[1]Clinical Laboratory,Linan People's Hospital, Hangzhou, China, [2]Institute of Immunology,School of Medicine,Zhejiang University, Hangzhou, China.

Cervical cancer is the second most common cancer among women worldwide and remains a clinical problem despite improvements in early detection and therapy. HPV DNA vaccines have become an attractive approach to treat HPV-related cancer. To investigate the effect of STING in immune response induced by plasmid encoding HPV E6E7 protein and to explore new strategies for prophylactic and therapeutic HPV DNA vaccines, C57BL/6 mice and TC-1 tumor cell bearing mice were immunized with pVAX-E6E7 alone or co-immunized with pVAX-STING. The specific CTL response and Th1 cell response were also assayed. The co-immunization of pVAX-STING and pVax-E6E7 significantly inhibited the growth of TC-1 after immunization and prevent the TC-1 tumor cell bearing mice from developing into tumor compared with the mice immunized with pVax-E6E7 alone. Furthermore, the immunological mechanism behind immune enhancing effect of STING can be attributed to increased cytotoxic T lymphocyte, accompanied by the up-regulation of Th1-cytokine IFN-γ. The result showed that co-administration of STING could elicit stronger immune response induced by HPV DNA vaccines and It provided scientific basis for the further use of STING as a HPV DNA vaccine adjuvant. This work was supported by grants from Zhejiang Provincial Natural Science Foundation of China (No. LY14H100003), Science and Technology Department of Zhejiang Province(No.2016C37121) and Health and Family Planning Commission of Zhejiang province (No.2016KYB032)

Maturation of dendritic cells (DC) is considered critical in cancer immunotherapy. Among different human subsets, BDCA-3 (CD141high-Clec9A$^+$), promote CD8 T-cell cross-priming against tumor antigens. Here, we evaluate two clinical grade stimuli for peripheral blood BDCA3 myeloid dendritic cells (mDCs), a rare DC subset that is currently being explored for use in immunotherapy. We applied an unbiased transcriptome-based method using both RNA-sequencing (RNA-seq) and microarraysIn particular, we analyzed the mRNA of human BDCA3$^+$ mDCs upon activation with two clinical-grade adjuvants, Hiltonol (poly ICLC, a TLR3 ligand) and protamine RNA (pRNA, aTLR7/8 ligand), and compared the data to unstimulated counterparts. Our results, based on both RNA-seq and microarray data, showed that Hiltonol and pRNA lead to almost identical changes in BDCA3 mDCs, both at the transcriptome and at protein levels. The gene ontology (GO) term analysis suggests that these changes were mainly related to activation and maturation pathways, including induction of type I IFN and IL-12 transcription, while pathways related to adverse effects or cell damage were not significantly affected. The combination of both stimuli in the DC cultures gave a very similar result as compared to either stimulus alone, suggesting no synergistic effect. To sum up, our results indicate that both Hiltonol as well as protamine mRNA are equally potent clinical grade adjuvants with comparable effects on BDCA3 mDCs after short-term culture. This paves the way for introducing BDCA3 mDCs into a clinical setting.

Anti-tumoral potential of granulysin-containing protein products directed against the Tn antigen*

***P. Guerrero**[1], R. Ibáñez[1], F. Corzana[2], R. Hurtado-Guerrero[3], A. Anel[1];*
[1]University of Zaragoza, Zaragoza, Spain, [2]La Rioja University, Logroño, Spain, [3]Institute for Biocomputation and Physics of Complex Systems (BIFI), Zaragoza, Spain.

Introduction: Granulysin is a protein present in the granules of human CTLs and NK cells, with cytolytic activity against microbes and tumors. Previous work from our group demonstrated the *in vivo* antitumoral activity of intratumoral injection of recombinant granulysin in two animal models of tumor development, breast adenocarcinoma and multiple myeloma. In the present work we have developed two granulysin-containing protein products directed against the MUC1 Tn antigen, expressed in several types of solid tumors. Material and Methods: 1) Recombinant granulysin or the protein products were tested for binding to cells negative for the MUC1 Tn antigen expression (MDA-MB-231), or to Tn$^+$ cells (Jurkat and MCF7) by flow cytometry and fluorescence microscopy. 2) Recombinant granulysin or the protein products were tested against cells negative for Tn expression (MDA-MB-231) or on Tn$^+$ cells (Jurkat and MCF7) and cell death was analyzed by annexin-V staining and 7-AAD incorporation. Results: We demonstrated that the protein products recognized the Tn antigen in an specific fashion on Tn-positive tumor cells. In addition, the bioactivity of the protein products against tumor cell lines expressing Tn is higher than that of granulysin alone. *The "protein products" are under patent tramitation

A novel marker for M2-polarization: Migration Stimulating Factor promotes monocyte chemotaxis

*T. Gulic[1,2], I. Laface[1], A. Inforzato[1,3], M. Oliveira[4], F. Petroni[1], S. Valentino[1], S. Davudian[1], P. Allavena[1], **B. Bottazzi**[1], A. Mantovani[1,3,5];*

Chronic inflammation is a well-known key component in preparing tumour microenvironment to acquire all the hallmark capabilities for tumour growth.Besides neoplastic cells, the tumor-associated macrophages (TAMs) are the principal leukocyte subset in tumour microenviroment directly affecting different biological activities, including neoplastic cell growth, neoangiogenesis, and extracellular matrix remodelling. Increasing evidences correlated the levels of tumor-associated macrophages (TAMs) with bad prognosis. We recently identified in M2 polarized macrophages up-regulation of a set of genes among which is Migration Stimulating Factor (MSF),a truncated isoform of fibronectin 1 initially described in fetal fibroblasts and tumor cells. Here we report that MSF was induced mostly by M-CSF, IL-4 and IL-10 but not by proinflammatory stimuli. RNA analysis clearly demonstrated that it is selectively associated with the M2 polarization of macrophages. We developed original reagents (recombinant protein, monoclonal antibodies) for MSF study. MSF production was confirmed by immunohistochemistry and immunofluorescence in human tumour cells and TAMs. Double immunostaining indicated that most of the CD68, CD206 and CD163 positive cells expressed MSF. rhMSF strongly stimulated tumor cells, monocytes and possible neutrophils migration, while it did not affect motility of NK, CD4$^+$and CD8$^+$cells.Checkerboard analysis revealed MSF as a gradient-dependent chemotactic molecule for human monocytes.These results suggest that MSF may facilitate monocyte extravasation and migration, a crucial event into inflame tissue. Modulating monocyte migration, MSF might promote and/or sustain a permissive microenvironment for cancer growth.

P.B1.01.08

Intra-tumoral production of IL18, but not IL12, by TCR-engineered T cells is non-toxic and counteracts immune evasion of solid tumors

***A. Kunert**[1], M. Chmielewski[2], R. Wijers[1], C. Berrevoets[1], H. Abken[2], R. Debets[1];*
[1]Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]University Hospital Cologne and Center for Molecular Medicine Cologne, Cologne, Germany.

Adoptive therapy with engineered T cells shows promising results in treating patients with malignant disease, but is challenged by incomplete responses and tumor recurrences. Here, we aimed to direct the tumor microenvironment in favor of a successful immune response by local secretion of interleukin (IL-) 12 and IL-18 by administered T cells. We engineered T cells with a melanoma-specific T cell receptor (TCR) and murine IL-12 and/or IL-18 under the control of a nuclear-factor of activated T-cell (NFAT)-sensitive promoter. These T cells produced IL-12 or IL-18, consequently enhancing levels of IFNγ, following exposure to antigen-positive but not negative tumor cells. Adoptive transfer of T cells with a TCR and inducible (i)IL-12 to melanoma-bearing mice resulted in severe, edema-like toxicity accompanied by enhanced levels of IFNγ and TNFα in blood, and reduced numbers of peripheral TCR transgene-positive T cells. In contrast, transfer of T cells expressing a TCR and iIL-18 was without side effects, enhanced the presence of therapeutic CD8+ T cells within tumors, reduced tumor burden and prolonged survival.

