptors (TLR) mediates a potent activation and maturation of dendritic cells (DC). Therefore, knowledge on TLR ligand responsiveness, which differs both with DC subset and species, is of major interest for vaccine adjuvant development. Method: Two methods to determine bovine DC activation after stimulation of PBMC with TLR ligands Gardiquimod, LPS, and Pam2CSK4 were compared: 1) Upregulation of the maturation marker chemokine receptor 7 (CCR7) as determined by flow cytometry after 4h stimulation, and 2) detection of phosphorylated p38 mitogen-activated protein kinase (MAPK) by phosphoflow after 15min. Results: After 4h stimulation of PBMC, all DC subsets upregulated CCR7 irrespective of the ligand used, which contradicted DC-subset specific TLR expression in cattle. By contrast, early detection of phosphorylated p38 in response to TLR ligands correlated with TLR gene expression data. In plasmacytoid DC, only Gardiquimod triggered p38 phosphorylation. As expected from TLR2 expression data, both conventional DC subsets were activated by Pam2CSK4. In contrast, none of the DC subsets, only monocytes responded to LPS, with increased p38 phosphorylation, again corresponding to the low TLR4 expression on blood DC of cattle. Conclusions: Bystander effects in PBMC cultures have a strong impact on TLR ligand responsiveness of DC subsets when CCR7 is analyzed after 4h. In contrast, flow cytometric detection of p38 phosphorylation in PBMC is a sensitive method to screen for functional and subset-specific TLR expression. This project was supported by the European Union's Horizon 2020 Program under Grant Agreement 633184.

P.A5.01.03
The impact of vaccine-induced innate signals on breadth and function of CD8 T cell responses

C. A. Bernhard[1], *H. Lauterbach*[2], *T. Brocker*[1];
[1]*BioMedical Center (BMC), Institute for Immunology, Planegg-Martinsried, Germany,* [2]*Bavarian Nordic GmbH, Planegg-Martinsried, Germany.*

Dendritic cells (DCs) are considered the most potent antigen-presenting cells (APCs), which directly prime or cross-prime MHC class I-restricted cytotoxic T lymphocytes (CTLs). In the context of vaccination with recombinant adenoviral vectors (rAd), we could previously demonstrate that also vaccine-infected CD169$^+$ and SIGN-R1$^+$ macrophages were sufficient to prime broad CTL responses by direct presentation in the absence of DCs (Bernhard et al., 2015).
In many cases, immunodominant CD8 T cell responses against prevalent epitopes are sufficient to mount effective anti-pathogen effector and memory CTL responses. However, for pathogens or tumors with effective immune evasion, escape from most CD8 T cell responses occurs. Then it is of great advantage to have a broad CTL repertoire for protection. However, the factors determining the capacities of vaccines to induce broad CTL responses are incompletely understood. Side-by-side comparison of CTL responses initiated by different APC types and direct comparison of vaccine vectors such as rAd and modified vaccinia virus Ankara (MVA) revealed differential potencies to induce broad vs. narrow CTL responses. Here, we analyse vaccine-intrinsic properties as well as their effects on lymphatic organs and cross-presenting XCR1$^+$ DCs that may determine the strength, breadth and quality of CTL responses after vaccination.

P.A5.01.04
In vivo effect of environmental pollution on the expression of CD64, CD14, INFgR, CD206 and AhR receptors in human alveolar macrophages infected with *Mycobacterium tuberculosis*

C. Carranza*, M. Pérez-Guzmán, M. Torres;*
National Institute of Respiratory Diseases, Mexico City, Mexico.

Introduction: The effects of air pollution on human health are a matter of great concern as more than two million deaths have been estimated to occur each year worldwide from direct damage to the respiratory system. Alveolar macrophages (AM) play an important role in the elimination of *Mycobacterium tuberculosis* (*Mtb*) and are efficient in ingesting contaminating particulate matter (PM) that have penetrated the barriers of innate immunity. The load, composition and size of PM could determine the innate and adaptive immune responses of AM. Materials and Methods: We studied the *in vivo* effects of PM on human anti-mycobacterial host immunity in AM obtained from healthy subjects living in Mexico City. We also evaluated whether PM induces *in vitro* changes in AM INFγR, CD14, CD64 and CD206membrane receptors, which are important in the protective response against *Mtb* infection. At the same time we evaluate the induction of the arylhydrocarbon receptor (AhR), that senses environmental toxins like PM. Results: PM reduced CD64 expression and increased CD206 and AhR expression, which suggests that the protective response against Mtb may be altered. The INFγR and CD14 receptors were not affected in response to PM. Conclusions: PM exposure affects immunity response against *Mtb* in AM. AM activation may be altered by decreased expression of CD64 while the anti-inflammatory response is favored by the expression of CD206 and AhR.

P.A5.01.05
Intravital imaging of neutrophil dynamics after LPS administration

N. Chen*, E. v. Grinsven, L. Koenderman, N. Vrisekoop;*
Laboratory of Translational Immunology, Utrecht, Netherlands.

Upon acute inflammation evoked by intravenous infusion of lipopolysaccharide (LPS) in healthy human volunteers, neutrophil numbers in the blood initially decrease the first 90 min and subsequently dramatically increase. During this neutrophilia extra neutrophil subsets appear in the blood that can be distinguished based on nuclear morphology and expression of CD16 and CD62L. Banded CD16^{low} as well as hypersegmented CD62^{low} neutrophils appear in the blood.
In this study we aimed to establish the mechanism behind the neutropenia found during the first 90 minutes after LPS administration. In addition we are investigating whether CD62L^{low} neutrophils i) shed CD62L directly in the blood stream, ii) loose CD62L upon rolling along the blood vessel, or iii) whether CD62L^{low} neutrophils are recruited to the blood from another location.
Intravital microscopy has revolutionized biomedical research during the last two decades and has been used extensively to study dynamic process in intact tissues of living animals. Here we intravitally image neutrophil dynamics and CD62L expression in blood vessels of the mouse ear upon LPS administration. During the first 90 minutes post LPS administration many neutrophils were found to decrease their speed and crawl along the blood vessels which could explain the lower neutrophil numbers collected in blood withdrawals. Some infrequent extravasation events could also be recorded. After 90 minutes more neutrophils started to appear in the blood stream, closely matching the dynamics found in blood withdrawals of both humans and mice post LPS administration. Upcoming experiments will image CD62L expression of neutrophils upon LPS administration.

P.A5.01.06
Propolis effects on human CD4+ T cells activation by LPS-treated dendritic cells

B. J. Conti[1], *K. B. Santiago*[1,2], *E. O. Cardoso*[1], *F. L. Conte*[1], *L. P. Oliveira*[1], *K. I. Tasca*[1], *M. A. Golim*[3], *M. T. Cruz*[4], *J. M. Sforcin*[1];
[1]*Department of Microbiology and Immunology, Biosciences Institute, UNESP, Botucatu, Brazil,* [2]*Integrated Regional Faculties of Avaré, Avaré, Brazil,* [3]*Laboratory of Flow Cytometry, Blood Center, School of Medicine, UNESP, Botucatu, Brazil,* [4]*Center for Neurosciences and Cellular Biology, Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal.*

Dendritic cells (DCs) represent a heterogeneous population of professional antigen presenting cells and are essential for recognition and presentation of pathogens to T cells. Propolis is a bee product demonstrating several biological properties, including its immunomodulatory effects. Here, we investigated the modulatory action of propolis in lymphocytes (CD4+ T cells) proliferation by LPS-stimulated DCs. DCs were generated from human monocytes and stimulated with LPS simultaneously or not with propolis for 48h. After, DCs were incubated with CD4+ T cells for 96h to analyze cell proliferation. Cell viability was assessed by MTT assay; DCs phenotype was confirmed by CD14$^-$/CD1a$^+$/CD83^{low} expression and proliferation (CFSE) by flow cytometry. Cell viability was not affected after DCs incubation with LPS or propolis. LPS alone increased CD4+ T cells proliferation whereas its combination with propolis maintained LPS activity in T cells. Since LPS is one of the most potent activators of DCs and able to activate a Th17 profile, propolis may favor its action and drive CD4$^+$ T cells to a pro-inflammatory response. Financial support: FAPESP: 2015/03493-3 and 2015/03409-2

P.A5.01.07
The circadian clock protein BMAL1 regulates IL-1β in macrophages via NRF2

J. O. Early[1], *D. Menon*[1], *C. Wyse*[2], *M. Cervantes*[2], *Z. Zaslona*[1], *D. Ryan*[1], *L. A. O'Neill*[1], *A. M. Curtis*[2];
[1]*Trinity biomedical sciences institute, Dublin, Ireland,* [2]*Royal College of Surgeons, Dublin, Ireland.*

The molecular clock, also termed the circadian clock, is the timekeeping system within all our cells that integrates many aspects of our biology to align with the 24 hr external environment. Cells of the innate immune system, including macrophages, have a robust molecular clock. BMAL1 is the major regulator of the molecular clock and its deletion in macrophages leads to a pro-inflammatory phenotype. However the molecular mechanisms by which the molecular clock controls inflammation are not fully known. We have discovered that BMAL1 is crucial in triggering antioxidant defence in macrophages. Using a systems level approach, we demonstrate that macrophages lacking *Bmal1* (and thus lacking a functional molecular clock) have diminished activity of NRF2, a key antioxidant transcription factor. *Bmal1* knockout macrophages have reduced levels of NRF2 protein and lower induction of NRF2 target genes including *Hmox-1* and *Gsr* following lipopolysaccharide (LPS) stimulation. The master antioxidant, glutathione, whose synthesis relies on NRF2 activity, is also severely reduced in cells lacking *Bmal1*.

Such impairments in NRF2 mediated antioxidant defense result in increased production of reactive oxygen species (ROS) in *Bmal1-/-* macrophages. Deletion of *Bmal1* boosts the transcription, translation and cleavage of the pyrogen IL-1β, a cytokine well documented to be under regulation by ROS and NRF2. We have shown that use of antioxidants or enhancement of NRF2 activity can rescue the pro-inflammatory phenotype of *Bmal1-/-* macrophages. These findings uncover a novel mechanism by which the circadian cycle can control disease progression in inflammatory diseases such as sepsis, asthma and rheumatoid arthritis.

P.A5.01.08

Liver injury after acute CCL_4administration is independent of Smad7 expression in myeloid cells

J. Endig[1], *D. Goltz*[2], *P. Sprezyna*[1], *L. Diehl*[1];
[1]*Institute of Experimental Immunology and Hepatology, Hamburg, Germany,* [2]*Institute of Pathology, Bonn, Germany.*

Myeloid cells are essential for liver homeostasis, initiation and determination of innate and adaptive immunity. Smad7 is an inhibitor of the transforming growth factor-β signalling pathway that not only regulates T cell differentiation but also inflammatory cellular processes. Knockdown of Smad7 in hepatocytes has been shown to promote liver fibrosis, but little is known about the effects of Smad7 in myeloid cells during inflammatory responses in the liver. Using mice with a myeloid specific knock-down of Smad7 (LysM-CrexSmad7$^{fl/fl}$) we investigated the impact of Smad7-deficiency in myeloid cells on liver inflammation and regeneration using the well-established model of CCl_4-mediated liver injury. Early (24/48h) and late (7d) time-points were analysed. We found that CCl_4 induces a severe liver injury, with elevated serum ALT levels, centrilobular and periportal necrosis, infiltrating myeloid cells, and an increase of inflammatory cytokines in the liver. Furthermore, as expected, inflammation peaked at 24h and subsided after 7d. However, there were no significant differences in the investigated parameters between the Smad7 wild type and Smad7 knock-down treatment groups. Thus our results suggest that inhibiting TGFβ signalling via Smad7 expression in myeloid cells is dispensable for the induction and control of liver injury.

P.A5.01.09

The role of inflammasomes in human dendritic cell subsets

L. Hatscher[1], *L. Heger*[1], *C. H. Lehmann*[1], *J. J. Lühr*[1], *L. Amon*[1], *G. F. Heidkamp*[1], *A. Hartmann*[2], *I. Ivanović-Burmazović*[3], *A. Purpojo*[4], *R. Cesnjevar*[4], *O. Groß*[5], *D. Dudziak*[1];
[1]*Department of Dermatology, University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nürnberg (FAU), Erlangen, Germany,* [2]*Department of Pathology, University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nürnberg (FAU), Erlangen, Germany,* [3]*Department of Chemistry and Pharmacy, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany,* [4]*Department of Pediatric Cardiac Surgery, University Hospital Erlangen, Friedrich-Alexander- University Erlangen-Nürnberg (FAU), Erlangen, Germany,* [5]*Institute of Neuropathology, Medical Center - University of Freiburg, Freiburg, Germany.*

Dendritic Cells (DCs) are potent antigen presenting cells and required for connecting innate to adaptive immune responses. Therefore inflammasomes, important for the defense against pathogens or for sensing many different pathogen-associated and danger-associated molecular patterns, play a crucial role in DC mediated immune responses. Growing evidence suggests an important function of inflammasomes in murine DCs but the specific role in the distinct human DC subsets has yet to be determined. In this ongoing study we show that stimulation of human CD1c$^+$ DCs with inflammasome ligands after TLR engagement induces the secretion of TH1 and TH17 polarizing cytokines, potentially resulting in an enhanced T cell response in contrast to TLR stimulation alone. Stimulation of CD1c$^+$ DCs with activators of NLRP1 or NLRP3 after TLR 7/8 engagement showed strong secretion of IL-1β, IL-12 and IL-23. Moreover, applying caspase-1 inhibitors effectively inhibited IL-1β secretion and therefore inflammasome and caspase activation. Activation of inflammasomes is frequently accompanied by pyroptosis, an inflammatory form of programmed cell death. Activating inflammasomes while maintaining cell viability was termed hyperactivation and has been described for OxPAPC, a mixture of oxidized phospholipids, in murine BMDCs. LDH release assays revealed only a slight or no cytotoxic effect for a few inflammasome activators in contrast to classical NLRP3 inflammasome activators such as ATP or Nigericin. Taken together, our results suggest promising effects for particular inflammasome ligands as potential hyperactivating adjuvants for boosting DC mediated immune responses.

P.A5.01.10

Activation of M(IFN-gamma) macrophages by *Porphyromonas gulae* LPS

J. A. Holden, *J. C. Lenzo, N. M. O'Brien-Simpson, E. C. Reynolds;*
Oral Health CRC, The University of Melbourne, Melbourne, Australia.

Porphyromonas gulae is an anaerobic Gram-negative bacterium that has been associated with periodontal disease in companion animals. Lipopolysaccharide (LPS) is a known virulence factor in bacteria such as *Porphyromonas gingivalis*, a closely related bacterium associated with chronic periodontitis in humans. However, the activity of *P. gulae* LPS has yet to be investigated. *P. gulae* LPS induced a similar level of TLR4 activation compared to *P. gingivalis* LPS, both significantly impaired compared to *E. coli* LPS. *P. gulae* and *P. gingivalis* LPS also had TLR2 activity; which could be partially reduced with lipoprotein lipase. *P. gulae* and *P. gingivalis* LPS activated interferon-gamma treated macrophages as evidenced by CD86 expression and low levels of nitric oxide synthesis, which was dependent on TLR2 signalling and partially dependent on the TLR4 signalling pathway. *P. gulae* LPS induced higher levels of inflammatory cytokines than *P. gingivalis* LPS, comparable to that induced by *E. coli* LPS, which was completely sensitive to deletion of the TLR2 signalling ability. These results demonstrate *P. gulae* may have a modified lipid A moiety and thus avoids TLR4 activation, similar to *P. gingivalis*.

P.A5.01.11

Gene expression profiles of human resident lamina propria dendritic cells predict a functional role in tissue repair and angiogenesis under inflammatory conditions

S. Kurzhals[1], *S. Schiessling*[2], *T. Giese*[1], *G. Wabnitz*[1], *A. Heidtmann*[1], *F. Lasitschka*[3], *M. AlSaeedi*[4], *M. Schneider*[4], *S. Meuer*[1], *J. Schröder-Braunstein*[1];
[1]*University Hospital Heidelberg, Institute of Immunology, Heidelberg, Germany,* [2]*Klinikum Oldenburg, Oldenburg, Germany,* [3]*University Hospital Heidelberg, Institute of Pathology, Heidelberg, Germany,* [4]*University Hospital Heidelberg, Heidelberg, Germany.*

Human intestinal lamina propria dendritic cells (LPDC) are known to be important regulators of intestinal adaptive immune responses. By extending dendrites through the intestinal epithelial layer they are capable of sampling intestinal luminal antigens. They subsequently transport these antigens to the mesenteric lymph nodes where they induce the activation and differentiation of antigen specific T-lymphocytes.
In contrast to their impact on intestinal adaptive immune responses, local functions of lamina propria DCs during intestinal inflammation remain mostly unknown. Using a human intestinal organ culture model, we demonstrate that -under inflammatory conditions- CD45$^+$, lineage$^-$, CD14$^-$, CD11c$^+$ myeloid LPDC are not only able to migrate out of the lamina propria onto the luminal side of the basement membrane following epithelial cell depletion. They also express higher levels of genes encoding inflammatory cytokines and chemokines such as *IL6, IL1B,* and *CCL22* as well as of mediators associated with tissue repair (*MMP12, CTGF, BMP6*) and angiogenesis (*VEGFA*) when compared to PB-DC. Interestingly, we observed increased mRNA levels of the IL-12 family cytokine subunits *IL23A* and *EBI3* while the mRNA levels of the corresponding binding partners IL12-p40 (for IL23p19), IL12-p35 and IL27-p28 (for EBI3) were not significantly increased. IL23p19 and EBI3 could potentially form the newly discovered IL-12 family member IL-39. According to recent studies IL-39 is involved in the regulation of inflammation by promoting neutrophil differentiation/expansion as well as wound healing.
These results implicate that human resident LP-DC are not only regulating innate and adaptive immune responses but have a much broader spectrum of tasks.

P.A5.01.12

The role of CR3 (CD11b/CD18) and CR4 (CD11c/CD18) in adherence under physiological and inflammatory conditions

S. Lukácsi[1,2], *T. Gerecsei*[3,4], *B. Francz*[5], *B. Szabó*[3], *R. Horváth*[4], *A. Erdei*[1,2], *Z. Bajtay*[1,2];
[1]*Department of Immunology, Eötvös Loránd University, Budapest, Hungary,* [2]*MTA-ELTE Immunology Research Group, Eötvös Loránd University, Budapest, Hungary,* [3]*Department of Biological Physics, Eötvös University, Budapest, Hungary,* [4]*Nanobiosensorics "Lendület" Group, Institute of Technical Physics and Material Sciences, Centre for Energy Research, Hungarian Academy of Sciences, Budapest, Hungary,* [5]*CellSorter Company for Innovations, Budapest, Hungary.*

CR3 and CR4 belong to the family of β_2-integrins and play an important role in phagocytosis, cellular adherence and migration. CR3 and CR4 are generally expected to mediate similar functions due to their structural homology and overlapping ligand specificity. Previously we proved that CR4 is dominant in the adhesion of monocytes, monocyte derived macrophages (MDMs) and monocyte derived dendritic cells (MDDCs) to fibrinogen under physiological conditions. Here we studied the expression of CR3 and CR4 and their participation in adherence to fibrinogen in inflammatory conditions induced by LPS.
The expression of CR3 and CR4 was monitored by flow cytometry at different time points during the LPS induced cell activation. Cell adhesion to fibrinogen was evaluated using a state-of-the-art biophysical method, namely the force of cell attachment was measured with a computer controlled micropipette using vacuum assisted fluid flow.
Comparing the amount of CR3 and CR4 on the cell surface we found that LPS treatment alters their expression differently on MDMs and MDDCs. Whereas on MDMs the expression of both CR3 and CR4 decreases (44%±4 and 64%±17, respectively compared to non-treated control cells), on MDDCs CR4 shows a significantly elevated level (up to 147% ±34), in contrast to the diminished expression of CR3 (73%±10). Applying the micropipette, we observed a reduced adhesion force in the case of the LPS treated cells, that was more pronounced in MDDCs than in MDMs. Using blocking antibodies we proved that adherence to fibrinogen is dominated by CD11c in both physiological and inflammatory conditions.

Metabolic conversion of IP_3 to IP_4 is required to operate Ca^{2+} entry and NFAT activation in dendritic cells in response to LPS

L. Marongiu[1], *F. Mingozzi*[1], *M. Di Gioia*[2], *L. Sironi*[1], *M. Garrè*[3], *D. Parazzoli*[3], *T. Morii*[4], *C. Cigni*[1], *R. Marzi*[1], *R. Rotem*[1], *M. Colombo*[1], *D. Prosperi*[1], *I. Zanoni*[2,1], *F. Granucci*[1];
[1]*University of Milano Bicocca, Milano, Italy,* [2]*Harvard Medical School and Division of Gastroenterology, Boston Children's Hospital, Boston, MA, United States,* [3]*IFOM, the FIRC institute of Molecular Oncology, Milano, Italy,* [4]*Institute of Advanced Energy, Kyoto University, Kyoto, Japan.*

Introduction. Following LPS exposure different NFAT members are activated in DCs. The initiation of the pathway that leads to nuclear NFAT translocation is dependent on CD14 that, through the activation of Src family kinases and PLCγ2, leads to Ca^{2+} mobilization and calcineurin activation. Nuclear NFAT translocation is required for IL-2 production and apoptotic cell death of terminally differentiated DCs. Here we analyzed the mechanism of Ca^{2+} mobilization in DCs.
Results. We demonstrated that mouse and $CD14^+$ human DCs expressed IP3R3 at the plasma membrane and that these receptors colocalized with CD14 in lipid raft. We found that the increase in cytosolic calcium concentration was due to a direct calcium influx from the extracellular space, with a mechanism dependent on IP_3R3, and required the production of IP4. Indeed, abrogation of IP3R3 or IP3KB in DCs also abrogated calcium mobilization and NFAT activation. Moreover, pharmacological inhibition of IP3KB restrains inflammatory events (increased vessel permeability or inflammatory arthritis) regulated by NFATs in the presence of LPS, similar to the direct inhibition of NFATs by nanodrugs.
Conclusions. Our results indicate that the mechanism of calcium influx triggered by CD14 requires the activation of IP3KB and therefore the metabolic conversion of IP_3 to IP_4. The release of IP4 close to the plasma membrane leads to the opening of IP_3R3 with the consequent induction of a monophasic Ca^{2+} influx necessary to activate the downstream events that trigger NFAT dependent transcriptional program. Therefore, IP3KB represents a new target for anti-inflammatory therapies aimed at inhibiting specific DC functions.

Human neutrophil-derived extracellular vesicles promote Th17 cell development

S. Mol[1,2], *E. W. Taanman-Kueter*[1], *M. H. Wauben*[2], *E. C. de Jong*[1], *T. Groot Kormelink*[1];
[1]*Department of Experimental Immunology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [2]*Department of Biochemistry and Cell Biology, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.*

Th17 cells are important effector cells in fighting extracellular pathogens and are crucial players in the pathology of autoimmune disorders. We have recently demonstrated that neutrophil-derived elastase is essential for DC-driven Th17 cell development. However, it is yet unknown whether the uptake of elastase by DCs is important, and if extracellular vesicles (EVs) are involved in this process. In this study we investigate the role of human neutrophil-derived EVs in the transfer of elastase and the induction of Th17 cells. Neutrophils were isolated from blood of healthy donors and cultured in the absence or presence of activating stimuli: TNFα, LPS, fMLP. After stimulation, cells were collected and survival and activation were analyzed using flow cytometry. EVs were isolated from supernatants by differential centrifugation. For quantification by high-resolution flow cytometry, this step was followed by density ultracentrifugation. We found that neutrophil activation by TNFα and LPS did not enhance EV release compared to non-activated neutrophils. Surprisingly, fMLP activation resulted in the release of less EVs. Next we evaluated the capacity of neutrophil-derived EVs (EV-enriched 100,000xg pellets) to induce Th17 cell development from naïve CD4+ T cells in co-cultures with *C. Albicans*-activated monocyte-derived dendritic cells. Preliminary data suggests that EVs derived from TNFα/LPS-activated neutrophils, but not EVs from non-activated and fMLP-activated neutrophils, enhance Th17 cell development. These results indicate that activated neutrophils release EVs that promote DC-driven Th17 cell development. Our findings highlight a yet undescribed mechanism on the control of adaptive immunity by innate immune cell-derived EVs.

P.A5.01.15

LPS-induced neutrophils activation is modulated by new anti-PDE4 compounds

A. Moniot[1], *C. Guillaume*[1], *I. Allart-Simon*[2], *J. Sapi*[2], *S. Gérard*[2], *S. C. Gangloff*[1], *F. Velard*[1];
[1]*EA4691 Bios, Reims, France,* [2]*UMR CNRS 7312 ICMR, Reims, France.*

Polymorphonuclear Neutrophils (PMNs) are inflammatory cells, whose activation leads to abundant secretion of interleukin-8 (IL-8) and matrix metalloprotease 9 (MMP-9). To limit exacerbated cells response and tissue damages, anti-inflammatory molecules are commonly used. In this field, novel therapeutics are constantly sought to increase the anti-inflammatory arsenal. Type IV phosphodiesterase (PDE-IV) is able to hydrolyze cyclic adenosine monophosphate (cAMP) into AMP. PDE-IV related activity is increased in inflammatory processes. In this context, the PDE-IV inhibitors have proved to be particularly promising.
In the here-presented *in vitro* work, we have tested five pyridazinone scaffold-based PDE-IV inhibitors for their capability to modulate intracellular cAMP and the expression of IL-8, MMP-9 and TNF-α by human neutrophils.
Our results confirmed that pro-inflammatory stimulus (LPS) induced a decrease in intracellular cAMP level, this decrease has been counteracted by all our molecules. None of them impaired either mRNA expression (RT-qPCR) or protein secretion (ELISA, zymography) in basal condition. In pro-inflammatory condition, IL-8, TNF-α and MMP-9 concentration was increased in cell culture supernatant (three-fold, thirty-fold and two-fold respectively, $p<0.05$) whereas no variation has been seen at the mRNA level. Of interest, zardaverine (positive control for PDE-IV activity inhibition) and our PDE-IV inhibitors are able to decrease IL-8 and TNF-α secretion by at least 20% and 65% versus LPS condition respectively, as well as MMP-9 activity by 33%.
Taking together, our data reveal that pyridazinone derivatives may be interesting candidates as therapeutics against inflammatory diseases as they demonstrated anti-PDE-IV activity and seemed to be able to limit neutrophils activation.

P.A5.01.16

HLA-DR, CD4 and CD45-RO in neutrophil extracellular traps

F. M. Rodriguez, ***I. Novak****;*
Institute of Cell Biology, Faculty of Medicine, Cordoba, Argentina.

Introduction: Neutrophil polymorphonuclear leukocytes (PMN) may express costimulatory B7 molecules: CD80 and CD86 and molecules of MHC II: HLA-DR after stimulation with lipopolysaccharide (LPS), this could allow them to acquire competence as a professional antigen presenting cell (APC). Early few works described expression of CD4 and CD45RO in human peripheral blood neutrophils with modulatory functions. Neutrophil extracellular traps (NETs) formed by chromatin and granular proteins are structures released by PMN under inflammatory conditions. In our previous work, the presence of CD80 and CD86 costimulatory molecules in NETs was described. Objectives: generation of NETs in PMN cultures, challenged with LPS and perform marking HLA-DR, CD80 and CD86. In NETs from PMN cultures and from co-cultures of PMN stimulated with LPS and mononuclear (MN) stimulated with OVA perform marking CD4 and CD45-RO. Methods: purified PMN and MN were obtained by density gradient centrifugation and autologous leukocyte cultures from healthy human blood samples with ethical consent, anticoagulated with heparin. PMNs were stimulated with LPS and MNs with OVA. Samples: 30 min. Immunofluorescence technique with anti-CD80, anti-CD86, anti HLA-DR, anti CD4, anti CD45-RO Abs, DNA stain with DAPI. Paired blood samples provided controls. Results: CD80, CD86 and HLA-DR molecules were observed in NETs. In co-cultures experiments with autologous MNs stimulated with OVA, positivity was also observed for CD4 and CD45-RO in NETs. Conclusions: the expression of molecules normally associated with APCs and, on the other hand, CD4 and CD45RO expression in NETs allow to think more roles of PMN in innate and adaptive immunity.

P.A5.01.17

Differential imprinting of $CD4^+$ T cell lung-homing capacity by conventional dendritic cells from inguinal and mediastinal lymph nodes

D. PEJOSKI[1,2,3], *P. Fontannaz*[1,2,3], *S. Grillet*[1,2,3], *D. Christensen*[4], *P. Andersen*[4], *P. Lambert*[1,2,3], *C. Siegrist*[1,2,3];
[1]*Department of Pathology and Immunology, Faculty of Medicine, University of Geneva, Geneva, Switzerland,* [2]*World Health Organization Collaborating Center for Vaccine Immunology, Faculty of Medicine, University of Geneva, Geneva, Switzerland,* [3]*Center for Vaccinology, Geneva University Hospitals, Geneva, Switzerland,* [4]*Statens Serum Institut, Copenhagen, Denmark.*

Novel adjuvants that instruct protective T cells to home to desired anatomical sites could be used to improve vaccine efficacy, for example against respiratory pathogens such as *Mycobacterium tuberculosis*. Dendritic cells (DCs) that drain different anatomical sites are capable of delivering tissue-specific 'imprinting' signals during T cell priming, which favor the establishment of T cell populations that home to the original site of DC-antigen (Ag) encounter. The imprinting signals provided by DCs have been defined for several tissues though it is unclear whether a similar imprinting phenomenon occurs for lung trafficking T cells. We therefore used a Poly(I:C) adjuvant and protein Ag vaccine model to compare airway and muscle-draining DCs in terms of phenotype and their ability to imprint T cell lung-homing markers. Our results demonstrate that Ag^+ $CD11b^+$ and $CD103^+$ conventional DC subsets are found in both intramuscular (i.m.)-draining inguinal lymph nodes (LNs) and intranasal (i.n.)-draining mediastinal LNs (ILN, MLN) after immunization. Importantly, cell-sorted Ag^+ $CD11b^+$ DCs from the MLN were superior, on a per-cell basis, to ILN-derived DCs at *in vitro* priming of $CD4^+$ T cells with a lung-homing phenotype. The MLN-DC primed T cells then showed an enhanced capacity for *in vivo* trafficking to the lung parenchyma when transferred into naïve mice, demonstrating that site-specific DC imprinting of lung-homing T cells occurs in this immunization model. Grant declaration: This work was supported by a Horizon2020 fund for TBVAC2020 project PHC-08-2014, paid by the Swiss Confederation SEFRI Contract 15.0033-4, 643381

P.A5.01.18

Glycan-binding profiles of human and murine dendritic cells

***E. Rapoport**, E. Moiseeva, S. Khaidukov, D. Aronov, G. Pazynina, S. Tsygankova, N. Bovin;*
Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation.

Modification of vaccine particles with glycan promotes binding to dendritic cells (DCs) resulted in augmenting of vaccine efficacy. Therefore, we used a library of 229 fluorescent glycoprobes (Glyc-PAA-fluo) to select potential glycan "vector". We found that the highest percent of probe-positive $CD14^{low/-}CD16^{+}CD83^{+}$ subpopulation containing blood circulating DCs was observed for GalNAcα1-2Galβ (A_{di}), $(Neu5Acα2-8)_3$ and for three mannose-reach glycans, namely (Galβ1-4GlcNAcβ1-2Manα)$_2$-3,6-Manβ1-4GlcNAcβ1-4GlcNAcβ, Manα1-3(Manα1-6)Manβ and Manα1-3(Manα1-6)Manβ1-4GlcNAcβ1-4GlcNAcβ. Mouse models are widely used to characterize different DCs subpopulations *in vivo* and *in vitro* as comparative genomics revealed functional equivalences between distinct human and mouse DCs subsets. The aim of this work was to compare glycan-binding profiles of circulating in human and murine blood DCs. Murine circulating DCs were identified as $CD11c^{+}CD14^{low/-}CD16^{+}CD80^{+}$ in the blood of BYRB male mice. High percent of positive bound murine $CD14^{low/-}CD16^{+}CD80^{+}$- cells were observed for A_{di}, $(Neu5Acα2-8)_3$ and Manα1-3(Manα1-6)Manβ1-4GlcNAcβ1-4GlcNAcβ. The other probes selected for human $CD14^{low/-}CD16^{+}CD83^{+}$ cells did not display any binding to murine $CD11c^{+}CD14^{low/-}CD16^{+}CD80^{+}$ cells. Thus, glycan-binding profiles of murine and human DCs are not identical that should be taken into account when the glycovaccines are tested on mice *in vivo*. This work was supported by grant 16-04-01084 of the Russian Foundation for Basic Research and EU FP7 Project UniVax (Health -F3-2013-60173), grant number 601738.

DOCK8 regulates macrophage migration through Cdc42 activation and LRAP35a interaction

***T. Sakurai**[1], A. Shiraishi[1], Y. Fukui[1,2];*
[1]Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan, [2]Reseach Center for Advanced Immunology, Kyushu University, Fukuoka, Japan.

Introduction: DOCK8 is an atypical guanine nucleotide exchange factor for Cdc42, and its mutations cause combined immunodeficiency in humans. Accumulating evidence indicates that DOCK8 regulates the migration and activation of various subsets of leukocytes, but its regulatory mechanism is not completely understood. Material and methods: Bone mallow-derived macrophages from $DOCK8^{+/-}$ or $DOCK8^{-/-}$ mouse were used for chemotaxis assay, immunofuruorescence staining, and biochemical analyses. Protein binding was assessed by immunoprecipitation, pull-down assays, and immunoblotting. Results: DOCK8-deficient macrophages exhibited a migration defect in a 2D setting. Although DOCK8 deficiency did not affect the global Cdc42 activation in macrophages, rescue experiments revealed that the guanine nucleotide exchange factor activity of DOCK8 was required for macrophage migration. We found that DOCK8 associated with LRAP35a, an adaptor molecule that binds to the Cdc42 effector myotonic dystrophy kinase-related Cdc42-binding kinase (MRCK), and facilitated its activity to phosphorylate myosin II regulatory light chain (MLC2). When this interaction was disrupted in wild-type macrophages, they showed a migration defect, as seen in DOCK8-deficient macrophages. Conclusion: DOCK8 links Cdc42 activation to actomyosin dynamics through the association with LRAP35a during macrophage migration.

Effects of propolis on human CD4+ T cells proliferation induced by MAGE-1-treated dendritic cells

***K. B. Santiago**[1,2], B. J. Conti[1], E. O. Cardoso[1], L. P. Oliveira[1], F. L. Conte[1], K. I. Tasca[1], M. A. Golim[3], M. T. Cruz[4], J. M. Sforcin[1];*
[1]Department of Microbiology and Immunology, Biosciences Institute, UNESP, Botucatu, Brazil, [2]Integrated Regional Faculties of Avaré, Avaré, Brazil, [3]Laboratory of Flow Cytometry, Blood Center, School of Medicine, UNESP, Botucatu, Brazil, [4]Center for Neurosciences and Cellular Biology, Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal.

Dendritic cells (DCs) are professional phagocytic cells that play an important role in the immune response and T lymphocytes stimulation. Propolis is a bee product that has been used since ancient times due to its many biological properties, such as the immunomodulatory action. This work aimed to investigate the modulatory action of propolis in T cells proliferation stimulated by DCs incubated with a tumor antigen (human MAGE-1) identified in melanoma and other types of tumors. Human monocytes and lymphocytes were obtained from healthy donors (n = 5) and isolated with magnetic beads. DCs were generated from human monocytes and stimulated with human MAGE-1 (10 µg/mL) simultaneously or not with propolis (5 µg/mL) for 48 h. After, DCs were incubated with T cells for 96 h to evaluate their proliferation. Cell viability was analyzed by MTT assay; DCs phenotyping ($CD14^{low}/CD1a^{high}/CD11c^{high}/CD83^{low}$) and T cell proliferation (CFSE) by flow cytometry. Significant differences were determined by analysis of variance followed by the Dunnett's test ($P < 0.05$). Propolis in combination or not with MAGE-1 did not affect DCs viability. Propolis alone increased T cell proliferation, and its combination with MAGE-1 presented a higher proliferation rate compared to control. Propolis exerted an immunomodulatory action in the presence of MAGE-1, suggesting that it leads to $CD4^{+}$ T cells activation and may favor a Th1 profile and consequently activation of cellular immunity. Financial support: FAPESP (2015/02596-3 and 2015/03493-3).

Endocytosis of particulate matter of neutrophils induced oxidative stress through dynamin

***y. yoshida**, T. Miyake, D. Wang, M. Shen, K. Morita;*
Univ.Occup.& Environ. Health, Dep. Imm., Kitakyushu, Japan.

We previously reported the biological effects of PM in vivo, however, few reports have focused on the relationship between PM inhalation and neutrophils. Here, we investigated the effect of PM particle size on neutrophils. Flow cytometry analysis indicated that 1 µm particles are readily endocytosed by neutrophils and that endocytosis is reduced at 4°C. Inhibitors of the pleckstrin homology domain of dynamin repressed this process; however, GTPase and clathrin inhibitors did not affect endocytosis. Endocytosis by neutrophils in Toll-like receptor 4 (TLR4)- and MyD88-knockout mice was reduced compared with that in wild-type mice, indicating that TLR4 and MyD88 are important for the process. Neutrophil-mediated endocytosis caused oxidative stress, and N-acetylcysteine enhanced endocytosis. Expression levels of the oxidative stress markers, heme oxygenase-1 and p62 protein, were increased in an endocytosis-dependent manner. Phagocytosed neutrophils produced IL-6 and TNFα, whose production was decreased by dynamin inhibitors. Overall, these results indicate that endocytosis and ROS production via TLR4 are important for the initiation of immune responses by neutrophils.

P.A5.02.01

Resolution of inflammation is altered in multiple sclerosis

***V. Chiurchiù**[1,2], A. Leuti[1,2], P. Norris[3], I. Riley[3], M. Albanese[4], L. Battistini[5], C. Serhan[3];*
[1]Neurochemistry of Lipids, European Center for Brain Research, Santa Lucia Foundation, Rome, Italy, [2]Department of Medicine, Campus Bio-Medico University of Rome, Rome, Italy, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, United States, [4]Neurology Unit, Department of Neurosciences, University of Rome Tor Vergata, Rome, Italy, [5]Neuroimmunology Unit, European Center for Brain Research, Santa Lucia Foundation, Rome, Italy.