Treatment with TCR+iIL-12 but not iIL-18 T cells resulted in enhanced intra-tumoral accumulation of macrophages, accompanied by a decreased frequency of therapeutic CD8+ T cells. In addition, when administered to mice, iIL-18 but not iIL-12 demonstrated a favorable profile of T cell co-stimulatory and inhibitory receptors. In conclusion, we observed that treatment with T cells engineered with a TCR and iIL18 T cells is safe and able to skew the tumor microenvironment in favor of an improved anti-tumor T cell response.

P.B1.01.10

IL-12-dependent Th1 priming by a DC vaccine in vivo requires cooperation of dendritic cells subsets

*D. Ashour, **M. B. Lutz**;*
University of Würzburg, Würzburg, Germany.

The production of heterodimeric IL-12p70 by injected vaccine dendritic cell (DCs) has been classically described as a key factor required for generating polarized T helper type-1 cell response (Th1). However, cocktail-matured DCs do not secrete IL-12 but readily induce Th1 responses when injected into mice and humans. Here, we tested for DC-DC cooperation enabling bystander IL-12 production for Th1 polarization in a DC vaccination model. Subcutaneously injected LPS-matured and OVA peptide loaded bone marrow-derived DCs (BM-DCs) migrated to the draining lymph node in the recipient mice and induced responder CD4+ OT-II T cells to polarize into Th1 cells. Injected CCR7-/- DCs, which lack migratory capacity, failed to induce OT-II cell priming and Th1 induction, indicating that the injected DCs provide the peptide presentation and costimulation. DC vaccination increased also the migration of all endogenous skin-resident DC subsets to the draining lymph nodes. However, only the $CD103^+$ dermal DCs showed increased IL-12p40-YFP production culminating at 72h after BM-DC injection. Surprisingly, injections of BM-DCs derived from p35-/- mice did not affect Th1 priming, while deficiency of p35 in the recipient mice abrogated the IL-12-dependent Th1 priming, which indicates that IL-12 production by endogenous DCs and not the injected BM-DCs is required for Th1 priming in this DC vaccine model in the draining lymph node. Further studies will show the requirement of IL-12 from $CD103^+$ dDCs for Th1 priming. Together, our data indicate that DC vaccines require a cooperation with endogenous DCs for optimal Th1 polarization of CD4+ T cells.

P.B1.01.11

Gene-edited chimeric antigen receptor (CAR) T cells: Tuning up for the next generation cancer immunotherapy

***H. R. Mirzaei**[1], F. Raghami[2], H. Mirzaei[2];*
[1]Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [2]Isfahan University of Medical Sciences, Isfahan, Iran, Islamic Republic of.

Recently clinical trials utilizing genetically engineered T cells expressing a chimeric antigen receptor (CAR) that is half monoclonal antibody and half T-cell receptor have demonstrated remarkable response in patients with advanced cancers like relapsed or refractory acute lymphoblastic leukemia (ALL) and lymphoma. Moreover, emerging chimeric genome editing tools such as zinc-finger nucleases (ZNFs), transcription activator-like effector nucleases (TALENs) and clustered regulatory interspaced short palindromic repeat (CRISPR)/Cas composed of sequence-specific DNA binding module(s) linked to a non-specific DNA cleavage domain have made possible to dramatically expand the ability to manipulate cells aim to treat and/or study a wide range of diseases including cancer. Here, we will discuss how joint application of these two chimeras will help us to manipulate CAR T cells aiming to enhance the efficacy of CAR T cell therapy in preclinical and clinical settings.

P.B1.01.12

Effects of ionizing radiations on T and B lymphocytes: a comparison between photons and protons

*F. Novelli[1], M. Vadrucci[2], M. M. Rosado[3], L. Picardi[2], C. Ronsivalle[2], E. Benvenuto[4], C. Marino[1], **C. Pioli**[1];*
[1]ENEA, Division of Health Protection Technologies, Rome, Italy, [2]ENEA, Laboratory of Development of Particle Accelerators and Medical Applications, Rome, Italy, [3]Freelance Research Consultant in Immunology, Rome, Italy, [4]ENEA, Laboratory of Biotechnology, Rome, Italy.

Photon radiotherapy (γ/X-rays) is widely used to treat a large variety of cancers, while particle-based radiotherapy (protons or carbon ions) represents a developing and valuable option, especially for cancers requiring more focused treatments. Indeed, proton beams display low entrance dose, uniform high dose on targeted tumor (spread-out-Bragg peak) and near zero dose beyond it, thus preserving not targeted tissues. Recent studies indicated that photon and particle radiations produce different biological effects, with relevant outcomes once combined as radio/immune-therapies.
We compared the effects of local *in vivo* exposure (2 Gy) to medium energy proton and X-ray beams on mouse lymphoid spleen cells. Proton irradiation was carried out with the 27 MeV beam produced by the TOP-IMPLART pulsed linear accelerator. For X-rays, a CHF320G generator (250 kV, 15 mA) was used. During the exposure, mice (C57Bl/6) were anesthetized; not targeted areas were protected by shields. At different time points after irradiation (1-28 days), mice were analyzed for number and phenotype of different T (CD4/CD8/Foxp3) and B (IgM/IgD) cell subsets, B and T cell proliferation, cytokine production (IL-2, IFNγ, IL-4, IL-17, IL-6, TNF, IL-10), and antibody production (IgM, IgG). Altogether, the results showed that local exposure to X-rays or protons induced changes in many of the analyzed parameters, with different effects and recovery time depending on the type of radiation used.
This research was partially supported by the BIOxTREME (Italian Space Agency) and the TOP-IMPLART (Regione Lazio, Italy) projects.

Activation of murine splenocytes against tumor cells by sensitization with babassu mesocarp

***L. P. Pontes**, J. G. Junior, E. A. Moraes, M. C. Pinto, G. C. Costa, R. N. Guerra, F. R. Nascimento, A. S. Santos;*
Federal University of Maranhão, São Luis, Brazil.

Introduction: *Attallea speciosa* Mart. (babassu) fruit contains a mesocarp that is rich in carbohydrates with immunomodulatory effects. The induction of the tolerogenic response is a tumor escape mechanism, and immunomodulator adjuvants have been studied to reestablish host immunogenicity. This study evaluates the adjuvant potential of babassu mesocarp carbohydrates in a tumor model. Materials and Methods: The polysaccharide obtained from aqueous babassu extract (20 mg/ml) was used tosensitizationthe animals inoculated or not with the tumor to obtain splenocytefor the phenotypic characterization and lymphoproliferation assay. Results:The babassu mesocarp extraction (BME) yield was 75.54%, and the total sugar concentration was 29.79 mg/ml-1 containing monosaccharides, reducing sugars, polysaccharides and 0.506 mg/ml-1 total protein. Chromatography analysis identified glucose, sucrose and fructose. Sensitization increased the spleen weight in the tumor group compared with the control, and a comparatively lower frequency of T helper and higher frequency of B-lymphocytes was also observed. The tumor+BME group had more cytotoxic T lymphocytes compared with the control. After co-culture with cancer cells, the tumor splenocytes showed lower proliferation, lower frequency of T helper cells and higher concentrations of interleukin (IL)-2, IL-6 and IL-10. However, the tumor+BME splenocytes presented results similar to the control, suggesting a reduction in the regulatory response of the tumor group. Conclusions:These results demonstrated that BME sensitization with cancer cells modulated an immune response in Balb/c animals, indicating an immunogenic effect. Key words: Arecaceae, *Attallea speciosa* Mart., adjuvant, carbohydrate, antitumor.

HPMA copolymer-bound doxorubicin as an endogenous vaccine substantially increases the therapeutic effects of check-point blockade monoclonal antibodies

***B. Rihova**[1], T. Etrych[2], R. Stepankova[3], V. Subr[2], K. Ulbrich[2], M. Kovar[3], M. Sirova[3];*
[1]Institute of Microbiology AS CR, Prague, Czech Republic, [2]Inst. Macromolecular Chemistry AS CR, Prague 6, Czech Republic, [3]Institute of Microbiology AS CR, Prague 4, Czech Republic.

DOX^{HYD}-pHPMA is doxorubicin bound to a synthetic polymeric carrier based on *N*-(2-hydroxypropyl)methacrylamide via a pH-sensitive hydrazone bond. It is effective anticancer polymeric prodrug with decreased side-toxicity and the ability to induce immunogenic cancer cell death releasing tumor antigens and thus acting as endogenous vaccine. We investigated a novel combination strategy using low dose of DOX^{HYD}-pHPMA and immune checkpoint blocking anti-CTLA-4 and anti-PD-1 mAbs to treat EL4 T cell lymphoma and 4T1 breast carcinoma. Acute model of disease when mice are transplanted once with a lethal dose of tumor cells was compared with chronic model where mice are injected six times every other day with a low number of tumor cells. Significant toxicity of anti-CTLA-4 and anti-PD-1 mAbs was seen in mice suffering from acute disease. Mice with chronic cancer respond to treatment much better than those with acute disease. Therapy with anti-CTLA-4 and/or with anti-PD-1 only led to twenty-five percent survival of the treated mice, which were considered long-term-survivors (LTS). On the other hand more than 60% of mice injected also with therapeutically suboptimal dose of DOX^{HYD}-pHPMA survived disease-free for more than 100 days. In germ-free mice, tumor grow was more aggressive, and the survival time was shorter. Treatment with DOX^{HYD}-pHPMA showed only limited anti-cancer effects while the combination with the anti-CTLA-4 monoclonal antibody significantly improved the therapeutic outcome. The best results were seen in germ-free mice monocolonized with *B. thetaiotaomicron.* This work was supported by the Ministry of Health CR (grant number 16-28600A) and the CSF (grant number 17-08084S).

P.B1.01.15

PD-L1 expression according to five monoclonal antibodies in urothelial cell cancer: concordance and clinical implications

M. Rijnders[1], *A. van der Veldt*[1], *T. Zuiverloon*[1], *J. Boormans*[1], *E. Zwarthoff*[1], *K. Grünberg*[2], *E. Thunnissen*[3], *M. Lolkema*[1], *R. Debets*[1], *R. de Wit*[1], *A. van Leenders*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Radboudumc, Nijmegen, Netherlands,* [3]*VUmc, Amsterdam, Netherlands.*

Introduction High PD-L1 expression is frequently applied as an inclusion criterion or stratification factor in clinical trials on immune checkpoint inhibitors (ICIs). However, the predictive value of PD-L1 in urothelial cell cancer (UCC) shows conflicting results, which may be confounded by the use of different PD-L1 companion diagnostics. The objective of this study was to accurately compare PD-L1 expression of five commercially available PD-L1 antibodies in UCC patients. **Methods** Tissue Microarrays (TMA) containing samples of 141 muscle-invasive UCC patients (≥pT2) were stained with the anti-PD-L1 antibodies 22C3, 28-8, SP142, SP263 and E1L3N on the Ventana Benchmark (SP142, SP263) and DAKO platforms (22C3, 28-8, E1L3N). PD-L1 expression was manually scored on tumor cells and infiltrating immune cells according to corresponding assay specifications used in clinical trials. **Results** PD-L1 expression was found to be positive in 20% (SP263), 21% (SP142), 23% (28-8), 27% (22C3), and 27% (E1L3N) of cases. No relations between clinicopathologic parameters and PD-L1 expression were observed. Concordance in treatment-determining score varied from 72% to 90% and was lowest for E1L3N (mean 75%). Considering only companion diagnostic tests 22C3, 28-8, SP142 and SP263, PD-L1 status was concordant in 78% of patients. When one test result was discordant (n=15; 11%), SP142 (n=7) and 28-8 (n=5) were most likely different. **Conclusion** Agreement of PD-L1 assessment is good with similar PD-L1 status by four antibodies used in companion diagnostic tests. Therefore, application of different companion PD-L1 antibodies and platforms may have limited effects on therapeutic decision making in ICI treatment.

P.B1.01.16

Oncolytic adenovirus coding for TNFa and IL-2 removes the need for lymphodepleting preconditioning in adoptive T-cell therapy

J. Santos[1,2], *V. Cervera-Carrascon*[1,2], *R. Havunen*[1,2], *S. Zafar*[2], *M. Siurala*[1], *S. Sorsa*[1], *M. Anttila*[3], *A. Hemminki*[1,2,4];
[1]*TILT Biotherapeutics Ltd, Helsinki, Finland,* [2]*Cancer Gene Therapy Group, Helsinki, Finland,* [3]*Finnish Food Safety Authority (EVIRA), Helsinki, Finland,* [4]*Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland.*

Introduction: Lymphodepleting preconditioning with high-dose chemotherapy remains a critical component for the clinical effectiveness of several adoptive T-cell therapy (ACT) strategies. This preconditioning step boosts the antitumor efficacy of transferred T cells through the decrease of tumor immunosuppression, however, with severe toxicity for patients. In contrast, oncolytic adenoviruses are safe and when engineered to express interleukin-2 (IL-2) and tumor necrosis factor alpha (TNFa), they can achieve immunomodulatory effects similar to lymphodepleting preconditioning.
Materials and Methods: Here, we compare the safety and efficacy of such adenovirus with a cyclophosphamide and fludarabine lymphodepleting regimen in the context of ACT. Since Syrian hamsters allow replication of a human adenovirus (Ad5/3-E2F-D24-hTNFa-IRES-hIL2; TILT-123), we used a pancreatic tumor model (HapT1) in syngeneic hamsters infused with tumor infiltrating lymphocytes (TIL). To study immune cells responsive to TNFa and IL-2, we used an immunocompetent mouse melanoma model (B16.OVA) infused with ovalbumin-specific T cells.
Results: Animals receiving oncolytic adenovirus therapy demonstrated better tumor growth control and survival compared with those receiving lymphodepleting preconditioning. Moreover, the adenovirus approach increased the levels of Th1-type cytokines and infiltration CD3+ T cells and CD11c+CD86+ dendritic cells. While lymphodepleting preconditioning resulted in severe toxicities in the heart and lungs, adenovirus therapy caused minimal changes in treated animals.
Conclusion: Overall, this data shows that ACT protocols using oncolytic adenovirus expressing IL-2 and TNFa do not require high-dose preconditioning chemotherapy. Clinical translation is ongoing in a Phase I clinical trial where melanoma patients administered with TIL therapy receive TILT-123 instead of lymphodepleting chemotherapy.

P.B1.01.17

Tumor-type-specific spatio-temporal shifts of lymphoid and myeloid populations during tumor growth and checkpoint blockade

S. T. T. Schetters*, L. J. Kruijssen, M. H. Crommentuijn, Y. Van Kooyk;*
VU University Medical Center, Amsterdam, Netherlands.

Suppression of the immune system by solid malignancies has proven to be a driving force of tumor development and an effective target for therapeutic intervention. Especially the suppression of cytolytic T cells through inhibitory receptors, like PD-1 and CTLA-4, can be blocked by antagonistic antibodies, reinvigorating existing anti-tumor responses. However, it unclear whether immune checkpoint interactions are heterogeneous within the tumor, how these interactions develop during tumor growth and which cell types interact in the tumor microenvironment. By using high dimensional flow cytometry and unsupervised clustering analyses based on immune checkpoints, we show heterogeneity of tumor-infiltrating $CD8^+$ and $CD4^+$ T cells in murine B16 melanoma and MC38 colorectal carcinoma. Also, we show that the myeloid- and tumor cell compartments provide the ligands for immune checkpoint suppression. Next, we show that therapeutic intervention using anti-PD1 treatment, changes lymphoid and myeloid populations and existing immune checkpoint interactions within the tumor. Finally, we reconstruct the tumor microenvironment using 8-color confocal microscopy and histocytometry analysis to spatially reconstruct the changing immune compartments of the tumor microenvironment.