Multiple sclerosis (MS) is a chronic inflammatory neurodegenerative disease associated to uncontrolled inflammation and autoimmunity. Recent studies suggest that these can be a consequence of failure to resolve inflammation, a process that strictly depends on a newly discovered genus of highly potent anti-inflammatory lipids derived metabolically from omega-3 essential fatty acids and termed specialized pro-resolving lipid mediators (SPMs), that include resolvins, lipoxins and protectins. Here, by means of targeted metabololipidomics, we found that levels of specific SPMs such as lipoxins A4 and B4 as well as resolvin D1 (RvD1) and protectins PD1 and PDX were increased in MS patients during the relapse phase, with RvD1 and PD1 being also reduced or undetected in the progressive phase. Principal Component Analysis (PCA) revealed differences in the production of specific pro-inflammatory mediators and SPMs according to the disease phase. Variations in the plasma levels of SPMs also significantly correlated with clinical scores and were also paralleled by contradistinctive expression of SPM biosynthetic enzymes (COX-2, LOX-5, LOX-15) and receptors (ALX/FPR2, GPR32, GPR18) in blood leukocytes. When treating peripheral blood leukocytes of relapse MS patients with several SPMs, we observed a significant effect in reducing their inflammatory profile in terms of cell activation and cytokines production. These findings show for the first time a dysfunction of the resolution pathway in the blood of MS patients, accounting for a possible role of SPMs as leads for the control of MS pathogenesis and progression by modulating key effector cells in the periphery.

P.A5.02.02

The T-cell response in ferrets against influenza A virus is influenced by the site of infection

*K. van de Ven, H. van Dijken, F. de Heij, **J. de Jonge**;*
National Institute of Public Health and the Enviro, bitlhoven, Netherlands.

Influenza A virus (IAV) infects millions of people each year, resulting in respiratory disease with symptoms ranging from a mild common cold to a severe fatal viral pneumonia. Vaccines may protect against multiple IAV subtypes by targeting conserved intracellular epitopes of IAV. By using ferrets, we can assess how the T-cell response against IAV is influenced by the site of induction, which IAV proteins are more likely to evoke an immune response and which proteins are involved in cross-protection. In a recent study, we infected ferrets (n=28) intranasal (i.n.) or intratracheal (i.t.) with H2N2 or PBS and analyzed samples from pre-infection and 14 days post infection. We found that i.n. infection with H2N2 invoked a stronger virus-specific T-cell response in the blood.
However, more CD8+ T-cells could be detected in the bronchoalveolar lavage of i.t. infected ferrets. T-cells showed strong responses against peptides of the conserved H2N2 proteins PA, PB1 and PB2, which corresponds with our observation that T-cells of H2N2 infected animals cross-react to H1N1. These results imply that the site of vaccination influences the T-cell response, which can contribute to the development of more efficient IAV vaccines against seasonal and pandemic IAV.

P.A5.02.03

Complement deficiency attenuated multiple organ failure in zymosan induced aseptic shock

P. Ganova[1], *V. Gyurkovska*[1], *L. Belenska-Todorova*[2], *N. Ivanovska*[1];
[1]*Institute of Microbiology, Sofia, Bulgaria,* [2]*Medical Faculty, Sofia University, Sofia, Bulgaria.*

Septic shock is a complex inflammatory disease associated with a high rate of mortality. It starts with an overwhelmed immune response to infectious agents or their products in which the activated macrophages, neutrophils and the complement system play important roles. Cytokines and inflammatory mediators produced and secreted at first hours can induce organ failure and damage. Shock was induced by intraperitoneal injection of 1 mg/g body weight of zymosan in BALB/c mice. Functional complement activity was exhausted by cobra venom factor (CVF) injection. The peritoneal cells were analyzed by flowcytometry for expression of monocyte/neutrophil markers and dendritic cells. Plasma samples were analyzed for glucose, alanine aminotransferase (ALAT), aspartate aminotransferase (ASAT), and bilirubin. Livers were conserved in paraffin blocks for histopathological examination. We have observed that complement depletion inhibited zymosan-induced organ dysfunction via decrease of liver injury and changes of hepatic enzyme levels. These effects were also attended with inhibition of spleen and liver enlargement, and by reduced number of pro-inflammatory cells in the peritoneal cavity. Lack of functional complement accelerated GM-CSF-induced bone marrow dendritic cell maturation. The findings presented here show that the development of organ failure can be positively influenced by an inhibition of the functional complement activity. Simulating thrombocyte transfusions to investigate the impact of the self HLA background in HLA antibody formation and the risk for platelet refractoriness

K. Geneugelijk*, T. de Hoop, E. Borst, E. Spierings;*
Laboratory of Translational Immunology, UMC Utrecht, Utrecht, Netherlands.

Platelet refractoriness is a severe condition in which thrombocytic patients fail to achieve sufficient platelet counts after thrombocyte transfusion. This condition can partially be ascribed to alloimmunization towards HLA-A and HLA-B expressed on platelets. However, only a portion of patients will develop HLA antibodies after multiple transfusions. Previous studies have shown that mismatched HLA-derived T-helper epitopes presented by HLA class II (PIRCHE-II) play a role in HLA-antibody formation. The aim of the current study is to investigate whether the patients' HLA background may impact the ability to develop HLA antibodies upon thrombocyte transfusion. To this end, a representative patient population was generated by extracting all HLA-A, -B, -C, -DRB1, and -DQB1 HLA typings that were performed in our center between January 2009 and July 2016. A virtual Caucasian thrombocyte donor population of 10 million individuals was modeled using HLA haplotype frequency tables. This virtual donor population was used to simulate 20 thrombocyte transfusions. PIRCHE-II numbers were calculated for each simulated thrombocyte transfusion. The maximal number of unique T-helper epitopes that patients encountered after 20 simulated thrombocyte transfusions ranged between 31 and 359 epitopes. All patients had encountered half of their maximal T-helper epitopes after only two thrombocyte transfusions. Our simulations show that the maximal number of unique T-helper epitopes after multiple thrombocyte transfusions is highly variable between patients, suggesting a potential role of the self HLA background in the ability to become platelet refractory.

Anthralin-induced skin inflammation is promoted by mast cells

A. Hartmann[1], *J. Sohl*[2], *J. Ringen*[1], *V. Tsvilovskyy*[3], *M. Bros*[4], *H. Schild*[1], *M. Freichel*[5], *T. Feyerabend*[6], *H. Rodewald*[6], *M. Radsak*[2], *M. Stassen*[1];
[1]*Institute for Immunology, University Medical Center, Mainz, Germany,* [2]*3rd Medical Department of the University Medical Center, Mainz, Germany,* [3]*Institute of Pharmacology, University of Heidelberg, Mainz, Germany,* [4]*Department of Dermatology, University Medical Center, Mainz, Germany,* [5]*Institute of Pharmacology, University of Heidelberg, Heidelberg, Germany,* [6]*German Cancer Research Center, Heidelberg, Germany.*

Psoriasis is an inflammatory skin disease characterized by abnormal proliferation of keratinocytes triggered by the cytokines IL-17A and IL-22. Due to its anti-psoriatic and anti-inflammatory action, the natural anthraquinone derivate anthralin is used for the effective treatment of psoriatic plaques without causing severe side effects. Whereas the underlying mechanisms are still not known in detail, anthralin affects growth and proliferation of skin cells. Interestingly, topical treatment with anthralin first enhances skin inflammation before psoriatic plaques begin to heal. In this context, increased mast cells numbers have been shown to be present in psoriatic plaques. Moreover, evidence is accumulating that mast cells contribute to the pathogenesis of psoriasis by secreting IL-17A and IL-22. Focusing the role of mast cells in anthralin-treated skin, we investigated whether mast cells are activated by anthralin *in vitro* and *in vivo. In vitro*, anthralin increases the concentration of intracellular Ca^{2+} in mast cells. Consequently, degranulation of mast cells and production of IL-6 are enhanced in the presence of anthralin. *In vivo*, anthralin causes severe skin inflammation, characterized by enhanced ear swelling, which is delayed in mast cell-deficient Cpa3-Cre mice. Histological staining of murine ear skin showed an enhanced proliferation of epithelial cells and massive mast cell degranulation rates following topical application of anthralin. Taken together, these findings suggest that mast cells contribute to the inflammatory action upon topical anthralin treatment.

Influenza A virus infection during pregnancy: elevated levels of pregnancy hormones alter immune reaction against influenza A virus

A. M. Hierweger[1,2], *G. Engels*[2,3], *K. Thiele*[2], *G. Gabriel*[4], *H. Mittrücker*[1], *P. C. Arck*[2];
[1]*Institute for Immunology, Hamburg, Germany,* [2]*Department of Obstetrics and Fetal Medicine, Laboratory for Experimental Feto-Maternal Medicine, Hamburg, Germany,* [3]*Viral Zoonoses and Adaptation, Heinrich Pette Institute, Leibniz Institute for Experimental Virology, Hamburg, Germany,* [4]*Viral Zoonoses and Adaptation, Heinrich Pette Institute, Leibnitz Institute for Experimental Virology, Hamburg, Germany.*

During the 2009 H1N1 influenza A virus (IAV) pandemic, pregnant women showed higher influenza related morbidity and mortality. Thus, it is of great clinical interest to investigate the pathogenesis and underlying altered immune responses leading to increased risk for pregnant women.
We previously developed an IAV mouse model where semiallogenically, Balb/c-mated C57BL/6 dams are infected with a 2009 pandemic H1N1 IAV strain. Pregnant mice demonstrate increased mortality and morbidity, which corresponds to the clinical observations in humans.
Using this mouse model, we could show reduced dendritic cell (DC) activation and subsequent reduced CD8 T cell responses in pregnant IAV infected mice compared to non-pregnant littermates. Elevated progesterone levels during pregnancy lead to immune adaptation and could probably account for some of our observations in pregnant IAV infected mice. Therefore, we infected pregnant mice lacking the progesterone receptor in DCs and observed increased survival compared to pregnant infected mice of the control strain. As progesterone can signal via the progesterone and glucocorticoid receptor, mice lacking the glucocorticoid receptor on DCs and T cells will be analysed upon infection. Using an in vitro assay, we could already observe increased apoptosis induction in T cells by progesterone.
These observations strongly support the concept that hormonal changes during pregnancy are relevantly involved in modulation of the immune response against the influenza virus. Whilst the immune modulation during pregnancy is advantageous for pregnancy maintenance it is associated with significant disadvantages for maternal health, mirrored by the increased risk for severe IAV infection.

Cigarette smoke differentially affects inflammatory response depending on exposure time points in a mouse model of nonalcoholic steatohepatitis

J. Kim[1], *Z. Zhou*[1], *H. Jeong*[1], *S. Choi*[2], *S. Lee*[3], *W. Kim*[1], *K. Lee*[2], ***B. Kim***[1];
[1]*Biosafety Research Institute and College of Veterinary Medicine, Chonbuk National University, Iksan, Korea, Republic of,* [2]*Inhalation Toxicology Center, Jeonbuk Department of Inhalation Research, Korea Institute of Toxicology, Jeongeup, Korea, Republic of,* [3]*Division of Biotechnology, College of Environmental and Biosource Science, Chonbuk National University, Iksan, Korea, Republic of.*

Introduction: We tried to demonstrate the impact on main stream cigarette smoke (MSCS) to nonalcoholic steatohepatitis (NASH) progression in sexually matured mice.
Materials and Methods: Mice were either fed a control diet or a methionine-choline deficient with high fat diet for 6 weeks. During the first (early exposure) or last (late exposure) three weeks of diet feeding, each diet group was exposed to MSCS (300 or 600 μg/L: CS300 or CS600) for 2 hours per day and 5 days per week. CS extract (CSE) was extracted from 3R4F reference cigarettes and used for *ex vivo* study.
Results: Hepatic or serum biochemical analysis showed that MSCS differentially modulated hepatic injury in NASH milieu depending on exposure time points. Consistently, histopathologic observation provided that NASH severity was increased in early exposure group, but decreased in late exposure group except for steatosis. Similar results were observed in NASH-related hepatocellular apoptosis and fibrosis as confirmed by TUNEL assay and Sirius red staining, respectively. Our *ex vivo* experiments showed that CSE treatment differentially regulated inflammatory responses in co-cultured hepatocytes and macrophages isolated from liver with steatohepatitis after 10 days or 3 weeks of diet feeding. Furthermore, CSE treatment differentially up- or down-regulated the expression levels of peroxisome proliferator-activated receptor-gamma (PPARγ) in co-cultured macrophages. Finally, CSE treatment differentially affects M1/M2 polarization in co-cultured macrophages.
Conclusions: Our findings indicate that opposite effects of MSCS on NASH progression are mediated by differential modulation of PPARγ and its-associated M1/M2 polarization in hepatic macrophages depending on exposure time points.

P.A5.02.08

Exhaustion and senescence markers in humanized mice confirm the potential use of such model for immunotherapy validation during HIV infection

L. Labarthe[1,2], *S. Henriquez*[1], *O. Lambotte*[1,3], *R. Le Grand*[1], *N. Legrand*[2], *C. Bourgeois*[1];
[1]*CEA - Université Paris Sud 11 - INSERM U1184, Immunology of Viral Infections and Autoimmune Diseases, IDMIT Department, IBFJ, Fontenay-aux-Roses, France,* [2]*Axenis S.A.S, Fontenay-aux-Roses, France,* [3]*Assistance Publique-Hôpitaux de Paris, Service de Médecine Interne et Immunologie Clinique, Groupe Hospitalier Universitaire Paris Sud, Hôpital Bicêtre, Le Kremlin-Bicetre, France.*

Humanized mice harbouring cellular and molecular components of the human immune system (HIS) represent a ground-breaking preclinical platform to study human immune cell behaviour. Before evaluating novel immunotherapies in the context of chronic HIV infection, we aimed to evaluate the exhaustion and senescence profile of human T cells in blood and lymphoid tissues of HIS mice.
In Balb/c $Rag2^{tm1Fwa}$ $Il2rg^{tm1Cgn}$ $Sirpa^{NOD}$ $Flk2^{tm1Irl}$ $HLA\text{-}A2^{Tg\text{-}HHD}$ (BRGSF-A2) HIS mice reconstituted with human cord blood $CD34^{+}$ cells, human hematopoietic cells represented 83% +/- 3,3% in spleen and 68% +/- 15,4% in bone marrow. The human T cell proportion as well as the hCD4: hCD8 T cell ratio were similar to those observed in humans. Naive T cells represented the major T cell compartment in blood and spleen whereas memory T cells were predominant in the bone marrow, as observed in humans. We next studied the basal expression level of exhaustion markers (such as PD-1 and TIGIT, that are important immune checkpoints) and senescence markers (CD57 and KLRG1). Human T cells developing in BRGSF-A2 HIS mice presented an exhaustion level similar to humans, with PD-1 expression being nearly constitutive in the bone marrow, whereas senescence level (as assessed by CD57) was slightly lower.
Overall, the proportion, differentiation, exhaustion and senescence profiles of human T cells in BRGSF-A2 HIS mice resemble those observed in human studies. The physiological expression levels of immune checkpoints in humanized mouse model will allow us exploring anti-immune checkpoints strategies in HIV-1 chronic infection, in order to optimize the current antiretroviral treatment.

P.A5.02.09

Characterization of a conditional and reporter mouse model for the Atypical Chemokine Receptor 2

V. Mollica Poeta[1,2], *M. Massara*[1,3], *R. Carriero*[1], *E. Setten*[1,3], *M. Locati*[1,3], *R. Bonecchi*[1,2];
[1]*Humanitas Clinical and Research Center, Rozzano, Italy,* [2]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy,* [3]*Department of Medical Biotechnologies and Translational Medicine, Università degli Studi di Milano, Italy.*

Introduction: Atypical chemokine receptor 2 (ACKR2) is a scavenger receptor able to bind and lead to degradation most CC inflammatory chemokines. Several studies reported its expression on human lymphatic endothelial cells and its implication in chemokine crosstalk that regulate different aspects of lymphatic vessels morphology and activity. Unfortunately, there are no techniques to study ACKR2 expression in mice, due to the lack of a working antibody. The aims of this project are to clarify ACKR2 expression in homeostatic or pathological conditions and to disclose the mechanism by which it could impact on vessels biology. **Methods:** We generated a conditional mouse model with a knock-out/knock-in strategy, by replacing the Ackr2 gene with a TdTomato/Luciferase reporter cassette. By ex vivo imaging system and FACS analysis, we evaluated the expression of ACKR2 in different mouse tissues, especially in the lung. Finally, we performed various lung inflammatory disease models in vivo. **Results:** We found a significant expression of ACKR2 in a restricted pulmonary endothelial cell population previously uncharacterized, that we deeper investigated through RNA-seq analysis. Then, we showed that Ackr2 deficiency in the lung endothelium alter the expression of endothelial cell regulators. We also provided evidence that the lack of ACKR2 had an impact on innate immune response. **Conclusion:** Taking advance of the reporter mouse model development, we clarify the role of the receptor in physiological and pathological context. This will arise the possibility in the future to validate ACKR2 as new target for innovative therapies for lung pathologies.

P.A5.02.10

Association of IL-17A and IL-17F gene polymorphisms with recurrent pregnancy loss in Iranian women

S. Najafi[1], *H. Hadinedoushan*[2], *G. Eslami*[2];
[1]*Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [2]*Yazd University of Medical Sciences, Yazd, Iran, Islamic Republic of.*

Purpose: Recurrent pregnancy loss (RPL) is defined as the occurrence of two or more miscarriages before the 20th week of pregnancy. T helper17 cells are a novel subset of T cells, which secrete IL (Interleukin)-17 and are known to be involved in inflammation, autoimmunity and rejection of non-self tissues. Herein, we studied the association between IL-17A rs2275913 and IL-17F rs763780 gene polymorphisms with RPL in Iranian women.
Methods: A case-controlled study was performed on two groups consisting of 85 healthy women with at least one delivery and 85 women with the history of two or more RPLs. The frequency of IL-17A rs2275913 and IL-17 F rs763780 polymorphisms were determined by PCR-RFLP.
Results: In the RPL group, the genotypes frequencies of rs2275913 polymorphism were GG (8.2 %), AG (30.6 %), and AA (61.2 %) and in the control group, were GG (3.5 %), AG (42.4 %) and AA (54.1 %). Statistical analysis showed no significant difference between the genotypes of AA, AG and GG in the two groups (p=0.1). The genotypes frequencies of rs763780 polymorphism were TT (43.5 %), TC (49.4 %) and CC (7.1 %) in the RPL group; whereas the frequencies were TT (25.9 %), TC (70.6 %) and CC (3.5 %) in the control group. Statistical analysis revealed a significant difference in the TT, TC, and CC genotypes frequencies between the case and the control groups (p=0.01).
Conclusions: Our findings indicate that IL-17F polymorphism, rs763780, might be associated with a high risk of RPL in Iranian women.

Innate and adaptive immune responses in GFP tagged endogenous retroviruses transgenic mice

E. Rauch[1], *M. Hohmann*[1], *T. Amendt*[1], *T. Winkler*[2], *A. Ruhl*[1], *S. Dehnert*[1], *S. Paul*[1], *S. Bauer*[1], *P. Yu*[1];
[1]*Institute of Immunology, Philipps-University Marburg, Marburg, Germany,* [2]*Nikolaus-Fiebiger-Center of Molecular Medicine, Friedrich-Albert University Erlangen- Nürnberg, Erlangen- Nürnberg, Germany.*

The human genome consists largely of inactivated endogenous retroviruses, but their expression and function remain very controversial. In contrast, some mouse strains do express murine ERVs, which are involved in diseases. Recently, it was demonstrated that ERVs of the MuLV type are reactivated in nucleic-acid-sensing TLR deficient and B cell deficient mice. One theory suggests that the increased ERV expression is due to an increased exposure to microbial ligands from the gut. In contrast, our lab suggested an active immune surveillance mechanism suppressing ERV reactivation *in vivo*. TLR7 and in a complementary function TLR3 and TLR9 induce an ERV-specific antibody response.
To study the molecular mechanisms of reactivation of ERVs we generated a novel transgenic mouse, with an endogenous GFP tagged MuLV (EGT-315). Further, we generated EGT-315 mice with TLR379-deficiency to study the viremic pathology. The measurement of the GFP signal from the ERV, indicated reactivation of retrovirus as early as 3 weeks. We observed that the viremia of MuLV-GFP increased in EGT-315 $Tlr7^{-/-}$ mice, whereas in mice with TLR7 the initially lower viremia is suppressed over time. Additionally, TLR7 competent EGT-315 mice produced antibodies against GFP and viral proteins in their plasma, in contrast to TLR7-deficient mice. To investigate the influence of the microbial environment on the activation of MuLV-GFP we stimulated EGT-315 splenic cells with LPS *in vitro*. This lead to a strong increase of MuLV-GFP expression.
Our novel *in vivo* model could be instrumental to understand mechanisms controlling endogenous and exogenous retroviruses.

P.A5.02.12

Prophylactic treatment with a recombinant banana lectin reduce severity of TNBS-induced colitis in BALB/c mice

M. Stojanović[1], *R. Miljković*[1], *A. Filipovic*[1], *I. Lukic*[1], *A. Inić-Kanada*[2], *M. Gavrovic-Jankulovic*[3], *E. Marinkovic*[1];
[1]*Institute of Virology, Vaccines and Sera – Torlak, Belgrade, Serbia,* [2]*Institute of Specific Prophylaxis and Tropical Medicine, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria,* [3]*Department of Biochemistry, Faculty of Chemistry, University of Belgrade, Belgrade, Serbia.*

The recombinant banana lectin (rBL), a structural and functional homolog of natural BL, modulates the immune milieu in the colon of BALB/c mice in a both dose- and time-dependent manner. The enhancement of a production of IL-2 dominates in the initial phase (24h), while the transitional enhancement of a (pro)inflammatory and regulatory cytokines' production occurs later (48h). We aimed to investigate on how the severity of the experimental colitis induced by 2,4,6-trinitrobenzene sulfonic acid (TNBS) in rBL-pretreated BALB/c mice correlates with the characteristics of the local immune milieu at the moment of a disease induction. The colitis was induced 24h or 48h upon a treatment with rBL (rectal administration, single dose of 0.5-50 rBL/kg BW). The characterization of the immune milieu at the moment of disease induction was done by determining the local concentration of cytokines (IL-2, IL-12, IL-23, IFNγ, IL-17, IL-6, IL-10 and TGFβ) and abundance of Foxp3+ Treg; severity of the colitis was assessed by measuring the weight loss. We have shown that (i) the reduction in severity of colitis induced 24h upon rBL treatment positively correlates to the local concentration of IL-2 and the abundance of Foxp3+ T cells, while (ii) for colitis induced 48h upon rBL treatment reduction in disease severity positively correlated to the ratio [IL-10]/[IFNγ]. This study also indicated that the reduction in the severity of colitis is not dependent only on rBL dosage but also on the timing of its administration. P.A5.02.13

Bardet-Biedl Syndrom protein complex in the signaling of the adaptive immune system

***O. Tsyklauri**, V. Niederlová, M. Huranová, O. Štěpánek;*
Institute of Molecular Genetics of the ASCR, v. v. i., Prague, Czech Republic.

BBSome is a transport protein complex, which is important for normal formation and functioning of primary cilium. Mutations in BBSome subunits cause a severe multiorgan disease called Bardet-Biedl Syndrome (BBS). Interestingly, that some of the proteins, which enable ciliary transport, also play a role in the formation of immunological synapse (IS), a contact site between an antigen presenting-cell and a lymphocyte. However, possible impact of BBSome in this process have not been investigated yet. Using YFP-labeled BBS4 subunit, we indicate that BBS4 actually localize to the IS during its formation. In order to investigate possible influence of BBS proteins on the immunity, we established mouse model of BBS (BBS4KO). Comparison of WT and BBS4KO mice confirm expression of BBS4 in normal T- and B-cells. BBS4KO mice have alterations in hematopoietic system, such as increased monocyte number, increased hemoglobin and elevated platelets number. Moreover, our preliminary data indicate that BBS4KO mice have a partial impairment in B-cells development. Further research will shed light on the functions of BBS proteins in immune cells.

P.A5.02.14

IL-33 receptor (ST2) expression on B cells during pregnancy and preterm birth

***N. J. Valeff**[1], L. V. Juriol[1], M. S. Ventimiglia[1], M. C. Abba[2], M. F. Quiroga[3], F. Jensen[1];*
[1]CEFYBO-CONICET, Buenos Aires, Argentina, [2]CINIBA-UNLP, Buenos Aires, Argentina, [3]INBIRS-UBA-CONICET, Buenos Aires, Argentina.

IL-33 is an alarmin released during cell injury caused by stress or infection and drives immune cells into regulatory functions to maintain tissue homeostasis. In the context of pregnancy, IL-33 was recently shown to induce the production of anti-inflammatory molecules by decidual B cells, protecting against preterm labor in human and mouse. Here we aimed to characterize the expression of IL-33 receptor (ST2) in B cells during pregnancy and in preterm birth. We began performing a genome-wide transcriptome profiling in isolated B cells from spleen of pregnant (P) and non-pregnant C57BL/6 mice (NP). Among other gene, we observed that expression of Il1rl1 (ST2) was significantly up-regulated in B cells from P compared to NP mice. Further flow cytometry analysis showed that expression of ST2 was increased on total splenic B cells from P compared to NP mice and it was predominantly expressed on $B220^{low}CD23^{neg}$ B1 B cell subset.
A kinetic analysis depicted that levels of splenic ST2-expressing B1 cells were significantly increased at early pregnancy (day 12) and mid-pregnancy (day 14) as compared to NP mice. Additionally, we evaluated the expression of ST2-expressing B cells in a murine model of preterm birth. Interestingly, the levels of ST2-expressing B cells were significantly increased in the spleen of LPS-induced preterm birth mice compared to normal pregnant mice. Bringing all these data together, our results reinforce the idea of IL-33 being a crucial cytokine controlling pregnancy outcome through a mechanism involving ST2 expression in B cells.

P.A5.02.15

Effect of adjuvant on immune responses to an experimental subunit vaccine antigen in sheep

***S. R. Wattegedera**[1], K. Stronach[2], E. Rampacci[3], N. Arteche Villasol[4], R. Tassi[1], J. Thomson[1], M. Rocchi[1], K. Aitchison[1], M. Livingstone[1], D. Longbottom[1], G. Entrican[1];*
[1]Moredun Research Institute, Penicuik, United Kingdom, [2]University of Edinburgh, Edinburgh, United Kingdom, [3]Universita degli Studi di Perugia, Perugia, Italy, [4]Universidad de Leon, Leon, Italy.

Introduction: The desired goal of vaccines to protect against intracellular bacterial infections is usually the induction of cellular T-helper (Th)-1 type immunity, characterised by the production of interferon (IFN)-gamma. This has been particularly challenging for subunit vaccine development in livestock. We have characterised cellular immune responses in sheep to an experimental chlamydial subunit vaccine antigen delivered in three adjuvants.
Materials and Methods: Groups of 35 sheep were immunised with a single inoculation of the experimental vaccine antigen formulated in two water-in-oil adjuvants (Montanide ISA 70 VG, Montanide ISA 61 VG) or saponin-derived QuilA. Peripheral blood mononuclear cells (PBMC) were isolated pre- and post-immunisation and re-stimulated *in vitro* with both the vaccine antigen and whole killed chlamydial elementary bodies (EBs). Recall responses were measured by the presence of cytokines in the PBMC culture supernates, with IFN-gamma as an indicator of Th1-type responses and interleukin (IL)-4 as an indicator of Th2-type responses.
Results: All three adjuvants induced antigen-specific immune responses that could be detected in recall assays to both the experimental vaccine antigen and whole chlamydial EBs. In each case, IFN-gamma was the dominant cytokine in the post-immunisation antigen-specific recall responses, with almost no antigen-specific IL-4 being detected. Mitogen-induced IFN-gamma and IL-4 was consistent pre- and post-immunisation. Of the three adjuvants, Montanide ISA 61 VG induced slightly higher levels of IFN-gamma.
Conclusions: Classical Th1-type responses can be elicited in sheep to a subunit antigen delivered in different adjuvants. The relative efficacy of these adjuvants needs to be determined using infection challenge models.

P.A5.02.16

The chemokine receptor CX3CR1 defines three antigen-experienced CD8 T cell subsets with distinct roles in immune surveillance and homeostasis

***C. Gerlach**[1,2], E. Moseman[2], S. M. Loughhead[2], D. Alvarez[2], A. J. Zwijnenburg[1,2], L. Waanders[2], R. Garg[2], J. C. de la Torre[3], U. von Andrian[2];*
[1]Karolinska Institutet, Stockholm, Sweden, [2]Harvard Medical School, Boston, United States, [3]The Scripps Research Institute, La Jolla, United States.

Infections induce pathogen-specific T cell differentiation into diverse effectors (Teff) that give rise to memory (Tmem) subsets. The cell-fate decisions and lineage relationships that underlie these transitions are poorly understood. Here, we found that the chemokine receptor CX3CR1 identifies three distinct $CD8^+$ Teff and Tmem subsets. Classical central (Tcm) and effector memory (Tem) cells and their corresponding Teff precursors were $CX3CR1^-$ and $CX3CR1^{high}$, respectively. Viral infection also induced a numerically stable $CX3CR1^{int}$ subset that represented ~15% of blood-borne Tmem cells. $CX3CR1^{int}$ Tmem cells underwent more frequent homeostatic divisions than other Tmem subsets and not only self-renewed, but also contributed to the expanding $CX3CR1^-$ Tcm pool. Both Tcm and $CX3CR1^{int}$ cells homed to lymph nodes, but $CX3CR1^{int}$ cells, and not Tem cells, predominantly surveyed peripheral tissues. As $CX3CR1^{int}$ Tmem cells present unique phenotypic, homeostatic, and migratory properties, we designate this subset peripheral memory (Tpm) cells and propose that Tpm cells are chiefly responsible for the global surveillance of non-lymphoid tissues.

Cell fate reprogramming of adult cells towards pluripotency or unrelated somatic cell-types has been explored in the context of regenerative medicine. Dendritic cells (DCs) are professional antigen presenting cells (APCs) specialized in the recognition, processing and presentation of antigens to T-cells, inducing adaptive immunity. We hypothesized that the unique properties of DCs could be induced in unrelated cell-types, allowing the direct control of immune responses with cell reprogramming. Here, the requirements to induce DCs were investigated using a combinatorial overexpression of Transcription Factors (TFs) in Clec9a-tdTomato mouse fibroblasts. This reporter system specifically marks the conventional DC lineage. We have identified Pu.1, Irf8 and Batf3 as sufficient and necessary to induce Clec9a reporter activation and establish DC morphology and phenotype in fibroblasts. Induced DCs (iDCs) express DC type 1 (cDC1) surface phenotype and transcriptional program, with features of interferon-induced maturation. Functionally, iDCs engulf proteins, dead cells and upon stimulation of toll-like receptors, secrete inflammatory cytokines. iDCs capture, process and present antigens to CD4+ T and remarkably, CD8+ T cells, a hallmark of cross-presenting DCs. Strikingly, vaccination of syngeneic tumor mouse models with iDCs inhibited tumor growth. Finally, transduced human fibroblasts acquire DC morphology, DC phenotype and competence to engulf proteins and dead cells. Hence, we provide evidence that antigen presentation and cross-presentation can be dynamically programmed by a small combination of TFs. These findings provide insights into cDC1 specification and a platform for future development of cancer immunotherapies based on cell reprogramming.

P.A5.02.18

TLR2-mediated inflammatory responses and their impact on the course of dengue virus infection

*A. Aguilar Briseno[1], V. Upasani[1,2], B. M. ter Ellen[1], J. Moser[3], P. Dussart[2], T. Cantaert[2], J. M. Smit[1], **I. A. Rodenhuis-Zybert**[1];*
[1]Department of Medical Microbiology, University of Groningen and University Medical Center Groningen, Groningen, Netherlands, [2]Institut Pasteur du Cambodge, International Network of Pasteur Institutes, Phnom Penh, Cambodia, [3]Departments of Pathology & Medical Biology and Critical Care, University of Groningen and University Medical Center Groningen, Groningen, Netherlands.

Clinical manifestations of dengue virus (DENV) infections range from a flu-like to a severe disease hallmarked by increased vascular permeability and/or plasma leakage. Exacerbated inflammation precedes severe disease; however, its underlying mechanisms are only partially understood. Consequently, there are no methods to predict or block DENV pathogenesis. Toll-like receptors (TLR) play a crucial role in the initiation of inflammation and containment of infections. Yet, prolonged activation of TLRs exacerbates inflammation, which ultimately leads to (vascular) immunopathology. We and others have shown increased expression of TLR2 on monocytes of DENV infected patients compared to healthy controls during the acute phase of infection. Here, we combined *ex vivo*and *in vitro*analyses to identify the relevance of TLR2 expression on peripheral blood mononuclear cells in DENV pathogenesis. We found that TLR2 expression on $CD14^{++}CD16^{-}$classical monocytes isolated during acute DENV infection correlated with disease severity. *In vitro*, blocking of TLR2 prior to DENV infection abolished inflammatory responses mediated by NF-kappaβresulting in diminished intracellular cytokine production and attenuated human endothelial cells activation. Furthermore, blocking the engagement of TLR2 and CD14 but not that of TLR1/6 significantly reduced infected cell-mass, suggesting that DENV usurps TLR2 and CD14 to establish infection. Consistent with these findings, in patients, DENV infection was evident primarily in $CD14^{++}CD16^{-}$monocytes, which correlated with the development of severe disease.Conclusively, our data reveal the fundamental role of TLR2 as a regulator DENV-induced inflammation and immunopathology. Pharmacological targeting of the TLR2 axis could form a strategy for mitigating the pathogenesis of severe disease.This study was supported by NWO-VENI grant and the Institut Pasteur International Network.

HIV-1 hijacks the complement system to escape degradation and promote viral dissemination by human Langerhans cells

***M. Bermejo Jambrina**[1], B. Nijmeijer[2], D. Wilflingseder[1], T. Geijtenbeek[2];*
[1]Department of Hygiene and Medical microbiology, Medical University of Innsbruck, Innsbruck, Austria, Innsbruck, Austria, [2]Department of Experimental Immunology, Amsterdam Infection and Immunity Institute, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

The role of complement in HIV-1 susceptibility remains unclear. *In vivo*, HIV-1 spontaneously activates complement in semen, plasma and at mucosal surfaces and is therefore coated after viral entry. However, whether this is involved in viral transmission is unknown. Langerhans cells (LCs) reside in mucosal tissue and are the first cells that encounter HIV-1 during sexual contact. LCs are able to limit dissemination by degrading HIV-1 via langerin-induced autophagic processes, preventing HIV-1 infection of LCs and transmission to T cells. We set out to investigate the role of complement in sexual transmission of HIV-1 using isolated human LCs and the *ex vivo* skin transmission model. Strikingly, complement-opsonized- HIV-1, in contrast to non-opsonized HIV-1, efficiently infected LCs, *in vitro* and *ex vivo*. Moreover, complement-opsonized-HIV-1 was efficiently transmitted to target T cells by LCs in the *ex vivo* skin transmission modelInfection and subsequent transmission of LCs were inhibited by blocking CR3 and CR4.
Using isolated activated LCs we observed that complement opsonization increased HIV-1 binding to LCs through CR3 and CR4. Langerin inhibition reduced binding of complement-opsonized-HIV-1 but both CR3 and CR4 were most important for binding. These data suggest that complement opsonization leads to a different routing of HIV-1 in LCs via CR3 and CR4 binding, evading antiviral function of langerin and increasing HIV-1 infection of LCs and subsequent viral dissemination. This study provides novel insight into the importance of complement in HIV-1 susceptibility and might lead to preventative strategies to prevent HIV-1 infection. This work was funded by EFIS.

P.A5.03.02

Unraveling the regulation of Antigen-specific Immunoglobulin Glycosylation

***E. L. de Graaf**[1], R. Visser[1], A. Hipgrave-Ederveen[2], C. Koeleman[2], E. van der Schoot[1], M. Wuhrer[2], G. Vidarsson[1];*
[1]Sanquin Research, Amsterdam, Netherlands, [2]Centre for Proteomics and Metabolomics, LUMC, Leiden, Netherlands.

We have recently found that antibodies formed against platelet and red blood cell antigens to be skewed towards a unique type of N-linked IgG Fc-glycan profile with decreased fucosylation, increased galactosylation and sialylation. The lowered core-fucosylation increases the affinity of the pathogenic antibodies to FcγRIIIa and FcγRIIIb, and hence platelet/RBC destruction. More remarkably, the Fc-glyco profile seems to be stable for years and even decades after immunization. In order to understand how the Ig glycosylation is regulated on the B cell level, we have set up a B cell culture system where we can follow antigen-specific glycosylation in clonally related cells. By following the development of an early memory B cell (i.e. CD27+, IgM+) into a late state memory B cell (CD27+, IgG+) characterized by low and high somatic hypermutation, respectively, we attempt to determine the point of IgG glyco-memory formation. Firstly, antigen-specific B-cell clones from affected donors were isolated, FACS sorted and individually expanded *in vitro*. Thereafter, antibody glycosylation profiles were determined by measuring Fc glycopeptide abundances from each supernatant, using liquid chromatography and mass spectrometry. Subsequently, the acquired B-cell-specific IgG glycoprofiles will be correlated to the clonal relation and mRNA expression of a panel of glycosylating enzymes of each clone. Initial results will be presented, providing more insight in the regulation of antigen-specific antibody glycosylation.

P.A5.03.03

NK-cell mediated ADCC via FcγRIIIa is affected by IgG3 polymorphisms

***S. W. de Taeye**, A. E. Bentlage, S. Lissenberg-Thunnissen, E. L. de Graaf, T. Rispens, G. Vidarsson;*
Sanquin, Amsterdam, Netherlands.