P.B1.01.18

Human Monoclonal IgGs derived from patients with Multiple Myeloma are able to penetrate living neoplastic cells and induce apoptosis

T. Stivarou[1], *I. Sarrigeorgiou*[1], *P. Chalas*[1], *A. Tsirogianni*[2], *P. Lymberi*[1], ***C. Tsigalou***[2];
[1]*Immunology Laboratory, Immunology Dept. Hellenic Pasteur Institute, Athens, Greece,* [2]*Immunology-Histocompatibility Dept. "Evaggelismos" General Hospital, Athens, Greece.*

Introduction:Antibodies able to penetrate living cells (CPAbs) have been well characterized in patients with SLE and in mouse models. Our lab has described the existence of CPAbs in health, derived either from unimmunized BALB/c mice or from intravenous immunoglobulin (IVIg).The development of human monoclonal IgG-CPAbs is of major importance in drug delivery and in cancer immunotherapy. The aim of the present study was to identify such mAbs among serum monoclonal immunoglobulins (M-IgG) from patients with Multiple Myeloma (MM), and further study their intracellular biological functions in neoplastic cells.
Methods:71 sera from IgG-MM patients were studied by in-house ELISAs against 7 self & non-self antigens.We purified 6 IgG, 5 polyreactive & 1 non-polyreactive by protein-G affinity chromatography and tested them in optimum conditions for ability to: 1) penetrate FcγR+ (Raji & MDA-MB-231) and FcγR- (NIH-3T3 & HeLa) cells by immunofluorescence,2) induce apoptosis on these cells by flow cytometry, and 3) hydrolyze plasmid &genomic DNA.
Results:The 5 purified M-IgGs tested were able to penetrate all cells, either FcγR+ or FcγR-, at 37oC in a dose- and time-dependent mode of entry, while 3/5 also penetrated cells at 4oC (energy-independent entry). All M-IgGs were polyreactive, accumulated in the cytoplasm, induced apoptosis especially in MDA-MB-231 cells, and hydrolyzed plasmid DNA isoforms(1/5 also hydrolyzed genomic DNA).
Conclusion:The IgG-MM sera represent an excellent source of human mIgGs exhibiting cell-penetrating ability and intracellular functionality, and can be exploited as a potential therapeutic tool, used either per se, or as carriers for intracellular drug delivery, or even both.

Highly specific targeting of human acute myeloid leukaemia (AML) cells using functionalised gold nanoparticles

I. M. Yasinska[1], *B. F. Gibbs*[1], *R. Hussain*[2], *G. Siligardi*[2], *E. Fasler-Kan*[3], *L. Calzolai*[4], *V. V. Sumbayev*[5];
[1]*University of Kent, Chatham Maritime, United Kingdom,* [2]*Diamond Light Source, Didcot, United Kingdom,* [3]*University Hospital Bern, Inselspital, Bern, Switzerland,* [4]*European Commission Joint Research Centre, Ispra, Italy,* [5]*University of Kent and Greenwich, Chatham Maritime, United Kingdom.*

Highly specific targeting of human malignant cells with the purpose of recognition and delivery of specific drugs into them is a very promising but not well developed complex of diagnostic and therapeutic strategies. It is a major focus of current molecular cancer research, Immunology and Nanomedicine. In this study we demonstrated for the first time a new approach for highly specific targeting of human acute myeloid leukaemia (AML) cells by functionalised gold nanoparticles carrying single-chain antibody against the immune receptor Tim-3 and rapamycin. Tim-3 is highly expressed in human AML cells. It is one of the key components of Tim-3/galectin-9 secretory pathway which is crucial for survival of malignant cells since it determines their ability to escape host immune surveillance. Thus, Tim-3 can be used as a target for specific recognition of AML cells. Rapamycin inhibits activity of mammalian target of rapamycin (mTOR), a master regulator of translational pathways in AML cells. Inhibiting the mTOR leads to a rapid killing of AML cells. Using these nanoconjugates we managed to successfully deliver rapamycin into the AML cells reaching attenuation of the mTOR activity. Concentration of rapamycin required to reach such an effect is at least 50 times lower compared to the one of free rapamycin required to achieve similar effect. We therefore concluded that our technology is of potential use for highly specific targeting of AML cells for the purpose of diagnosis and possibly therapy. The nanoconjugates can be used to specifically identify malignant blood cells thus allowing rapid AML diagnosis.

P.B1.01.20

Exosome mediated protective cancer vaccine: in vivo performance

M. Yildirim[1], *I. Evcili*[1], *N. Bozbeyoglu*[1], *G. G. Kaya*[1], *G. Aykut*[1], *G. Gucluler*[2], *A. Kamacıoglu*[1], *G. Alıskan*[3], *I. Gursel*[1];
[1]*Bilkent University-Department of Moleculer Biology and Genetics, Ankara, Turkey,* [2]*2Immunology and Allergy Unit, Department of Medicine Solna, Karolinska Institute, and Karolinska University Hospital, Stockholm, Sweden,* [3]*3Depertmant of Biological Sciences, Middle East Technical University, Ankara, Turkey.*

Exosomes are naturally occurring nanosized vesicles that have attracted considerable attention as drug delivery vehicles. Recently, nanoparticles were explored extensively for drug delivery applications aiming to obtain better therapeutic read-outs due to their low toxicity and biocompatibility. Herein, we describe a simple method to externally load magnetic iron oxide nanoparticles (FeO-NPs) along with TLR ligands within exosomes. The internalization and immunostimulatory activities of unloaded or TLR3, TLR9 ligand and FeO-NP loaded exosomes were analyzed either on RAW264.7 murine macrophage-like cell line or on splenocytes at various time and dose intervals. Furthermore, therapeutic efficacy of exosomes loaded with FeO-NPs and TLR ligands (i.e. Exo(pI:C+CpG+FeO))were tested on hu-HUH7-bearing athymic mice. Our data showed that FeO-NPs loaded exosome (Exo(FeO)) uptake by RAW264.7 and splenocytes enhanced up to 10-fold and 3-fold, respectively compared to unloaded exosomes. Moreover, co-encapsulation of CpG with FeO-NPs (Exo(CpG+FeO)) within exosomes significantly magnified CpGODN internalization by RAW 264.7 macrophages compared to FeO-NP devoid CpG ODN loaded exosomes (Exo(CpG)). As expected, Exo(CpG+FeO) treated splenocytes secreted higher amounts of IL-12 compared to Exo(CpG). Lastly, mice were xenotransplanted with HUH7 cells and palpable tumor formation was formed. Tumor-bearing animals that were treated with Exo(pI:C+CpG+FeO)(3x injections @3day intervals) significantly regressed tumor development compared to free mixture treated group. When exosomal therapeutic vaccine was administered there were >70% tumor mass reduction. In conclusion, this study implicated that loading FeO-NPs and TLR ligands within exosomes offers an effective theranostic approach for developing targeted exosomes that could boost their therapeutic impact.

Implantable, pre-activated microconed-Si scaffold vaccines for cancer therapy

I. Zerva[1], *C. Lanara*[2], *E. Stratakis*[2], *I. Athanassakis*[1];
[1]*Department of Biology, University of Crete, Heraklion, Greece,* [2]*FORTH, Heraklion, Greece.*

Therapeutic vaccines are an active immunotherapy of cancer selection aimed at the patient's therapy using immune system of the patient. Over the years, the lack of effective active immunotherapies for cancer have led to the development of many new strategies. One of the major problems is the failure of development of immune responses against tumor antigens since these are usually recognized as antigens themselves. It has been shown that new tumor-specific antigens is an approximate time-consuming, costly and of limited effectiveness. Previous studies have shown that implantable microstructured 3-dimensional scaffolds can support the adhesion of macrophages and after implantation in vivo causes the necessary inflammatory reaction in the body accompanied by secretion of specific antibody, and development T- and B-cell memory. The proposed investigation is the use of the technology of silicon Scaffold in development of an immune response against cancer cells of the host. The study concludes the experimental breast cancer model in Balb/c mice. After reaching the carcinogenic 4T1 cells, the animals implanted with a pre-activated silica scaffolding to which the antigen is the cell histocompatible 4T1 cell extract. This method allows the natural selection of immunogenic epitopes for the development of specific cellular and humoral response against the tumor. The purpose of the research is to regulate the tolerance balance/host immunity and the development of individualized specific response against the tumor. The application of such technology to humans will be of great importance opening novel areas of research and treatment.

Cessation of thymic activity impairs pTreg differentiation and enhances spontaneous and therapeutic tumor immune-surveillance

J. Almeida-Santos*, M. Bergman, I. Cabral, I. Caramalho, J. Demengeot;*
Instituto Gulbenkian de Ciência, Oeiras, Portugal.