Besides immunoglobulin isotypes and subclasses, polymorphisms in the immunoglobulin gamma heavy chain gene form another layer of variation to the humoral antibody response (IgG allotypes). From the four IgG subclasses (IgG1-4), most variation has been found in IgG3. Interestingly, several allotypes have been linked with susceptibility to various infectious diseases or auto-immune diseases. To study the influence of the polymorphisms on IgG effector functions, we produced all the described allotypes (27 allotypes, anti-RhD specificity) and subsequently assessed Fc gamma receptor (FcγR) binding with surface plasmon resonance (SPR). When we compared IgG3 allotypes, we observed small differences in binding to Fc gamma receptors FcγRIIa and FcγRIIIa. Most prominently, allotype IGHG3*18 and IGHG3*19 bound less well to FcγRIIIa than all the other IgG3 allotypes. The three-fold lower affinity of these allotypes for FcγRIIIa directly correlated with a reduced capacity to induce ADCC. Allotype IGHG3*18 and IGHG3*19 express a unique tryptophan at position 292 in the CH2 domain instead of an arginine, which is not found in the other IgG subclasses. Since residue 292 is not directly involved in binding to FcγRIIIa, we hypothesize that the variation at position 292 alters the conformation of the loop that interacts with FcγRIIIa, which is a likely possibility based on available structural data. Future experiments are necessary to understand the interaction of IgG allotypes with FcγR, but also the neonatal Fc-receptor, and complement. These experiments should give new insights how these allotypes may possibly be linked with susceptibility to infectious diseases, allo- or auto-immune diseases.

P.A5.03.04

T cells enhance direct infection of NK cells by viruses, leading to enhanced effector functions

*M. Lambregts, N. Swaans, M. Emmelot, E. A. van Erp, D. van Baarle, **J. de Wit**;*
National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands.

Natural Killer (NK) cells are important in virus-infections and were originally believed to mainly recognize and eliminate infected cells through cytotoxicity. Increasing evidence now illuminates the immune modulatory functions of NK cells, via (pro-)inflammatory cytokines or intercellular interactions, underlining the complexity of NK-cell crosstalk with both innate and adaptive immune cells.
Previously, we found a significant contribution of NK cell to the IFN-γ response against mumps virus (MuV). Here we sought to investigate the direct effects of virus-interactions with NK cells, and the crosstalk with other immune cells herein.
Incubation with live MuV resulted in a substantial infection of isolated human NK cells (up to 45%). NK cell infection was even further enhanced in presence of other PBMCs (up to 80%), implying crosstalk with other immune cells. Indeed, depletion of T cells reduced the infection of NK cells. The T-cell mediated enhanced infection of NK cells was also observed for other viruses (including measles and respiratory syncytial virus), suggesting a broader phenomenon. Following infection, NK cells were strongly activated and displayed enhanced effector functions, as shown by IFN-γ production and release of granzymes and perforin.
The implication of the enhanced effector functions on the NK-mediated immune modulation remains to be elucidated.

Introduction: The inflammasomes play a crucial role in the immune response to viral infection. Activation of inflammasome triggers the cleavage of caspase-1 and maturation of IL1β, a critical step for an efficient infection control. The positive relation between IL1β release and adaptive immunity has been exhaustively described, but hepatitis seems to be negatively influenced by the inflammasome. In HCV patients, IL1β level is augmented and it has been associated with immunopathology and viral load. Therefore, the aim of this work was to further analyze the role of the Caspase-1-IL1β axis in the initiation of adaptive immune responses. Methods: Cells and animals were infected with Mouse Hepatitis Virus strain A59 (MHV). We use WT and Caspase 1-deficient mice (Casp1$^{-/-}$). Results: BMDCs derived from Casp1$^{-/-}$ and wt mice were infected with MHV and inflammasome activation was analyzed. Data have shown that MHV infection induced IL1β release on WT mice, but not on Casp1$^{-/-}$BMDCs. Then, in vivo studies have shown that Casp1 deficiency ameliorates MHV-induced hepatitis. Survival rates revealed that Casp1$^{-/-}$ mice are resistant to MHV infection, while only 25% of wt mice survive at 20dpi. In accordance, liver from Casp1$^{-/-}$ mice showed reduced levels of MHV-RNA and augmented liver CD8-Tcells infiltration. Moreover, Casp1$^{-/-}$ mice have elevated number of MHV-specific CD8-T-cells and higher expression of CD107a marker. Finally, in vivo CTL activity assay confirmed that Casp1$^{-/-}$ mice have higher MHV-specific CTL activity than wt mice. Conclusion: We found that Caspase 1 activity is crucial in the modulation of CD8-T-cell response to coronavirus-induced hepatitis.

A phosphatidylinositol 4, 5-biphosphate (PIP2) metabolism-derived amplification loop fuels the sustained initiation of B cell activation

W. LIU*, C. Xu;*
TSINGHUA UNIVERSITY, BEIJING, China.

Lymphocytes have evolved sophisticated signaling amplification mechanisms to efficiently activate downstream signaling following detection of rare ligands in their microenvironment. B cell receptor microscopic clusters (BCR microclusters) are assembled on the plasma membrane and recruit signaling molecules for the initiation of lymphocyte signaling after antigen binding. Here, we identified a signaling amplification loop derived from phosphatidylinositol 4, 5-biphosphate (PIP2) for the sustained B cell activation. Upon antigen recognition, PIP2 was depleted by phospholipase Cγ2 (PLCγ2) within the BCR microclusters and was regenerated by phosphatidic acid (PA)-dependent type I phosphatidylinositol 4-phosphate 5-kinase (PIP5K) outside of the BCR microclusters. The hydrolysis of PIP2 inside of the BCR microclusters induced a positive feedback mechanism for its synthesis outside of the BCR microclusters. The falling gradient of PIP2 across the boundary of BCR microclusters was important for the efficient formation of BCR microclusters. Our results identified a PIP2 derived amplification loop that fuels the sustained initiation of B cell activation.

Anti-domain 1 beta2-glycoprotein I antibodies induce activation of monocytes and NK cells, and provoke prothrombotic settings

A. Martirosyan[1], *T. Papajik*[2], *S. Margaryan*[1,3], *Z. Mikulkova*[3], *L. Slavik*[2], *J. Ulehlova*[2], *E. Kriegova*[3], *G. Manukyan*[1,3];
[1]*Laboratory of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia,* [2]*Department of Hemato-oncology, Faculty of Medicine and Dentistry, Palacky University Olomouc and Faculty Hospital, Olomouc, Czech Republic,* [3]*Department of Immunology, Faculty of Medicine and Dentistry, Palacky University Olomouc and Faculty Hospital, Olomouc, Czech Republic.*

Introduction: It has been suggested that antibodies against domain 1 (D1) of β2-glycoprotein I (β2GPI) have clinical relevance in antiphospholipid syndrome (APS) patients, and strongly correlate with thrombosis and pregnancy complications. The direct influence of anti-D1 β2GPI on activation and pro-thrombotic activity of immune cells has not been studied yet. We aimed to determine the influence of anti-D1 β2GPI IgG antibodies on immune cells *in vitro*. Methods: For this, peripheral blood mononuclear cells from 11 healthy individuals were incubated (for 24 hours) with: 1) pooled plasma (n=6) derived from APS patients contained anticardiolipin antibodies (aCL), lupus anticoagulant (LA), anti-β2GPI and anti-D1 β2GPI; 2) pooled plasma (n=6) derived from APS patients contained aCL, LA, anti-β2GPI, and negative for anti-D1 β2GPI; 3) seronegative (negative for antiphospholipid antibodies) pooled plasma (n=6). Results: The presence of anti-D1 β2GPI markedly induced a proinflammatory phenotype of monocytes and NK cells in comparison with the cells cultured with anti-D1 β2GPI-negative and seronegative plasma. Particularly, anti-D1 β2GPI significantly increased % and MFI of CD142 (tissue factor, TF), HLA-DR and CD11 on healthy monocytes. A greater percentage of CD69+ NK cells was found upon cultivation with anti-D1 β2GPI+ plasma. Expression of IgG receptor FcγRIIIa (CD16) on both monocytes and NK cells was down-regulated by anti-D1 β2GPI + plasma. Conclusion: Taking together, for the first time, we demonstrated strong activation of monocytes and NK cells exposed to anti-D1 β2GPI. Prominently, anti-D1 β2GPI induced substantial increase in expression of monocytic TF favoring an initiation of thrombus formation. Grant support: IGA UP_2018_016

Antigen-specific activation of murine B lymphocytes *in vitro*

S. Michelchen*, K. Hanack;*
University of Potsdam, Department of Biochemistry and Biology, Potsdam, Germany.

Introduction: The generation of monoclonal antibodies by hybridoma technology is currently performed by immunizing animals such as mice with the desired antigen. The immune reaction takes place *in vivo* without any opportunities to intervene. The transfer of antigen-specific immune responses to *in vitro* conditions would allow a monitoring of these processes in a defined culture environment. For this, a simplified set-up was established in which only B lymphocytes were cultured with supplements mimicking the *in vivo* conditions of antigen-specific activation.
Methods: Murine splenic B lymphocytes from naive mice were isolated by magnetic cell sorting and cultivated *in vitro* with different combinations of antigen, αCD40-antibody, LPS, IL4 and IL7. As antigen a viral protein from the hamster polyomavirus capsid (VP1) was used. Antibody responses were determined by ELISA and Western Blot. B cell phenotypes were investigated by flow cytometry. Positive cultures were used to generate stable antibody producing hybridomas.
Results: VP1-specific antibody responses in *in vitro* cultures could be detected from day 3 on with specific IgM-responses. At day 9 we detected specific IgG-antibodies in cultures stimulated with antigen, αCD40-antibody and IL4. By fusion of antigen-specific B lymphocytes we were able to create IgM- and IgG-producing hybridoma cell lines.
Conclusions: Specific B cell activation *in vitro* was successfully shown within 10 days of *in vitro* culture. Combined with hybridoma technology, this method could be a powerful future approach in the field of antibody production.

Despite recent advances in antiretroviral-therapy (ART) for HIV-infection, life-long treatment is required as the virus persists in latently infected cells. Latently infected cells contain integrated virus but can escape immune-recognition due to minimal transcription. Innovative approaches eliminate latency by activating HIV-transcription to stimulate viral-production, which can lead to virus-mediated cytotoxicity or immune recognition of infected cells and ultimate elimination of HIV. We hypothesized that stimulation of CD4⁺ T-cells through the CD27/CD70-pathway would be a potent driver for HIV-transcription. Stimulation of naïve CD4⁺ T-cells with anti-CD3 antibody and CD70 ligand resulted in their potent activation, increased proliferation, granzyme B and perforin production, as compared to conventional anti-CD3/anti-CD28 antibody co-stimulation. In an *in vitro* model of HIV-infection of CD4⁺ T-cells, co-cultured with monocytes to facilitate infection of resting cells, stimulation with anti-CD3/CD70 compared to anti-CD3/anti-CD28 resulted in a lower frequency of virus activation. Moreover, in a reciprocal experiment with resting CD4⁺ T-cells stimulated *in vitro* via the CD27- or CD28-pathway prior to infection, strikingly, we found less virus-positive CD4⁺ T-cells under CD27-stimulating conditions, suggesting these cells were refractory to HIV-infection. We then stimulated CD4⁺ T-cells collected from HIV+ individuals on ART *ex vivo* and quantified cell-associated unspliced HIV-RNA by qPCR. Further, we performed single-cell RNA-sequencing on CD28- or CD27-activated cells to delineate gene expression profiles associated with these signaling pathways and to understand their differing effect on HIV-infection. Overall, our studies reveal novel insights into the potent effects of CD27/CD70 stimulation on CD4⁺ T-cells and containment of viral infection in HIV+ patients.

Cell adaptation of monoclonal antibodies produced by Chinese hamster Ovary (CHO) cell to grown in serum-free medium

***W. Puangmanee**;*
Faculty of Tropical Medicine, Bangkok, Thailand.

Wilarat Puangmanee[1], Pongrama Ramasoota[1], Pannamthip Pitaksajjakul[1]
1 Department of Social and Environmental Medicine, Faculty of Tropical Medicine, Mahidol University

Monoclonal antibody (MAb) is one of the most widely used substance for biopharmaceuticals and therapeutics for viral disease, especially dengue virus which is one of important re-emerging virus may causing life-threatening disease around the world. MAb can be produce using immunoglobulin G (IgG) gene cloning and expression in Mammalian Chinese Hamster Ovary (CHO) cell. Therefore, in vast value, it is necessary to produce in efficient large-scale production for control quality of MAbs. From our successful generation, human monoclonal antibodies (HuMAbs) were produced by fusion between myeloma cells and B-cells using hybridoma technology. These HuMAbs showed cross-neutralizing activity to dengue virus 4 serotypes. The recombinant IgG form of those HuMAbs showed prefer neutralizing (NT) activity.
For further characterization and standardization of HuMAbs, generaton of stable CHO cells for HuMAb production is required. In this study, plasmid of HC and LC were transfected to CHO cell using lipofectamine 2000. Then, stable CHO cells were selected by two antibiotics, puromycin and hygromycin. Then, high producer CHO cell was selected by flow cytometer. The single clones were subcloned by limiting dilution. Single clone that showed high production of HuMAb were screened by IgG quantitation ELISA. Stability of stable CHO cell was tested. The clones that showed high stability in antibody production were re-cloned and proceeded for suspension cell adaptation and production in serum-free medium for further scale-up.

PD1 ligand regulation during viral infection: Primus inter pares

***M. Raftery**, J. Hofmann, G. Schönrich;*
Institut für Virologie, Berlin, Germany.

Enhancement of the immune response to tumours and infections by blocking inhibitory co-stimulation has become an established success. In particular blocking of the CD28 family member PD1 on T cells and its ligands, PD-L1 and PD-L2, has proven therapeutically effective. The regulation of these ligands, however, has not yet been fully elucidated although cell-surface expression is known to be induced by interferons.In order to better quantify the upregulation of PD-L1 and PD-L2 in response to stimuli we exposed primary cells (fibroblasts, endothelial cells, dendritic cells and PBMC) to different interferons and PAMPs as well as to active viral infections. Cells were analysed by flow cytometry and functional assays.Comparison between Type I, II and III interferons showed a surprising divergence between otherwise similar cytokines, ranging from no induction (III) to strong (II). Similarly, some viral PAMPs showed strong induction whereas others such as RIG-I appeared to be ineffective. Viral infection in general rapidly induced PDL expression. This might argue for a role in the innate immune response to viral infection in addition to downregulation of the adaptive immune response as has been previously demonstrated. In agreement with this was the association of bystander activation with PDL expression in response to primary infection of PBMC. We propose that the PD1 system has a role to play in innate as well as adaptive immunity.

Alum induces rapid NADPH-oxidase independent NET release in human neutrophils

***M. Reithofer**[1], D. Polak[1], C. Kitzmüller[2], G. Greiner[3], B. Bohle[2], B. Jahn-Schmid[1];*
[1]Institute for Pathophysiology and Allergy Research, MCCA PhD Programme, Vienna, Austria, [2]Institute for Pathophysiology and Allergy Research,, Vienna, Austria, [3]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria, Vienna, Austria.

Alum is the most widely used adjuvant, though the mechanism behind its adjuvanticity is not totally solved. In mice, host-derived DNA has been reported to be involved in the adjuvant effect of alum. Neutrophils are the first cells at the site of injection and in response to strong or particulate stimuli neutrophils have the ability to simultaneously release extracellular DNA and granular material, so-called neutrophil extracellular traps (NETs) which are able to trap and kill microbes.
Here, we investigated alum-induced NET-formation in human neutrophils and its underlying pathway. Neutrophils were stimulated with alum or PMA and ionomycin as positive controls. Strong NET-formation was induced by all stimuli as visualized by fluorescence microscopy showing co-localization of extracellular DNA and different granular proteins. In addition, alum-induced neutrophil elastase activity was found in supernatants. Inhibition of downstream signalling molecules by using a plate-reader assay to quantify released DNA were performed, to reveal the pathway underlying NET-formation. Ionomycin and alum-induced mitochondrial reactive oxygen species (mROS), whereas PMA triggered cytoplasmatic NADPH oxidase-dependent ROS. Alum induced rapid DNA-release similar to ionomycin and dependent on phagocytosis, extracellular calcium and NFκB signalling. Furthermore, a significant dependence on necroptosis signalling similar to crystal-induced NET release was found. During the process of NET formation, increased glycolysis, as well as mitochondrial respiration was observed.
Together, alum potently induces a rapid mROS dependent NET-release in human neutrophils *in vitro,* utilizing energy from glycolysis and mitochondrial respiration. These NETs may represent danger-associated molecular patterns involved in the initial immune response to alum-adjuvated vaccines.

P.A5.03.13

Distinct roles for Btk in the formation of the B cell immune synapse

***S. Roman-Garcia**[1], S. R. Gardeta[1], S. V. Merino-Cortes[1], M. J. de Bruijn[2], R. W. Hendriks[2], Y. R. Carrasco[1];*
[1]CSIC, Madrid, Spain, [2]Erasmus University Medical Center, Rotterdam, Netherlands.

Bruton's tyrosine kinase (Btk) has a key role in the signaling pathways of receptors essential for the B lymphocyte response. Given its implication in B cell-related immunodeficiencies, leukemias/lymphomas and autoimmunity, Btk is studied intensely and is a target for therapy. Here we report distinct roles for Btk in antigen-triggered immune synapse (IS) formation of mouse primary B cells. Btk recruitment to the plasma membrane regulates the B cell ability to trigger IS formation as well as its appropriate molecular assembly; Btk shuttling/scaffold activities seem more relevant than the kinase function on that. Btk-kinase activity controls antigen accumulation at the IS through the PLCγ2/Ca^{2+} axis. Impaired Btk membrane-recruitment or kinase function likewise alters antigen-triggered microtubule-organizing center (MTOC) polarization to the IS, B cell activation and proliferation. We also show that, for B cell function, IS architecture is as important as the quantity of antigen that accumulates at the synapse.

P.A5.03.14

IL-10 competence and production in murine B cells: find the differences!

***S. Tonon**[1], F. Mion[1], J. Dong[2], H. Chang[2], M. Colombo[3], E. Dalla[1], A. Radbruch[2], C. E. Pucillo[1];*
[1]University of Udine, Udine, Italy, [2]German Rheumatism Research Center (DRFZ), Berlin, Germany, [3]Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy.

Under physiological conditions the immune system is maintained under homeostasis thanks to the balance between the regulatory and the effector compartment. Regulatory cells can be detected among several immune populations: B cells with regulatory functions have been described, but still no transcription factor to identify them has been discovered. Our working hypothesis is that we can distinguish between IL-10-competent B cells and IL-10-producing B cells, where the first class is ready for IL-10 production immediately after stimulation, while all the others are instructed by the surrounding environment. After 48 hours of stimulation IL-10 production can be induced by infective stimuli, such as LPS or CpG, but not by immune-mediated like through CD40. Very interestingly, if cells that are pre-stimulated through CD40 receive a second stimulation they start transcribing *il10*: these cells are competent for IL-10 production. Of note, the same concept can be applied in the *ex vivo* situation. Indeed, among total murine splenic B cells stimulated for 5 hours with LPS, PMA and ionomycin, only the 2-3% is able to immediately produce IL-10 and these are genuine IL-10 competent B cells. We set up a method to isolate them at very high purity taking advantage of an IL-10 secretion assay combined with FACS-sorting. On these two populations we performed several analysis, trying to understand which are the mechanisms at the basis of IL-10 production. We first analysed the timing of IL-10 production and then compared the transcriptomic signature of IL-10-competent and non-competent B cells with the public database ImmGen.

P.A5.03.15

Activation of the cGAS-STING pathway by chitosan requires the engagement of Dectin-1

J. L. Turley;
Trinity College Dublin, Dublin 2, Ireland.

The cationic polysaccharide, chitosan is an effective adjuvant that induces humoral immunity and Th1 cell responses following vaccination by injection or mucosal routes, supporting its application as an alternative to alum for vaccines that promote cell-mediated immunity.
We previously reported that chitosan promotes dendritic cell (DC) maturation by inducing type I interferons and enhances antigen-specific Th1 responses in a type I IFN receptor-dependent manner. We have shown this response is dependent on C type lectin (CTL) Dectin-1 sensing, mitochondrial disruption, subsequent mtDNA release and the cGAS-STING sensing pathway. Here we propose that chitosan binds to the Dectin-1 receptor leading to the activation of phospholipase Cγ-2 (PLCγ-2) and the efflux of calcium from the endoplasmic reticulum (ER). A localised actin polymerisation event then brings the ER and mitochondria into close proximity, allowing a disproportionate amount of calcium to flow into the mitochondria. High calcium levels in the mitochondria result in increased ROS production and mitochondrial depolarisation, likely contributing to the subsequent release of mtDNA. Our data indicate that the immunomodulatory properties of chitosan result from this calcium-driven ROS production. This work provides evidence for the first time of a link between CTL receptors and intracellular nucleic acid receptors leading to dendritic cell maturation and enhanced cellular immunity.

P.A5.03.16

Selective recruitment of CD8⁺ T cells against a novel 12-mer A*68:01-restricted influenza peptide reflects the importance of HLA and TCR profiles

*E. B. Clemens[1], **C. E. van de Sandt**[1,2], E. Grant[1], S. Gras[3], J. Rossjohn[3], W. Chen[4], K. Kedzierska[1];*
[1]University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [2]Sanquin Blood Supply Foundation, Amsterdam, Netherlands, [3]Monash University, Melbourne, Australia, [4]La Trobe University, Melbourne, Australia.

Influenza A viruses are responsible for seasonal epidemics and sporadic pandemics that result in significant health, social and economic costs worldwide. In contrast to strain-specific antibodies, immunity provided by CD8⁺ T cells is long-lasting and cross-strain specific, making it an attractive target for novel universal one-shot vaccine strategies. We recently identified a novel 12-mer peptide from influenza A virus NP protein ($NP_{145-156}$) restricted by HLA-A*68:01. To determine the potential for NP_{145}-specific CTL to contribute to anti-influenza immunity, we dissected the characteristics of this response in A*68:01⁺ individuals (0-25% allele frequency, depending on ethnicity). We observed NP_{145}-specific responses in ~50% of individuals, ranging from immunodominant to subdominant in magnitude. Remarkably, individuals who did not respond to this epitope nevertheless contained populations of naïve NP_{145}-specific CD8⁺ T cells, suggesting that this precursor population is present but not effectively recruited during infection.
Crystal structure analysis of the A*68:01-NP_{145} complex showed that the central region of the NP_{145} peptide is highly flexible and may present a difficult target for TCR recognition, especially as A*68:01 does not ligate CD8 for enhancement of TCR-pMHC binding. Single-cell multiplex RT-PCR analysis of TCRαβ heterodimers revealed that recruitment of high affinity NP_{145}-specific responses was dependent on expression of distinct TCRαβ signatures characterized by long CDR3α and -β loops. Our data highlight the role of individual HLA profiles and intrinsic CD8⁺ T cell quality in determining recruitment of effective epitope-specific responses during infection.

P.A5.03.17

Bystander T-cells support clonal T-cell activation by controlling the release of dendritic cell-derived immune-stimulatory vesicles.

*M. Lindenbergh[1], D. Koerhuis[1], T. Driedonks[1], R. Wubbolts[1], W. Stoorvogel[1], **M. Boes**[2];*
[1]Utrecht University, Utrecht, Netherlands, [2]UMC-Utrecht, Utrecht, Netherlands.

Extracellular vesicles (EVs) that are released by immune cells are studied intensively for their functions in immune regulation and are scrutinized for their potential in human immunotherapy, for example against cancer. In our search for signals that stimulate the release of functional EVs by dendritic cells (DC) we co-cultured human monocyte-derived DC (moDC) with fixed autologous T-cells. LPS-activated moDC changed their morphological characteristics in response to contact with activated bystander T-cells, while non-activated bystander T-cells had no effect. Exposure of moDC to activated bystander T-cells stimulated the release of moDC-derived EV-associated proteins, including CD9, CD63, CD81, HLA class I, and ICAM-1, although these effects were highly variable between donors, and significant increases could be established only for CD63 and ICAM-1. The release of small RNA species was strongly increased upon interaction with activated bystander T-cells, specifically miR155a, known as a central modulator of T-cell responses, was highly increased in EVs from moDC. Functionally, we observed that EVs from moDC licenced by activated bystander T-cells displayed an enhanced capacity for antigen-specific T-cell activation. Taken together, these results suggest that non-cognate interactions between DC and bystander T-cells can modulate third party antigen-specific T-cell responses via EVs.

P.A5.03.18

Leukocyte iRhom2 regulates basal cardiac function

***S. L. M. Walker**, J. Sanchez, A. Gutierrez Del Arroyo, G. Ackland;*
William Harvey Research Institute, London, United Kingdom.

Introduction: The heart is an immunologically active site, even under basal conditions. Cardio-immune cross-talk regulates myocardial structure and function in basal and pathological conditions. Signaling via TNFR2 may play a cardioprotective role, implicating tumour necrosis factor alpha (TNF-a) in the pathogenesis of cardiac failure. Here, we examined the impact of ADAM-17 sheddase activity on cardiac function using iRhom2 deficient mice in whom only myeloid cells are ADAM-17 deficient, and therefore incapable of shedding TNF-a and CD62L.
Methods: Wild-type and iRhom2 deficient mice of either gender (age 8-12 weeks) underwent echocardiography (Vevo3100, VisualSonics) to measure cardiac physiologic function. Peripheral and cardiac-resident leukocytes were phenotyped by flow cytometry. Molecular markers of cardiac stress (ANP; atrial natriuretic protein) and mitophagy (parkin) were quantified using RT-PCR and Western Blot.
Results: We confirmed that cardiomyocytes express TACE in iRhom2-deficient mice. Peripheral leukocytes, including neutrophils, from iRhom2-knockout mice failed to shed CD62L in response to sterile inflammation (MFI CD62L: KO 7530±3221 Wt 1128±1668; p<0.001; KO n=17 Wt n=12). Constitutively, iRhom2-deficient mice had higher cardiac output at baseline (KO 23.13±1.93 mL/min, Wt 18.05±3.33 mL/min; p<0.001; KO n=11, WT n=9). ANP mRNA was elevated in ventricular tissue of iRhom2-knockout mice ($2^{\Delta CT}$: KO 1.04±0.52 Wt 0.42±0.01; p<0.005; KO n=5 WT n=7), as well as parkin protein levels (Densitometry: KO 0.94±0.97 Wt 0.11±0.10; p<0.05; KO n=5 Wt n=5).
Conclusions: The inability of myeloid cells in iRhom2 deficient mice to cleave CD62L and generate TNF-a is associated with constitutive cardiac injury. This data supports the hypothesis that leukocytes are pivotal in influencing basal cardiac function.

P.A5.03.19

HSPCs prevent chronic stress-induced immune suppression

***D. Yin**[1], H. Zhang[1], Y. Z. Caudle[1], A. Qin[2];*
[1]ETSU College of Medicine, Johnson City, United States, [2]Xiangya School of Pharmaceutical Sciences, Central South University, Changsha, China.

Introduction. Chronic stress has been demonstrated to exert a significant suppressive effect on immune functions. Hematopoietic stem progenitor cells (HSPCs) significantly modulate the immune system. However, the mechanisms responsible for this phenomenon remain to be elucidated. **Methods.** BALB/c male mice were placed in a 50-ml conical centrifuge tube with multiple punctures to establish a chronic restraint stress model. Alterations of regulatory T cells (Tregs) and cell sorting of Tregs for suppressive function assay were investigated. The serum levels of IL-10, IL-12, IL-1β,-10, TGF-β1 was assessed. The expression of STAT4, IL-12Rβ1, Foxp3, CTLA-4, and GITR were determined. **Results**. Administration of HSPCs prevent expansion and alleviate the suppressive activity of Tregs during chronic stress. Moreover, we found this protective effect is dependent on IL-12. IL-12/STAT4 signal provides a critical role against the expansion of Tregs following chronic stress. When neutralizing antibody against IL-12 or treatment with selective STAT4 inhibitor was co-administered with HSPCs in chronic stressed mice, the protective effect of HSPCs was abrogated. Furthermore, HSPCs administration promotes IL-12 production by splenocytes in chronic stressed mice. **Conclusions.** HSPCs prevent chronic stress-induced Tregs expansion in an IL-12/STAT4 dependent manner. Our studies suggest that HPSCs might offer a novel therapeutic strategy against the deleterious effects of chronic stress on the immunosuppression. This work was supported in part by grant NIGM114716.

P.A5.03.20

Dysfunctional proteolysis of CD74 by SPPL2a provokes a humoral response towards CD74 that is specific for ankylosing spondylitis and rheumatoid arthritis

*T. van Kempen[1], E. Leijten[1], M. Lindenbergh[2], M. Olde Nordkamp[1], C. Driessen[3], R. Lebbink[1], M. Wenink[1], N. Baerlecken[4], T. Witte[4], T. Radstake[1], **M. Boes**[1];*
[1]UMC-Utrecht, Utrecht, Netherlands, [2]Utrecht University, Utrecht, Netherlands, [3]Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [4]Medical University Hannover, Hannover, Germany.

Ankylosing spondylitis (AS) is associated with autoantibody production to Class II MHC-associated invariant chain peptide, CD74/CLIP. Mechanisms contributing to this antigen-specific autoimmunity are unknown. We addressed the cause for production of CD74/CLIP-specific antibodies, and observed that AS and rheumatoid arthritis (RA) patient monocytes have compromised activity of the CD74 processing enzyme signal peptide peptidase-like 2A (SPPL2a) and, consequently retained CD74-p8 N-terminal fragments in endosomal compartments. Using THP-1 cells lacking SPPL2a, we reveal a role for SPPL2a in endosomal architecture and surface-directed trafficking of HLA class II, full-length CD74 and CD74-p8. In patient monocytes, we confirm contraction of endosomal size and increase in surface-display of HLA class II and full-length CD74. Moreover, most patients with CD74-p8 accumulation have presence of IgA anti-CD74/CLIP antibodies in serum. Thus, our findings support that SPPL2a dysfunction underscores anti-CD74/CLIP autoantibody formation in AS and RA, through expediting increased display of CD74 self-antigen at the cell surface.

Transcriptional regulation of the IL-2 gene through Tip60 acetyltransferase binding in the ARRE-2 enhancer element

I. Aggeletopoulou, *I. Panagoulias, F. Karagiannis, P. Davoulou, T. Georgakopoulos, A. Mouzaki;*
Laboratory of Immunohematology, Division of Hematology, Department of Internal Medicine, Faculty of Medicine, University of Patras, Patras, Greece.

Introduction: Acetyltransferase Tip60 regulates gene transcription by interacting with promoter binding factors. Our recent publication has shown that IL-2 expression is blocked by a transcriptional silencer, Ets-2, that binds to the ARRE-2 element of the IL-2 promoter without physical interaction with NFAT-2, which binds to the same element promoting IL-2 activation. In this work, we studied the role of TIP60 on the IL-2 regulation through its possible interactions with Ets-2 and NFAT-2. Methods: Tip60, Ets-2 and NFAT-2 interactions were investigated by co-immunoprecipitation experiments in Jurkat cells in the absence (CM) or presence of the mitogens phorbol myristate acetate and ionomycin (P/I). Co-localization of Tip60, Ets-2 and NFAT-2 in Jurkat cells ±P/I was investigated by co-immunofluorescence. ChiP analysis was performed to determine Tip60 and Ets-2 binding to the IL-2 promoter. Results: Tip60 overexpression and silencing resulted in the activation and suppression of the IL-2 gene, respectively. Tip60 and Ets-2 interaction and co-localization was observed in CM and P/I conditions whereas Tip60 and NFAT-2 interaction was observed in P/I conditions only. In unstimulated cells, both Tip60 and Ets-2 bound to the ARRE-2 region. In contrast, P/I stimulation resulted in the departure of Tip60 and Ets-2 from ARRE-2 and the binding of Tip60 to the core promoter.Conclusion: Tip60 interacts with Ets-2 in both CM and P/I and with NFAT-2 in P/I conditions. We suggest that Tip60 contributes to the IL-2 transcriptional activation by dissociating Ets-2 from its binding site and permitting NFAT-2 binding to the ARRE-2 element.

P.A5.04.02
Aurora A function in CD8 killing activity

A. Alcaraz-Serna[1], *E. Bustos-Morán[1], N. Blas-Rus[1], S. Iborra[2], F. Sanchez-Madrid[1];*
[1]Servicio de Inmunología, Hospital Universitario La Princesa, Universidad Autónoma de Madrid, Instituto Investigación Sanitaria La Princesa (IIS-IP), Madrid, Spain, [2]Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain.

Aurora A has been studied in cell cycle progression and tumor generation. Recent work has revealed an unexpected function of Aurora A during inflammation and graft versus host disease development. However, the role of Aurora A in CD8+ T cell effector function and its cytotoxic T lymphocytes-mediated antiviral response has not been explored. To study the role of Aurora A in the CD8 lymphocyte cytotoxic function regulation, an in vitro study has been performed by flow cytometry analysis of CD107 surface expression and cytotoxic assays. Additionally, an in vivo analysis was conducted by infecting mice adoptively transferred with OT-I CD8 T cells and challenged with a Vaccinia-OVA infection in the presence of a specific drug inhibitor of Aurora A. Aurora A inhibition leads to an impairment either on the peptide-specific cytotoxicity and on the degranulation ability of CD8+ T cells. This finding was observed both in mice and human. Moreover, Aurora A blockade seems to reduce the transcriptional induction of genes classically related to the effector function of cytotoxic T lymphocytes, such as granzyme B or perforin. Finally, through an in vivo model of Vaccinia infection we have proved that Aurora A is necessary for the CD8+ T cells-mediated antiviral response. We can then conclude that Aurora A activity is a key factor for the cytotoxic T lymphocytes effector function and also for its action against a viral infectious threat.

P.A5.04.03
The role of DNA damage response in modulating functional plasticity of macrophages

A. Bansal, *B. Schumacher;*
CECAD Research Center , University of Cologne, cologne, Germany.

Introduction - The key innate immune players like neutrophils and macrophages generates potent genotoxic species (ROS and NOS) during infection and tissue injury, suggesting interplay and overlap between DNA damage response (DDR) and innate immune response. However, molecular mechanisms linking DDR with innate immune response are still poorly understood. Therefore, we addressed the following questions: 1) Does DDR prime the macrophages, thus predefining immune response to forthcoming stimuli? 2) What are the key molecular players and signaling pathways underlying the interplay of DDR and innate immune response? **Materials and Methods** - Macrophages were primed with low dose of UV light, which causes moderate and uniform DNA damage. Henceforth, UV primed macrophages are referred as "M_{DDR}". To define M_{DDR} activation and polarization, immune phenotyping, seahorse metabolic energetic analysis and *in vitro* functional assays (endotoxin tolerance assay, phagocytosis and gap closure assay) were performed. The phosphoproteomics analysis was carried out to identify key molecular players linking DNA damage and immune response of M_{DDR} cells. **Results** - The M_{DDR} cells express upregulated actin remodeling genes and have alerted metabolic energetics. Our, *in vitro* functional assays demonstrate that M_{DDR} cells are endotoxin tolerant, have increased phagocytosis capacity and secrete cytokines which increases endothelial cells migration. The phophoproteomics data analysis further suggests, the possible role of DDR-induced histone modification and remodeling in functional gain of M_{DDR} macrophages. **Conclusions** Collectively, our findings show that DNA damage response activation is sufficient to prime the macrophage and modulate its immune function.

Recurrent aphthous stomatitis and role of metals in the etiology

J. Bartova[1], *J. Petanová[2], Š. Podzimek[1], M. Janovská[1], M. Libánská[1], H. Tlaskalová[3], Z. Jirásková-Zákostelská[4], L. Izakovičová[5], S. Slezáková[5];*
[1]Institute of Dental Research,GUH and 1st Faculty of Medicine CHarles University, Prague, Czech Republic, [2]General University Hospital and 1st Faculty of Medicine CHarles University, Prague, Czech Republic, [3]Institute of Mikrobiology, Academy of Sciences of the Czech Republic, Prague, Czech Republic, [4]Institute of Microbiology ,Czech Academy of Sciences, Prague, Czech Republic, [5]Clinic of Stomatology and departmment of Pathophysiology,faculty of Medicine MU, Brno, Czech Republic.

Recurrent aphthous stomatitis (RAS) is the most common disease of oral mucosa, affecting 20-25 % of population worldwide. Nevertheless its etiopathplogy remains unexplained. This condition is characterized by multiple recurrent ulcers with circumscribed margins and yellow floors. RAS is considered to be a multifactorial disorder, the immune and genetic predisposition are proposed to play a major role. The aphthaeeruption ccan be initiated by local trauma, some medication, stress and nutritional factors.
This study examined the presence of hypersensitivity to dental and enviromental metals in patients with clinical diagnosis RAS. The group of patients were examined throught medical history, dental examination and by using a modified test of blast transformation for metals - MELISA. 70 patients and 20 healthy controls without history of RAS were enrolled to this study. Metals with the most significant differences between tested 20 metal in lymphocyte reaction were Hg, Zn, Zr and Ni. The study is supported by grant Czech Health Research Council nr. 15-29336-A.

A mobile endocytic network connects clathrin-independent receptor endocytosis to recycling and promotes T cell activation.

E. B. Compeer[1,2], *F. Kraus[2,3], M. Ecker[2], G. Redpath[2], M. Amazier[4], N. Rother[2], P. Nicovich[2], N. Kapoor-Kaushik[2], Q. Deng[5,6], G. Samson[7], Z. Yang[2], J. Lou[2], M. Carnell[2], H. Vartoukian[7], K. Gaus[2], J. Rossy[2,8];*
[1]University of Oxford, Oxford, United Kingdom, [2]University of New South Wales, Sydney, Australia, [3]Monash Biomedicine Discovery Institute, Melbourne, Australia, [4]Garvan Institute of Medical Research, Sydney, Australia, [5]University of New SOuth Wales, Sydney, Australia, [6]Commonwealth Scientific and Industrial Research Organisation, Geelong, Australia, [7]Biotechnologie Institut Thurgau, Thurgau, Switzerland, [8]Biotechnology Institute Thurgau, Thurgau, Switzerland.

Endocytosis of surface receptors and their polarized recycling back to the plasma membrane are central to many cellular processes, such as cell migration, cytokinesis, basolateral polarity of epithelial cells and T cell activation. Little is known about the mechanisms that control the organization of recycling endosomes and how they connect to receptor endocytosis. Here we followed the endocytic journey of the T cell receptor (TCR), from internalization at the plasma membrane to recycling back to the immunological synapse. We showed that TCR triggering leads to its rapid uptake through a clathrin-independent pathway. Immediately after internalization, TCR is incorporated into a mobile and long-lived endocytic network demarked by the membrane-organizing proteins flotillins. Although flotillins are not required for TCR internalization, they are necessary for TCR its recycling to the immunological synapse, TCR its nanoscaled spatial surface distribution, TCR signalling, and efficient primary T cell activation. Collectively, our data supports a model in which a novel endocytic sorting machinery underpinned by flotillins promotes the recycling of internalized TCR complexes to the immunological synapse to coordinate TCR nanoscaled organization that supports efficient T cell activation.

P.A5.04.06
High Arginase-1 levels in neonatal monocytes interfere with bakterizidal functions and production of cytokines

S. Dreschers, *K. Ohl, C. Platen, K. Tenbrock, T. Orlikowsky;*
Children`s University Hospital Aachen, Aachen, Germany.

Introduction: Bacterial infections enhance serum levels of arginine due to protein catabolism. Monocytes and monocytes derived macrophages (MΦ) express the enzyme arginase-1 and iNOS which metabolize arginine. Activity of iNOS and arginase-1 results in opposing effects: either the pro-inflammatory response (NO^- and ROS-production) and enhanced bacterial inactivation or an anti-inflammatory response via production of IL-10 and expansion of Th2-like T-cell subsets. Controlling the arginine metabolism can be predetermining the course of a bacterial infection. **Hypothesis:** High arginase-expression in MΦ of newborn macrophages (CBMΦ) strengthens anti-inflammatory responses compared to PBMΦ.

Material and methods: Polarization of monocyte-derived MΦ from cord blood and from adult peripheral blood (PBMΦ) according to published protocols. FACS-based immunotyping of receptors and metabolic products (ROS- und NO^--concentrations). *In-vitro E.coli* infection assay. Detection of cytokines (ELISA). **Results**: Arginase-1 expression levels in M2a- and M2c-CBMΦ were found three times overexpressed compared to corresponding PBMΦ subtypes ($p < 0.05$). M2- and M1-CBMΦ arginase-1 levels were twice as high as in corresponding PBMΦ subtypes ($p < 0.05$). IL-10-production and -secretion was enhanced in all subtypes of CBMΦ compared to PBMΦ ($p<0.05$). Nonetheless, infection caused a TNF-alpha/IL-10-ratio, biased to the inflammatory state. Infected M1-CBMΦ secreted more IL-6 compared to M1-PBMΦ. In anti-inflammatory subsets (M2-, M2a-, M2c-MΦ), infection-induced NO^--production was comparable. M1-CBMΦ produced less NO^- than M1-PBMΦ. All MΦ subsets featured equal phagocytosis-capacity. Intracellular killing of was unaltered. M2c-CBMΦ ROS production was lowered compared to M2c-PBMΦ. **Conclusion:** Overexpression of Arginase-1 in CBMΦ, is attributed to stronger pro-inflammatory responses. Bactericidal functions were unaffected.

P.A5.04.07
A key role for microRNAs in regulating IL-17 *versus* IFN-g production by gd T cells

*T. Amado[1], N. Schmolka[1], D. Sobral[2], F. Enguita[1], D. Inácio[1], B. Silva-Santos[1], **A. Gomes**[1,3];*
[1]Instituto de Medicina Molecular, Lisbon, Portugal, [2]Instituto Gulbenkian de Ciência, Oeiras, Portugal, [3]Escola Superior de Tecnologia da Saúde de Lisboa, Lisbon, Portugal.

γδ T cells are an important source of the pro-inflammatory cytokines IL-17 and IFN-γ under (patho)physiologic conditions. In the mouse, CD27+ γδ T cells are committed to IFN-γ expression, whereas their CD27- counterparts make IL-17 but are capable of co-expressing both cytokines under inflammatory conditions. We aim to characterize a novel layer of microRNA-mediated regulation of effector γδ T cell differentiation. First, by comparing the microRNA pools of the two CD27-based γδ T cell subsets, we found that miR-146a was selectively enriched in CD27- γδ T cells and restricted their IFN-γ production by targeting Nod1 mRNA. Next, to overcome the caveat of using surface markers, which do not allow isolation of pure populations of IL-17 or IFN-γ producing γδ T cells, we used a double reporter IL-17-GFP: IFNg-YFP mouse strain.
Pure IL-17+ or IFN-γ+ γδ T cell populations were isolated from peripheral lymphoid organs and subjected to next generation sequencing analysis of both microRNA and mRNA repertoires.
This allowed us to identify, for the first time, miRNA and mRNA signatures directly associated with cytokine expression, rather than TCR Vγ usage or maturation markers. Furthermore, differentially expressed miRNAs and mRNAs were bioinformatically integrated into networks that allowed the identification of 6 miRNAs predicted to target key determinants of the IL-17 program; and 3 miRNA candidates for the IFN-γ program of γδ T cells. Ongoing molecular assays provide an unprecedented functional characterization of the impact of microRNAs on the identity and differentiation of effector γδ T cell subsets.

P.A5.04.08
Expression of endogenous Interleukin-36 activity

***A. Jaafar**, M. Nicklin;*
University of Sheffield, Sheffield, United Kingdom.

INTRODUCTION: IL-36 cytokines comprise three agonists, IL-36α, IL-36β, IL-36γ, and antagonist IL-36Ra. IL-36 appears to be an important mediator for inflammation and immunity, particularly in the skin and other epithelia.
Material and methods: We used rhIL-1α, rhN^6-IL-36α and rhTNF at close to saturating concentrations to activate the IL-36 genes. IL-36 mRNAs were detected in both HaCaT (an untransformed human KC line) and HT-29 (a human colorectal carcinoma/epithelial cell line).
RESULTS: RT-PCR and RT-qPCR showed that IL-36β, Il-36γ, IL-36R and IL-36Ra mRNA were expressed in HaCaT in monolayer. Cell de-differentiation and differentiation of HaCaT in monolayer by Ca^{2+} modulation had little effect on the inducibility of IL-36β or IL-36γ. IL-36β, IL-36γ and IL-36R mRNA were also expressed by HT-29 but the standardised levels of IL-36β and IL-36γ were an order of magnitude lower compared with HaCaT. In HaCaT, the inducer cytokines were effective in the order TNF>IL-1>IL-36. In HT29 IL-36 was more effective than IL-1. HaCaT also responded to inducers of IL-8/CXCL8 secretion in the order TNF>IL-1>IL-36. In HT-29, IL-8 secretion was very effectively induced by rhIL-36α.
CONCLUSION: Expression levels of IL-36β and IL-36γ seem to be intrinsically cell line dependent. Maximum expression in HaCaT was an order of magnitude stronger than in HT-29. In HaCaT, dependence of IL-36 expression on even gross changes in cell morphology was weak. In both HaCaT and HT-29, there was a correlation between the proportionate increase in IL-8 secretion and the expression of IL-36 genes, which may reflect relative expression of cell surface receptors

P.A5.04.09
Investigating the post-transcriptional cooperation of Roquin and Regnase-1 in T cell differentiation

***N. Kronbeck**[1], G. Csaba[2], R. Zimmer[2], V. Heissmeyer[1];*
[1]Biomedical Center Munich, Ludwig-Maximilians-Universität, München, Germany, [2]Department of Informatics, Ludwig-Maximilians-Universität, München, Germany.

Gene regulation on the post-transcriptional level exerts essential control over immune responses and is needed to prevent autoimmune diseases.The RNA-binding proteins Roquin-1 and its paralog Roquin-2 were found to be essential for the prevention of autoimmunity and autoinflammation by controlling T cell activation and differentiation. Roquin proteins recognize *cis*-elements in the 3' UTRs of target mRNAs with different "functional" affinity/avidity and induce mRNA decay post-transcriptionally. In T cells, the expression of Roquin proteins themselves is regulated by proteolytic MALT1 cleavage downstream of the T cell receptor in a signal strength-dependent manner. The endonuclease Regnase-1 is regulated in the very same way by MALT1 cleavage. Moreover Roquin proteins and Regnase-1 share a common set of mRNA targets and can cooperate in the regulation of mRNAs. Additionally a conditional deletion of Regnase-1 in mouse T cells leads to a similar autoimmune phenotype as the knockout of Roquin-1/2 in T cells. These findings suggest that increasing TCR signal strength might gradually inactivate Roquin and Regnase1 and thus cause differential target mRNA derepression that specifies cell fate decisions and effector functions of T cells. By comparing conditional knockouts of either Roquin-1/2, Regnase-1 or all three proteins in T cells we want to elucidate how Roquin and Regnase-1 cooperate in the regulation of specific mRNAs and which consequences this cooperation has on cell fate decisions of T helper cells and the development of autoimmunity.

P.A5.04.10
The role of dendritic cells in lactobacilli-mediated dampening of pro-inflammatory immune responses

***G. Lasaviciute**, J. Quin, A. Östlund Farrants, E. Sverremark-Ekström;*
Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm University, Stockholm, Sweden.

During the last years, research has focused on the interplay between the microbiota and the immune system. Lactobacilli, which are frequently found in the human gut, are of particular interest due to their beneficial probiotic properties. Previous results from our group and others suggest that lactobacilli modulate T-cells responses *in vitro*, however, the mechanisms involved are not yet fully understood. Since antigen presenting cells (APCs) like dendritic cells (DCs) are responsible for immune activation, we are interested whether lactobacilli induce epigenetic events in DCs and influence their functional phenotype. Our preliminary results show that 2h stimulation of monocyte-derived DCs with *Lactobacillus (L.) reuteri*-cell free supernatant (CFS) induce maturation of DCs in terms of increased cell surface and gene expression of CD83. We also show that the expression of pro-inflammatory cytokines IL-6 and IL-23 is upregulated in *L. reuteri*-CFS stimulated cells. Further, the results from chromatin immune precipitation (ChiP) experiments show that chromatin accessibility at the promoter region of genes encoding markers important for DC maturation and function clearly differs between *L. reuteri*-CSF and *Staphylococcus aureus*-CFS stimulation. To date, we hypothesize that changes in histone modifications, which can be identified by "activating and silencing marks", and recruitment of different transcription factors at the promoter region of DCs genes might contribute to lactobacilli-mediated immune regulation.

P.A5.04.11
IL-36 is activated by several pathogen-derived proteases and thus functions as a global alarmin of epithelial infection

*J. Ainscough[1], **T. Macleod**[1], M. Stacey[1], M. Wittmann[1,2];*
[1]University of Leeds, Leeds, United Kingdom, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom.

The interleukin (IL)-1 family of cytokines are fundamental regulators of the innate immune system, pivotal in initiating and orchestrating inflammation. IL-36γ is a recently described IL-1 family member expressed at epithelial barriers that drives immune responses against a range of pathogenic insults. As with other IL-1 family members, IL-36γ is expressed as an inactive precursor that must undergo proteolytic truncation to become biologically active. Initial experiments incubating IL-36γ in pathogenic bacterial and fungal conditioned media illustrated IL-36γ is susceptible to cleavage by pathogen-derived proteases. Importantly, analysis by mass spectrometry showed Aspergillus fumigatus (Af), Trichophyton rubrum (Tr) and Streptococcus pyogenes (Sp) cleave IL-36γ to its potent pro-inflammatory truncation (IL-36γ S18). Subsequent experiments utilising protease-knockout strains and recombinant proteases demonstrated IL-36γ activation is mediated by virulence factors secreted by Af and Sp. Challenging oral epithelial cells with heat fixed Af and Sp increased expression of IL-36γ, whilst addition of live pathogens caused both IL-36γ release and activation. Furthermore, IL-36γ activation was inhibited when experiments were repeated with protease-knockout strains. In summary, these investigations show invasive bacterial and fungal pathogens induce IL-36γ production and release from epithelial cells and secrete proteases which activate the cytokine once it has been released. Given that IL-36γ is activated by such a broad range of pathogen-derived proteases, it is postulated this cytokine functions as a sensor of exogenous protease activity, thus is a broad alarmin of infection. Ultimately, this mechanism may represent an essential mediator of host defence against a variety of important human pathogens.

P.A5.04.12

Nanoscale organisation of the T cell receptor by the chemokine receptor CCR5

A. Martín-Leal[1], *R. Blanco*[1], *J. Casas*[2], *M. T. Rejas*[3], *C. Drechsler*[4], *M. Moreno*[1], *S. Escudero*[1], *W. Schamel*[5], *G. Fabriás*[2], *B. Alarcón*[3], *H. M. van Santen*[3], *S. Mañes*[1];
[1]*Centro Nacional de Biotecnlogía-CSIC, Madrid, Spain,* [2]*Institute of Advanced Chemistry of Catalonia (IQAC-CSIC), Barcelona, Spain,* [3]*Centro Biología Molecular Severo Ochoa (CSIC-UAM), Madrid, Spain,* [4]*Department of Pharmaceutical Technology and Biopharmacy, University of Freiburg, Freiburg, Germany,* [5]*BIOSS Centre for Biological Signalling Studies and Faculty of Biology, University of Freiburg, Freiburg, Germany.*

Chemokines and their receptors are key molecules that coordinate trafficking of lymphocyte subtypes. CCR5, the chemokine receptor for the ligands CCL3, CCL4 and CCL5, is also a costimulatory receptor necessary for maximal activation of $CD4^+$ T cells. This latter activity requires antigen-mediated stimulation of the T cell receptor (TCR) and CCR5 ligand secretion by both the antigen-presenting cell and the T-cell. Although the role of CCR5 in naïve $CD4^+$ T cell activation is well-established, whether it has additional functions in antigen-experienced T cells remains unknown. The TCR is organised in nanoclusters, which are larger in activated and memory than in naïve counterparts. This reorganisation to larger TCR oligomers explains the increased antigen sensitivity of preactivated T-cells, probably because the nanoclusters can be stimulated at lower antigen concentrations than monomeric TCRs. We report that CCR5 activity determines TCR nanocluster size and valency in antigen- experienced T cells. This activity is $CD4^+$ T lymphocyte-specific and independent of CCR5-induced costimulatory signals. CCR5-induced TCR nanoclustering was associated to changes in cell lipid composition. Activated $CCR5^-CD4^+$ T cells had higher ceramide levels than $CCR5^+$ counterparts, coinciding with increased expression of several ceramide synthase isoforms in the $CCR5^-$ cells. In sphingomyelinase-treated live cells and in artificial liposomes, ceramide levels critically determined TCR nanocluster size. Finally, CCR5 deficiency impaired antigen sensitivity of antigen- experienced $CD4^+$ T cells *in vitro*, and reduced T-cell help for immunoglobulin class switching *in vivo*. Our results identify a CCR5 role in TCR nanocluster formation, and suggest CCR5 participation in memory T-cell function.

The Role of heterotrimeric G Proteins in Homing and Migration of Lymph derived T cells

G. E. Patzer[1], *M. Permanyer Bosser*[1], *M. Friedrichsen*[1], *M. Galla*[2], *R. Förster*[1];
[1]*Institute of Immunology, Hannover, Germany,* [2]*Institute of Experimental Hematology, Hannover, Germany.*

The process of lymphocyte homing to the lymph nodes (LNs) via specialized high endothelial venules is well studied while the mechanisms how lymphocytes enter the LN via afferent lymphatic vessels remain largely elusive. Previous studies using intra-lymphatic delivery of cells showed that naïve CD4+ T cells reach the T cell zone (TCZ) of lymph nodes through the medullary sinuses while activated CD4+ T cells can migrate into the TCZ directly through the SCS in a CCR7-dependent manner. However, activated $CCR7^{-/-}$ T cells are still able to enter the LN parenchyma to some extent while pertussis toxin treated T cells are retained in the SCS indicating that other chemokine receptors and/or signaling pathways must be involved in LN homing and intranodal migration. Using the CRISPR-Cas9 technology we now report the generation of activated primary CD4+ T cells deficient for Gαi2, Gαi3 or for both molecules to assess the effect of Gαi-subunit mediated homing and migration of lymph-derived T cells. Preliminary data indicate that single knockout of either Gαi2 or Gαi3 has limited effect on transwell cell migration assays, as well as on the egress of intralymphatically injected T cells from the SCS into the LN parenchyma. The migration distance of Gαi2-deficient T cells from the SCS into the LN parenchyma was reduced while in double knockout T cells the migration into the parenchyma was impaired compared to wild-type cells. However, unlike Pertussis-toxin treated cells, the double knockout T cells were not retained in the SCS.

Dissecting the role of HDAC1 and HDAC2 in the induction of $CD4^+$ T cells with cytotoxic effector function

T. Preglej[1], *P. Hamminger*[1], *L. Andersen*[1], *T. Bulat*[2], *L. Göschl*[3], *R. Tschismarov*[4], *B. Strobl*[2], *C. Bock*[5], *C. Seiser*[6], *W. Ellmeier*[7];
[1]*Division of Immunobiology, Institute of Immunology, CePII, Medical University of Vienna, Vienna, Aus, Vienna, Austria,* [2]*Institute for Animal Breeding and Genetics, University of Veterinary Medicine, Vienna, Austria,* [3]*Division of Rheumatology, Medicine III, Medical University of Vienna, Vienna, Austria,* [4]*Max F. Perutz Laboratories, Vienna Biocenter, Medical University of Vienna, Vienna, Austria,* [5]*Medical Epigenomics Laboratory, CeMM, Vienna, Austria,* [6]*5Max F. Perutz Laboratories, Vienna Biocenter, Medical University of Vienna, Vienna, Austria,* [7]*Division of Immunobiology, Institute of Immunology, CePII, Medical University of Vienna, Vienna, Austria.*

$CD4^+$ T cells with a cytotoxic phenotype ($CD4^+$ CTLs) play important roles in antiviral and antitumor immunity. Recently, we showed that the histone deacetylases HDAC1 and HDAC2 are essential for the maintenance of $CD4^+$ lineage integrity by preventing a Runx3/CBFβ-dependent induction of a cytotoxic program. In the current study, we want to gain further mechanistic insights in the individual role of HDAC1/HDAC2 in the networks controlling $CD4^+/CD8^+$ T cell identity. Since HDAC1/HDAC2-doubly-deficient $CD4^+$ T cells display reduced survival and thus preclude the analysis of these cells in more details, we generated mice with a T cell-specific deletion (*Cd4*-Cre) of the two *Hdac1* alleles and one *Hdac2* allele ($HDAC1^{cKO}HDAC2^{HET}$ mice). $HDAC1^{cKO}HDAC2^{HET}$ $CD4^+$ T cells acquire $CD8^+$ effector functions upon activation, characterized by high production of IFN-γ, and by the increased expression of T-bet, granzyme B and perforin, but not CD8α. Furthermore Runx3 is up-regulated, whereas ThPOK expression is reduced. Activated $HDAC1^{cKO}HDAC2^{HET}$ $CD4^+$ T cells express high levels of CRTAM, a $CD4^+$ CTL marker, and show high cytotoxic activity towards target cells *in vitro*. The induction of the CTL program correlates with a strong increase in phosphorylated STAT1 and inhibition of IFN-γ/STAT1 signaling in $HDAC1^{cKO}HDAC2^{HET}$ $CD4^+$ T cells attenuates up-regulation of $CD8^+$ lineage genes. Finally, in a murine MCMV model, preliminary data indicate that $HDAC1^{cKO}HDAC2^{HET}$ mice display higher levels of virus-specific $CRTAM^+/CD103^+$ $CD4^+$ T cells upon infection. These results demonstrate that HDAC1/HDAC2 play essential roles in the induction of $CD4^+$ T cells with cytotoxic effector function. Supported by FWF (P26193)

P.A5.04.15

Variation of TNF-alphareceptors co-expression on peripheral blood mononuclear cell subset in health

A. Alshevskaya, J. Lopatnikova, J. Zhukova, F. Kireev, ***S. Sennikov****;*
Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation.

The aim of the study was to examine the expression level of type 1 and 2 receptors to TNF-alpha (TNFR1/TNFR2) on main immune subsets of peripheral blood cells.
Methods: The study was conducted on 46 healthy donors (18-77 years). Co-expression and number of TNFR1/2 were calculated for monocytes, B-cells, T-cells, as well as among: cytotoxic T-cells, T-helpers, activated CD8+ and CD4+ cells, memory T-cells and naive T-cells, and T-regulatory cells by flow cytometry analysis (BD FacsVerse, USA).
Results: The highest percentage of double positive cells was in activated cytotoxic T-cells subset (25.8%), slightly lesser - in monocytes (15.2%), cytotoxic T-memory cells (14.3%) and CD5+ B-cells (13.9%),total B-cell pool and activated T-helper (11.5%); for the remaining subpopulations, proportion of double-positive cells did not exceed 10%. For all populations studied, small fraction of cells expressed only TNFR1 (and it was always at least twice lower than percentage of double-positive cells) was observed. The almost complete absence of cells expressing only type 1 receptors (less than 0.5%) was identified for T-regulatory cells, cytotoxic and T-regulatory memory cells and CD5+ B-cells. Conversely, the proportion of cells expressing only type 2 receptors in all studied populations was more than 25% and at least twice the proportion of double-positive cells.
Conclusion: The distribution of TNFR1/2 differed significantly among the main immune subsets, which can lead to different levels and types of cell response to the cytokine. Simultaneous presence of both types of receptors on the cell surface is associated with increase of their expression density.

Immunomodulatory properties of advanced glycation end-products formed from different substrates

M. M. Staniszewska[1,2], *K. Gostomska-Pampuch*[1], *I. Jonik*[2], *A. Bronowicka-Szydełko*[3], *M. Krzystek-Korpacka*[3], *A. Gamian*[1];
[1]*Laboratory of Medical Microbiology, Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland,* [2]*Laboratory of Separation and Spectroscopic Method Applications, Centre for Interdisciplinary Research, The John Paul II Catholic University of Lublin, Konstantynow 1J, 20-708 Lublin, Poland, Lublin, Poland,* [3]*Department of Medical Biochemistry, Wroclaw Medical University, Chalubinskiego 10, 50-368 Wroclaw, Poland, Wroclaw, Poland.*

Introduction: Glycation plays a role in pathogenesis of several diseases, including diabetes and cancer. Hyperglycemia and oxidative stress enhance generation and accumulation of Advanced Glycation End-products (AGEs), the heterogeneous adducts with distinct properties. AGEs can initiate inflammatory response, but effect of individual products is not well known. Our goal was to learn about immune response on treatment with AGEs generated from different substrates. **Materials and Methods:** Model AGEs were synthesized on myoglobin using glucose, methylglyoxal, glycolaldehyde, and trans-2-nonenal in dry state or in solution. The cellular effect was tested on PMA-activated THP1 cells treated for 48h with 100 μg/ml of AGEs. Secretion of proinflammatory (IL-6, IL-8, TNF-α, and INF-γ), adaptive immunity (IL-2, IL-4, GC-MSF) and anti-inflammatory factors (IL-10) was assessed in culture medium using Multiplex analysis (Bio-Rad). **Results:** There was distinct response of THP1 cells to AGEs generated under different glycation conditions. GA-AGE was the most potent activator. It enhanced secretion of pro-inflammatory cytokines as well as the adaptive immunity factors. In contrast, the most cited AGEs formed from Glc only slightly enhanced production of some cytokines. Glc-AGE also had no effect on adaptive immunity factors. Cell treatment with MGO-AGE and T2N-AGE had negative effect on secretion of all studied pro-inflammatory and adaptive response factors. Additionally, Glc-, MGO-, T2N-derived AGEs decreased secretion of anti-inflammatory cytokine IL-10. **Conclusions:** Immune response to AGEs is unique for individual products and depends on the substrates or conditions of glycation process. The final effect might reflect the composition of AGEs mixture present in microenvironment.

P.A5.04.17

Blocking the assembly of TLR9 signaling complexes

*A. Javmen, H. Szmacinski, J. R. Lakowicz, **V. Y. Toshchakov**;*
University of Maryland, Baltimore, United States.

TLR9 stimulation activates nuclear factor-κB, leading to production of proinflammatory cytokines. Excessive TLR activation can cause inflammatory disease. This study has examined cell-permeating decoy peptides (CPDP) derived from TLR9 TIR domain. CPDP that included TLR9 TIR AB loop, β-strand B, and N-terminal residues of BB loop, 9R34, inhibited TLR9 signaling most potently. Peptides derived from α-helices C, D, and E (αC, αD, αE) also inhibited TLR9-induced cytokine activation, but were less potent than 9R34. 9R34 did not inhibit TLR2/1, TLR4, or TLR7 signaling. The N-terminal deletion modification of 9R34, 9R34-ΔN, inhibited TLR9 to the same extent as the full length 9R34. Binding of 9R34-ΔN to TIR domains was examined using cell-based FRET/FLIM approach. Cy3-labeled 9R34-ΔN dose-dependently decreased fluorescence lifetime of TLR9 TIR-Cerulean fusion protein. Cy3-9R34-ΔN also bound TIRAP TIR, albeit with a lesser affinity, but not MyD88 TIR; whereas peptide from the opposite TIR surface (αE) bound both adapters and TLR9. Intraperitoneal administration of 9R34-ΔN suppressed the ODN 1668-induced systemic cytokines and lethality in mice. This study identifies an in vivo-potent, TLR9-specific inhibitory peptide that targets both receptor dimerization and adapter recruitment. Location of TIR segments that represent inhibitory peptides suggests that TIR domains of TLRs and TLR adapters interact through structurally homologous surfaces within primary receptor complex, leading to formation of a double-stranded, filamentous structure that can elongate either bidirectionally, from two ends in the presence of TIRAP and MyD88, or unidirectionally, only through the αE end, in TIRAP-deficient cells.

Elevated Nuclear Lamin A is Permissive for Neutrophil Transendothelial Migration but not for Motility through Dense Collagen I Barriers.

***S. K. Yadav**[1], S. W. Feigelson[1], F. Roncato[1], M. Antman-Passig[2], O. Shefi[2], J. Lammerding[3], R. Alon[1];*
[1]Weizmann Institute of Science, Rehovot, Israel, [2]Faculty of Engineering, Bar Ilan Institute of Nanotechnologies and Advanced Materials, Bar Ilan University, Ramat Gan, Israel, [3]Nancy E. and Peter C. Meinig School of Biomedical Engineering, Weill Institute for Cell and Molecular Biology, Cornell University, Ithaca, New York, United States.

Nuclear deformation is a rate limiting step for migratory cells to pass through narrow spaces. Mechanical stability of the nucleus is dictated by lamins, intermediate filament proteins which form a structural network underlying the inner nuclear membrane. Lamin A is a key intermediate filament component of the nuclear lamina which is downregulated during granulopoiesis. When elevated, lamin A restricts nuclear squeezing through rigid confinements. The nuclei of circulating T cells and neutrophils express low levels of lamin A/C. To address the role of nuclear deformability and mechanical stiffness in leukocyte migration through endothelial barriers and collagenous matrices, we used a model system based on DMSO differentiated HL-60 (dHL-60) cells overexpressing CXCR2 which upon in vitro differentiation give rise to neutrophil-like leukocytes which demonstrate robust ability to cross inflamed endothelial cells under shear flow. We then tested how upregulation of lamin A in these dHL-60 cells affects their ability to transit through rigid micron-scale constrictions, endothelial monolayers and collagen I barriers.

Background: Recently it was shown that a prolonged treatment of non-atherosclerotic mice for 12 weeks with lipopolysaccharide (LPS), an endotoxin involved in sepsis, induced thickening of the aortic heart valve. As most patients with aortic valve (AV) stenosis do have atherosclerosis, we wanted to study the effect of LPS on AV in an atherosclerotic mouse model on the short term.
Methods: ApoE3*Leiden mice were fed with an atherosclerotic diet and subsequently were injected with either LPS or saline and sacrificed at 2 or 15 days post LPS- or saline-injection. These mice were compared with age-matched non-atherosclerotic C57BL/6 control mice. AVs were assessed for valve size, fibrosis, glycosaminoglycans (GAGs), lipids, calcium deposits, iron deposits and inflammatory cells.
Results: LPS-injection caused a borderline significant increase in average AV thickness at 15 days (32.3 μm) and a significant increase in maximal leaflet thickness (128.4 μm) compared to saline-injected mice (32.3 μm; p=0.076 and 67.8 μm; p=0.013 respectively). LPS-injection however did not significantly affect AV area, fibrosis, GAGs and lipids. Furthermore, no calcium deposits were found. Iron deposits, indicative for valve hemorrhage were observed in one AV from the saline-injected group (9.1 %) and in five AVs from the LPS-injected group (29.4 %). No significant differences in inflammatory cell infiltration were observed upon LPS-injection.
Conclusion: LPS caused a borderline significant AV thickening and significant increased maximal leaflet thickness in atherosclerotic ApoE3*Leiden mice, coinciding with increased valve hemorrhage. These results indicate that systemic infection-related acute inflammation can exacerbate AV stenosis on the short term.

Mitochondrial hyperpolarization induced by Complex-V restriction maintains naïve CD8⁺ T-cell at check

***M. Berger**, A. Saragovi;*
Hebrew University, Jerusalem, Israel.

Recent thymic emigrants (RTEs) represent an immature T-cell subset characterized by a reduced propensity to proliferate following stimuli. Here we describe the discovery of a metabolic checkpoint modulating T-cells propensity to initiate a response upon priming. We demonstrate that RTEs are phenotypically distinct from mature naïve CD8⁺ T-cells by reduced OXPHOS, increased glycolysis, and substantially elevated mitochondrial membrane polarization. We define mitochondrial complex-V restriction as the mechanism governing these metabolic differences. Following these findings, we show that mitochondrial hyperpolarization, driven by ATP synthase restriction, limits naïve CD8⁺ T-cells propensity to respond to diverse stimuli independent of ATP production. Tracing mitochondrial biogenesis in vivo, we reveal that mitochondrial polarization modulates proliferation capabilities of naïve CD8⁺ T-cells upon priming by regulating the acquisition of mitochondrial biomass. Our study defines mitochondrial hyperpolarization induced by complex-V restriction as a critical checkpoint directly controlling RTEs propensity to proliferate upon stimuli allowing intact T-cell population and diversity.

P.A5.05.02

The role of TCR affinity in the CD4+ T-cell response to mycobacterial infection

***N. Bhattacharyya**[1], L. Daniel[1], C. Counoupas[1], S. A. Stifter[1], P. Bertolino[2], C. G. Feng[1];*
[1]The University of Sydney, Camperdown, Australia, [2]Centenary Institute, Camperdown, Australia.

The differentiation of CD4+ T-cells is essential for the generation of effectors with differential cytokine secretion patterns required for combating distinct organisms. Whilst the influence of innate cytokines on CD4+ T-cell polarisation is well established, the direct role of T-cell receptor (TCR) affinity on the differentiation and effector function of CD4+ T-cells is poorly understood. Studies titrating antigen dose or altering peptide affinities have implicated strong TCR signaling the in the development of both Th1 and Tfh cells. To directly investigate the influence of affinity, we use two transgenic mice lines with high (C24) and intermediate (C7) binding affinity for the same epitope on early antigenic target number 6 (ESAT-6), an immunodominant *M.tuberculosis* antigen. Following infection with recombinant BCG expressing ESAT-6, high affinity CD4+ T-cells underwent earlier activation and expanded to a greater extent. Moreover, high affinity CD4+ T-cells acquired Tfh-like phenotypes earlier than their lower affinity counterparts. Importantly, in contrast to low affinity T cells which traffic rapidly into the red pulp, an area populated with mycobacterium-infected F4/80 macrophages, high affinity CD4+ T-cells preferentially localised to B-cell follicles and sequestered from infected macrophages. Taken together our findings suggest that TCR signal strength can determine the intra-splenic localisation of Ag-specific effector CD4+ T cells. They have important implications on our understanding of the regulation of CD4+ T cell-mediated immunity against persistent intracellular infection in lymphoid tissues.

Transcription factor Ets-2 is involved in the regulation of key lymphotropic factors

***P. Davoulou**, I. Aggeletopoulou, I. Panagoulias, A. Mouzaki;*
Division of Hematology, Department of Internal Medicine, Faculty of Medicine, University of Patras, Patras, Greece.

Introduction: Transcription factor Ets-2 is involved in diverse biological functions and transcriptional regulation. Recent work in our laboratory has shown that in naive T helper cells IL-2 expression is blocked by Ets-2. In this work we studied the role of Ets-2 in the regulation of expression of key lymphotropic factors (NFAT2, NF-κB p65, c-Jun and the kinase CDK10) which play a pivotal role in activation and differentiation of T and B cells. Methods: Jurkat, H938 (T lymphocytic cell lines) and HEK cells (embryonic kidney cell line), were transfected with increasing amounts of an Ets-2 overexpressing vector (pCDNA-ets2) in the presence (P/I) or absence (CM) of mitogens. Ets-2 mRNA overexpression was confirmed by real time PCR. Ets-2 overexpression and lymphotropic factor expression at protein level were assessed by Western blot.

Results: Overexpression of Ets-2 in Jurkat and H938 cells induced NFAT2, NF-κB p65 and c-Jun protein levels under both CM and P/I conditions.
In unstimulated H938 cells, it led to a reduction in CDK10 levels, whereas in stimulated cells Ets-2 over-induced CDK10 levels. In unstimulated HEK cells, increasing amounts of pCDNA-ets2 led to an increase in c-Jun and CDK10 levels; in contrast, in stimulated HEK cells resulted in a reduction in CDK10 and c-Jun levels. Conclusion: Ets-2 is involved in the regulation of expression and synthesis of key lymphotropic factors. Our results set the stage for further studies to elucidate the role of Ets-2 in the regulation of signaling pathways involved in the activation and differentiation of T and B lymphocytes.

Antigen dependent TCR repertoire relation of human cT_{FH} and non-cT_{FH} CD4 T cells

M. Hu[1,2]*, A. Cassotta*[1,2]*, A. Lanzavecchia*[2]*, F. Sallusto*[1,2]*;*
[1]*Microbiology and Immunology, ETH Zurich, Zurich, Switzerland,* [2]*Institute for Research in Biomedicine, Bellinzona, Switzerland.*

Human cT_{FH} (circulating follicular helper T) cells are a subset of CD4 memory T cells identified in peripheral blood that express the follicular homing chemokine receptor CXCR5. Our understandings about the relation between cT_{FH} cells and non-cT_{FH} CD4 memory T cells counterpart, as well as how cT_{FH} relates to *bona fide* lymphoid T_{FH} in regards to function, clonality and lineage still remain incomplete. We seek to study these questions in the context of antigen specific response and by adopting high throughput next generation sequencing to investigate TCR repertoire overlapping.
Firstly, we found out the TCR repertoire relation between cT_{FH} and non-cT_{FH} displayed antigen dependent pattern. C.Albicans, Tetanus toxoid specific cT_{FH} cells were more clonally related with their non-cT_{FH} counterpart, while influenza vaccine specific cells showed a very low level of TCR overlapping between the two. This distinct sharing pattern by flu led us to investigate the possible relation of flu specific cT_{FH} cells with GC T_{FH} cells. *Ex-vivo* stimulation demonstrated the enrichment of Candida, Tetanus specific cells was in the $ICOS^-PD1^-$ cT_{FH} subset, while flu specific cells were remarkably enriched in $PD1^+$ cT_{FH} subset. This was interestingly reflecting the linage relations revealed by TCR sequencing. Future plan is to further discriminate between $ICOS^-PD1^-$ and $PD1^+$ subpopulations of cT_{FH} cells in aspects of their clonal relations with non-cT_{FH} cells, and their phenotypic resemblance with GC T_{FH} cells. This study will reveal the heterogeneity within cT_{FH} cells in terms of antigen specific clonal relations with non-cT_{FH} and its undescribed antigen types dependency.

P.A5.05.05
TCR signaling strength promotes differentiation of human T follicular helper cells

T. Jorritsma[1]*, N. J. Verstegen*[1,2]*, P. A. Unger*[1]*, B. P. Nicolet*[1]*, M. Aalbers*[1]*, A. ten Brinke*[1]*, M. van Ham*[1,2]*;*
[1]*Sanquin Research & Landsteiner Laboratory, Dept of Immunopathology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [2]*Synthetic Systems Biology and Nuclear Organization, Swammerdam Institute for Life Sciences, University of Amsterdam, Amsterdam, Netherlands.*

T follicular helper (Tfh) cells promote antibody diversification and B cell differentiation though their localization in germinal centers, the specific action of costimulatory molecules and the Tfh cytokine IL-21. We previously reported that, in addition to IL-21, human Tfh cells may plastically coexpress the Th1 cytokine IFN-γ and/or the Th2 cytokine IL-4. As IFN-γ directs chemokine expression during B cell differentiation and IL-4 promotes memory B cell formation, it is important to elucidate how cytokine coexpression in Tfh cells is controlled. Here we identified TCR signaling strength as an important regulator of plasticity in the Tfh-like, IL21-producing cell population. IL-21 expression is favored by high TCR signaling in human naive $CD4^+$ T cells. In line with the known preference for Th1 skewing under those conditions, the fraction of IL21-producing cells that coexpress IFN-γ progressively increases with TCR signaling strength. In contrast, coexpression with IL-4 decreases, as also in Tfh cells, IL-4 benefits from low TCR signaling. Similar to the notion that Th1/Th2 polarization is largely mutually exclusive, demonstrated by the inhibitory effect of hallmark cytokines IFN-γ and IL-4 on Th2 and Th1 differentiation respectively, we demonstrate that IL-4 inhibits generation of Tfh-like, IL21-producing cells whereas IL-21 promotes autocrine IL-21 expression, but inhibits expression of the Th2-cytokine IL-4. These data show how formation of Tfh-like, IL21-producing cells and coexpression of other effector cytokines to modulate B cell differentiation is regulated by the magnitude of TCR signaling and availability of IL-4 and IL-21, which may be instrumental to improve vaccine effectiveness.