It is well established that depletion or inhibition of regulatory T cells (Treg) in mice and humans, favors immune rejection of solid tumors. While it has been proposed that both thymic- and peripherally-derived Treg (tTreg and pTreg, respectively) can infiltrate the tumor environment, their relative contribution to tumor progression is still unclear. As recent thymic emigrants (RTE) have been shown to be the preferential precursors of pTreg in specific assays, we hypothesize that ongoing thymic activities play a role in tumor immune tolerance.
To test this hypothesis, we assessed whether: i) the higher capacity of RTE to convert into pTreg is also true in a tumor context; ii) newly converted pTreg are required for tumor progression; and iii) thymectomy improves tumor immuno-therapies.
By performing adoptive transfer experiments into lymphopenic hosts, and testing several tumor models, we evidence that immature CD4 cells remain the preferential precursors of pTreg in a tumor context. Using genetically (DEREG) and surgically (Thymectomy) engineered mice to control Treg and RTE numbers in the periphery, we demonstrate that while depletion of Treg limits tumor growth, prevention of pTreg generation through elimination of RTE amplifies this effect. Moreover, we show that limiting thymic activities through thymectomy enhances the efficacy of anti-CTLA-4 immunotherapy.
In conclusion, our work suggests that natural or therapeutic thymic restriction may be beneficial in cancer treatment.

P.B1.02.02

Exploring novel anti-tumor roles of genome-damaging AID/APOBEC3 enzymes in breast cancer

M. Asgharpour*, M. Larijani;*
Immunology and Infectious Diseases Program, Division of BioMedical Sciences, Faculty of Medicine, Memorial University of Newfoundland, St John s, Canada.

Introduction: AID/APOBEC3 cytidine deaminases are genome-editing enzymes that function to boost immunity. It is established that AID/APOBEC3s are an endogenous source of DNA damage leading to initiation and evolution of different cancer types, including breast cancer. We hypothesized that depending on expression levels, AID/APOBEC3s could also have anti-tumor functions.
Methods & Results: We established a first of its kind inducible expression system in which we control expression levels of AID, APBOEC3B and APOBEC3G in breast cancer cells. We verified enzymatic activity of each enzyme and inducible expression of RNA and protein was demonstrated by qRT-PCR, fluorescent microscopy, and flowcytometry. Using MTT, apoptosis and wound-healing migration assays, we observed both tumorigenic and anti-tumor effects depending on different expression levels of the enzymes. The observed effects of AID/APOBEC3s on tumor behavior were in accordance with gene expression levels of key factors involved in cancer cell death and migration as assessed by qRT-PCR.
Conclusion: AID/APOBEC3s play both pro- and anti-tumor roles depending on expression level. This finding represents a paradigm shift as AID/APOBEC3s have thus far been considered strictly as pro-tumor agents. It suggests the possibility of future therapeutic avenues through exploiting these enzymes.
Acknowledgment: This research is supported by funding from CIHR and IDRC. Mahdi Asgharpour is a trainee in the Cancer Research Training Program of BHCRI, with funds provided by TFRI.

Enhanced expression of CCL5 upon the LCMV infection intratumorally leads to the massive NK cells migration to the site of the tumor that further promotes tumor regression

H. A. Bhat[1,2];
[1]*Institute of Immunology, Essen, Germany,* [2]*University Hospital Essen, Instute of Immunology, Uniklinic Esen, Germany.*

In our melanoma model, we used two different human melanoma cells lines Mamel-86A and Mamel-51 we grow both of these cells lines in the NODSCID mice and when the tumor was of measurable size we treated it with lymphocytic choriomeningitis Virus (LCMV) intratumorally. Mamel-86A showed the massive regression where as Mamel-51 turned to be resistant to our therapy. To further, address the question we check the chemokine profile and we also look for interferon upregulating genes and Pro-Apoptotic genes. What we find that many interferon genes are strongly upregulated in the Mamel-86A and in Mamel-51 the expression is very poor likewise, pro-apoptotic genes are also highly expressed in the Mamel-86A compared to the Mamel-51. When we look for the chemokine profile we analysed that CCL5 and CCL10 were strongly upregulated in the Mamel-86A compared to the Mamel-51, But CCL5 showed the highest upregulation than all other chemokines. To further address this question of massive regression upon LCMV infection in Mamel-86A we focused on NK cells whether they might have the role to play in our melanoma model. We were wondering may be some other cells types might be involved for that reason we infect the NSG mice with the Tumor (Mamel-86A) and treated the one group with LCMV to our surprise the tumor growth did not showed any sign of regression even with the LCMV injection intratumorally. we found out upon LCMV injection more and more NK cells migrate to the site of the tumor and lead to regression.

Human recombinant Tumor Necrosis Factor-Related Apoptosis-Inducing Ligand (TRAIL) secreted by *Lactococcus lactis* acts synergistically with cytostatics in elimination of human colon cancer cells *in vitro*.

***K. Ciacma**, J. Wieckiewicz, M. Siedlar, J. Baran;*
Jagiellonian University Medical College, Kraków, Poland.

Introduction: One of the leading problems in the current treatment of colon cancer is resistance of the tumor cells to chemotherapy. TRAIL is a natural protein that effectively kills many types of tumor cells and potentially may act synergistically with some chemotherapeutics. However, the biological half-life of TRAIL in mammalian organism is very short, significantly affecting its therapeutic effectiveness. The aim of our study is to investigate, if non-pathogenic *Lactococcus lactis* bacteria can be used as a safe carrier of the TRAIL, enabling both, the control of TRAIL secretion over a period of time and elimination of tumor cells *in vitro*.
Methods: Recombinant plasmid harbouring hsTRAIL-cDNA was constructed and transformed *via* electroporation into *L.lactis* NZ9000 cells. Synthesis and secretion of hsTRAIL was determined in broth supernatants by PCR, ELISA and Western blot. Antitumor activity of hsTRAIL in broth supernatant, used as a single agent and in combination with 5-fluorouracil (5-FU), irinotecan (CPT-11), metformin (MetF), puromycin (Puro) against human colon cancer HCT116 cells was examined *in vitro* by MTS assay. Apoptosis of cancer cells was confirmed by Annexin V binding and flow cytometry analysis. Elimination of HCT116 cells in a co-culture with *L.lactis*(hsTRAIL+) was assessed by MTS assay.
Results: hsTRAIL produced by *L.lactis*(hsTRAIL+) effectively kills HCT116 cells and acts synergistically with cytostatics: 5-FU, CPT-11, MetF and Puro, enhancing elimination of colon cancer cells *in vitro*.
Conclusion: *L.lactis*(hsTRAIL+) bacteria produce biologically active hsTRAIL with potential application for colon cancer immunotherapy.
Acknowledgments: Study supported by National Science Centre (UMO2014/15/B/NZ5/03484) and H2020-MSCA-RISE-2017 (777682, CANCER).

P.B1.02.05

Bovine herpesvirus 4-based vector delivering the full length xCT DNA efficiently protects mice from mammary cancer metastases by targeting cancer stem cells Bovine herpesvirus 4-based vector delivering the full length xCT DNA efficiently protects mice from mammary cancer metastases by targeting cancer stem cells

***L. Conti**[1], G. Donofrio[2], G. Tebaldi[2], S. Lanzardo[1], R. Ruiu[1], E. Bolli[1], A. Ballatore[1], V. Rolih[1], F. Macchi[1], F. Cavallo[1];*
[1]MOLECULAR BIOTECHNOLOGY CENTER, TURIN, Italy, [2]University of Parma, PARMA, Italy.

Despite marked advancements in its treatment, breast cancer is still the second leading cause of cancer death in women aged 20 to 59 years, due to relapses and distal metastases. Breast cancer stem cells (CSCs), are a cellular reservoir for recurrence, metastatic evolution and disease progression, making the development of novel therapeutics that target CSCs, and thereby inhibit metastases, an urgent need. We have previously demonstrated that the cystine-glutamate antiporter xCT (SLC7A11), a protein that was shown to be overexpressed in mammary CSCs and that plays a key role in the maintenance of their redox balance, self-renewal and resistance to chemotherapy, is a potential target for mammary cancer immunotherapy. We developed an anti-xCT viral vaccine that is based on the bovine herpesvirus 4 (BoHV-4) vector, which we have previously showed to be a safe vaccine that can transduce cells in vivo and confer immunogenicity to tumor antigens. We show that the vaccination of BALB/c mice with BoHV-4 expressing xCT (BoHV-4-mxCT), impaired lung metastases induced by syngeneic mammary CSCs both in preventive and therapeutic settings. Vaccination induced T lymphocyte activation and the production of anti-xCT antibodies that can mediate antibody-dependent cell cytotoxicity (ADCC), and directly impair CSC self-renewal and redox balance. Our findings pave the way for the potential future use of BoHV-4 vectors that target xCT in metastatic breast cancer treatment.

P.B1.02.06

High-dimensional profiling of immune subsets in mouse glioblastoma models reveals a tumor-induced 'tolerogenic' microenvironment.

***M. H. W. Crommentuijn**, S. T. Schetters, S. A. Dusoswa, L. J. Kruijssen, Y. van Kooyk;*
VU University Medical Center, Amsterdam, Netherlands.

Tumor cells can manipulate their microenvironment to suppress anti-tumor immunity, which affects patient survival. Modulation of inhibitory immune checkpoints through antibody therapy has shown promising results in several types of cancer, especially of those expressed by T cells. Glioblastoma is the most common, malignant form of primary brain cancer with a very dismal prognosis. As current therapies are insufficient, immune checkpoint inhibition could prove useful. Using advanced multiparameter flow cytometry and t-SNE unsupervised clustering, we performed a high-dimensional subset analysis and assessed co-expression of immune checkpoints and immune checkpoint ligands in two different mouse glioblastoma models. When comparing systemic effects with the brain tumor microenvironment and contralateral hemisphere of the same mouse, we observed a significant increase of CD4 T cells with a highly specialized phenotype, characterized by expression of TIGIT, PD-1, and, to a lesser extent, HVEM. PD-1 expression was also significantly increased on both OVA-antigen-specific CD8 T cells and non-OVA-antigen-specific CD8 T cells. Furthermore, analysis of the myeloid compartment showed massive infiltration of macrophages in the brain tumor microenvironment. Co-expression of immune checkpoint ligands such as PD-L1, CD155 and BTLA was observed on both microglia and infiltrating macrophages. Together, these results suggest a glioblastoma-induced 'tolerogenic' tumor microenvironment, within several different populations of infiltrating immune cells. Upregulation of certain immune checkpoints on lymphoid cells or their ligands on myeloid or tumor cells, could serve as potential targets for combination therapy.

Expansion and characterization of human tumor infiltrating lymphocytes (TILs) in colorectal cancer (CRC)

***M. Español-Rego**[1], R. Cabezón[2], G. Flórez-Grau[3], C. España[1], E. Pineda[4,5], A. Ginés[6], M. Juan[1,2], J. Maurel[4,5], D. Benítez-Ribas[1,7];*
[1]Immunology department, Hospital Clínic de Barcelona, Barcelona, Spain, [2]Institut d'investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, [3]Tumor Immunology, RIMLS, Radboudumc, Nijmegen, Netherlands, [4]Medical Oncology Department, Hospital Clínic de Barcelona, Barcelona, Spain, [5]Translational Genomics and Targeted Therapeutics in Solid Tumors Group, IDIBAPS, University of Barcelona, Barcelona, Spain, [6]Department of Gastroenterology, CIBERehd, Hospital Clínic de Barcelona, Barcelona, Spain, [7]Fundació Clínic, Barcelona, Spain.

Introduction
CRC is one of the most frequent cancer worldwide and less than 40% of patients remain free of progression 12 months after diagnosis. Immunotherapeutic approaches to enhance anti-tumour T cell response have been developed, such us vaccination, immune-checkpoint inhibitors or adoptive cell therapy.
Our aim was to expand and characterize CRC TILs, as a preclinical work useful in tumour immunology
Methods
Eleven primary CRC tumour biopsies were obtained from 9 patients undergoing colonoscopy. Biopsies were obtained from 7 untreated patients and 2 patients before treatment and after first-line progressive disease. Biopsies were processed to obtain a cell suspension by mechanical and enzymatic dissociation. Cells obtained were plated for TIL growth in medium supplemented with IL-2 and anti-CD3-CD28. TILs phenotype was evaluated by flow cytometry: CD3, CD4, CD8, PD1, CTLA4, IFNγ, IL17 and IL10. Data was acquired on FACSCanto II^{BD} and analyzed using BD-FACSDiva software.
Results
TILs were obtained in 10/11 tumour samples. Generally, after 2-weeks of expansion a minimum amount of $4x10^6$ TILs were expanded (mean $35,3x10^6$). On average, 97.3% of TILs were CD3+, with a CD4/CD8 ratio of 9.6. Expression of PD1 and CTLA4 was 1.9% and 0.3% in CD4+ and 1% and 0.3% in CD8+, respectively. 47.8% CD4+ and 71% CD8+ expressed IFNγ, while 21.2% CD4+ and 37.5% CD8+ expressed IL17. No expression of IL10 was detected.
Conclusion
This work shows our capability to obtain TILs and provides new data about the tumoral microenvironment in CRC that could be applied to design new therapies for these patients.

Anti-migratory property of the dual delivery of SN38-Snail siRNA CMD-chitosan nanoparticles on prostate cancer cells

***M. Farzi**[1], A. Afkham[2], S. Sadreddini[2], S. Dolati[3], N. Manafi Afkham[1], M. Yousefi[1];*
[1]Drug Applied Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, TABRIZ, Iran, Islamic Republic of, [2]Immunology Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, TABRIZ, Iran, Islamic Republic of, [3]Department of Immunology, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Iran, TABRIZ, Iran, Islamic Republic of.

Background: Prostate cancer is the leading cancer diagnosed in men in the US each year. Chitosan nanoparticles have become of great interest for nanomedicine, biomedical engineering and development of new therapeutic drug release systems specially siRNA. Snail and SN38 proteins have moved into the fast lane of development and cancer biology with the epithelial-mesenchymal transition (EMT). In the present study, we aimed to design chitosan/CMD nanoparticles for the efficient encapsulation of the anti-cancer drugs SN38 and Snail-specific siRNA. Methods: Physicochemical characteristics of the synthesized chitosan nanoparticles (140KD) were analyzed using Scanning Electron Microscopy (SEM). Serum & heparin stability and in vitro released assays were done. Anti-migratory property of the dual delivery of SN38-Snail siRNA CMD-chitosan nanoparticles was investigated through quantitative measurement of E-cadherin and Claudin-1 expression level in PC-3 human metastatic prostate cancer cell line. The potential effects of the nanoparticles on migration capability of the prostate cancer cells was also assessed using wound healing assay. Results: Our findings evidently showed 3.12 (±0.62) and 3.02 (±0.28) fold increases in E-cadherin and Claudin-1 mRNA after 24h, respectively.

The upregulation of E-cadherin and Claudin-1 mRNA were continued to 5.6 (±0.91) and 4.42 (±0.61) fold after 48h, respectively. Moreover, co-delivery of SN38and Snail specific siRNA by chitosan nanoparticles resulted in significant inhibition of PC-3 cells migration behavior. Conclusions: In conclusion, In conclusion, our results revealed that dual delivery of ChNPs encapsulating SN38 and Snail-specific siRNA may has a great impact on the treatment of prostate cancer.

Polymer-mediated tumor immunotherapy by in situ activation of antigen presenting cells

J. Hahlbrock[1]*, D. Arnold-Schild*[1]*, J. Stickdorn*[2]*, J. Braun*[3]*, M. Bros*[3]*, S. Grabbe*[3]*, L. Nuhn*[2]*, H. Schild*[1]*;*
[1]Institute for Immunology, Mainz, Germany, [2]Max Planck Institute for Polymer Research, Mainz, Germany, [3]Department of Dermatology, Mainz, Germany.