P.A5.05.06
Antigen-dependence of cell cycle speed during priming shapes CD8 T cell memory

L. Kretschmer[1]*, M. Flossdorf*[1]*, M. Plambeck*[1]*, J. Mir*[1]*, A. Toska*[1]*, Y. Cho*[1]*, I. Treise*[2]*, D. H. Busch*[1,3,4]*, V. R. Buchholz*[1]*;*

Initial antigen encounter triggers T cells to proliferate at speeds close to the physiologic maximum of mammalian cells. T cell memory, on the other hand, is maintained in absence of antigen by exceedingly rare cell divisions. The transition between these fundamentally distinct proliferative programs has been difficult to resolve via population-based analyses. Here we combined an approach for mapping the fate of single CD8 T cells, developed in our laboratory (*1-3*), with the timed depletion of peptide-pulsed Dendritic cells (DCs) *in vivo*. Computational modelling and cell cycle analyses showed that long before reaching peak expansion, slower cycling central memory precursors (CMPs) segregated from rapidly dividing effector subsets. Moreover, timed DC depletion revealed that cycling speed of CMPs was selectively dependent on sustained antigenic stimulation. Accordingly, recall responses were impaired when primary antigen availability was curtailed but not when inflammatory stimuli were reduced. By identifying an antigen-dependent hierarchy of cell cycle speeds among emerging CD8 T cell subsets, we provide crucial mechanistic insights important to guide future vaccination strategies and adoptive T cell therapy.

Identification of novel modulators of MR1 trafficking using a gene trap screen in haploid cells

C. Kulicke[1]*, E. De Zan*[2]*, M. Salio*[1]*, P. Klenerman*[3,4]*, S. Nijman*[2]*, V. Cerundolo*[1]*;*
[1]*MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom,* [2]*Ludwig Institute for Cancer Research Ltd. and Target Discovery Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom,* [3]*Peter Medawar Building for Pathogen Research, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom,* [4]*Translational Gastroenterology Unit, John Radcliffe Hospital, Headington, Oxford, United Kingdom.*

The monomorphic MHC-I-related protein 1 (MR1) presents bacterial metabolites to mucosal-associated invariant T (MAIT) cells, an innate-like subset of T lymphocytes. The known MAIT-activating MR1 ligands are intermediates of riboflavin synthesis, a pathway specific to certain fungi and bacteria and, thus, intrinsically non-self for humans. Here, we use a functional genetic screening technique based on insertional mutagenesis of the near-haploid human cell line HAP1 to discover novel players in MR1 antigen presentation and trafficking. A HAP1 clone overexpressing MR1 was transduced with a gene trap virus to inactivate genes in an unbiased manner. Subsequently, the mutagenised population was treated with the MR1-stabilising ligand Acetyl-6-Formylpterin and stained for MR1 surface expression. The tails of the distribution were FACS sorted to enrich for cells in which positive or negative regulators of MR1 were inactivated. Mapping of the viral insertion sites by Illumina deep sequencing allowed identification of genes statistically overrepresented in either of the two sorted populations which constitute putative modulators of MR1 intracellular trafficking or MR1 stability. The most significant positive regulator of MR1 surface expression identified in our screen was β_2-microglobulin, confirming its indispensable role in the surface translocation of MR1. A number of other putative regulators of MR1 trafficking were taken forward into a CRISPR/Cas9-based validation approach and tested in functional and biochemical assays.

P.A5.05.08
Erythrocyte derived interleukin-33 instructs the specification of iron-recycling macrophages

Y. Lu*;*
University of Cambridge, Cambridge, United Kingdom.

Tissue-resident splenic red pulp macrophages (RPM) contribute to red blood cell blood homeostasis by phagocytosing damaged or senescent erythrocytes and releasing heme-associated iron for recycling during erythropoiesis. Heme, a metabolite of erythrocyte degradation, induces the SpiC transcription factor expression in monocyte-derived macrophages, and promotes their differentiation into a precursor pre-RPM phenotype ($CD11b^{hi}$ $F4/80^{lo}$ $SpiC^{lo}$) [Kohyama M, Nature 2009] [Haldar M, Cell 2014]. However, the requirements for differentiation into the mature RPM phenotype ($CD11b^{lo/-}$ $F4/80^{hi}$ $SpiC^{hi}$) remain unknown. Here, we demonstrate that IL-33, co-operates with heme to induce high levels of SpiC in monocyte-derived macrophages, and promotes the generation of mature RPM. Mice deficient for the IL-33 receptor ST2 display a cell-autonomous deficit in monocyte-derived RPM, with a profound phenotypic alteration of the remaining RPM. Consequently, aging ST2-deficient mice have a profound defect in iron-recycling and develop substantial splenic iron deposition. Mechanistically, we show that IL-33 is stored in erythrocytes and is required together with heme, to induce the differentiation of pre-RPM into tissue-resident RPM. Thus, reconstitution of RPM-deficient *Il33*$^{/}$ mice with wild type, but not *Il33*-deficient, erythrocytes substantially restores the generation of RPM. This IL-33-elicited promotion of RPM is dependent on the MyD88 and ERK1/2 pathways downstream of IL-33/IL1RL1 signalling. This work identifies an exquisite co-operation between two microenvironmental cues for the differentiation of a tissue-resident macrophage subset, and it is example of a local cytokine-dependent functional specialisation of a tissue-resident macrophage subset. The work also provides new insights into the role of IL-33/ST2 pathway in iron homeostasis

P.A5.05.10

The potential role of Delta42PD1-TLR4 pathway in augmenting Vdelta2 T cell stimulation of CD4+ T cell response

Y. Mo[1], *A. K. Cheung*[2], *Z. Chen*[1];
[1]*AIDS Institute, Research Center for Infection and Immunity, Department of Microbiology, Li Ka Shing Faculty of Medicine, University of Hong Kong, Hong Kong SAR, China,* [2]*Department of Biology, Hong Kong Baptist University, Hong Kong SAR, China.*

Immune system plays a crucial role in different diseases directly or indirectly, for instance, acquired immunodeficiency diseases and cancer progression. PD-1 and its ligands, PD-L1 and PD-L2, negatively regulate the immune response via suppressing T cell functions. In contrast, a novel alternatively spliced isoform of human PD-1, named as Δ42PD1, may serve as a new immune-stimulator due to its characteristics that it does not bind to either PD-L1 or PD-L2 and that it can bind to TLR4. Our recent study found an increased level of Δ42PD1 protein on Vδ2 subset of γδ-T cells in HIV-1 acute patients, which induced intestinal inflammation. To further define the function of Δ42PD1, we show here that activated Vδ2 T cells *in vitro* elevated Δ42PD1 level while co-upregulated MHC class II expression. Since it was reported that Vδ2 T cells can act as an antigen presenting cell, we hypothesize that Δ42PD1 on Vδ2 T cells could play a role in stimulating CD4 T cell responses.
By investigating TLR4 level on $CD4^+$ T cells, our results showed that TLR4 could be upregulated upon pan-activation, with particularly significant high expression on the $CD45RA^+CD45RO^+$ transitional subset of $CD4^+$ T cells. Furthermore, co-culture experiments of virus-induced Δ42PD1$^+$Vd2 T cells and autologous effector cells resulted in the $CD45RO^+CD45RA^+CD4^+$ cells being activated measured by IFN-γ production, which is impaired when blocking antibody against Δ42PD1 was used. Therefore, our study suggests that the Δ42PD1/TLR4 pathway has a novel niche in stimulating the $CD45RA^+CD45RO^+CD4^+$ subset exhibited by Vδ2 T cells.

The environmental exposure is more important than BCG vaccination for the maturation of infant Vγ9Vδ2 T cells

M. Papadopoulou[1,2], *T. Dimova*[2], *W. Hanekom*[3], *E. Nemes*[3], *D. Vermijlen*[1,2];
[1]*Department of Pharmacotherapy and Pharmaceutics, Université Libre de Bruxelles, Brussels, Belgium,* [2]*Institute for Medical Immunology, Université Libre de Bruxelles, Brussels, Belgium,* [3]*South African Tuberculosis Vaccine Initiative, University of Cape Town, Cape Town, South Africa.*

γδ T cells are unconventional lymphocytes sharing attributes of both innate and adaptive immunity. Vγ9Vδ2 T cells, which react towards microbe- and host-derived non-peptidic metabolites (phosphoantigens), are the major γδ T cell population in adult human peripheral blood. Some of their main effector functions, such as IFNγ production, are already programmed before birth. Therefore, we wanted to investigate the effect of an early phosphoantigen encounter on infant Vγ9Vδ2 T cells. For that, blood was collected from 10-week-old infants vaccinated at birth or not with the phosphoantigen-containing BCG vaccine as well as from newborns and adults. We performed flow cytometry assays *ex vivo* or after *in vitro* stimulation of PBMCs and analysis of the γδ TCR repertoire. Our data indicate that there is no significant difference on the phenotype or the effector functions and that there is no outstanding change in the γδ TCR repertoire between the vaccinated and non-vaccinated infants. However, infant Vγ9Vδ2 T cells, independent of their BCG status, showed striking differences compared to their neonatal counterparts such as a high expression of the cytotoxic mediators granzyme B and perforin, which was not observed in other T cell subsets. In conclusion, our data indicate that other environmental encounters of infants are more important than BCG vaccination for the early phenotypic and functional evolution of the Vγ9Vδ2 T cells.

P.A5.05.12

Role of PARP-1 in regulatory Foxp3CD4 T and helper-17 T cell differentiation

F. Novelli, ***C. Pioli****;*
ENEA, Division of Health Protection Technologies, Rome, Italy.

Recent findings highlighted the role of ADP-ribosylating enzymes in inflammation and immune responses, with PARP-1 (poly(ADPribose)polymerase-1) playing a relevant role in leukocyte activation and differentiation. We had found that PARP-1 deficient (PARP-1KO) mice display increased number of regulatory $CD4^+Foxp3^+$ T cells (Tregs) in central as well as peripheral lymphatic organs compared with wild-type (WT) controls. PARP-1KO Tregs were functional as assessed both *in vitro* and *in vivo*. While in a chimera competitive assay PARP-1KO thymocytes generated higher numbers of Tregs compared with WT cells, we wondered whether conversion of naïve CD4 cells to inducible Tregs (iTregs) was also affected. Purified naïve CD4 cells from PARP-1KO mice, stimulated *in vitro* with CD3/CD28 and TGFβ1, expressed Foxp3 mRNA at higher levels and generated a greater number of $Foxp3^+$ iTregs than the WT counterpart. Interestingly, *in vitro* differentiation of purified naive CD4 cells to Th17 cells, as induced by CD3/CD28, TGFβ1 and IL-6, was not affected by PARP-1 deficiency. In peripheral lymphatic organs, conversion to $Foxp3^+$ iTregs occurs upon stimulation by dendritic cells (DCs) in a tolerogenic context. Noteworthy, we found that purified WT naïve CD4 cells, stimulated with CD3 and TGFβ1 in the presence of either WT or PARP-1KO DCs, generated comparable numbers of $Foxp3^+$ iTregs. At variance, WT DCs induced a higher frequency of $IL17^+CD4^+$ cells compared with PARP-1KO DCs. Altogether, these results indicate that PARP-1 plays an important role in the balance between regulatory and Th17 cell differentiation with the involvement of both CD4 T cell intrinsic and DC-mediated effects.

Lyme disease is caused by the spirochete *Borrelia burgdorferi.* Two ubiquitous lipids of *Borrelia burgdorferi*, BbGL-I and BbGL-II, comprise 35% of the total lipid mass of the bacteria and are specifically synthesized by pathogenic *Borrelia* spp. It is known from previous studies that BbGL-II can bind to CD1d and activate CD1d restricted NKT cells. In this study, we carried out FACS-sorting with CD1b-BBGL-II tetramers, to obtain a T cell line from a Lyme disease patient that recognizes BbGL-II presented by CD1b. The T cell clone binds to CD1b-BbGL-II tetramers but not to mock loaded CD1b tetramers or CD1b loaded with the negative control lipid phosphatidylglycerol. Although there is specific recognition of the CD1b-BbGL-II complex using tetramers, the primary T cells produce comparable levels of IFN-γ in an ELISPOT assay when stimulated with CD1b-expressing antigen presenting cells in the presence or absence of BbGL-II lipid. Whereas the primary T cells preferably bind to CD1b tetramers loaded with BbGL-II, we think that the activation by antigen presenting cells without the addition of BbGL-II is caused by a combination of a low affinity interaction with endogenous lipid-loaded CD1b and a high expression level of CD1b on the antigen presenting cells. We call this phenomenon "antigen-modulated autoreactivity" against the CD1b molecule, where there is an increased reaction to an antigen over a baseline autoreactivity of the T cell towards CD1b. Furthermore, Lyme disease patients were screened for the presence and frequency of CD1b-BbGL-II specific T cells using CD1b tetramers.

P.A5.05.15

The role of the transcription factor Interferon-Regulatory Factor 4 in regulation of Th17 cells

C. Schmidt*, A. Harberts, F. Raczkowski, H. W. Mittrücker;*
Institute of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

The transcription factor Interferon Regulatory Factor 4 (IRF4) is an essential regulator of $CD4^+$ T cell maturation to different Th cell lineages. As a consequence, IRF4 is essential for effective T cell responses against various pathogens. Here, we aim to characterize the role of IRF4 in Th17 cell differentiation, as well as in the maintenance of the differentiation status and function of these cells. $CD4^+$ T cells from *Irf4*$^{+/+}$, *Irf4*$^{+/-}$ and *Irf4*$^{-/-}$ mice are stimulated under Th17-inducing conditions and cultured for up to three weeks with IL-7 and IL-23. At different time points, the expression of lineage-specific transcription factors and cytokines is determined by intracellular mAb staining and FACS. In addition, $CD4^+$ T cells from *Irf4*$^{fl/-}$ × CreERT2 mice are stimulated and the remaining functional *Irf4*^{fl} allele is subsequently deleted by CreERT2 activation with tamoxifen. First results indicated that induction of Th17 cells strictly depended on the presence of IRF4 during T cell activation, since *Irf4*$^{-/-}$ T cells failed to upregulate RORγt and to produce IL-17A. In contrast, when the functional *Irf4* allele was deleted in $CD4^+$ T cells from *Irf4*$^{fl/-}$ × CreERT2 mice after stimulation, cells retained the capacity to produce IL-17A. So far our results suggest that maintenance of Th17 cells is less dependent on IRF4 than the induction of these cells. Further studies are planned to investigate the role of IRF4 in induction and stability of Th17 cells in vivo in a mouse infection model.

P.A5.05.16
Identification of factors driving induction of liver resident CD8⁺T cells following viral vector vaccination

***A. J. Spencer**, A. Gola, M. Ulaszewska, S. Sebastian, A. V. Hill;*
The Jenner Institute, Oxford, United Kingdom.

$CD8^+$ T cells play a pivotal role in mediating protection from liver-stage malaria, but this protection requires high numbers of $CD8^+$ T cells which are able to locate and kill infected cells during the short time parasites are present in the liver. To improve viral vectored vaccine efficacy, we recently developed a two-step vaccination approach, termed "prime-target", where $CD8^+$ T cells are primed by intramuscular vaccination, followed by an intravenous administration of viral vector, enabling targeting of $CD8^+$ T cells to the liver. This approach leads to high numbers of $CD8^+$ T cells in the liver and much greater levels of efficacy against malaria sporozoite challenge. While both effector and tissue resident (T_{rm}) cells alone can mediate protection, T_{rm} cells are more efficient; we therefore aimed to identify the optimal vaccination regimen for induction of T_{rm} cells.
In this study we tested three different viral vectors, Adenovirus, Modified Vaccinia Ankara and Adeno-Associated Virus, for their abilities to target $CD8^+$ T cells to the liver. In response to all vectors, we observed a correlation between the frequency of antigen specific cells and frequency of T_{rm} cells, however the ratio differed between vectors. Each vector varies in the level and duration of antigen expression and induction of pro-inflammatory signals, suggesting that both of these factors could have an impact on T_{rm} induction. Further experiments are therefore underway to elucidate the impact of antigen level and inflammatory signals on the induction of T_{rm} cells.

P.A5.05.17
Human liver- and skin-derived NK cells exhibit antigen-specific memory responses

*V. Stary, J. Strobl, P. Starlinger, **G. Stary**;*
Medical University of Vienna, Vienna, Austria, Vienna, Austria.

Mounting evidence suggests that NK cells can develop long-lived and highly specific memory to a variety of haptens and viral antigens in mice and in non-human primates. The existence and consequences of antigen-specific NK cell memory still needs to be proven. We isolated NK cells of human livers and blood from individuals vaccinated against hepatitis A and/or B, characterized them phenotypically and functionally in killing assays against antigens the patients had been vaccinated. We evaluated the distribution and function of NK cells in epicutaneous patch test reactions of nickel-sensitized patients, an effector site of adaptive immune responses. In contrast to the peripheral blood, two distinct NK cell populations were found in the liver based on their expression of CD16 and CD49a. $CD49a^+CD16^-$ liver NK cells (54.6% ± 4.2 of total NK cells) performed antigen-specific killing of hepatitis A or B-pulsed autologous B cells matching the patients' vaccination status. Blood-derived and $CD49a^-CD16^+$ liver NK cells did not exert antigen-specific cytotoxicity, but recognized MHC-I^{low} target cells. 57.8 ± 5.1 % of total NK cells in nickel-induced epicutaneous patch tests were found to belong to the $CD49a^+CD16^{low}$ NK cell subset and were capable of specific lysis of nickel-pulsed autologous target cells. These results suggest that antigen-specific memory NK cells in humans are present in the liver and, in case of adaptive immune responses, as effector cells in inflamed skin. The underlying mechanisms for specific recognition of viral antigens and haptens by human memory NK cells might form the basis to target NK cells.

P.A5.05.18
The soluble cytoplasmic tail of CD45 (ct-CD45) in human plasma contributes to keep T cells in a quiescent state

*A. Puck[1], S. Hopf[1], M. Modak[1], O. Majdic[1], P. Cejka[1], S. Blüml[2], C. Arnold-Schrauf[1], J. G. Gerwien[3], K. S. Frederiksen[3], E. Thell[4], J. Leitner[1], P. Steinberger[1], R. Aigner[1], M. Seyerl-Jiresch[1], G. J. Zlabinger[1], **J. Stöckl**[1];*
[1]Institute of Immunology, Medical University of Vienna, Vienna, Austria, [2]Department for Rheumatology, Medical University of Vienna, Vienna, Austria, [3]Novo Nordisk A/S, Biopharmaceuticals Research Unit, Måløv, Denmark, [4]Department for Gynecology, St. Josef Hospital, Vienna, Austria.

The cytoplasmic tail of CD45 (ct-CD45) is proteolytically cleaved and released upon activation of human phagocytes. It acts on T cells as an inhibitory, cytokine-like factor in vitro. Here we show, that ct-CD45 is abundant in human peripheral blood plasma from healthy adults compared with plasma derived from umbilical cord blood and plasma from patients with rheumatoid arthritis (RA) or systemic lupus erythematosus (SLE). Plasma depleted of ct-CD45 enhanced T-cell proliferation, while addition of exogenous ct-CD45 protein inhibited proliferation and reduced cytokine production of human T lymphocytes in response to TCR signaling. Inhibition of T- cell proliferation by ct-CD45 was overcome by co-stimulation via CD28. T-cell activation in the presence of ct-CD45 was associated with an upregulation of the quiescence factors Schlafen family member 12 (*SLFN12*) and Krueppel-like factor 2 (*KLF2*) as well as of the cyclin-dependent kinase (CDK) inhibitor *p27kip1*. In contrast, positive regulators of the cell cycle such as cyclin D2 and D3 as well as *CDK2* and *CDK4* were found to be downregulated in response to ct-CD45. In summary, we demonstrate that ct-CD45 is present in human plasma and sets the threshold of T cell activation.

P.A5.05.19
Resting memory CD4 T cells are generated following prolonged cell division

*J. Sarkander, M. Mursell, Y. Yamasaki, S. Hojyo, **K. Tokoyoda**;*
Deutsches Rheuma-Forschingszentrum Berlin, Berlin, Germany.

CD4 T cell memory is fundamental for long-lasting immunity and effective recall responses following infection or vaccination. We have so far determined that resting memory CD4 T cells specific for systemic antigens preferentially reside in the bone marrow (BM) and that splenic $CD49b^+$T-bet^+ activated CD4 T cells are defined as the precursors of BM memory CD4 T cells. However, it remains elusive how the memory precursors are generated through cell division and interaction with antigen-presenting cells. We here show that the precursors of resting memory CD4 T cells are generated via sustained interaction with dendritic cells and augmented cell division in the late activation phase of a primary immune response. Interestingly, treatment with a cytostatic drug or blockage of CD28/B7 co-stimulatory pathway in the late activation phase abrogates the generation of the memory precursors. Following the sufficient cell division, memory precursors can specifically downregulate CCR7 and upregulate IL-2Rβ, suggesting that loss of CCR7 and gain of IL-2 signaling are required for the migration and survival of the precursors of BM memory CD4 T cells, respectively.

New insights into mechanisms of sterile inflammation

*N. Freise, A. Burghard, T. Ortkras, N. Daber, T. Vogl, J. Roth, **J. Austermann**;*
Institute of Immunology, Muenster, Germany.

Background: Sepsis is a disease, caused by pathogens, that is still associated with high mortality rates worldwide. After an early strong inflammatory phase, sepsis patients might develop a secondary hypo-reactive state, called endotoxin-tolerance. In this case, invading pathogens cannot be recognized by the immune system and severe secondary infections can arise. However, in 30% of sepsis patients an initial microbial trigger is missing. We recently demonstrated that under sterile conditions endogenous proteins like the alarmins S100A8/A9 are able to induce a hypo-responsiveness of phagocytes, a mechanism we called stress-tolerance.
Objectives: The goal of the present study was to analyze molecular mechanisms underlying stress-induced tolerance in phagocytes and their relevance *in vivo*.
Methods: We investigated the activation of certain signaling pathways in stress-tolerant human or murine phagocytes *in vitro* and *in vivo*. Therefore we performed ImageStream, multiplex, ELISA and western blot analysis and a D-Gal model of septic shock. We also analyzed blood samples of cardiopulmonary bypass patients.
Results: We identified two main signaling pathways to be involved in S100-induced tolerance of phagocytes: the PI3K/AKT/GSK3 and the JAK/STAT pathway. *In vivo* data show a protective effect of a GSK-3 inhibitor on the survival rate of mice during septic shock. Furthermore, master regulator proteins of the JAK/STAT pathway seem to have an important function in phagocytes of cardiopulmonary bypass patients.
Conclusion: The alarmins S100A8/A9 induce stress-tolerance in phagocytes via the PI3K/AKT/GSK3 and the JAK/STAT pathway, relevant for development of a hyporective state in hypoinflammation in cardiopulmonary bypass patients.

P.A5.06.02
Vitamin B complex therapy suppresses neuroinflammation and improves recovery of injured peripheral motor nerve

***B. Bozic Nedeljkovic**[1], S. Dacic[1], P. Nedeljkovic[2], A. Ehmedah[1], B. Draskovic Pavlovic[3], D. Vucevic[3], S. Pekovic[4];*
[1]Faculty of Biology, Belgrade, Serbia, [2]Institute for Orthopedic Surgery "Banjica", Belgrade, Serbia, [3]Military Medical Academy, University of Defense in Belgrade, Belgrade, Serbia, [4]Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia.

Statement of the Problem: Peripheral nerve injury (PNI) leads to series of cellular and molecular events necessary for axon regeneration and reinnervation of target tissues. Macrophage recruitment that occurs immediately after PNI aids production of cytokines and neurotrophic factors necessary for axon regeneration. Calcium entry via L type of voltage-dependent calcium channels (LVDCCs) is involved in the processes underlying macrophages activation. The aim of this study was to evaluate influence of vitamin B complex therapy on: recovery of motor function after PNI; processes of neuroinflammation that are in part regulated by $Ca_V1.2$ subunit of LVDCCs. Methodology: Adult male AO rats were used. Surgery: Motor branch of femoral nerve was transected and reconstructed by end-to-end anastomosis. Experimental groups: (O) operated, (OT) operated and daily treated with vitamin B complex for 14 days. (S) sham-operated animals, underwent the same procedure but without transection of nerve. Pre- and post-operatively behavior tests were performed. Animals were sacrificed 1, 3, 7, and 14 days post-injury.

Findings: Treatment with vitamin B complex applied immediately after PNI enhanced recovery of walking function, decreased muscle atrophy and improved *musculus quadriceps* activity evaluated by EMG. Additionally, it decreased pro-inflammatory and increased anti-inflammatory cytokines expression and reduced $Ca_v1.2$ expression on activated macrophages. Conclusion & Significance: Vitamin B complex therapy down-regulates expression of $Ca_v1.2$ type of LVDCCs on activated macrophages and suppresses neuroinflammation, thereby contributing to motor function recovery of injured nerve, suggesting possible implementation in therapy of PNI, which remains to be explored.

P.A5.06.03
TLR antagonist immunosuppressive A151 ODN acts through metabolic reprogramming by suppressing PI3K/AKT/mTOR pathway

O. Bulut[1], *V. Yazar*[1], *G. Kilic*[1], *N. Surucu*[2], *M. Gursel*[2], *I. Gursel*[1];
[1]*Bilkent University, Ankara, Turkey,* [2]*Middle East Technical University, Ankara, Turkey.*

Introduction: A151 ODN, a synthetic oligonucleotide mimetic of telomeric TTAGGG motifs, has great therapeutic potential as an immunosuppressor, not only acting as a TLR9 antagonist, but also downregulating either STAT3 or AIM2. mTOR is a critical downstream element of PI3K/AKT pathway. It is of growing interest how metabolic reprogramming through mTOR regulates immune cell function. Of note, Treg reprogramming is due to targeted mTOR inhibition leading a shift from glycolysis to FA oxidation. This study aims to reveal A151 ODN's action on metabolic reprogramming through mTOR pathway.
Methods: Mouse splenocytes were stimulated with i) mu-TLR9 ligand, ii) A151 or iii) their combinations. Also, fresh PBMC were stimulated similarly with i) hu-TLR9 ligand ii) A151 and iii) their combinations for 2-8h. Status of several mTOR pathway elements were assessed by qRT-PCR, WB and flow cytometric assays.
Results: Data revealed that A151 downregulated mTOR and several downstream targets such as Eif4e and Rps6ka1, both in the absence and presence of CpG ODN. A151 also downregulated PI3Kcs delta and AKT activator Pdpk1. A151 treatment reduced phosphorylation of mTOR and several targets (4ebp1, Foxo1 and Foxo3) while increasing AMPK phosphorylation, a repressor of mTOR. In PBMCs, A151 downregulated expression of mTOR and Glut1 which regulates glycolytic capacity.
Conclusion: These data suggests that inhibitory role of A151 ODN might be dependent on mTOR pathway. We propose that Treg promoting capacity of A151 ODN could be through metabolic programming via mTOR suppression.

P.A5.06.04
Implication of annexin A1 in Lupus Nephritis

F. Dhaffouli[1], *H. Hachicha*[2], *H. Mnif*[3], *N. Elloumi*[1], *S. Feki*[2], *R. Fakhfakh*[1], *T. Boudawara*[3], *k. Kammoun*[4], *H. Masmoudi*[2];
[1]*Autoimmunity and Immunogenetics unit UR12SP14, Habib Bourguiba University Hospital, Sfax, Tunisia, Sfax, Tunisia, Tunisia,* [2]*Immunology Department, Habib Bourguiba University Hospital, Sfax, Tunisia, Sfax, Tunisia, Tunisia,* [3]*Anatomopathology Department, Habib Bourguiba Hospital, Sfax, Tunisia, Sfax, Tunisia, Tunisia,* [4]*Nephrology Department, University Hospital; Renal pathology unit 12ES14, faculty of medecine of Sfax, Tunisia, Sfax, Tunisia, Tunisia.*

Systemic lupus erythematosus (SLE) is an autoimmune disorder that can affect skin, joints, kidney, and central nervous system. Lupus nephritis (LN) is one of the most serious manifestations of SLE.
Annexin A1, a protein coded by the ANXA1gene, is implicated in apoptosis. Previous studies showed high expression of AnxA1 in different nephropathy diseases.
Our aim was to investigate the genetic polymorphism of AnxA1 in SLE and to determine the expression of annexin A1 in renal biopsies of SLE patients.
Our study included 94 lupus patients and 120 matched controls. Polymorphism of AnxA1 [rs2811226] was genotyped using a PCR-RFLP technique.
AnxA1 expression in kidney was carried out on 28 renal biopsy of LN patients and 8 renal tissues obtained from the normal part of nephrectomized kidney and cadaver kidney (autopsy) from subjects without inflammatory renal disease, used as controls. Biopsies were stained by immunohistochimestry.
In SLE patients, the G allele of rs2811226 SNP was significantly increased ($p<0.05$). The expression of this allele was associated with LN ($p=0.044$).
AnxA1 expression hasn't showed any significant difference in neither glomeruli nor tubules between patients and controls. However, the intensity of AnxA1 expression in glomeruli was significantly lower in class II compared with proliferative classes: class III ($p=0.050$) and class III+V, IV + V ($p=0.029$). These findings suggest that AnxA1 could play a role in the persistence and progression of glomerular disorders.
Our results show that ANXA1 could serve as a severity marker in LN and help clinician for the monitoring of lupus patients.

P.A5.06.06
Aberrant VISTA expression on CD45RA$^+$CD25^{dim} Th-cells in Giant Cell Arteritis

R. Hid Cadena, *R. D. Reitsema, W. H. Abdulahad, M. Huitema, A. M. Boots, P. Heeringa, E. Brouwer;*
University Medical Center Groningen, Groningen, Netherlands.

Background: The replenishment of naïve T-cells is severly restricted by thymic involution with ageing. In the past, our group identified CD45RA$^+$CD25^{dim} Th-cells as a subset of post-thymically expanded naïve Th-cells in healthy aged individuals. Immune homeostasis of naïve Th-cells is important in defective immune responses in age-related immune-disorders such as Giant Cell Arteritis (GCA). Recently, a loss of immunoinhibitory checkpoints has been implicated in GCA. The possible contribution of Immune Checkpoint (IC) pathways to the dysregulation of Th-cells, especially in CD45RA$^+$CD25^{dim} Th-cells in GCA has not yet been studied.
Objectives: We aimed to investigate the expression of different IC molecules on circulating CD45RA+CD25^{dim} Th-cells of GCA-patients and compare it with matched healthy controls (HCs).
Methods: In a cross-sectional study, fresh blood samples were obtained from 33 GCA-patients with/without immunosuppressive treatment (glucocorticoids) and 12 sex/age-matched HCs. The frequency of the expression of different IC including CD28, Cytotoxic T-Lymphocyte-associated antigen-4 (CTLA-4), Programmed death- 1 (PD-1), and V-domain Ig suppressor of T-cell activation (VISTA) were determined on CD45RA+CD25^{dim}CD4+Th-cells of GCA-patients and HCs by flow cytometry.
Results: Proportion of circulating CD45RA+CD25^{dim}Th-cells in GCA-patients was not different when compared to HCs. The frequency of CD28, CTLA-4 and PD-1 expression on CD45RA+CD25^{dim}Th-cells also remained unchanged. Interestingly, proportion of VISTA expression on these cells was significantly decreased in GCA-patients.
Conclusions: In GCA-patients, lower frequencies of VISTA+CD45RA+CD25^{dim}Th-cells were noted. Decreased VISTA expression in GCA-patients could play a role in the regulation of Th-cell activation or inhibition. The functional consequences of IC modulation within particular subsets requires further investigation.

P.A5.06.07
Propranolol influences EAE development by impairing antigen presenting cell migration into the draining lymph nodes

I. Vujinovic[1], *I. Pilipovic*[1], *R. Petrovic*[1], *Z. Stojic-Vukanic*[2], *N. Arsenovic-Ranin*[2], ***G. M. Leposavic***[2];
[1]*Institute of Virology, Vaccines and Sera "Torlak", Belgrade, Serbia,* [2]*University of Belgrade-Faculty of Pharmacy, Belgrade, Serbia.*

Introduction: Catecholamines are implicated in development of multiple sclerosis and EAE in Dark Agouti (DA) rats. To enlighten their β-adrenoceptor-mediated immunomodulatory action, DA rats of both sexes immunized for EAE were subjected to seven-day-long treatment with propranolol (β-adrenoceptor blocker) starting at the day of immunization. Methods: The migration of antigen presenting cells (APCs) into the draining lymph nodes (dLNs) was examined using CFSE-based assay. Frequency of activated CD4+ T cells, their proliferation and frequency of IL-17-producing CD4+ T (Th17) cells in dLNs, and their infiltration into spinal cord, were analyzed using flow cytometry. Propranolol effects on CD4+ cell proliferation and Th17 cell polarization, and IL-2 and Th17 polarizing cytokine and chemokine expression in dLNs/ dLN cell cultures were examined using flow cytometry and ELISA/qRT-PCR. Results: Irrespective of sex, propranolol reduced the incidence and postponed clinical EAE onset by impairing migration of antigen-carrying APCs into the dLNs (due to diminished dLN CCL19/21 expression). Consequently, propranolol diminished CD4+ T-cell activation/proliferation, and Th17 cell number in dLNs and spinal cord. To corroborate these findings, propranolol exerted stimulatory effects on CD4+ cell proliferation (through stimulation of IL-2 secretion) and Th17 cell differentiation (reflecting enhanced Th17 polarizing cytokine production) in dLN cell cultures. Conclusions: Irrespective of sex, the stimulatory effects of propranolol on dLN CD4+ T lymphocyte proliferation and activated/matured APC Th17 polarizing capacity were insufficient to overcome its inhibitory influence on APC migration, so propranolol impaired Th17 generation in dLNs of EAE rats, and postponed EAE development. (Grant 175050, MESTD, The Republic of Serbia).

Fcμ receptor as a new costimulatory molecule for T cells

A. Meryk[1], *L. Pangrazzi*[1], *M. Hagen*[1], *F. Hatzmann*[1], *B. Jenewein*[1], *B. Jakic*[2], *N. Hermann-Kleiter*[2], *G. Baier*[2], *J. Jylhävä*[3], *M. Hurme*[4], *K. Trieb*[5], *B. Grubeck-Loebenstein*[1];
[1]*Institute for Biomedical Aging Research, Innsbruck, Austria,* [2]*Division of Translational Cell Genetics, Innsbruck, Austria,* [3]*Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden,* [4]*Faculty of Medicine and Life Sciences, Tampere, Finland,* [5]*Department of Orthopedic Surgery, Wels, Austria.*

The Fc receptor for IgM (FcμR) regulates cellular activation of various cell types. FcμR deficient mice display dysregulated function of neutrophils, dendritic cells, and defects in B cell homeostasis. In contrast, the function of FcμR on human T cells is still unclear. We found that FcμR is mostly stored inside the cell and that surface expression is tightly regulated. Decreased surface expression was found on T cells from elderly individuals, which was associated with alterations in the methylation pattern of the *FCMR* gene. Binding and internalization of IgM stimulates transport of FcμR to the cell surface to ensure sustained IgM uptake. Concurrently, IgM accumulates within the cell and the surface expression of other receptors increases, among them, the TCR and costimulatory molecules. This leads to enhanced TCR signaling, proliferation and cytokine release, in response to low, but not high doses of antigen. Our findings indicate that FcμR is an important regulator of T cell function and reveals a new mode of interaction between B and T cells.

P.A5.06.09

Human bone marrow adipocytes display distinct immune regulatory properties

C. Miggitsch[1], *B. Jenewein*[1], *A. Meryk*[1], *K. Trieb*[2], *W. Zwerschke*[1], *B. Grubeck-Loebenstein*[1];
[1]*Institute for Biomedical Aging Research, Innsbruck, Austria,* [2]*Department of Orthopedic Surgery, Klinikum Wels, Wels, Austria.*

The bone marrow (BM) is a primary lymphoid organ of the human immune system where T and B cell precursors are generated and antigen-experienced adaptive cells are maintained. The BM has proven to be a major reservoir of resting memory T cells and long-lived plasma cells, capable of providing protection against recurrent infections. The survival and maintenance of these cells is mediated by cytokine and chemokine producing stromal cells and myeloid cell types, forming specific areas known as BM niches. However, no information is yet available on the production of memory T cell survival factors by BM fat tissue and the interaction with adaptive immune cells in the BM. Using microarrays, we show that bone marrow fat significantly differs from subcutaneous fat regarding specific gene expression profiles including inflammatory responses. Reduced expression levels of the adipocyte-specific genes may suggest that the BM is an immune regulatory organ. Higher expression of the effector/memory T cell survival factors IL-7 and IL-15 were found in BM compared to subcutaneous adipocytes. The expression of the pro-inflammatory molecules TNFα and IL-6, which contribute to the low-grade inflammatory background known as “inflamm-aging” observed in elderly persons, was also higher in BM fat. With our data, we can show that the unique phenotype of BM adipocytes expressing pro-inflammatory cytokines may have a negative effect on long-lived plasma cells while maintaining effector/memory T cells.

P.A5.06.10

The role of thioredoxin interacting protein (TXNIP) in T cell activation

S. Nagel[1], *S. Ziola*[1], *P. Krammer*[1], *K. Gülow*[1,2];
[1]*German Cancer Research Center (DKFZ), Heidelberg, Germany,* [2]*University Hospital Regensburg (UKR), Regensburg, Germany.*

T cells undergo rapid proliferation and differentiation upon stimulation of the T cell receptor (TCR). We have shown that regulation of TCR-induced oxidative signaling is crucial for control of a T cell immune response. TXNIP is a negative regulator of the oxidative defense controlling the intracellular redox equilibrium. Thus, TXNIP is a promising candidate for regulating T cell signaling. We demonstrate that TXNIP is downregulated independently of ROS upon TCR activation. To examine the molecular mechanism and the resulting effects of TXNIP downregulation upon TCR triggering a CRISPR-Cas9 knockout of TXNIP (TXNIP KO) in Jurkat T cells was generated. By means of TXNIP KO clones the role of TXNIP in T cell activation was addressed. Thereby, we have shown that TXNIP deficiency has no impact on activation-induced oxidative signaling. Nonetheless, we could determine that TXNIP KO T cells show enhanced CD95 death ligand (CD95L/FASL/APO-1-L) expression as well as activation-induced cell death (AICD) upon TCR triggering. Therefore, TXNIP seems to have an impact on activation-induced transcription factors and thus, gene target expression. Hence, a better understanding of the role of TXNIP in T cell activation will give new insights into physiological processes like regulation of a T cell immune response. This knowledge is helpful in modulation of T cell responses to prevent autoimmunity or to activate T cells in a tumor setting. The work was supported by the European Union (FP-7 Health, SyStemAge) and the Wilhelm-Sander-Stiftung (2012.077.2).

P.A5.06.12

Identification of human self-reactive iNKT cells

J. PERROTEAU[1], *L. Hesnard*[1], *M. Devilder*[1], *B. Navet*[1], *L. Gapin*[2], *E. Scotet*[1], *L. Gautreau-Rolland*[1], *X. Saulquin*[1];
[1]*Centre de Recherche en Cancerologie et Immunologie Nantes-Angers, Nantes, France,* [2]*National Jewish Health - University of Colorado, Denver, United States.*

Invariant Natural Killer T (iNKT) lymphocytes express both NK receptors and a semi-invariant αβ TCR restricted by the CD1d molecule presenting glycolipids. Among them, αGalactosylCeramid (αGC) is a potent ligand of all iNKT cells. In some contexts, iNKT cells are also able to detect endogenous glycolipids, which highlights their self-reactivity. However, the mechanisms underlying this autoreactivity are still poorly understood.
By using a tetramer-associated magnetic approach, we generated several iNKT cell lines from the peripheral blood of healthy donors. These cell lines reacted similarly against hCD1d+ target cell lines after loading with aGC, but in a different manner against unloaded hCD1d+ target cells, expressing endogenous glycolipids, both? in terms of cytotoxicity and cytokines production. Moreover we demonstrated that the auroreactivity is dependent on TCR-CD1d signaling. The analysis at the clonal level (n=12) of an autoreactive cell line also revealed an important heterogeneity between clones in terms of self-reactivity. We found identical alpha and beta chain TCR sequences in all the clones obtained, suggesting that expression of particular TCR sequence is not sufficient to induce self-reactivity. Comparative RNAseq analysis revealed a direct correlation between the tyrosine kinase SYC expression-level and autoreactivity, while an inverse correlation was observed with the expression of the phosphatase DUSP2. As SYC and DUSP2 are respectively implicated in TCR signal transduction and modulation of Th17 cells development (Muro et al., 2018; Lu et al., 2015), our results suggest that the balance of expression of these 2 proteins could modulate the intrinsic autoreactive potential of human iNKT cells.

P.A5.06.13

Neutrophils driving unconventional T cells are essential for resistance to sarcomas

A. Ponzetta[1], *M. Barbagallo*[1], *R. Carriero*[1], *M. Molgora*[1], *C. Perucchini*[1], *S. Carnevale*[1], *E. Magrini*[1], *F. Gianni*[1], *P. Kunderfranco*[1], *N. Polentarutti*[1], *F. Pasqualini*[1], *S. Di Marco*[1], *D. Supino*[1], *S. Pilotti*[2], *E. Bonavita*[1], *M. Galdiero*[1], *C. Garlanda*[3], *A. Mantovani*[3], *S. Jaillon*[3];
[1]*Humanitas Clinical and Research Center, Rozzano, Italy,* [2]*Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy,* [3]*Humanitas University, Pieve Emanuele, Italy.*

Neutrophils represent a fundamental mechanism of antimicrobial resistance and inflammation. Moreover, neutrophils have emerged as important players in the activation, orchestration and regulation of adaptive immune responses. Neutrophils are a component of the tumor microenvironment (TME) and have been shown to promote progression. On the other hand, unleashed neutrophilic effectors have also been reported to mediate anti-cancer resistance. Antibody-mediated depletion used to investigate the role of neutrophils in tumor progression suffers from limitations, including duration, specificity and perturbation of the system. We therefore used a genetic approach to investigate the role of neutrophils in primary 3-methylcholanthrene (3-MCA)-induced sarcomagenesis. Neutrophils were found to play an essential role in resistance against primary carcinogenesis by driving an interferon-γ dependent type 1 immune response. Neutrophils selectively caused type 1 polarization of $CD4^-$ $CD8^-$ unconventional T cells (UTCs) in the TME. In human undifferentiated pleomorphic sarcomas (UPS), unlike other sarcomas, granulocyte-colony stimulating factor receptor *(CSF3R)* expression and a neutrophil signature were associated with better outcome and with a type 1 immune response. Thus, neutrophils, by driving a type 1 immune response and polarization of UTCs, mediate resistance against murine and human sarcomas.

P.A5.06.14

Investigating the molecular basis of Roquin-mediated control of T cell fate decisions

H. Schmidt[1], *V. Heissmeyer*[1,2];
[1]*Ludwig-Maximilians-Universität (LMU), Biomedical Center (BMC), Institute of Immunology, Planegg-Martinsried, Germany,* [2]*Helmholtz Zentrum, Munich, Germany.*

Post-transcriptional gene regulation by RNA-binding proteins (RBPs) controls T cell fate decisions. The RBPs Roquin-1 and -2, encoded by the genes *Rc3h1* and *Rc3h2,* serve redundant functions in T cells. They bind via their ROQ domain to 3′-untranslated regions (3′-UTRs) of mRNAs and control mRNA stability and expression. Interestingly, *sanroque* mutant mice harboring a single ROQ domain point mutation or mice lacking Roquin-1/2 protein expression revealed accumulations of Tfh and Th1 or Tfh and Th17 effector T cells, respectively. Since the Roquin-1^{san} protein is a functional hypomorph of Roquin-1, we hypothesize that the molecular regulation of Th1 versus Th17 differentiation is determined by a graded loss-of-function of Roquin. Therefore, we investigate the effects of (i) graded Roquin reduction by increasing deletion of *Rc3h1* and *Rc3h2* alleles, by (ii) introducing ROQ domain mutations that attenuate affinities to mRNA targets and (iii) by pharmacologically modulating MALT1-induced cleavage of Roquin or stimulating T cells with increased TCR signal strength. Our preliminary data indeed indicate that graded loss of Roquin correlates with increased effector-memory phenotypes of CD4 and CD8 T cells and *ex vivo* analyses suggest graded target upregulation including ICOS, Ox40 and CTLA-4 transcripts. Furthermore, minimal Roquin amounts were still effective to suppress Th17 differentiation as measured by IL-17A and RORyt expression. In future studies, we will seek to uncover how graded T cell stimulation regulates differential Roquin activities that mediate T lymphocyte fate-specifiying mRNA repression.

P.A5.06.15

Noradrenaline synthesized locally in draining lymph node cells modulates CD4+ T-cell development in rat EAE model: a role for α_1-adrenoceptor

I. Pilipovic[1], *I. Vujnovic*[1], *R. Petrovic*[1], *D. Kosec*[1], ***Z. Stojić-Vukanić***[2], *G. Leposavic*[2];
[1]*Institute of Virology, Vaccines and Sera ”Torlak”, Belgrade, Serbia,* [2]*University of Belgrade - Faculty of Pharmacy, Belgrade, Serbia.*

Introduction: It has been suggested that: i) noradrenaline synthesis in ,,adrenergic“ immune cells changes during development of EAE and multiple sclerosis and ii) noradrenaline influences EAE development through α_1-adrenoceptor. To elucidate mechanisms standing behind this phenomenon, α_1-adrenoceptor-mediated influence of draining lymph node (dLN) cell-derived noradrenaline on CD4+ T-cell response in dLNs from Dark Agouti rats of both sexes immunized for EAE was examined. Methods: Cells recovered from dLNs on 7^{th} day post-immunization were examined for noradrenaline synthesis/content and α_{1B}-adrenoceptor expression using HPLC and/or flow cytometry. Additionally, effects of prazosin (α_1-AR blocker) on CD4+ T-cell proliferation, the frequency of IL-17+ CD4+ T-cells and regulatory (Foxp3+CD25+) CD4+ T-cells (Tregs), activational/maturational molecule expression on antigen presenting cells (APCs) and their cytokine profile in dLN cell culture were examined using flow cytometry and/or qRT-PCR/ELISA. Results: Irrespective of sex, conventional CD4+ T-cells and Tregs, and APCs from rat dLNs synthesized noradrenaline, while only Tregs and APCs expressed α_{1B}-adrenoceptor.
In myelin basic protein-stimulated dLN cell cultures from rats of both sexes prazosin increased Treg frequency and Foxp3 expression, but diminished co-stimulatory CD80 and CD86 molecule expression on APCs, thereby reducing CD4+ cell proliferation.

Additionally, prazosin diminished expression of Th17 polarizing cytokines (IL-1β and IL-23) in dLN cell cultures, and reduced the frequency of all IL-17+ CD4+ T-cells, and those coexpressing GM-CSF. Conclusions: The study indicates that in rats of both sexes immunized for EAE, dLN cell-derived noradrenaline through α_1-adrenoceptor influence generation of (auto)immune IL-17+ CD4+ T-cell response and thereby EAE development. Increased expression of checkpoint inhibitors on CD4⁺ T-cells during CPS immunisation is associated with slower acquisition of immunity

X. Yap[1], *J. Walk*[1], *I. J. Reuling*[1], *W. Gramans*[1], *G. van Gemert*[1], *R. Siebelink-Stoter*[1], *M. van de Vegte-Bolmer*[1], *K. Teelen*[1], *E. M. Bijker*[1,2], *A. Scholzen*[1,3], *R. W. Sauerwein*[1];
[1]Department of Medical Microbiology, Radboud University Medical Center, Nijmegen, Netherlands, [2]Department of Pediatrics, Radboud University Medical Center, Nijmegen, Netherlands, [3]Innatoss Laboratories B.V., Oss, Netherlands.

Malaria poses a significant burden to global health, yet much remains unknown about the development of immunity to the malaria parasite *Plasmodium falciparum*. Chloroquine chemoprophylaxis with *P. falciparum* sporozoites (CPS) immunisation induces highly effective sterile protection in naïve volunteers. However, some volunteers are protected after the first immunisation (fast responders), whereas others require two or more immunisations to be fully protected (slow responders). Checkpoint inhibitors are regulatory molecules which inhibit immune responses, including acquisition of adaptive immunity. Blocking checkpoint inhibitors drastically improves survival in murine malaria studies. However, the importance of checkpoint inhibitors in malaria vaccination has not yet been established.
Expression of checkpoint inhibitors CTLA4, TIM3, and PD-1 was measured by flow cytometry on CD4⁺, CD8⁺, and γδ T-cells, and NK cells from 32 immunised volunteers in two CPS immunisation trials (NCT02080026, NCT02098590). Expression of TIM3 on CD4⁺ and CD8⁺ T-cells (p=0.0167, p=0.0152) and CTLA4 on CD8⁺ T-cells (p=0.0255) differed significantly between fast and slow responders. Furthermore, when expression of all inhibitory markers was summed into a cumulative inhibitory Z-score, CD4⁺ T-cells from fast responders had a significantly lower inhibitory score (p=0.0234) compared to slow responders.
This study demonstrates for the first time that fast responders to malaria vaccination have lower checkpoint inhibitor expression than slow responders. Further studies will examine whether individuals vary in their capacity to express checkpoint inhibitors and produce immunosuppressive cytokines after restimulation with *P. falciparum*-infected erythrocytes. These findings provide insight into how individual immunosuppressive profiles prior to vaccination can affect malaria vaccination efficacy.

P.A5.06.17

CHARACTERIZATION OF HUMAN MONOCLONAL ANTIBODIES AGAINST DENGUE VIRUS NS1 PROTEIN

K. Siriporn, *Pannamthip Pitaksajjakul, Pongrama Ramasoota, Khwanchit Boonha, Wilarat Poungmanee;
Tropical Medicine, Bangkok, Thailand.*

Background: Dengue hemorrhagic fever caused by dengue viruses is a public health problem in tropical and subtropical regions. Today, dengue is considered one of the most important arthropod-borne viral diseases in humans in terms of morbidity and mortality. The dengue virus (DENV) non-structural 1 (NS1) protein plays a critical role in viral RNA replication and has a central position in DENV pathogenesis. During the last three decades, the DENV NS1 protein has also been intensively investigated as a potential target for vaccines and immunotherapy. However, anti-NS1 antibody was recently interested as one factor of severe dengue infection due to their cross-reactivity with human molecules such as endothelial cell, integrin and plasminogen, causing some severe symptoms like vascular leakage. Project description: To identify anti-NS1 human monoclonal antibodies (HuMAbs), in this study, HuMAbs were generated by hybridoma technology by fusing of human PBMCs with human fusion partner cell (SPYMEG). HuMAbs specific for NS1 protein of dengue virus were screened and confirmed by western blot analysis. Target epitope of anti-NS1 was also determined by random peptide phage display. Genetic information of those anti-NS1 HuMAbs was elucidated. Conclusion: This is the first study described the generation and characterization of full IgG human monoclonal antibody specific to NS1 protein of Dengue virus. These characterizations could be used for a study of DENV pathogenesis and dengue vaccine constituents in the future.

Human oral epithelial cells inhibit Th1 cell responses in a cell contact-dependent manner

J. L. Sanchez-Trincado Lopez, *M. Gomez-Perosanz, M. Molero-Abraham, E. M. Lafuente, P. A. Reche;
Department of Immunology, School of Medicine, Madrid, Spain.*

The oral mucosa is a site of intense immunological activity, where tolerogenic and defensive responses are articulated. The underlying mechanisms resulting in active immunity or tolerance are poorly understood but it is evident that oral epithelial cells (OECs) of the mucosa ought to play an important role. Here, we have characterized the ability of human oral squamous cell carcinoma cell lines and primary oral epithelial cells to modulate immune responses. OECs constitutively express CD40 and respond to inflammatory stimulation by increasing MHC II expression without CD80 and CD86 costimulation. Co-culture of OECs with dendritic cells (DCs) drastically reduced IL-12 released by DCs after exposure to bacteria and induced a tolerogenic phenotype characterized by reduced MHC II, CD80 and CD86 expression and increased IL10 production in the presence of primary OECs. OEC-conditioned DCs were unable to promote Th1 differentiation as determined by a lack of IFNγ production in allogenic activated CD4⁺ T cells. Moreover, OECs were able to abrogate CD25 and CD69 expression, T cell proliferation and the release of IFNγ and TNFα when co-cultured with anti-CD3+anti-CD28 stimulated CD4⁺ T cells. The inhibition on T cell activation was TGF-β independent but cell-contact dependent. Our data indicate that the oral epithelium promotes an anti-inflammatory state by conditioning DCs maturation and by dampening Th1 cell responses through direct epithelial-T cell contact.

P.A5.06.19

Phenotype of monocyte-derived dendritic cells in response to halophilic archaea *Halorhabdus rudnickae* and *Natrinema salaciae*

K. Krawczyk[1], *A. Bekier*[1], *M. S. da Costa*[2], *L. Albuquerque*[2], *M. Kowalewicz-Kulbat*[1];
[1]1Department of Immunology and Infectious Biology, Faculty of Biology and Environmental Protection, University of Lodz, Lodz, Poland, [2]Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal.

Introduction: The domain *Archaea* is one of the three domains of life. This domain comprises many extreme halophiles, defined as microorganisms that inhabit hypersaline environments. Halophilic archaea strains of *Halorhabdus rudnickae* WSM-64^T and WSM-66, were isolated from the hypersaline environment in Barycz mining area belonging to the Polish Salt Mine Company "Wieliczka". *Natrinema salaciae* strain MDB25^T was isolated from the deep, hypersaline anoxic Lake Medee in the Eastern Mediterranean Sea. The role of archaea as part of the human microbiome has been described but still remains unknown how halophiles can interact with the human cells. **Aim:** The aim of this study was to determine the effect of *Hrd. rudnickae* and *N. salaciae* on the phenotype of the human monocyte-derived dendritic cells (Mo-DC). **Materials and methods:** Monocytes were isolated from the human blood by MACS and incubated for 6 days with cytokines to generate Mo-DC. Mo-DC were stimulated with *N. salaciae* MDB25^T and *Hrd. rudnickae* WSM-64^T and WSM-66. The expression of CD86, CD80, HLA-DR, CD40 and DC-SIGN on the surface of Mo-DC was analyzed by flow cytometry. **Results:** We observed significantly decreased expression of CD80, HLA-DR and DC-SIGN receptors on the surface of *Hrd. rudnickae* WSM-64^T and WSM-66, and *N. salaciae* MDB25^T-stimulated Mo-DC, compared to unstimulated cells. There were no differences in the expression of CD40 and CD86. **Conclusion**: Our results suggest that halophiles possess the ability to diminish some signals in immune synapse what may have an impact on the naive T cell differentiation. Further research should provide insights into DC and T cell cytokine production.

P.A5.07.01

Type 1 hypersensitivity and reduced level of interferon-ã in cement loaders

M. O. Akiibinu[1], *T. Oduola*[2];
[1]Caleb University Lagos, Lagos, Nigeria, [2]Usmanu Danfodiyo University, Sokoto, Sokoto, Nigeria.

Introduction: Immunomodulatory potentials of cement particles have not been well researched in occupationally exposed Nigerians. This study was designed to investigate the possibility of type 1 hypersensitivity reaction and cellular activation in cement exposed workers. **Methods:** Twenty-nine male cement loaders who had direct exposure to cement dust and gases for a period of 2-30 years in Elephant / Lafarge Cement Depot Ibadan, Nigeria, were recruited for this study. Another twenty apparently healthy individuals who had no interaction with cement served as controls. Plasma immunoglobulin E (IgE) and interferon-gamma (IFN-γ) were determined in them using enzyme linked immunosorbent assay methods. **Results:** The results showed significantly ($p<0.05$) higher level of plasma IgE in cement loaders compared with controls. IFN-γ decreased significantly ($p<0.05$) in cement loaders compared with controls. There was no significant ($p>0.05$) correlation between the IgE, IFN-γ and period of exposure in the cement loaders. **Conclusion:** Cement dust could evoke IgE production and possibly inhibits certain cell types secreting IFN-γ in occupationally exposed workers.

P.A5.07.02

CD5signalosome coordinates TCR signals to control the generation of peripherallyinduced regulatory T cells

G. BLAIZE[1], *N. Rouquié*[1], *M. Marcellin*[2], *M. Benamar*[1], *A. Gonzalez de Peredo*[2], *O. Schiltz*[2], *R. Lesourne*[1];
[1]*CPTP InsermU1043 CNRSUMR5282, TOULOUSE, France,* [2]*IPBS UMR5089, TOULOUSE, France.*

Introduction: CD5 proteins are TCR co-receptors initially described as negative regulators of T cell signaling and T cell responses. Despite many studies performed mainly in cell lines, the molecular mechanisms mediated by CD5 on primary T cells remain unclear.
Results: We performed mass spectrometry (MS) analysis of CD5 partners in primary T cells. We identified a molecular complex recruited on CD5 upon TCR engagement. In this complex, the ubiquitin ligase Cbl is the most abundant protein. We identified Y429 of CD5 as a potential target of Cbl binding. We designed transgenic mice expressing the Wt CD5 ($CD5tg^{Wt}$) or a mutated form of CD5 on its Y429 ($CD5tg^{Y429F}$), in which we demonstrate by MS that the recruitment of all CD5 partners is impaired. In the context of CD5, we identified Cbl as an adaptor molecule allowing the recruitment of CD5 partners to the Y429 of CD5. Our results show that the molecular complex recruited on CD5 regulates both positively and negatively TCR signaling pathways and acts negatively on conventional T cell activation/proliferation and on iT_{reg} generation *in vitro* and *in vivo*.
Conclusion: In this work, we revisited CD5 mechanisms and functions by identifying Y429 of CD5 as a critical residue to recruite CD5 partners. Our work suggests that CD5 could optimize immune responses by setting the threshold for conventional T cell and pT_{reg} biological functions.

P.A5.07.04

Investigating the interaction and orientation of the immune cell proteins CD2, CD4 and CD45 on model membranes using hydrodynamic trapping

V. Junghans[1], *A. M. Santos*[2], *S. J. Davis*[2], *P. Jönsson*[1];
[1]*Lund University, Lund, Sweden,* [2]*University of Oxford, Oxford, United Kingdom.*

Different proteins play an important role during the cell-cell contact formation and are highly organized in respect to their size and function. However, crucial information about intermolecular interactions and height-dependent orientation of the proteins, especially the glycoprotein CD45, are lacking. We show by using hydrodynamic trapping (HDT) how these missing parameters for the immune-cell molecules CD2, CD4 and CD45 can be obtained[1].
In HDT a micropipette is positioned above a supported lipid bilayer (SLB) and negative pressure applied through the micropipette results in accumulation of the proteins attached to the SLB[2]. Relating the protein accumulation to the trapping strength both the molecular size/orientation as well as the intermolecular force between the proteins can be determined. In our system CD2 and CD4 oriented in an upright position from the bilayer, whereas CD45 had more freedom rotating relative to the surface. With increasing surface coverage, this flexibility reduced and CD45 positioned upright. Neither of the studied proteins aggregated or formed dimers but glycosylation had a high effect on the protein interaction. Trapping of two proteins simultaneously led to size-dependent protein segregation in the trap. Thus, the HDT method opens for new information about membrane protein behaviour and shows how protein flexibility and glycosylation can dominate this behaviour.

Nanobodies from transgenic mice

T. Eden, S. Menzel, T. Schäfer, A. Eichhoff, F. Haag, ***F. Koch-Nolte****;*
University Medical Center Hamburg, Hamburg, Germany.

Llamas and other camelids carry a variant immunoglobulin locus that encodes antibodies composed only of heavy chains. The single variable domain of these antibodies (designated VHH or nanobody) has been shaped by evolution for high solubility and stability, independent of a partner VL domain. With their long CDR3s, nanobodies can reach hidden epitopes that are not accessible for conventional antibodies. Nanobodies can be used in monovalent format, e.g. for high resolution microscopy or as crystallization chaperones. Due to their high solubility and stability nanobodies can readily be fused to other proteins. For example, fusion to other nanobodies yields bispecific or multispecific reagents, fusion to the hinge-and Fc domains heavy chain antibodies of any desired isotype. In order to facilitate the generation of nanobodies for biomedical applications, we have generated nanobody-transgenic mice by transferring an engineered llama IgH locus to IgH-ko mice. Immunization of these mice induces antigen-specific heavy chain antibody responses with efficient VDJ recombination, somatic hypermutation, and class switch from IgM to IgG. These mice thus provide a flexible new platform for generating innovative nanobody-based biologics. They also provide a basis for genetic modification of nanobodies and the generation of designer nanobodies.

P.A5.07.06

MHC presentation is limited by the availability of MHC molecules rather than by the supply of peptide ligands

L. R. Komov*, D. Melamed Kadosh, E. Barnea, A. Admon;*
Technion-Israel Institute of Technology, Haifa, Israel.

Despite the importance of peptide presentation by the MHC class I, some aspects of the MHC processing and presentation are yet unsolved. One of those questions is whether the MHC presentation level is limited by the availability of peptide ligands within the ER or by the supply of peptide-receptive (empty) MHC molecules. Our study clarifies this issue by inducing major perturbations and competition for MHC ligands in human breast cancer cells (MCF-7). The cells were treated with interferons, which led to elevated presentation levels of the MHC-B molecules with their bound peptidome, relative to the MHC-A and MHC-C molecules of the same cells. This result was unexpected, since all of the MHC allotypes of the MCF-7 cell line present peptides with similar molecular properties; the treatments were expected to have similar effect on all of the MHC allotypes. Furthermore, high expression levels of recombinant soluble MHC-A were induced in the cells, to create a competition for peptides between the soluble and the identical endogenous membranal MHC-A. This competition did not affect the membranal MHC-A presentation levels or its bound peptidome. Our results suggest that in contrary to the common opinion, the MHC presentation levels are limited by the availability of peptide-receptive molecules rather than by the supply of peptides. These findings are important for the basic understanding of the antigen processing and presentation pathway, as well as vaccines design for pathogens infections and cancer immunotherapy. Specialized pro resolving mediators as novel therapeutic agents in treating neuroinflammation

A. Leuti[1,2], *E. Bisicchia*[3], *A. Cordella*[3,4], *V. Sasso*[3], *M. D'Amelio*[3,2], *N. Mercuri*[3,4], *M. Viscomi*[3], *V. Chiurchiù*[1,2];
[1]*Lipid Neurochemistry Unit, European Center for Brain Research (CERC), IRCCS Santa Lucia Foundation, Roma, Italy,* [2]*Department of Medicine, Campus Bio-Medico University of Rome, Rome, Italy,* [3]*1IRCCS Santa Lucia Foundation, Roma, Italy,* [4]*Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy.*

Specialized pro resolving mediators (SPMs) are a novel class of endogenous lipids, produced by innate immune cells from essential omega-3 polyunsaturated fatty acids, that orchestrate the resolution of inflammation (i.e. the spontaneous confinement and regression of the inflammatory wave started by the immune response) and promote tissue regeneration. SPMs are emerging as crucial players in several central and peripheral diseases caused by chronic and unconfined inflammation. Herein, we investigated the involvement and therapeutic outcome of a specific SPM, termed resolvin D1 (RvD1), in two neuropathological paradigms, namely a rat model of remote and focal brain damage, obtained through hemicerebellectomy (HCb), and in a transgenic alpha-synuclein (a-Syn) overexpressing rat model of Parkinson's disease, for both of which neuroinflammation is a key hallmark. HCb-injured animals displayed reduced levels of RvD1 in cerebrospinal fluid (CSF) and unchanged levels in plasma, whereas such SPM was increased in CSF and decreased in plasma of α-Syn rats at an early stage of the disease characterized by a precocious neuroinflammation, dopaminergic and motor dysfunctions but absence of dopaminergic neuronal loss. Chronic administration of RvD1 in HCb reduced glial activation and blocked inflammatory-induced neuronal cell death in remote regions. Similarly, early and chronic 2 months treatment in a-Syn rats halted neuroinflammation, improved striatal dopaminergic synaptic function and improved motor-behaviour functions. Overall, our findings strongly suggest that, not only the uncontrolled inflammation observed in these models can be ascribed to an impaired SPM-dependent resolution machinery, but also, that specific resolvins represent novel and safe therapeutics for neuroinflammatory brain diseases.

P.A5.07.08

Inhibition of TLR and TLR+BCR dependent functions of human B cells by Complement Receptor Type 1 (CD35)

B. Mácsik-Valent*;*
Department of Immunology, Budapest, Hungary.

Although it is well accepted that separate activation of the complement system and Toll-like receptors (TLRs) initiates and shapes the adaptive immune response, much less is known about the modulation of various B cell functions by the simultaneous activation of these two systems. Therefore we investigated how engagement of complement receptor type 1 (CR1) influences the activation of human B cells induced by TLR7 and TLR9 with or without a BCR stimulus. Resting tonsillar B cells were activated via BCR by a suboptimal dose of $F(ab')_2$ anti-human IgG/M/A and via TLR7 and TLR9 by synthetic activators. The stimuli were applied either separately or simultaneously in the presence or absence of the CR1 ligand, a multimeric "C3b-like C3". The effect of CR1 clustering was assessed on proliferation (^{3}H-thymidine incorporation), cytokine secretion (ELISA), antibody production (ELISPOT) and expression of activation markers (flow cytometry).

We show that CR1 clustering significantly and dose dependently reduces the TLR9-induced activation of tonsillar B cells, but has no effect on the TLR7-induced functions. The enhanced response to the simultaneous engagement of TLR7 or TLR9 with the BCR was also significantly inhibited by CR1 clustering. Our data demondtrate that engagement of CR1 downregulates the TLR9-induced B cell functions but does not influence the TLR7 mediated processes. Interestingly however, when B cells are simultaneously triggered via BCR+TLR7 or BCR+TLR9, CR1 clustering inhibits the B cell response. We assume that CR1 exerts its inhibitory effect by acting on signalling molecules linked to both BCR and TLR9 in human B cells.

P.A5.07.09
c-Myc in T lymphocytes: How is it controlled? What does it control?

***J. M. Marchingo**, L. V. Sinclair, D. A. Cantrell;*
Cell Signalling and Immunology Division, School of Life Sciences, The University of Dundee, Dundee, United Kingdom.

T cells undergo massive cell growth, rapid proliferation and differentiation to form a protective immune response. The proto-oncogenic transcription factor c-Myc plays a critical role in this process. To explore c-Myc function in T cells we used high-resolution mass spectrometry to compare the effect of c-Myc deficiency on the global proteome of antigen receptor-stimulated CD4 and CD8 T cells. Using this technology we quantified the expression of ~6700 proteins. c-Myc-deficiency reduced the copy number of ~4,400 and 2,400 proteins in CD8 and CD4 T cells respectively. The magnitude of c-Myc effect on individual proteins was selective. For example, while the amino acid transporter Slc7a5 was decreased 40 and 30-fold in CD8 and CD4 T cells, the glucose transporter Glut3 was 2.1 and 2.9-fold higher in the c-Myc-deficient CD8 and CD4 T cells respectively. In contrast Glut1 was the same across all conditions.
Systems with substantial biosynthetic defects can confound our ability to distinguish which proteins become dysregulated first and whether the effects are direct. For example Slc7a5 and c-Myc are both reported to regulate the other's expression in T cells but deficiency in either also substantially compromises RNA and protein biosynthesis. We investigated how nutrient availability and transporter levels interplayed with c-Myc expression. We found that c-Myc induction required extrinsic amino acids, but that Slc7a5 deficiency did not alter c-Myc induction; however it did compromise maintenance of c-Myc levels. Thus, c-Myc initiation of Slc7a5 triggers a positive feedback loop to maintain expression of both proteins and drive T cell growth.

P.A5.07.10
sFasL mediates proinflammatory activation of neutrophils from type 2 diabetes mellitus without affecting apoptosis

***S. Margaryan**[1,2], A. Witkowicz[3], A. Martirosyan[2], A. Partyka[3], L. Karabon[3], G. Manukyan[1,2];*
[1]Russian-Armenian University, Yerevan, Armenia, [2]Institute of Molecular Biology NAS RA, Yerevan, Armenia, [3]L. Hirszfeld Institute of Immunology and Experimental Therapy, Wroclaw, Poland.

Introduction: Type 2 diabetes mellitus (T2DM) is a chronic metabolic condition characterized by insulin resistance and pancreatic β-cell dysfunction. Immune cell activation associated with persistent low-grade inflammation play a prominent role in apoptosis-mediated β-cell destruction and vascular injury in T2DM. Despite Fas/FasL axis was implicated in the development of diabetes-related complications, the role of soluble FasL (sFasL) is still unknown. Therefore, we aimed to analyze the influence of sFasL on neutrophil activation and apoptosis *in vitro*. Methods: For this, transcriptional and expression levels of pro-inflammatory and apoptotic genes were measured in neutrophils from T2DM patients (n=16) and healthy controls (n=15) exposed with sFasL for 3 hours. Results: sFasL significantly increased mRNA levels of NF-κB, IL-1β, caspase-1 in neutrophils isolated from T2DM patients which was associated with the increased CD18 MFI. At the same time, apoptotic rates of the cells from both studied groups were unaffected by sFasL, which was accompanied by the unchanged mRNA levels of Bax, decreased mRNA levels of caspase-3 and decreased number of Fas (CD95) positive neutrophils. In T2DM, the presence of sFasL significantly increased production of IL-8 by whole blood cells compared to both control cultivation and sFasL-induced healthy cells. Conclusion: Thus, we showed an enhanced inflammatory response of neutrophils from T2DM patients to sFasL without acceleration of apoptosis, which may play an important role in induction and/or sustaining of inflammation in the disease.

P.A5.07.11
The 20s immunoproteasome and the constitutive proteasome bind with the same affinity to PA28αβ and equally degrade FAT10

***n. roverato**;*
university of konstanz, konstanz, Germany.

The 20S immunoproteasome (IP) is an interferon(IFN)-γ - and tumor necrosis factor (TNF) -inducible variant of the 20S constitutive proteasome (CP) in which all its peptidolytically active subunits β1, β2, and β5 are replaced by their cytokine inducible homologues β1i (LMP2), β2i (MECL-1), and β5i (LMP7). These subunit replacements alter the cleavage specificity of the proteasome and the spectrum of proteasome-generated peptide ligands of MHC class I molecules. In addition to antigen processing, the IP has recently been shown to serve unique functions in the generation of pro-inflammatory T helper cell subtypes and cytokines as well as in the pathogenesis of autoimmune diseases, but the mechanistic involvement of the IP in these processes has remained elusive. In this study we investigated whether the IP differs from the CP in the interaction with two IFN-γ/TNF inducible factors: the 11S proteasome regulator PA28αβ and the ubiquitin-like modifier FAT10 (ubiquitin D).

Progesterone suppresses the inflammatory state of innate cells in peripheral blood and cervical mucous

***G. R. Sooranna**, N. M. Shah, A. Cocker, N. Singh, M. R. Johnson;*
Imperial College London, London, United Kingdom.

Introduction: Progesterone (P4) has been shown to be an effective immune-modulator and, in reproductive tissue, P4 suppresses inflammation and maintains uterine quiescence. In clinical practice, P4 supplementation is an effective treatment for the prevention of preterm birth (PTB). Our hypothesis was that P4 skews innate cell phenotype systemically in peripheral blood and locally in cervical mucous, to attenuate inflammatory responses. Method: We recruited pregnant patients (N=6) between 13-20 weeks of gestation identified as high risk for developing PTB and thus commenced on P4 treatment. Peripheral blood (PB) and cervical brush samples (Cb) were collected before and one month after starting P4. Flow-cytometric analysis of PB and Cb mononuclear cells (PBMC and CbMC) was performed. All p-values were two-tailed and unadjusted and significance was defined as $p < 0.05$. Results: P4 treated women (n=6) showed a significant decrease in peripheral blood classical monocytes (CD14+CD16-; p=0.0218) but stable granulocyte proportions. In addition, post P4 treatment CbMC showed a decrease in total neutrophils (p=0.0456), and an increase in apoptotic CD14+ neutrophils (p=0.0313). However, the expression of HLA-DR and CD66b on cervical neutrophils was either unaffected or increased, and this was accompanied by a trend suggesting an increased proportion of macrophages. Conclusion: P4 treatment is associated with attenuation of inflammatory innate cell phenotype, which likely reflects the overall anti-inflammatory effect of P4. Despite these effects on the cervix, the immune-protective potential of cervical mucous does not appear to be hampered.

P.A5.07.13
Functional CD169 on macrophages mediates interaction with dendritic cells for CD8$^+$ T cell cross-priming

***D. van Dinther**[1], H. Veninga[1], S. Iborra[2], E. G. Borg[1], L. Hoogterp[1], K. Olesek[1], M. R. Beijer[1], H. Kalay[1], J. Garcia-Vallejo[1], K. L. Franken[3], L. B. Cham[4], K. S. Lang[4], Y. van Kooyk[1], D. Sancho[2], P. R. Crocker[5], J. M. den Haan[1];*
[1]VUmc Amsterdam, Amsterdam, Netherlands, [2]Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain, [3]LUMC, Leiden, Netherlands, [4]University Duisburg-Essen, Essen, Germany, [5]University of Dundee, Dundee, United Kingdom.

Splenic CD169$^+$ macrophages are located in the marginal zone to efficiently capture blood-borne pathogens. Here, we investigate the requirements for the induction of CD8$^+$ T cell responses by antigens (Ags) bound by CD169$^+$ macrophages. Upon Ag targeting to CD169$^+$ macrophages, we show that Batf3-dependent CD8α$^+$ dendritic cells (DCs) are crucial for DNGR-1-mediated cross-priming of CD8$^+$ T cell responses. In addition, we demonstrate that CD169, a sialic acid binding lectin involved in cell-cell contact, preferentially binds to CD8α$^+$ DCs and that Ag transfer to CD8α$^+$ DCs and subsequent T cell activation is dependent on the sialic acid-binding capacity of CD169. Finally, CD8+ T cell responses to vaccinia virus infection are dependent on functional CD169. Together, these data indicate that the collaboration of CD169$^+$ macrophages and CD8α$^+$ DCs for the initiation of effective CD8$^+$ T cell responses is facilitated by binding of CD169 to sialic acid containing ligands on CD8α$^+$ DCs.

Numerous studies performed on purified CD4$^+$ T cells have shown that the cytokine cocktail (IL-1β/IL-6/IL-23) is required for Th17 cell polarization, whereas the role of TGF-β remains controversial. We examined how Th17 response is modulated in the whole peripheral blood mononuclear cell (PBMNC) cultures, which better reflect conditions *in vivo.* PBMNC were isolated from healthy volunteers. The cells were cultivated under different conditions in the presence of IL-1β/IL-6/IL-23, with or without TGF-β. For stimulation, phytohemaglutinine (PHA) or CD3/CD28 antibodies were used. Some cultures were treated with either IL-10, TGF-β or IFN-γ neutrilizing antibodies.

Our results indicated that in PHA- and CD3/CD28-stimulated PBMNC cultures the production of IL-17 was significantly higher (670pg/mL and 930 pg/mL), respectively, compared to unstimulated cultures (48pg/mL) and this finding correlated with the number of cells. The IL-1β/IL-6/IL-23 cocktail significantly augmented the production of IL-17 in unstimulated and CD3/CD28-stimulated PBMNC cultures, but not in PHA-stimulated cultures. The addition of TGF-β to the cytokine cocktail inhibited the production of IL-17 in all three culture systems. The opposite effect was seen when anti-TGF-β or anti-IFN-γ antibodies were added. It is interesting that anti-IL-10 antibody augmented the percentage of IL-17$^+$ cells, but the production of IL-17 was reduced in the supernatants. In conclusion, our results showed that IL-1β/IL-6/IL-23 stimulated differentiation and activation of Th17 cells in PBMNC cultures, but the effect depended on the type of T-cell activation stimuli. The Th17 response was better when TGF-β and Th1-signaling pathways were inhibited. However, the role of IL-10 signaling pathway remains unclear.