Immunotherapy has become a promising tool to treat cancer as shown by the use of checkpoint inhibitors. However, dependent on the tumor entity, there are still high recurrence rates and many patients suffer from immune related adverse events. Consequently, there is still high medical need for the development of specific tumor immunotherapies. We were able to design nanogel formulations which are degradable under acidic conditions and can be functionalized by covalent binding of the TLR7-agonist IMDQ and the tumor antigen OVA. Both, the nanoparticle itself and OVA are fluorescently labeled, which allowed biodistribution analyses. Intravenous application revealed an accumulation of the nanoparticles in the spleen with OVA-positive macrophages and elevated B cell numbers. Additionally, we found an uptake of functionalized nanoparticles in BMDCs as well as an enhanced BMDC maturation status. Interestingly, we observed a higher $CD8^+$ T cell response after treatment with nanoparticles which were functionalized through covalent binding of IMDQ and OVA (NP(IMDQ+OVA)) compared to a higher $CD4^+$ T cell response after treatment with nanoparticles to which IMDQ was covalently bound but OVA added in a soluble form (NP(IMDQ)+sOVA). In line with these results, we observed an increased IgG2a antibody production in sera of mice which were immunized with NP(IMDQ)+sOVA and an increased $CD8^+$ T cell response in splenocytes derived from mice treated with NP(IMDQ+OVA). Taken together, these results show promising effects of functionalized nanoparticles which involve $CD4^+$ and $CD8^+$ T cells as well as B cells. Next, therapeutic effects in mice carrying OVA-expressing tumors will be analyzed.

P.B1.02.10

Tumour escape in the microenvironment of penile carcinoma - PD-L1 related parameters predict lymph node metastases and survival

S. Ottenhof[1]*, N. Pocorni*[1]*, R. Djajadiningrat*[1]*, H. Thygesen*[1]*, J. de Jong*[2]*, T. de Gruijl*[3]*, S. Horenblas*[4]*,* ***E. S. Jordanova***[5]*;*
[1]Dutch Cancer Center, Amsterdam, Netherlands, [2]Dutch Cancer Center-AvL, Amsterdam, Netherlands, [3]CCA-VUmc, Amsterdam, Netherlands, [4]Dutch Cancer Center_AvL, Amsterdam, Netherlands, [5]Center for Gynecologic Oncology Amsterdam, Amsterdam, Netherlands.

In the complex interplay between cancer and the hosts immune system, the tumour is threatened by the natural anti-tumour response of cytotoxic T-cells (CTL). However, CTL's are 1) inhibited by regulatory T-cells (Tregs), 2) mislead by aberrant HLA expression by the tumour cells and 3) deactivated by Programmed Death Ligand 1 (PD-L1) on tumour cells or on tumour infiltrating macrophages (TIM). This study aims to gain insight in immunological factors and their prognostic value for lymph node metastases and disease specific survival (DSS) in penile cancer (n-213). HPV-status, different levels of HLA-expression and PD-L1-expression on tumour, stroma and TIM were known from previous studies. Sections were stained for macrophage-marker CD163, CTL-marker CD8, and Treg-marker FoxP3. These parameters were included in multivariable regression models testing the prognostic value for lymph node involvement (LN+ or LN-) and DSS. Multivariable analyses showed three independently prognostic factors for both lymph node status and DSS: 1) PD-L1+ TIM (unfavourable), PD-L1 margin expression (favourable), and a high intra-tumoral CTL/Treg ratio in the presence of PD-L1+ TIM (favourable). This means that PD-L1+ TIM and PD-L1 margin expression were independently predictive in absence of HPV. A PD-L1 expression pattern predominantly at the tumour-stroma margin predicts good prognosis, while the negative predictive value of PD-L1+ TIM appear to be compensated by a high CTL/Treg ratio. These results strengthen the rational for anti-PD-1/PD-L1 immunotherapy in penile carcinoma.

P.B1.02.11

Drug-induced hyperploidy stimulates an antitumor NK cell response mediated by NKG2D and DNAM-1 receptors

S. Lorenzo-Herrero*, C. Sordo-Bahamonde, A. Acebes-Huerta, A. R. Folgueras, L. Huergo-Zapico, S. González, A. López-Soto;*
University of Oviedo, Oviedo, Spain.

Introduction: Formation of polyploid or aneuploid cells is a pathological hallmark of malignant tumors. In addition to cell cycle checkpoints, cancer cell DNA ploidy is subjected to extrinsic controls operated by activation of T-cell mediated immune responses. Whether the innate immune system, and specifically natural killer (NK) cells, have a role in this process has not been deciphered yet.
Materials and Methods: Tumor cell lines were exposed to hyperploidy-inducing agents and surface expression of NK cell ligands was analyzed by flow cytometry. NK cell cytotoxic activity and cytokine production was evaluated after co-culture with treated tumor cells. Pharmacological and genetic approaches were used to study the intracellular mechanism involved in the upregulation of NK cell ligands in hyperploid cancer cells.
Results: Herein, we report that drug-induced polyploidy in cancer cells activates antitumor responses mediated by NK cells. Hyperploidy-inducing agents strongly upregulate the surface expression of NKG2D and DNAM-1 ligands in tumor cells. Further, drug-induced hyperploidy modulates the repertoire of activating receptors and the cytokine profile of NK cells, rendering tumor cells more susceptible to NK cell-mediated lysis. Two stress-related signaling pathways, DNA damage and endoplasmic reticulum stress responses, were involved in the stimulation of MICA, a key NKG2D ligand, in hyperploid cells.
Conclusion: Overall, our findings indicate that, besides the cytotoxic effect on tumor cells, the therapeutic activity of anti-mitotic drugs can also be mediated by the induction of a coordinated antitumor immune response involving NK cells.

P.B1.02.12

TARGETING CD70 FOR THE TREATMENT OF B CELL LYMPHOMA

L. Rohrbeck*, J. Ma, J. Coquet;*
Karolinska Institutet, Stockholm, Sweden.

CD70 is a member of the TNF family that is typically only transiently expressed on several types of immune cells in settings of immune activation. It ligates its receptor CD27, thereby activating various signaling pathways within the target cell. In contrast, CD70 is highly and persistently expressed on a number of malignant cells, particularly on B cell lymphomas. This finding suggests an advantageous role for CD70 in these cells. To date, very few studies have looked into the ability of CD27 to activate CD70 and hence knowledge about the function of CD70 activation in cancers and its downstream signaling pathway(s) is unknown.
The aim of this project is to study the role of CD70 in B cell lymphomas and multiple myeloma and to investigate how cancers benefit from the expression of this protein. So far, we have generated a couple of CD70-deficient cell lines using CRISPR/Cas9 technology. Genome-wide expression arrays will be performed to identify downstream targets of CD70, while knock-out lines will serve as negative controls. Cell proliferation and survival of treated and untreated CD70 knockout cells in combination with various anti-cancer therapeutics will also be assessed by flow cytometry, Finally, we will test the function of CD70-positive and -negative cell lines in mice by monitoring lymphoma growth, drug sensitivity and their impact on the tumor microenvironment. Our preliminary analysis suggests that stimulation of CD70 on cancer cells may promote the immune suppressive cytokine IL-10.

Repurposing antiviral T cells to fight tumors

P. C. Rosato*, M. J. Stolley, S. P. Wijeyesinghe, C. E. Nelson, R. L. Davis, L. S. Manlove, C. A. Pennell, B. R. Blazar, M. A. Geller, A. Grad, V. Vezys, D. Masopust;*
University of Minnesota, Minneapolis, United States.

Overcoming the immunosuppressive tumor microenvironment remains a major impediment to successful cancer immunotherapy. Virus-specific memory T cells are positioned throughout the entire body to sense reinfection and recrudescence. When that same virus is reencountered, these T cells sound an alarm that induces a local immunostimulatory environment that activates and recruits many arms of the immune system. As memory T cells are present in abundance in nearly every tissue and can be triggered by cognate peptide alone, we tested whether we could hijack antiviral CD8+ T cells in tumors to reverse the immunosuppressive tumor microenvironment. We observed that, like healthy tissue, mouse and human tumors are commonly surveyed by virus-specific memory CD8+ T cells. In mouse tumor models, local delivery of adjuvant-free peptide derived from previously encountered viruses recapitulated the sensing and alarm T cell function: recruiting and activating both the innate and adaptive immune system. This viral peptide therapy arrested mouse melanoma tumors and treatment synergized with anti-PD-L1 checkpoint blockade to eliminate measurable tumors and prevented recurrence in 33% of mice. Over half of cured mice rejected subsequent tumor challenges at distant sites, indicating that effective systemic tumor-specific immunity was established. Furthermore, the transcriptional inflammatory response seen in mouse tumors was recapitulated in *ex vivo* organotypic slice cultures of human tumors, supporting the clinical translatability of this therapy. This study demonstrates that natural and existing antiviral immunity can be repurposed to fight tumors without the need for adjuvant, reinfection, or personalized identification of immunogenic tumor neo-antigens.