Complement factors F, B, H and schizophrenia in Armenians

R. Zakharyan[1,2]*, H. Ghazaryan*[2]*, A. Arakelyan*[1,2]*;*
[1]*Russian-Armenian University, Yerevan, Armenia,* [2]*Institute of Molecular Biology NAS RA, Yerevan, Armenia.*

Immune system alterations contributed to schizophrenia. We aimed to assess the blood levels of complement factors F (FB) and FH in schizophrenia. According to the results, the FB serum levels were 1.3 times decreased in patients compared to controls (meanSD,ug/mL: 220.061.04 versus 276.865.46, p<0.01). No significant difference in the mean FB between antipsychotic-free and treated patients was detected. This reduction may reflect the increased activity of alternative pathway and consequent increased FB degradation. The FH levels were equal in study groups. Further evaluation of the total FH, its 402H and 402Y variants (Y402H, rs1061170) in patients and controls was performed. We found no significant difference in the total FH levels between groups (265.6±28.4 vs 241.9±52.1, p>0.5). Also, there was no difference in total FH between 402H minor variant carriers (YH+HH) and standard variant (YY) homozygotes (235.9±49.2 vs 247.4±56.1, p>0.5) and between the groups (270.9±44.2 vs 286.5±95.6, p>0.5). In controls the 402H level tended to be lower in YH+HH than in YY (255±24.4 vs 283.2±27.3, p=0.05). In patients the 402Y levels were lower in YH+HH (71.92±57.9 vs 216.2±79.9, p<0.0001). The 402H levels in patients were marginally lower compared to 402Y level (89.6±110.4 vs 144.1±100.5, p=0.06), whereas a significantly increased 402H level compared to 402Y in controls was observed (265.6±28.4 vs 79.6±71.9, p<0.0001). These results suggested the important role of FB and FH in schizophrenia. Further replication studies are needed to confirm these findings.

Development of novel tools to investigate trogocytosis in T lymphocytes

S. Zenke[1]*, J. Braun*[1]*, S. Ammann*[2]*, N. Beyersdorf*[3]*, P. Aichele*[4]*, G. Griffiths*[2]*, J. Rohr*[1]*;*
[1]*Center for Chronic Immunodeficiency, Freiburg, Germany,* [2]*Cambridge Institute for Medical Research, Cambridge, United Kingdom,* [3]*Institute for Virology and Immunobiology, Würzburg, Germany,* [4]*Institute of Immunology, University Medical Center Freiburg, Freiburg, Germany.*

T cells have long been known to extract surface molecules from antigen-presenting cells – a process termed “trogocytosis”. However, the molecular requirements and biological function of this process is incompletely understood. In order to investigate the mechanisms and function of trogocytosis in T cells we generated cell lines stably expressing an antigenic peptide covalently linked to a blue fluorescent pMHC-complex in addition to red fluorescent B7-molecules. Using these artificial antigen presenting cells (APCs) we find that naïve CD8+ T cells rapidly and efficiently acquire peptide-MHC complexes and B7 molecules from artificial APCs. This process is dependent on specific interactions between the T cell receptor/peptide-MHC and CD28/B7. Transfer of B7 does not require specific TCR engagement, but concomitant pMHC-recognition increases the efficacy of B7 transfer. Furthermore, we show that a substantial part of trogocytosed molecules can be re-expressed on the T cell surface – a finding that we confirmed to also occur in murine models *in vivo*. Currently, we are interfering with specific cellular function to reveal the molecular mechanisms underlying trogocytosis in T cells. In summary, trogocytosis constitutes a mechanism how T cells can efficiently acquire and re-express surface molecules from neighbouring cells – thereby equipping them with the armamentarium of bona-fide APCs.

Introduction: One of the major challenges for the use of implantable biomaterials is to develop strategies that moderate the innate host inflammatory reaction. Among biomaterials that are considered for clinical applications, hydrogels have gained a significant interest due to their tunable mechanical properties. However, only few are used in clinics because hydrogels, like other biomaterials, induce FBRs after implantation. The severity of the hydrogel-induced FBR is different for each biomaterial. To identify modifications that suppress the FBR, we developed four novel low molecular weight supramolecular hydrogels that were tested and compared in a mouse model of subcutaneous implantation.
Methods: Subcutaneous implantation of hydrogels was performed in mice to assess different aspects of the FBR. The type of inflammatory cells in the surrounding tissue, as well as within the hydrogels, was determined by histology. Specific markers for angiogenesis, macrophage polarisation, and fibroblast were labeled to assess the FBR. Mass spectrometry was used to characterize degradation products of the hydrogel biomaterial.
Results and Conclusion: Our results indicate that all novel low molecular weight hydrogels showed low inflammatory response by modulating the macrophage polarisation, enhancing vascularisation in the surrounding tissue, and absence of fibrous capsule formation. A potential angiogenic property of the degradation product is currently under investigation. The results indicate that hydrogels are potential Biomaterial candidate for various application such as tissue engineering and medical devices.
Keywords: Foreign body reaction, macrophages, inflammation, fibrosis, hydrogels.

Metabolic mimicry of regular high-intensity exercise modulates neutrophil function.

J. Sanchez*, S. Walker, A. Gutierrez del Arroyo, G. L. Ackland;*
Queen Mary University of London, London, United Kingdom.

Introduction
Regular high-intensity exercise is associated with longevity and improved health. Modulation of innate immunity may contribute to the positive impact of exercise, although the mechanisms remain unclear. High-intensity exercise is characterised by accumulation of lactate as a product of anaerobic glycolysis. We examined whether mimicking repeated high-intensity exercise through direct, repeated exogenous administration of lactate may modulate innate immune responses.
Methods: C57BL/6 mice were randomised to receive injected intraperitoneal (200µl) injections of either saline or sodium-lactate to mimic high-intensity exercise on 5 consecutive days. 24h after the last pre-treatment, zymosan (1mg) was injected to elicit neutrophil influx into the peritoneum. Peritoneal lavage and bone marrow were harvested either 2.5h or 5h later. Neutrophil CD11b expression and ex-vivo phagocytosis of *Staphylococcus aureus* bioparticles by peritoneal neutrophils were assessed by flow cytometry.
Results: More CD45$^+$CD11b$^+$Ly6G$^+$ cells (11.05±2.37x10^6/ml) were present in the peritoneum after sodium-lactate pre-treatment, compared to saline (3.96±1.13x10^6/ml; n=11/group, p=0.02) after 2.5h of zymosan injection. Sodium-lactate pre-treatment was associated with a reduction in peritoneal neutrophil CD11b expression (median fluorescence intensity (MFI): 3277±642), compared to saline pre-treatment (MFI: 7662±1207; n=7, p=0.008) after 5h of zymosan injection. However, bone-marrow resident neutrophils had similar CD11b expression, irrespective of pre-treatment (p=0.85). Sodium-lactate pre-treatment augmented ex-vivo phagocytosis of *S. aureus* by 848 bioparticles (95% confidence intervals: -49 to 1744; n=5, p=0.06).
Conclusion: Mimicking high-intensity exercise by exogenous pre-treatment with sodium-lactate modulates the neutrophil response to acute inflammation.

P.A5.07.19

Changes in the T cell receptor repertoire during treatment interruption in paediatric patients with HIV

T. C. Attenborough[1]*, K. Schou Sandgaard*[1]*, B. Margetts*[1]*, S. Adams*[2]*, R. Callard*[1]*, A. Gkazi Soragia*[1]*, N. Klein*[1]*;*
[1]*UCL Great Ormond Street Institute of Child Health, London, United Kingdom,* [2]*Great Ormond Street Hospital for Children, London, United Kingdom.*

Antiretroviral therapy (ART) is generally very effective in children infected with HIV, and they can often recover from the depletion of CD4$^+$ T cells caused by the disease. However side effects can sometimes lead to medication nonadherence or medical recommendation for a treatment break. Studies have already shown that CD4$^+$ cell levels are generally restored with ART reintroduction. This study used Next Generation Sequencing (NGS) techniques to examine the impact of ART interruption and reintroduction on the T cell receptor (TCR) repertoire in great detail.
We used NGS to estimate the TCR repertoire from 4 paediatric patients living with HIV. The samples were accessed from a randomised controlled trial and span before, during, and after a 48 week ART treatment interruption. The samples were purified to collect the naive CD4$^+$ T cells and memory CD8$^+$ T cells from each sample.
We found similarities in the TCR repertoire profiles before the ART interruption and post reintroduction. We were able to track specific CDR3 sequences over time. A large number of CDR3 sequences were also shared between the patients, and showed several different patterns over the time.
The similarity of the TCR repertoire profiles at the beginning and end of the study suggests that in general, the treatment interruption in paediatric patients doesn’t appear to have long term negative effects on the TCR repertoire. We also found CDR3 sequences in both naive CD4$^+$ T cells and memory CD8$^+$ T cells that were shared between patients.

P.A6.01.01
The effect of PI3K pathway in response to TLR stimulation of Rendu-Osler-Weber syndrome patient

N. Bozbeyoglu[1], *G. G. Kaya*[1], *M. Yildirim*[1], *I. Evcili*[1], *I. C. Ayanoglu*[2], *O. Ardeniz*[3], *M. Gursel*[2], *I. Gursel*[1];

Rendu-Osler-Weber syndrome is a rare autosomal dominant disease which is characterized by lesions occuring due to vascular enlargement in the skin and mucosa. Additionally, Common Variable Immunodeficiency (CVID) is the most common primary immunodeficiency that is manifested by recurrent infections and inflammations, although symptoms of individuals are variable. In this study, due to the possibility of differences in PI3K/AKT/mTOR pathway, stimulation of TLR pathways, gene expression and plasma cytokine levels are examined from peripheral blood of Rendu-Osler-Weber (ROW) patient. Isolated PBMC was stimulated with PMA/Ionomycin, CD3/CD28, LPS, CpG ODNs (K- and D-types). The IL-4, IL-8, IL-10, IL-17 and IFN-γ levels were measured by ELISA. It was observed that when stimulated with PMA/Ionomycin and CD3/CD28 ligands, IFN-γ level did not differ compared to healthy measurements, whereas LPS induced significant increase. When PBMCs were stimulated with PMA/Ionomycin, IL-4, IL-10, IL-17 levels were lower than healthy PBMC levels. Plasma cytokine levels were measured by CBA. IFN-γ and IL-10 levels were significantly higher than healthy levels. The inflammation panel analyses via Nanostring™ revealed that TLR2, TLR4, TLR7/8, NF-κB, Stat1, IL-15 levels were magnified compared to healthy PBMCs. PI3K pathway analyses implicated that RTK gene level was increased, whereas mRNA levels of Ras, PKCs, ERK were decreased in ROW patient. There was insufficient data for PI3K and PTEN mRNA levels. The chemokine network analyses suggested an increased expression of STATs. Strikingly, chemokine receptors were decreased. Our investigation implied that ROW patients responses could be worsen during ongoing active infection.

P.A6.01.02
Late onset of maternal CD8 T-cells GVHD in a toddler with JAK3 severe combined immunodeficiency

R. de la Varga Martínez[1], *J. M. Lucena Soto*[1], *W. Goycochea-Valdivia*[2], *P. Sánchez-Moreno*[2], *P. Olbrich*[2], *B. de Felipe*[2], *B. Sánchez*[1], *O. Neth*[2];
[1]*Servicio de Inmunología. UGC de Laboratorios Clínicos. Hospital Universitario Virgen del Rocío, Sevilla, Spain,* [2]*Paediatric Infectious Diseases, Rheumatology and Inmunology Unit, Hospital Universitario Virgen del Rocío, Instituto de Biomedicina de Sevilla, Sevilla, Spain.*

Introduction: Autosomal recessive severe combined immunodeficiency (SCID) due to Janus kinase (JAK) 3 deficiency is characterized by a T-B+NK- phenotype. Objective: To describe a delayed presentation of maternal CD8 engraftment in a 15-month-old boy associated with fever, failure to thrive, hepatomegaly and atopic dermatitis. Prior to his referral he had persistent CMV viremia (PCR max 1500c/ml) not receiving antiviral treatment and MMR vaccine given aged 12 months was not associated with complications. Family history revealed parental consanguinity and a sister died at 7 months due to infectious complications. Material and methods: Immunophenotype using flow cytometry in peripheral blood, quantification of immunoglobulins and next generation sequencing of the genes related to SCID were performed. Results: Lymphocyte subsets showed absent levels of CD4+ T-cells, decreased NK-cells, normal CD8+ T-cells and elevated B-lymphocytes. IgG and IgM levels were normal for age (IgA absent). T-cell receptor excision circles (TRECS) and kappa-deleting recombination excision circles (KRECS) of the dried blood sample were 0/punch and 31/punch (normal >6 and >4/punch, respectively). Maternal CD8+ engraftment was confirmed using HLA-DR typing. The variant c.2892G>C (p.Lys964Asn), not previously described, was found to be homozygo in the JAK3 gene and confirmed by Sanger sequencing. Conclusions: We describe a child with a combined immunodeficiency and late onset of maternal CD8+ GVHD due to a new homozygous mutation in JAK3. Interesting the toddler did not suffer from disseminated CMV infection nor live vaccine associated complications to be expected in this immunocompromised host, probably due to the "protective" effect of maternal CD8 cells.

P.A6.01.03
A novel splicing mutation in a patient with Griscelli syndrome type 2

R. de la Varga Martínez[1], *M. López-Marcos*[2], *A. Pérez-Sánchez*[3], *P. Olbrich*[2], *B. Sánchez*[1], *O. Neth*[2], *J. M. Lucena Soto*[1];
[1]*Servicio de Inmunología. UGC de Laboratorios Clínicos. Hospital Universitario Virgen del Rocío, Sevilla, Spain,* [2]*Paediatric Infectious Diseases, Rheumatology and Inmunology Unit, Hospital Universitario Virgen del Rocío, Instituto de Biomedicina de Sevilla, Sevilla, Spain,* [3]*Department of Neonatología. Hospital Universitario Virgen del Rocío, Sevilla, Spain.*

Introduction: Griscelli syndrome type 2 (GS2, OMIM 214450) is a rare disease of autosomal recessive inheritance. It is characterized by hypomelanosis with immunologic abnormalities with or without neurologic impairment, is caused by mutation in the RAB27A gene. Objective: To describe a novel splicing mutation in a patient with GS2 in a newborn with silver hair, hepatosplenomegaly, pancytopenia and hemophagocytic lymphohistiocytosis (HLH). Material and methods: A newborn 13-day-old female was referred to the immunology department for suspicion of SG2. Quantification of soluble IL-2 receptor (sIL2R) and Sanger sequencing (3-8 exons and adjacent intronic regions of the RAB27A gene) was performed. Results: The patient met diagnostic criteria for HLH (6/8): persistent fever, splenomegaly, cytopenias (haemoglobin 92 g/L, platelets $9x10^9$/L, neutrophils $0.0x10^9$/L), low levels of fibrinogen (0.73 g/L), raised levels of ferritin (18107 µg/L) and sIL2R (118.39 ng/ml [0-7.5]). Due to the clinical instability BMA was not performed and NK cell activity studies were not available. The presence of the variant g.IVS6+1G>C is detected in homozygous at position g.67589663 of intron 6 of the RAB27A gene. These change causes an anomalous processing of the mRNA of the gene. Conclusions: This variant is described as polymorphism: rs756071120, found in heterozygous in a healthy control. However, we consider this to be a pathogenic mutation as the mutation affects an invariant dinucleotide splicing site, is in homozygous and the analysis of the mRNA shows anomalous processing. The results confirm the suspected SG2.

P.A6.01.04
Influence of an osteolysis predisposing allele TNF-238*A on the cytokine expression pattern of blood cells from total hip arthroplasty (THA) patients with mild and severe osteolysis

R. Fillerova[1], ***T. Dyskova***[1], *P. Schneiderova*[1], *V. Smotkova-Kraiczova*[1], *J. Gallo*[2], *E. Kriegova*[1];
[1]*Dept. of Immunology, Palacky University, Olomouc, Czech Republic,* [2]*Dept. of Orthopaedics, Palacky University&University Hospital, Olomouc, Czech Republic.*

Introduction: Individual susceptibility to periprosthetic osteolysis (PPOL) around total hip arthroplasty (THA) is associated with genetic variations in cytokine genes. Thus, cytokine pattern may differ in THA patients with mild and severe PPOL and in patients carrying a risk allele TNF-238*A, associated with severe osteolysis. Methods: Peripheral blood mononuclear cells (PBMCs) obtained from 31 THA patients with severe (n=23) and mild (n=8) osteolysis carrying (n=12)/non-carrying (n=19) a TNF-238*A risk allele were stimulated for 12h by lipopolysaccharide (LPS). Conditioned media were collected and protein concentrations of cytokines IL-2, IL-5, IL-10, IFN-γ, TNF-α, VEGF, and RANKL were measured by Luminex and ELISA. Results: Elevated expression of IL-2, IL-5, VEGF, and RANKL ($P<0.05$) was observed in supernatants from patients with severe comparing to mild osteolysis, irrespective of TNF-238 genotype. Patients with TNF-238 GG genotype with severe osteolysis showed up-regulated expression of all studied cytokines, except IL-10 and VEGF, comparing to those with mild osteolysis. In severe osteolysis, the carriers of rare TNF-238*A allele showed lower expression of IL-2, IFN-γ, TNF-α, and RANKL ($P<0.05$) when comparing to non-carriers. Conclusion: Alteration in cytokine expression pattern in LPS-stimulated PBMCs from THA patients with mild and severe osteolysis and differing by TNF-238*A genotype was observed. Molecular mechanisms by which TNF-238*A allele increases a risk of severe osteolysis should be further investigated. Grant support: MZ CR VES16-31852A, MZ ČR VES15-27726A, IGA UP_2018_016, MH CZ - DRO (FNOL, 00098892)

P.A6.01.05
TLR Dependent Immune Responses of Patient Displaying Common Variable Immunodeficiency Like Symptoms

I. Evcili[1], *G. G. Kaya*[1], *M. Yıldırım*[1], *N. Bozbeyoglu*[1], *I. C. Ayanoglu*[2], *Ö. Ardeniz*[3], *M. Gürsel*[2], *I. Gürsel*[1];
[1]*Bilkent University, Ankara, Turkey,* [2]*Middle East Technical University, Ankara, Turkey,* [3]*Ege University Faculty of Medicine, Izmir, Turkey.*

The innate immune system uses germline coded receptors to detect pathogens and mount acute innate response that helps to protect host from infection. Toll-like receptors (TLRs) and other pathogen dependent pattern recognition receptors play important role in this response. Common Variable Immunodeficiency (CVID) is the most common primer immunodeficiency seen in adults. Vitamin D and VDR have been reported to have an effect on TLR2. In this study, PBMCs from CVID-susceptible VDR+ patient was treated with TLR and Inflammasome ligands (Pam3CSK4, P (I: C), LPS, R848, Resiquimod, CpG ODNs, Nigericin and ATP) for 24h. IFNγ, IL-4, IL-8, Pan-IFNα and IP-10 levels were determined from the supernatants by ELISA. Total RNA isolated from PBMCs was studied with Nanostring™ inflammation panel. Th1/Th2/Th17 phenotyping was performed by flow cytometry and IP-10 and IL-1β levels in plasmas were determined by CBA. Both Nanostring™ and CBA analyses revealed that patient plasma had elevated IP-10 level. In addition, Nanostring implicated that patient's TLR3 and TLR7/8 mRNA levels were lower than healthy PBMCs. Lower pan-IFNα and IFNγ and higher IL-8 secretions in response to p(I:C), R848 and Resiquimod stimulation were observed compared to healthy controls. Similarly, TLR9 ligand stimulation gave lower pan-IFNα than healthy subject PBMCs. As a result, modulation of TLR pathways may offer new treatment options for CVID patients.

P.A6.01.06

Simple sequence repeat controls sex-dependent susceptibility to autoimmunity

***G. Fernandez Lahore**, M. Förster, M. Johannesson, R. Holmdahl;*
Karolinska Institutet, Solna, Sweden.

Complex autoimmune diseases have a strong genetic component. While genome-wide association studies have been very successful at identifying genetic determinants of large effect size, these studies run into limitations both in the identification of low effect size variants, and in the functional interpretation of identified non-coding variants. This creates a gap of unexplained genetic contribution has been termed *missing heritability*. Mouse genetic studies aid in the search for new genetic determinants by offering stable experimental conditions and the possibility for functional characterization. In this study we identified a non-coding simple repeat that reduced disease severity in mouse models of arthritis, multiple sclerosis, and delayed-type hypersensitivity in a sex-specific manner. We found that the simple repeat interfered with DNA-binding of the transcriptional regulator CTCF by creating a base pair change AC to GG within the CTCF consensus motif.
As a consequence, it affected the expression profile of nearby genes, including the TCR co-stimulator *Cd2*, changing the reactivity of peripheral T cells. We found that these changes in expression were specific to female mice, suggesting an involvement of sex hormones. Indeed, castration of female mice both regulated binding of CTCF to the candidate site, and was sufficient to reverse the protective effect in the EAE model of multiple sclerosis. In conclusion, we identified a non-coding simple repeat that dictates the expression profile of surrounding genes in a sex-dependent manner, culminating in a sexually dimorphic autoimmune phenotype.

P.A6.01.07

Genetic study in a spanish cohort of Narcolepsy type 1 patients and susceptibility to autoimmune diseases

***M. Fernández-Arquero**, B. González Fernández, L. N. Campo Blázquez, E. Rodríguez, I. Villalibre-Valderrey, S. Sánchez-Ramón, F. J. Martínez-Orozco;*
San Carlos University Hospital, Madrid, Spain.

Introduction. Narcolepsy Type 1 (NT1) affects between 0.025-0.40% population in Europe. This chronic rare sleep disorder is characterised by excessive daytime sleepiness, cataplexy and disturbed nocturnal sleep. It is caused by a selective loss of hypocretin-producing neurons due to a mechanism of neural destruction that indicates an autoimmune pathogenesis. There is also a strong association with HLA genes, as the 82% of patients display the DQB1*06:02 allele. The purpose of this study is to analyse the role of the HLA genes in NT1 patients and the susceptibility to autoimmune diseases. **Material and methods.** A total of 62 DNA samples from NT1 patients were analysed. Each DNA was purified through MagNApure automatic technology (Roche®, Switzerland). The DNA quantification was performed using Nanodrop spectrophotometer (Thermo Fisher Scientific®, USA) and HLA match study was done via Luminex technology (Diagnostica LongWood®, Spain). **Results.** 54 NT1 patients out of 62 (82% in NT1 vs. 22% in controls, $P<10^{-5}$) had the DQB1*06:02 allele. Moreover, 22 NT1 patients out of 62 (35.48%) had one or more autoimmunity diseases (AD) associated. Within this group, 18 displayed the DQB1*06:02 allele (81.81% in NT1 with AD vs. 22.62% in controls, $P<10^{-5}$), whereas 4 patients were DQ2 positive because the DR3 allele was significantly more frequent than in controls (75% in NT1 with AD vs. 22% in controls, P<0.001). **Conclusion.** The DQB1*06:02 allele plays an important role in NT1 patients. Furthermore, there is a high frequency of ADs in NT1, which suggests the idea that narcolepsy has an autoimmune pathogenesis.

P.A6.01.08

Celiac Disease: a dose-dependent effect of HLA-DQB.1*02 gene to genetic susceptibility in paediatric patients

***M. Fernández-Arquero**, L. N. Campo Blázquez, B. González Fernández, A. Bodas, A. García-Ron, M. T. de Santos Moreno, K. Guevara, S. Sánchez-Ramón;*
San Carlos University Hospital, Madrid, Spain.

Introduction: Celiac disease (CD) is a T cell-mediated, tissue-specific autoimmune disease which is found in genetically susceptible individuals who carry the HLA-DQB1*02 or DQB1*08 genes. This pathology causes damage to the small intestinal mucosa when gluten or related prolamines, are ingested. In these patients, the small bowel biopsies have been widely accepted as a gold standard for diagnosis. However, is barely known the effect that HLA-DQB1 gene dose has in predisposition to CD. The aim of this study is to analyse the role of the HLA-DQB1*02 genes in paediatric patients. **Material and methods**: 200 DNA samples were analysed from CD diagnosed patients (100) and healthy donors as controls (100). Each DNA was obtained with Magnapure automatic technology (Roche®, Switzerland). The DNA quantification was done through Nanodrop spectrophotometer (Thermo Fisher Scientific®, USA) and HLA match study was performed using Luminex technology (Diagnostica Longwood®, Spain). **Results**: We observed 92% of the patients displayed the DQA.1*05 and DQB.1*02 alleles, in contrast to controls: 25,6% (p<0.0001). The DR7, DQ2 and/or DR4, DQ8 haplotypes, were present in those CD patients that didn't carry the DQαβ heterodimer. Moreover, a 58% of patients displayed the DRB.1*07 allele carrying DQ2 haplotype, in contrast to controls: 3,3% (p<0.0001). **Conclusions:** We remark the role of DQB.1*02 as a strong marker of genetic predisposition in paediatric patients, which could be used as possible prognostic factor of CD. The presence of DRB.1*07, agree with an additive effect of DQ2 haplotype to that conferred by the DQ2.5 when these are present.

P.A6.01.09

Heterozygous mutation in BCL10 in a patient with T lymphopenia and ulcerative colitis

Caspase recruitment domain-containing (CARD) family adaptors form heterotrimers with B-cell lymphoma 10 (BCL10) and mucosa-associated lymphoid tissue lymphoma-translocation gene 1 (MALT1). CARD-BCL10-MALT1 (CBM) complex activates nuclear factor (NF-κB) in both the innate and adaptive arms of immunity. Inherited defect of human BCL10 complete deficiency was recently reported in a child with a broad combined immunodeficiency. This patient suffered a chronic non-specific colitis with moderated lymphocytic infiltration in lamina propia. We report here a new mutation of BCL10. The patient carrying the mutation is an adult with chronic primary T lymphopenia, low B cell levels and ulcerative colitis. A heterozygous mutation in BCL10 was found (L8P). In spite of normal BCL10 expression, this patient has an impaired NF-κB-mediated function in fibroblast similar to the one observed in the first patient reported. Our results show that BCL10 L8P heterozygous mutation can be responsible of this new phenotype.

P.A6.01.10

A rare cause of immunodeficiency: glycogen storage disease type 1b

*B. Erdur, I. Parlak, M. Köse, E. Şahin, E. Özbek, **F. Genel**;*
Department of Pediatrics Dr.Behcet Uz Children's Hospital, Izmir, Turkey.

Glycogen storage diseases (GSD) are inherited metabolic diseases characterized by accumulation of glycogen in tissues. GSD type 1b effects lipid, carbonhydrate and purin metabolism and neutropenia may occur. The patients are susceptible to recurrent bacterial infections and have recurrent oral ulcers due to immune dysfunction caused by a combination of neutropenia and impaired phagocytic functions. Here we present an infant with GSD type 1b admitted for failure to thrive, abdominal distention, and developed hypoglycemia during the follow up. We want to take attention to this rare disease. A 2,5 months old girl infant admitted to our hospital for failure to thrive, abominal distention and recurrent bacterial infections. In her previous history despite appropriate brestfeeding she had inadequate weight gain. Her parents were second degree relatives. On physical examination rounded "doll's face", abdominal distention and hepatomegaly were found. Laboratory tests revealed neutropenia, elevated liver transaminases, serum lactat and uric levels and hyperlipidemia. Hypoglycemia occured during the follow up. With these clinical findings GSD type 1b was considered and genetic analysis was performed. Homozygous mutation in SLC37A4 gene was found. Enzymatic analysis supported the diagnosis. Nutritional management was regulated to prevent the child from hypoglycemia and GM-CSF was given. In infants with hepatomegaly, hypoglycemia, elevated transaminases, neutropenia and recurrent bacterial infections GSD type 1b should be considered for diagnosis. With early nutritional interventions and intensive treatment of the infections in neutropenic patients and short-term treatment with GM-CSF for serious infections, the life quality and life expectancy of the patients may be improved.

P.A6.01.11

Innate immune responses in MHC class I deficiency resulting from β2-microglobulin gene mutation

B. Kayaoglu[1], *N. Sürücü*[1], *A. Eden*[2], *H. Uçkun*[2], *M. Özışık*[2], *I. C. Ayanoglu*[1], *B. Geçkin*[1], *A. M. Acar*[1], *Ö. Ardeniz*[2], *M. Gürsel*[1];
[1]*Department of Biological Sciences, Middle East Technical University, Ankara, Turkey,* [2]*Medicine Division of Allergy and Clinical Immunology, Ege University Medical Faculty, Izmir, Turkey.*

Introduction: A novel mutation in β2-microglobulin gene has been recently identified in two Turkish siblings, resulting in low numbers of $CD8^+$ T cells and absence of MHC class I expression. Although such a phenotype would be expected to result in susceptibility to mainly viral infections, the 26-year-old male patient (one of the siblings) was fairly asymptomatic compared to his sister, who suffered from multiple forms of immune dysregulation. Herein, we aimed to investigate the underlying cause of innate immune system hyperactivation by means of functional assays.
Methods: PBMCs from patient and healthy donors were stimulated with various pattern recognition receptor (PRR) ligands and immune responses were analyzed using cytokine ELISA. STAT phosphorylation and cytosolic ROS production were assessed by flow cytometry. Gene expression was analyzed by Nanostring inflammation panel.
Results: Stimulation of cells with various PRR ligands resulted in diminished pro-inflammatory cytokine production in the patient as opposed to an increase in type I IFN secretion when compared to healthy controls. Patient PBMC spontaneously secreted IP10 in the absence of stimulation. Nanostirng gene expression analysis was consistent with protein level analysis, indicative of enhanced type I IFN signature. In addition, the patient's neutrophils were observed to produce spontaneous ROS and this patient was found to have high percentage of low density neutrophils (LDG) that was absent in healthy individuals.
Conclusion: Presence of hyperactive neutrophils and LDGs may explain resistance to bacteria while an increased type I IFN signature may explain the resistance to viral infection in this patient.

P.A6.01.12

The NGS approach in evaluation of known and novel mutations associated with X-linked agammaglobulinemia (XLA)

I. Kofiadi[1], *I. Manto*[1], *E. Latysheva*[1], *T. Latysheva*[1], *A. Nikiforova*[2], *G. Gudima*[1], *M. Khaitov*[1];
[1]*FSBI "NRC Institute of Immunology" FMBA of Russia, Moscow, Russian Federation,* [2]*DNA-Technology, JSC, Moscow, Russian Federation.*

The XLA specified as primary humoral immunodeficiency with apparent genetic component. The disease predominantly manifested in patients bearing mutations in BTK gene and characterized by the failure to produce mature B-lymphocytes. The differential diagnosis from other PIDs, characterized by similar symptoms, but requiring other treatment, is quite challenging without genetic confirmation. Currently the most effective and relevant approach for target genetic screening is NGS. We developed the test system covering 19 exons of BTK gene suitable for Ion PGM platform. The study enrolled 7 patients with possible XLA (ESID criteria) between 18 and 36. 4 patients showed single pathogenic mutations. One patient had 3 different mutations and another one had 4 different mutations. In addition, one patient with apparent symptoms of XLA had no mutations in BTK gene. The results were compared with most relevant and complete databases: BTKbase and LOVD, as well as checked for citation in PubMed. Analysis showed that 5 mutations were not indexed in databases. Two of them NM_000061.2:c.241-1G>A and NM_000061.2:c.1178-1G>A were previously described by Stewart D.M. (2001) and Toth B. (2009) respectively. Three mutations considered to be new and, presumably, pathogenic: two deletions -NP_000052.1:p.Met570del/NM_000061.2:c.1708_1710delATG; p.Cys145Alafs*31/NM_000061.2:c.433delT and one SNP - NM_000061.2:c.1909-1G>A. The obtained results confirm the utility of NGS approach in evaluation of BTK mutation profile. The genetic data will be used in further follow-up and characterization of T-cell immunity of XLA patients. Non-confirmed diagnosis will be reconsidered and subjected for further investigation. New mutations will be submitted to BTK mutation databases.

P.A6.01.13

Characterization of the monocyte/macrophage compartment in a patient with a novel *CSF1R* mutation causing hereditary diffuse leukoencephalopathy with spheroids

D. Quandt[1], *T. Kraya*[2], *T. Pfirrmann*[3], *A. Kindermann*[1], *J. Kohlhase*[4], *D. Stoevesandt*[5], *K. Hoffmann*[6], *P. Villavicencio-Lorini*[6];
[1]*Departement of Anatomy and Cell Biology, University of, Halle, Germany,* [2]*Department of Neurology, University of, Halle, Germany,* [3]*Institute of Physiological Chemistry, University of, Halle, Germany,* [4]*SYNLAB MVZ Humangenetik Freiburg, Freiburg, Germany,* [5]*Department of Radiology, University of, Halle, Germany,* [6]*Institute of Human Genetics, University of, Halle, Germany.*

Colony-stimulating factor 1 receptor (CSF1R) is a tyrosine kinase transmembrane protein that mediates proliferation, differentiation and survival of monocytes/macrophages and microglia by activation through the cytokine CSF1 or IL-34. Interestingly, *CSF1R* gene mutations cause hereditary diffuse leukoencephalopathy with spheroids (HDLS), an autosomal-dominantly inherited microgliopathy leading to rapid neurocognitive decline with high lethality. By detailed clinical assessment and targeted gene sequencing we identified a novel *CSF1R*-indel mutation in a 44-year old female patient with a complex neuropsychiatric clinical presentation, initial signs of cerebral gliosis, and positive family history. By FACS analysis of peripheral blood monocytes we detected marginal elevated cell surface protein levels of the CSF1 (CD115) receptor. Interesting, we found an increased number of total blood monocytes. Subdividing monocyte populations by flow cytometry revealed a decreased frequency of non-classical monocytes in the blood of the patient. Of particular note, we discovered an increased Tyr723 autophosphorylation by intracellular flow cytometry in peripheral monocytes, indicating a gain-of-function effect of the mutation. Ongoing analyses will reveal whether there is an altered potential of macrophage differentiation and polarization. Furthermore pharmacological inhibition of the CSF1R by the use of GW2580, shown to arrest microglial proliferation, will be applied in vitro to study potential treatment options for this novel *CSF1R*-indel mutation.

P.A6.01.14

Investigation of heterozygous *NFKB1* variants in a common variable immunodeficiency cohort

C. Schröder[1], *T. Witte*[1], *R. Jacobs*[1], *T. Dörk*[1], *B. Grimmbacher*[2], *R. E. Schmidt*[1], *F. Atschekzei*[1];
[1]*Hanover Medical School, Hannover, Germany,* [2]*Center for Chronic Immunodeficiency, Freiburg, Germany.*

The transcription factor nuclear factor kappa B (NF-κB1) is sequestered within the cytoplasm of every cell. During activation of the canonical NF-κB pathway, NF-κB1 translocates to the nucleus and binds to the promotors of its target genes. NF-κB1 has been linked with a diversity of diseases, including asthma, AIDS, diabetes and cancer. More recently, it has been shown that *NFKB1* mutations could lead to haploinsufficiency of the active subunit p50 and therefore could cause the CVID phenotype. CVID as a syndrome comprises a heterogeneous group of molecular diseases, characterized by a significant hypogammaglobulinemia of unknown cause.
Genomic DNA for targeted-NGS was isolated from whole blood. Detected mutations were validated by Sanger sequencing. PBMCs were isolated by density gradient centrifugation and stimulated with PMA plus ionomycin and analyzed using immunoblotting with antibodies against NF-κB1 p105 and p50.
In our study we identified five novel heterozygous mutations in *NFKB1* in seven patients by targeted NGS. Among those, one frameshift deletion, three single base-pair insertions, one missense and one splice site mutation were observed. *NFKB1* mutations occur in our CVID cohort with a prevalence of 1:30. In all affected members of three families, their mutations lead to a reduction of the active NF-κB1 subunit p50. Nevertheless, the mutations segregate with incomplete penetrance in families.
Mutations in *NFKB1* lead to reduced levels of p50. Due to the incomplete segregation of penetrance, other causes, like epigenetic changes or intestinal microbiome alteration may promote the onset of disease.

P.A6.01.15

Molecular and bioinformatics characterization of a novel mutation in *STXBP2* gene: a case report on Familial Hemophagocytic Lymphohistiocytosis

L. Viñas-Gimenez[1,2], *L. Donadeu*[1,2], *E. Alvarez de la Campa*[1,2], *R. Colobran*[1], *A. Català*[3], *X. de la Cruz*[2], *L. Alsina*[3], *J. Sayos*[1,2], *M. Martínez-Gallo*[1];
[1]*Vall d'Hebron University Hospital, Barcelona, Spain,* [2]*Institut de Recerca Vall d'Hebron (VHIR), Barcelona, Spain,* [3]*Hematology Department, Hospital Sant Joan de Déu., Barcelona, Spain.*

Familial Hemophagocytic Lymphohistiocytosis (FHL) is a rare autosomal recessive disorder characterized by uncontrolled immune activation but ineffective response. Disease-causing mutations have been reported in several genes: *PRF1*-FHL2, *UNC13D*-FHL3, *STX11*-FHL4 and STXBP2-FHL5. All FLH forms are first diagnosed based on clinical symptoms and laboratory findings following accepted guidelines. We present a 2-year-old baby-boy from non-consanguineous parents that developed two episodes of EBV-HLH in 4 months. His older brother died at the age of 3 years of HLH also triggered by EBV infection. Functional test revealed impaired cytotoxicity, reduced CD107a Mean-Fluorescence-Intensity (MFI) but normal percentage of NK cells expressing CD107). Genetic analysis identified a compound heterozygous mutations in *STXBP2* gene, one a previously reported in exon 15 (c.1247-1G>C) and the second a novel mutation in exon 9 (c.728T>G (p.L243R)). The L243 residue is evolutionarily highly preserved and PyMOL prediction indicates that sits at the centre of a rich network of interactions important for stabilizing domains 2 and 3 of the STXBP2 protein. Transfection of constructs with the mutated and WT sequences into COS7 cells resulted in good level of WT but no expression of STXBP2-L243R, confirming PyMOL prediction. Overall the known effect of the allele pV417LX126 plus the in-silico analysis and transfection experiments of the L243R allele indicate that all the remaining degranulation function of STXBP2 is attributable to the pV417Lfs allele. This would explain the results of functional assays, i.e., impaired cytotoxicity with reduced CD107a surface expression as measured by MFI but normal as percentage of CD107a+ NK cells after stimulation.

P.A6.01.16

Clinical and Immunologic Data in Two Groups of Familial and Sporadic Patients with Common Variable Immunodeficiency

***R. Yazdani**, A. Valizadeh, G. Azizi, H. Abolhassani, A. Aghamohammadi;*
Research Center for Immunodeficiencies (RCID), Tehran, Iran, Islamic Republic of.

Introduction: Common variable immunodeficiency (CVID) is the most frequent symptomatic primary immunodeficiency disease and its prevalence varies significantly among different population. Minority of CVID patients present a familial aggregation suggesting a higher probability of heritable genetic defects. **Methods:** A total of 235 registered CVID patients were evaluated in this cohort study. Familial and sporadic patients were stratified and demographic information, clinical records, laboratory and molecular data were compared among these two groups of patients. **Results:** Multiple cases were identified in 12 families (30 patients) and sporadic presentation in 120 cases. The rate of parental consanguinity (83.3%) and clinical presentation of lymphoid malignancy (20.7%) were predominant in familial CVID patients, whereas significantly increased recurrent upper respiratory infections were recorded in sporadic patients (0.3 infections per year). Probands of familial group were presented with a higher severity score resulting in a profound mortality rate (41.7% after 30-years follow-up) comparing to the non-proband CVID patients in the same families with a lowered diagnostic delay. **Conclusion:** Familial CVID patients had a specific signature in clinical presentation and immunologic profile and a high consanguinity in this group of patients suggests a Mendelian trait with an autosomal recessive inheritance pattern. Diagnosis of an index patient within a multiple case families significantly improves the diagnostic process and outcomes of the yet asymptomatic patients

P.A6.01.17

First case with cernunnos deficiency from the national Iranian registry

***R. Yazdani**[1], H. Abolhassani[1], J. Tafaroji[1], G. Azizi[1], A. Hamidieh[1], J. Chou[2], R. S. Geha[2], A. Aghamohammadi[1];*
[1]Research Center for Immunodeficiencies (RCID), Tehran, Iran, Islamic Republic of, [2]Division of Immunology Boston Children's Hospital, and Department of Pediatrics, Harvard Medical School, Boston, USA, Boston, United States.

Introduction: Severe combined immunodeficiency (SCID) is a heterogeneous group of genetic disorders. Cernunnos is a DNA repair factor that is involved in Non-homologous end-joining (NHEJ) process. Impairment in Cernunnos leads to a genetic disease characterized by neural disorders, immunodeficiency and increased radiosensitivity.
Methods: We obtained clinical manifestations and immunological findings by reviewing hospital records. Mutation analysis was done by whole exome sequensing and the mutation was confirmed by sanger sequencing.
Results: We herein describe a SCID patient with T- B+ phenotype who had a mutation in Cernunnos gene and manifested recurrent infections, microcephaly and growth retardation with hypogammaglobulinemia. Furthermore, our patient was associated with BCG adenitis and autoimmunity that less is observed in patients with Cernunnos deficiency.
Conclusions: In contrast to previous reported Cernunnos-deficient patients, our patient had normal B-cell number along with normal IgA and IgM, suggesting a leaky form of Cernunnos deficiency due to residual count of B cells in our patient. Cernunnos deficiency should be considered in children with recurrent bacterial infections, microcephaly and growth retardation, in spite of having normal B-cell as well as normal IgM and IgA level.

P.A6.02.01

Association of interferon regulatory factor (IRF 5) gene (rs2280714) SNP with systemic lupus erythematosus patients

*H. Hamid[1], A. Waqar[1], S. Ullah[1], A. Jamal[1], S. Pervaiz[2], S. Jahan[3], N. Afzal[3], **B. Adil**[4];*
[1]ICBS, Faculty of Health and Allied Sciences, Lahore, Pakistan, [2]King Edward Medical University, Lahore, Pakistan, [3]University of Health Sciences, Lahore, Pakistan, [4]Faculty of Health and Allied Sciences, Lahore, Pakistan.

Background- Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disorder. Center for disease control (CDC)-Atlanta estimated 1.8 to 7.6 per 100,000 people affected with SLE per year in the USA. SLE is a heterogeneous disease. Various genome wide association studies have shown association of interferon regulatory factor 5 (IRF5) gene with SLE. Therefore, this study was aimed and designed to determine single nucleotide polymorphism (SNP) in IRF5 gene restriction site (rs2280714) in local SLE patients and healthy controls.
Objective- To determine the frequency IRF5 (rs2280714) gene polymorphism in SLE patients and healthy controls
Materials and methods- It was a case control study. Eighty samples were recruited for each of the two study groups. DNA extraction was carried out using standard phenol-chloroform technique. Further, samples were processed by PCR-RFLP (Restriction fragment length polymorphism) conventional method. Polymorphism analysis and allele frequencies were compared between groups using chi-square test.
Results- It revealed that SNP in IRF5 gene (rs2280714) is not associated with SLE in Pakistani population. CC genotype is more frequent among various major clinical manifestations of SLE.
Conclusion- This study might incorporate with even better clarification of underlying etiological and prognostic factors regarding SLE.

P.A6.02.02

Identification of *Tyk2* loss-of-function mutations in a cohort of B cell acute lymphoblastic leukemia patients and characterization of B cell dysregulated function in *TYK2*-deficient mice

***I. Bodega-Mayor**[1], E. A. Turrubiartes[1], I. Cortegano[2], M. L. Gaspar[2], B. de Andrés[2], E. Fernández-Ruiz[1];*
[1]Instituto de Investigación Sanitaria Princesa (IIS-IP), Madrid, Spain, [2]Centro Nacional de Microbiología, Instituto de Salud Carlos III (ISCIII), Madrid, Spain.

B-acute lymphoblastic leukemia (B-ALL) is the most prevalent childhood hematological malignancy. In these patients, mutations in genes associated with JAK/STAT signaling are frequent. Tyrosin kinase 2 (TYK2) is a member of the Janus kinase family (JAKs), involved in several cytokine signaling pathways, and therefore it is important in hematopoiesis and immune system. *TYK2*-null mice show deficient tumour surveillance and resistance to LPS-induced septic shock, however the implication of B cells in these phenotypes is still unknown.
Using next-generation sequencing, we have sequenced DNA from 65 B-ALL patients at diagnosis and identified two mutations not previously reported and eight polymorphisms in *Tyk2*. We have tested in vitro these new mutations and one polymorphism, and they showed an impaired signaling in response to IFN-alpha, resembling the kinase-dead form of the protein.
Additionally, we have studied the B cell compartment of *TYK2*-null mice after in vivo immunization. We have observed an altered humoral B cell response to a T-dependent antigen (NP-OVA), with a significant reduction of memory switched B cells and specific IgM and IgG2a sera. These mice respond also deficiently after the T-independent stimulation with LPS, by decreasing the total number of marginal zone B cells and increasing follicular B cells.
In conclusion, 3% of ALL-B patients studied carried new loss-of-function mutations in *Tyk2*. In mice, TYK2 is necessary for an appropriate response to T-dependent and T-independent antigens and the homeostasis of the B cell compartment. These data postulate TYK2 as a key player in the regulation of the B cell function.

P.A6.02.03

Functional characterization of disease associated variants of human complement Factor H-related protein 5

***M. Cserhalmi**[1], B. Uzonyi[1], D. Csuka[2], K. Uray[3], A. Iliás[1], Z. Prohászka[2], M. Józsi[1];*
[1]Department of Immunology, Eötvös Loránd University, Budapest, Hungary, [2]3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary, [3]MTA-ELTE Research Group of Peptide Chemistry, Hungarian Academy of Sciences, Eötvös Loránd University, Budapest, Hungary.

Complement is a major humoral arm of innate immunity that plays important roles in the protection against infections, regulation of inflammation and disposal of immune complexes and cellular waste. Dysregulation of the complement alternative pathway is involved in the pathogenesis of several diseases, including the kidney disease C3 glomerulopathy. Factor H is a main inhibitor of the alternative pathway; however, the role of the factor H-related FHR proteins is less characterized. FHR5, which consists of 9 complement control protein (CCP) domains, was described to bind C-reactive protein (CRP) and C3b. Our aim was to map the ligand binding sites in FHR5 and characterize FHR5 variants described in patients. Wild type and mutant FHR5 were expressed in insect cells. Binding studies were performed by ELISA and surface plasmon resonance (SPR). Fifteen amino acid-long peptides of FHR5 CCPs 3-9 and mutant peptides were synthesized on Mimotopes NCP gears. SPR experiments showed that FHR5 G278S and R356H association (k_a) to C3b was decreased, but FHR5 R356H dissociation (k_d) from C3b was slower, while that of G278S was faster than the wild type FHR5. Similar results were obtained by ELISA, indicating weaker C3b binding by FHR5 G278S. Epitope mapping revealed that C3b binding to FHR5 peptides with K144N, V170M, N178S was increased and binding of CRP to the R356H and M514R mutant peptides was decreased compared to wild type peptides. Altogether, our results identify amino acids within FHR5 involved in binding C3b and CRP, and reveal altered ligand binding by some mutant FHR5 proteins.

P.A6.02.04
NFATc1 activity is indispensable for T cell development

S. Giampaolo[1], *S. Klein-Hessling*[1], *F. Berberich-Siebelt*[1], *E. Serfling*[1], *A. Patra*[2];
[1]*Institute of Pathology and Comprehensive Cancer Center Mainfranken, University of Würzburg, Würzburg, Germany,* [2]*Institute of Translational and Stratified Medicine, Peninsula Schools of Medicine and Dentistry, University of Plymouth, Plymouth, United Kingdom.*

In lymphoid cells NFATc1, NFATc2 and NFATc3 transcription factors are expressed and involved in antigen-receptor signaling. Specifically, NFATc1 plays a critical role in thymocyte differentiation and survival. During T cell development in the thymus, the $CD4^-CD8^-$ double-negative (DN) cells differentiate to the $CD4^+CD8^+$ double-positive (DP) stage where they undergo the process of positive- and negative- selection to finally give rise to the $CD4^+$ or $CD8^+$ single positive (SP) T cells. Based on the expression of CD25 and CD44 molecules, the DN thymocytes again consist of four distinct populations: $CD44^+CD25^-$DN1, $CD44^+CD25^+$DN2, $CD44^-CD25^+$DN3 and the $CD44^-CD25^-$DN4 cells. The DN1-DN3 cells are critically dependent on IL-7 signaling for their survival and differentiation. We have shown previously that IL-7 signaling activates NFATc1 in the preTCR-negative DN thymocytes in a Jak3-dpendent manner leading to its nuclear translocation. Survival of DN thymocytes is partly due to an NFATc1-mediated transcriptional upregulation of the pro-survival molecule Bcl2 in these cells. *In vivo* binding studies by ChIP-Seq analysis of thymocytes confirmed the binding of NFATc1 to the *Bcl2* gene locus. The indispensability of NFATc1 activity was evident as a hematopoietic cells-specific ablation of NFATc1 activity resulted in an arrest of thymocyte differentiation at the DN1 stage leading to lymphopenia. On the other hand, overexpression of a constitutively active NFATc1 resulted in an impaired transition of DN3 cells to the DN4 stage, again leading to lymphopenia. These observations suggest that a threshold level of NFATc1 activity is critical for efficient T cell development.

P.A6.02.06
Chronic mucocutaneous candidiasis associated with a rare molecular defect: TRAF3IP2 mutation

N. E. Karaca, *A. Aykut, E. Parıltay, A. Durmaz, O. Cogulu, G. Aksu, N. Kutukculer;*
Ege University Medical School, Izmir, Turkey.

Chronic mucocutaneous candidiasis (CMC) is characterized by recurrent or persistent infections of skin, mucous membranes or nails with *Candida albicans* and sometimes staphylococcal infections. Patients with autosomal dominant (AD) Hyper-IgE syndrome (STAT3 deficiency) and STAT1 gain-of-function mutation, AR deficiencies in IL-12RB1, IL-12p40, CARD9 or APACED (autoimmune-poliendocrinopathy-candidiasis-ectodermal dystrophy) syndrome develop CMC as a major infectious phenotype. IL-17 receptor A/C F and ACT1 defects in the IL-17 signaling pathway also lead to CMC.
A 19-month-old-girl, born to second-degree consanguineous parents, referred with recurrent oral trush and skin eruptions. Elder brother had also CMC. Physical examination revealed oral mucosal candidiasis and multiple pustular eruptions all over the body. Hypergammaglobulinemia was observed. Absolute neutrophil counts, lymphocyte subgroups, IgE level and oxidative burst activity were normal. *Candida albicans* grew in the mouth swab culture and *S. Aureus* was isolated from the wound swab. A homozygous c.1569G> C (p.Trp532Cys) mutation was detected in the *TRAF3IP2* gene with the targeted next generation sequencing-based Ion AmpliSeq ™ Primer Immunodeficiency Panel. The parents were shown to carry the same mutation as heterozygous. All complaints were recovered by the treatment with trimetoprim-sulfometaxazole and fluconazole prophylaxis.
TRAF3IP2 (TNF-Receptor-Associated-Factor3-Interacting-Protein2) encodes the Act1 molecule, an adapter protein with ubiquitin-ligase activity that binds the IL-17receptor to downstream signaling pathways. ACT1 defects affecting the IL-17signaling pathway in AR CMC cases should also be kept in mind in the differential diagnosis. To our knowledge, this is the first ACT1 deficiency patient after two siblings who were published in 2013 by Boisson B et al.

P.A6.02.07
Overproduction of XBP1s protects from ER stress induced apoptosis in cystic fibrosis primary monocytes

S. Lara Reyna[1], *T. Scambler*[1], *J. Holbrook*[1], *C. Wong*[1], *H. Jarosz-Griffiths*[1], *F. Martinon*[2], *S. Savic*[1], *D. Peckham*[1], *M. F. McDermott*[1];
[1]*Univeristy of Leeds, Leeds, United Kingdom,* [2]*Univeristy of Lausanne, Lausanne, Switzerland.*

The cystic fibrosis transmembrane regulator (CFTR) is a transmembrane protein, involved in the transport of bicarbonate and chloride ions. Mutation of the CFTR causes cystic fibrosis (CF), resulting in recurrent pulmonary infections and autoinflammation mainly in the lungs. The CFTR is assembled and modified in the endoplasmic reticulum (ER) and, when mutated, accumulation of the CFTR leads to activation of the unfolded protein response (UPR). The UPR comprises three ER transmembrane proteins, known as PERK, IRE1, and ATF6. Chronic UPR activation, through its PERK arm, is linked with apoptosis through accumulation of CHOP. PERK activation can be inhibited by $p58^{IPK}$ production, which is induced by IRE1 activation through XBP1s. The aim of this study was to investigate UPR activation in CF patients.
Patients' peripheral blood mononuclear cells (PBMCs), primary monocytes, and human bronchial epithelial cells (HBEC), were used to evaluate UPR activation, using qPCR and flow-cytometry. LPS, tunicamycin and thapsigargin were used as cellular UPR stimulants to assess UPR activation.
Gene expression revealed a significant increase in *XBP1s* in HBEC lines, PBMCs, and monocytes from CF patients. IRE1α protein expression was also increased in the three CF cell lines. Furthermore, CF monocytes pre-treated with the IRE1 inhibitor, 4μ8C, showed a significant increase in the activity of PERK, including ATF4, GADD34, and CHOP, after UPR activation. Finally, PERK overactivation correlated with the downregulation of $p58^{IPK}$ in CF monocytes after 4μ8C pre-treatment.
Data suggest that misfolded CFTR proteins induce ER stress in CF. Furthermore, XBP1s overproduction protects CF cells from CHOP-induced apoptosis.

Linker for activation of T cells (LAT) inhibits development of aggressive thymic lymphomas by downregulating Notch-1 and pTa expression

K. Marek-Bukowiec[1,2], *M. Zalas*[1], *M. Lisowska*[1], *B. Malissen*[3], ***A. Miążek***[1,4];
[1]*Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland,* [2]*Ośrodek Badawczo Rozwojowy, Wojewódzki Szpital Specjalistyczny, Wroclaw, Poland,* [3]*Centre d"immunologie de Marseille Luminy, Marseille, France,* [4]*Wroclaw University of Envronmental and Life Sciences, Wroclaw, Poland.*

Linker for Activation of T Cells (LAT) is a raft-associated, transmembrane adaptor protein whose expression promotes expansion and selection of thymic T cell precursors. In LAT deficient mice (*LAT-/-*) thymocyte development is arrested at the CD4-8-25+ (DN3) stage but this block can be relieved when these mice are crossed with a transgenic line bearing a chronically active allele of LCK kinase (LCK^{Y505F}). Similar effect can also be observed in CD3e-/-LCK^{Y505} crosses accept that the former but not the latter mice develop fully penetrant, aggressive thymic lymphoma (T-ALL) characterized by a CD4lowCD8+ (DP) phenotype. Here, we aimed at identifying gene expression differences underlying the LCK driven DN3 to DP transition in *LAT-/-*LCK^{Y505F} versus control CD3e-/-LCK^{Y505} mice. We focused on gene transcripts *representative* of 15 different *signaling pathways* related to T-ALL. Comparative, transcriptomic analysis of pre-leukemic DP thymocytes from 3 week old mice led to identification of hyperactive Notch signaling pathway as an early, critical, LCK-driven oncogenic signal leading to the initiation of T-ALL. Our result imply that the functional LAT signalosome downregulates Notch and its target genes (i.e. pTa) at the DP stage of thymocyte development thus contributing to the restoration of their sensitivity to negative selection preventing oncogenic transformation.

P.A6.02.09
Celiac disease in patients from Cantabria (northern Spain): distribution of risk HLA haplotyes

L. Riesco-Davila, F. Ausin Ortega, ***M. Lopez-Hoyos****, J. Ocejo-Vinyals;*
Hospital Universitario Marqués de Valdecilla, Santander, Spain.

Celiac disease is one of the most prevalent genetically determined autoimmune diseases, and one of the diseases with strongest association with particular HLA haplotypes, specifically with DQ2 and DQ8.
Regarding the risk of the HLA haplotypes, several discrepancies among populations have been found, mainly due to no take into account the difference between the HLA DQ2.2 and DQ2.5 molecules.
For this reason, we genotyped 781 celiac disease patients (492 children < 15 years old, and 289 adults) who fulfilled the ESPGHAN criteria for this disease by using PCR-SSO in a Luminex platform.
In our population, when we analyzed together children and adults, we found some differences in the frequency of the haplotypes associated with an increased susceptibility to celiac disease compared with previously reported populations, and in the risk that these haplotypes conferred to the disease, mainly in the distribution of DQ2.2/DQ2.2, DQ2.2/x, DQ2.2/DQ7 and DQ8 either in homocigosity or heterocigosity. Interestingly, half of DQ2.2/x carried the DQA1*04 in trans position. We think that the main reasons of these differences are: a) the different prevalence of these haplotypes among populations and b) lack of separate analysis between DQ2.2. and DQ2.5.

P.A6.02.10

Association of HLA alleles and haplotypes with susceptibility to hidradenitis supurativa

*G. Ocejo-Vinyals, M. González-Gay, **L. Riesco-Davila**, I. Vilanova, J. Cantos Mansilla, C. Duran, R. Blanco, M. Gonzalez-Lopez;*
Hospital Universitario Marqués de Valdecilla, Santander, Spain.

Hidradenitis suppurativa (HS) is a chronic, inflammatory skin disease of the hair follicle characterized by relapsing painful inflammatory nodules, abscesses and fistula tracts in the apocrine gland-bearing areas of the body. Its pathogenesis is not completely understood. Familial HS have shown autosomal-dominant inheritance caused by mutations in the γ-secretase genes (*PSENEN*) but most of the HS patients do not present these mutations. To date, only one published study tried to study the role of HLA A, B or DR antigens as a factor contributing to a genetic susceptibility to HS without significant results. 106 patients with HS and 262 healthy controls were studied for the distribution of the HLA-A, B, C, DRB1, DQA1 and DQB1 alleles by using a PCR-SSOP technique and Luminex analysis. We found differences in the distribution of HLA, A, B, DRB1, DQA1 and DQB1 alleles. After Bonferroni correction, only HLA class II remained significant. DRB1*07 (p=0.026, OR 0.45 IC95% 0.27-0.74) and DQB1*02 (p=0.0005, OR 0.45 IC95% 0.27-0.67) were found to be more frequent in controls than in HS patients. By contrast, DQB1*03:01 was more frequent in HS patients (p = 0.00007, OR 2.36, IC95% 1.60-3.50). Haplotype DRB1*07-DQA1*02-DQB1*02 was found to be more frequent in healthy controls (p = 0.0005, OR 0.35, IC95% 0.19-0.62). To the best of our knowledge, this is the first reported association of HLA alleles with susceptibility or protection to HS. DQB1*03:01 (DQ7) would be an allele predisposing to HS whereas DRB1*07 and DQB1*02 alleles, and DRB1*07-DQA1*02-DQB1*02 haplotype would confer protection against HS.

P.A6.02.11

Association between KIR genes and hidradenitis suppurativa in Cantabria (northern Spain)

*M. Gonzalez-Gay, J. Ocejo-Vinyals, **L. Riesco-Davila**, I. Vilanova, J. Cantos Mansilla, C. Duran, R. Blanco, M. Gonzalez-Lopez;*
Hospital Universitario Marqués de Valdecilla, Santander, Spain.

Hidradenitis suppurativa (HS) is a chronic, inflammatory skin disease of the hair follicle characterized by relapsing painful inflammatory nodules, abscesses and fistula tracts in the apocrine gland-bearing areas of the body, most commonly in the axillae, inguinal and anogenital regions. To date, no study has looked for the role of the killer cell immunoglobulin-like receptors genes (KIR) in the pathogenesis of this disease. KIR, found on the surface of natural killer (NK) cells, play a key role in controlling the innate response. To study the role of the presence / absence of KIR genes in the pathogenesis of HS. In the same way, KIR haplotype and genotype distribution is analysed.A total of 106 patients with HS and 262 age and sex-matched healthy controls were studied for the presence / absence of KIR genes by PCR-SSO and Luminex analysis. We only found a weak difference in the distribution of KIR genes between HS patients and healthy controls. Only KIR2DL3 was found to be less frequent in HS patients vs healthy controls (79 % vs 89.8%, p = 0.13 OR 0.42 IC95% 0.22-0.81) suggesting a protective role against HS. This is the first study trying to find an association of KIR genes with HS. Our results suggest that KIR genes do not influence in a significant way on resistance/susceptibility to HS.

P.A6.02.12

PTPN22 gene polymorphisms in Iranian patients with Ulcerative Colitis

***M. Sadr**[1], N. Soleimanifar[1], N. Ebrahimidaryani[2], N. Rezaei[2];*
[1]Molecular Immunology Research Center,Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [2]Tehran university medical of science, Tehran, Iran, Islamic Republic of.

Inflammatory bowel disease (IBD) is an idiopathic chronic recurrent gastrointestinal inflammatory disorder, which categorizes based on clinical, histological and immunological findings into two main forms of Crohn's disease (CD) and ulcerative colitis (UC). PTPN22 gene located on chromosome 1p13 and expressed exclusively in immune cells, encodes a lymphoid-specific intracellular protein tyrosine phosphatase which, is involve in T cell receptor signaling pathway. Since BD is an autoimmune disease, this study was done to examine five functional polymorphisms of PTPN22 gene to illustrate the role of this gene in this disease.
Using the Real-time PCR allelic discrimination method, 67 samples of unrelated patients with UC and 93 samples of healthy controls were genotyped. Using Fisher exact test or Chi-square test, genotypic and allelic frequencies were estimated.
The results of our study indicated a remarkable correlation of alleles and genotypes at rs1310182 as follow T allele (OR = 0.33 - 0.83, 95 % CI = 0.53, P <0.01), C allele (OR = 1.19 - 2.94, 95 % CI = 1.87, P <0.01), TT genotype (OR = 0.19 - 0.94, 95 % CI = 0.43, P= 0.03) and CC genotype (OR = 1.13 - 4.76, 95 % CI = 2.32, P <0.01) in UC.
This association study showed that rs1310182 SNP of PTPN22 could have role in UC; however, more researches on this topic are needed.

Pathogenic *NFKB2* variant in the ankyrin repeat domain causes defective class-switched B cells and variable T cell defects *ex vivo*

***P. Tuijnenburg**[1], H. Lango Allen[2], G. J. de Bree[3], S. Savic[4], M. H. Jansen[1], S. O. Burns[5], C. Stockdale[4], I. Simeoni[2], E. M. van Leeuwen[6], J. E. Thaventiran[7], T. W. Kuijpers[1];*
[1]Department of Pediatric Hematology, Immunology and Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands, [2]Department of Haematology, University of Cambridge, Cambridge, United Kingdom, [3]Department of Internal Medicine, Academic Medical Center, Amsterdam, Netherlands, [4]Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, St James's University Hospital, Leeds, United Kingdom, [5]Department of Immunology, Royal Free London NHS Foundation Trust, University College London Institute of Immunity and Transplantation, London, United Kingdom, [6]Department of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands, [7]Department of Medicine, University of Cambridge, Cambridge, United Kingdom.

Introduction: Genetic studies are identifying an increasing number of monogenic causes of Common Variable Immunodeficiency (CVID), a heterogeneous disorder characterized by recurrent infections, low serum immunoglobulins and poor vaccination responses. The cellular phenotype of those monogenic immunodeficiencies carries important information on major signaling pathways such as the canonical and non-canonical NF-κB pathway. The effect of heterozygous *NFKB1* mutations on lymphocytes have recently been characterized, however phenotype and function in heterozygous *NFKB2* mutations are not yet described in full detail. **Methods:** We studied 2 unrelated CVID pedigrees with 4 cases of pathogenic stop gain variants (c.1903C>T) in the ankyrin repeat domain (ARD) of NF-κB2, leading to a premature truncation of the protein at p.Arg635Term (R635X) identified by Whole Genome Sequencing (WGS) as part of the NIHR BioResource - Rare Disease study. We performed extensive immunophenotyping and CFSE-labeled PBMC cultures to examine B and T cell proliferation, plasmablast differentiation and immunoglobulin production. **Results:** *NFKB2* R635X cases showed reduced class-switched memory B cells but were able to induce (immature) plasmablasts, yet unable to produce IgG and IgA *ex vivo*. Moreover, *NFKB2*-defective B cells differed from patients with NF-κB1 loss-of-function by the absence of an expanded $CD21^{low}$ B cell population, associated with autoimmunity. An abnormal *ex vivo* T cell phenotype was observed in the two clinically affected index cases, which is currently being further investigated. **Conclusion:** In conclusion, pathogenic stop variants in the ARD of *NFKB2* can cause CVID with an abnormal B cell phenotype and variable T cell defects.

The generation of high affinity antibodies is dependent on somatic hypermutation (SHM). SHM is initiated by the activation induced cytosine deaminase (AID) which generates U:G mismatches in the B-cell receptor encoding genes. Error-prone and error-free processing of U:G mismatches creates a typical spectrum of point mutations. Limitations in obtaining genetically defined patient material has prohibited the generation of SHM data sets to test if and to what extend insights on SHM in mice apply to humans.
We performed next generation sequencing of the B-cell receptor heavy chain locus in a unique group of patients with bi-allelic mutations in genes involved in BER (*UNG*), or MMR (*MSH2, MSH6,* or *PMS2*). Our ARGalaxy analysis pipeline revealed a selective skewing of SHM patterns in all patients emphasizing the importance of UNG, MSH2, MSH6 and PMS2 in processing SHM intermediates. Our results are best compatible with a five pathway model of SHM: (1) replication opposite U generates C/G to T/A transitions; (2) translesion synthesis across UNG-generated abasic site generates C/G transitions and transversions; (3) long-patch BER involving UNG and polymerase eta generates MSH2/MSH6-independent A/T mutations; (4) a major MSH2/MSH6 dependent A/T mutation pathway involving polymerase eta; (5) the MSH2/MSH6 and UNG hybrid pathway that generates a substantial proportion of G/C transversions. PMS2 is important in the generation of SHM, however its exact contribution remains unclear.
This study is the first applying NGS on genetically well-defined human B cell samples and establishes the 5 pathway model for the mechanism of SHM based on human data.

Systemic Lupus Erythematosus (SLE) is considered as prototypic autoimmune disease and although heavily studied remains enigmatic. SLE is rare in children but if occurs early in life, it is associated with considerably higher morbidity and mortality. In the assumption that in Pediatric SLE (pSLE) a stronger genetic component is expected, we performed exome sequencing in 25 severe, early onset familial pSLE patients. Consanguinity, disease severity and multiple-case families were considered as priority in patient recruitment. Apart from known disease causing complement deficiencies (*C1Q* deficiencies) which have been reported previously, we identified several unexpected disease causing variants to date reported in the context of primary immunodeficiency rather than SLE. While 5 patients showed *C1QA*, *C1QB* and *C1QC* deficiency, mutations in several other genes such as *TREX1*, *PRKCD*, *DNASE1L3* and *ACP5* were identified. In total we could solve 40% of the cases by this approach and out of 25 we had 20% *C1Q* deficiency. Although *C1Q* detection is possible by other methods, sequencing provides a fast and unbiased method to identify disease etiology in SLE patients apart from complement deficiency. Moreover, identification of the molecular diagnosis is crucial for treatment stratification and genetic counselling in these families.

The phagocyte respiratory burst is mediated by the phagocyte NADPH oxidase, a multi- protein subunit complex that facilitates production of reactive oxygen species and which is essential for host defence. Monogenic deficiency of individual subunits leads to chronic granulomatous disease (CGD), which is characterized by an inability to make reactive oxygen species, leading to severe opportunistic infections and auto-inflammation. However, not all cases of CGD are due to mutations in previously identified subunits. We recently showed that Eros, a novel and highly conserved ER-resident transmembrane protein, is essential for the phagocyte respiratory burst in mice because it is required for expression of gp91phox-p22phox heterodimer, which are the membrane bound components of the phagocyte NADPH oxidase.
We now show that the function of EROS is conserved in human cells. CRISPR-mediated deletion of EROS in human PLB-985 cells abolished expression of gp91phox and p22phox as well as the phagocyte respiratory burst. Both gp91phox-p22phox expression and reactive oxygen species production could be restored to such cells by lentivirally mediated restoration of EROS expression. Further, we describe a case of CGD secondary to a homozygous EROS mutation that abolishes EROS protein expression. This work demonstrates the fundamental importance of EROS in human immunity and describes a novel cause of CGD

P.A6.02.17

Mucosal macrophages express elevated levels of HDAC9 in inflamed and uninflamed mucosa of Crohn's disease, but not ulcerative colitis

M. Ghiboub[1], *J. de Bruyn*[1], *C. Wichers*[2], *T. Radstake*[2], *K. Reedquist*[2], *M. Wildenberg*[1], *J. C. Broen*[2], *D. Geert R*[1], *W. de Jonge*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Utrecht Univeristy Medical Center, Utrecht, Netherlands.*

Histone-deacetylases (HDACs) are a group of enzymes that control histone/non-histone deacetylation. Certain members of HDAC family control the function of macrophages. We aimed to study the expression of HDACs in mucosal macrophages isolated from inflammatory bowel diseases (IBD) patients.
Macroscopically inflamed and non-inflamed colon resection tissue were collected from 15 Crohn's disease (CD) and 9 ulcerative colitis (UC) patients operated on for therapy refractory disease. Lamina propria was separated from the muscularis externa, and a targeted array for epigenetic enzymes was performed.
From our array, gene expression of HDAC9 in non-inflamed mucosa from CD was elevated compared to non-inflamed mucosa from UC (p=0.005). In addition, in CD, HDAC9 mRNA level was increased in inflamed tissue in comparison to non-inflamed tissue (p=0.046). To assess the relevance of HDAC9 gene expression in terms of protein level, immunofluorescence staining of HDAC9 protein was undertaken in tissue sections from inflamed and non-inflamed mucosa. CD68 was used as a pan-macrophage marker. In conjunction with the expression data, HDAC9 protein was found highly expressed in inflamed tissue. HDAC9 was predominantly localized in the cytoplasmic compartment of macrophages in non-inflamed tissue, whilst HDAC9 localized to the nucleus of macrophages in inflamed tissue. We suggest here, that HDAC9 can serve as an additional marker to distinguish CD from UC in tissue biopsies. Furthermore, we show for the first time that HDAC9 protein is expressed in mucosal macrophages of CD patients, indicating its potential in mediating macrophages function in IBD. Further studies are currently being undertaken to elucidate the role of HDAC9 in CD pathogenesis

Dichloroacetate and metformin sensitize human tumor cells to the cytotoxic action of NK cells and CTL

J. Marco-Brualla[1], *N. Allende-Vega*[2], *O. Gonzalo*[1], *I. Marzo*[1], *M. Villalba*[2], ***A. Anel***[1];
[1]*University of Zaragoza, Zaragoza, Spain,* [2]*Institute for Regenerative Medicine and Biotherapy (IRMB), Montpellier, France.*

Introduction: Dichloroacetate (DCA), an inhibitor of pyruvate dehydrogenase kinase, forces cells to obtain energy through mitochondrial oxidative phosphorylation and is used in the treatment of lactic acidosis. Metformin is the most common treatment of type II diabetes, and decreases glucose concentration in blood. It inhibits mitochondrial complex I, but has pleiotropic effects, e.g., activation of AMPK.
Materials and Methods: Several leukemic or multiple myeloma cell lines were supplemented for 72h with non toxic concentrations of DCA or of metformin, and then they were used in cytotoxic assays with expanded allogeneic NK cells or cytotoxic T lymphocytes (CTL). Results: DCA sensitizes the human multiple myeloma MM1.S to cytotoxicity exerted by NK cells and by CTL. The combined blocking of NKG2D ligands and LFA-1 abrogates DCA sensitization to CTL without affecting basal cytotoxicity. LFA-1 blocking abrogates NK cell cytotoxicity on MM1.S cells and, in consequence, also DCA sensitization. On the other hand, metformin sensitizes the human B-CLL cell line Mec1 to CTL and especially to NK cells. This sensitization is also observed in Mec1 cells overexpressing the anti-apoptotic proteins Bcl-x_L. LFA-1 blocking, but not NKG2D ligand blocking, abrogates the metformin-induced sensitization to NK cells observed on Mec1 and on Mec1-Bcl-x_L cells. Finally, metformin sensitization to NK cell cytotoxicity on Mec1-Bcl-x_L cells is partially prevented by death receptor blocking. All these data offer a new approach to the improvement of tumor immunotherapy by the combination with metabolic inhibitors.

P.B1.01.02

The influence of tetraspanin CD37 on the expression and distribution of CD20 on lymphoma B cells

A. B. Arp, *C. M. de Winde, M. Bezembinder, E. Jansen, S. J. van Deventer, A. B. van Spriel;
Department of Tumor Immunology, Radboud Institute for Molecular Life Sciences, Radboud university medical center, Nijmegen, Netherlands.*

Immune cell function is heavily dependent on the proper localisation of many surface molecules. This localisation is for a large part orchestrated by tetraspanin proteins. This superfamily of 4-transmembrane proteins forms protein clusters to ensure proper distribution of surface receptors needed for immune cell interactions. Tetraspanin CD37 is exclusively expressed by immune cells, with its highest expression on B cells. Recent findings of our group show a critical role for CD37 expression in the clinical outcome of patients suffering from aggressive B cell lymphoma.
The standard treatment for B cell lymphoma is a combination therapy using chemotherapy (CHOP) and the anti-CD20 antibody Rituximab. Patients with CD37-negative lymphoma respond less to this combination therapy, indicating that CD37 controls expression and/or distribution of CD20 on the cell surface. This is supported by preliminary data showing that lymphoma cell lines lacking CD37 often also lack CD20 expression. Importantly, these B cell lines are less responsive to Rituximab treatment when compared to CD37-positive lymphoma cell lines.
We aim to elucidate the role of CD37 in the expression, distribution and localisation of CD20 on healthy B cells, lymphoma cell lines and patient lymphoma cells. We established an extensive array of aggressive B cell lymphoma models in which CD37 expression is manipulated by either overexpression or complete knock-out using the CRISPR/Cas9 technique. This study not only provides fundamental insights into how CD37 organises the B cell membrane, but also contributes to the development of new immunotherapies for patients with aggressive B cell lymphoma.

P.B1.01.03

Melanin is superior to other adjuvants to trigger CD8 T cells in subunit vaccines

*C. Banissi[1], F. Sejalon[1], T. Tran[2], E. Tartour[2], **A. F. Carpentier**[1];*
[1]Hopital Saint Louis, Paris, France, [2]INSERM U970, Paris, France.

Introduction: Synthetic melanin bound to subunit vaccine antigens enhances CD8+ T-cell responses in mice, when combined with a TLR9 agonist. We here compared the efficacy of various vaccine adjuvants, alone or in combination with melanin, to trigger CD8 T-cell responses. Material and Methods: Two peptides containing a gp100 or an ovalbumine epitope were mixed with L-Dopa and further oxidized to generate melanin-bound peptides. Different TLR9 agonists (CpG-28, 1826, ISS), polyinosinic-polycytidylic acid (Poly-IC), Freund adjuvant (v/v), or aluminium hydroxide (Alum, v/v) were used as adjuvants in vaccine formulations. C57BL/6 mice were immunized subcutaneously (n=8/group), and the CD8 immune response was assessed with epitope-specific IFNγ production by splenocytes. Results: When Alum was used as an adjuvant, no significant CD8 response was seen, even with melanin-bound peptides. With Freund adjuvant, combined or not with a TLR9 agonist, a mild CD8 response was seen using either free or melanin-bound peptides. On the contrary, both TLR9 agonists and poly-IC elicited a CD8 T-cell response with free peptides, and this response was several fold enhanced when melanin-bound peptides were used, making this combination an order of magnitude greater than any others. Analysis of dextramer$^+$ CD8$^+$ cells showed an effector memory CD8$^+$ T-cells phenotype. The minimal dose of peptides required to trigger immunity was 0.5 µg. Immunization against the ovalbumin epitope inhibited the growth of ovalbumin-positive tumors. Conclusion: The conjugation of synthetic melanin to peptides represents a very simple means of triggering CD8 T-cell response, which should be particularly useful in cancer immunotherapy against neo-epitopes.