The combination of magnetic nanoparticles and magnetic fields induces T cell retention both *in vitro* and *in vivo*

L. Sanz-Ortega[1], *J. M. Rojas*[1], *A. Marcos*[2], *Y. Portilla*[1], *J. V. Stein*[2], *D. F. Barber*[1];
[1]*Department of Immunology and Oncology, Centro Nacional de Biotecnología, Madrid, Spain,* [2]*Theodor Kocher Institute, Bern, Switzerland.*

Introduction: A main limitation in cell-based therapies is the dispersion of the administered cells resulting in a small proportion reaching the site of interest. Manipulating cells to target a region could be a strategy to solve this problem. T cells loaded with magnetic nanoparticles (MNPs) could be used for this purpose as long as their functions are not impaired. Here, we evaluate whether MNPs could serve to magnetically guide T cells. **Methods:** Jurkat and murine T cells were used to assess several aspects of T cells after MNP treatment. MNP interactions with T cells together with some important cell functions were evaluated. The *in vitro* and *in vivo* manipulation of MNP-loaded cells with an external magnetic field (EMF) was also analyzed. **Results:** MNPs remain mainly in the cell membrane of T cells. MNPs did not alter cell surface markers expression but slightly reduce the chemotactic response, which can be rescued using EMFs. EMFs can also enhance the *in vitro* retention of MNP-loaded cells in flow conditions. Moreover, we observed an *in vivo* accumulation of T cells in the lymph nodes (LNs) promoted by MNP loading and enhanced by localized EMFs. Finally, MNPs and EMF can reduce the speed of naïve T cells in the LNs. **Conclusions:** This work shows the use of MNPs and EMFs to guide and retain T lymphocytes to certain regions without affecting crucial biological aspects. These studies reveal an interesting approach to promote cell retention that could be implemented in cell-based therapies to improve their efficacy.

P.B1.02.16

Reinforcing dendritic cells for cancer immunotherapy: diverse ways to target antigens to human skin

L. Bellmann[1], *C. H. Tripp*[1], *J. Schulz*[2], *B. del Frari*[1], *P. Milne*[3], *M. Collin*[3], *C. Münz*[4], *C. Rademacher*[2], *N. Romani*[1], ***P. Stoitzner***[1];
[1]*Medical University of Innsbruck, Innsbruck, Austria,* [2]*Max Planck Institute of Colloids and Interfaces, Potsdam, Germany,* [3]*Newcastle University, Newcastle, United Kingdom,* [4]*University of Zürich, Zürich, Switzerland.*

Dendritic cells (DC) are essential for the induction of primary immune responses, and hence preferred targets for immunotherapy of cancer. Skin DC express C-type lectin receptors such as Langerin or DEC-205 for recognition of antigens. Langerin is expressed mainly on Langerhans cells (LC), whereas DEC-205 is expressed by dermal DC and LC. We aim to load skin-resident DC with antibody-antigen fusion proteins directed against these C-type lectin receptors or with antigens encapsulated in liposomes coated with a Langerin ligand. Langerin monoclonal antibody (mAb) injected intradermally into human skin explants was detected exclusively in LC, whereas DEC-205 mAb targeted both dermal DC and LC. A model antigen (EBNA1) fused to DEC-205 mAb elicited EBNA1-specific T cell responses. Liposomes coated with a Langerin ligand showed exclusive binding to LC in cell suspensions obtained from healthy human skin. These liposomes were rapidly incorporated into LC as visualized by confocal microscopy. Furthermore, to test our vaccination approaches in an *in vitro* model, we generated monocyte-derived Langerhans-like cells, which displayed between 50-80% of Langerin expression on the surface and also showed upregulation of CD83 and HLA-DR upon stimulation with a maturation cocktail. In summary, our study will provide a deeper insight into DC-targeted cancer vaccines, their uptake, intracellular trafficking and antigen processing in skin DC. Furthermore, liposomes provide a flexible platform that will allow us to encapsulate antigens to investigate their potential for targeted delivery. Ultimately, this DC-based immunotherapy can be used to increase response rates when used in combination with immune checkpoint inhibitors.

Phenotypic patterns of tumor-infiltrating T and NK cells reflect tumor grading in renal carcinoma

Z. Strizova[1], *P. Taborska*[1], *D. Stakheev*[1], *K. Havlova*[2], *S. Vesely*[2], *J. Bartunkova*[1], *D. Smrz*[1];
[1]*Department of Immunology, 2nd Faculty of Medicine, Charles University in Prague and Motol University, Prague, Czech Republic,* [2]*Department of Urology, 2nd Faculty of Medicine, Charles University in Prague and Motol University, Prague, Czech Republic.*

INTRODUCTION: Adoptive cell immunotherapy (ACI) is a promising approach in the treatment of multiple cancers. However, its efficacy in treatment of renal cell carcinoma (RCC) is low. Low efficacy is caused by a failure to obtain highly potent tumor-reactive lymphocytes after expansion of tumor-infiltrating lymphocytes (TILs). Therefore selective expansion of TIL populations with a potent cytotoxic and migratory activity is needed. In our study we evaluated the localization of cytotoxic/migratory NK, NKT and T cells infiltrating the tumor, peritumoral and adjacent healthy renal tissue. METHODS: 14 patients who underwent radical nephrectomy were included in the study. 42 tissue samples were obtained from the kidney, the tumor and peritumoral tissue, sliced and enzymatically dissociated into single cell suspensions. These cells were then analyzed for the expression of established markers of lymphocyte cytotoxicity - TRAIL and FasL, and a surrogate marker of lymphocyte migratory activity - PECAM-1. The stained cells were analyzed by flow cytometry and the findings correlated with clinical and histopathological data. RESULTS: A tendency to a higher tumor infiltration with PECAM-1$^+$FasL$^+$ T and NK cells was observed in low grade tumors (grade 2) rather than in poorly differentiated high grade tumors (grade 3). In NK cells, this trend was significant (P=0.003). Moreover, PECAM-1$^+$FasL$^+$ NK cells were most frequent in peritumoral tissue. CONCLUSION: The frequency of cytotoxic/migratory NK, NKT and T cells within the tumor and the surrounding milieu is affected by tumor grading. These results may provide important information for development of TIL expansion protocols for ACI of RCC.

Expanded tumor infiltrating lymphocytes upregulate 4-1BB in response to renal cell carcinoma

S. D. van Asten[1,2], *R. de Groot*[3,2], *M. M. van Loenen*[3,2], *A. Bex*[4], *J. de Jong*[4], *D. Amsen*[3,2], *R. M. Spaapen*[1,2], *M. C. Wolkers*[3,2];
[1]*Dept. of Immunopathology, Sanquin Research, Amsterdam, Netherlands,* [2]*Landsteiner Laboratory, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands,* [3]*Dept. of Hematopoiesis, Sanquin Research, Amsterdam, Netherlands,* [4]*The Netherlands Cancer Institute, Amsterdam, Netherlands.*

The transfer of autologous tumor infiltrating lymphocytes (TILs) is a promising therapy for solid tumors. Patients suffering from renal cell carcinoma (RCC) respond to immunotherapy such as high dose IL-2, albeit with severe toxicities. TIL therapy may therefore be more suitable to treat this tumor type. Previously we successfully expanded tumor reactive TILs from non-small cell lung cancer (NSCLC). Here we cultured TILs from 16 RCC patients. The proliferation rates were lower compared to what we previously found for non-small cell lung cancer (NSCLC) arguing for the presence of suppressive tumor derived factors. T cells of 11 out of 16 patients showed clear upregulation of the activation marker 4-1BB upon exposure to tumor digests and no or lower reactivity to healthy kidney tissue from the same patient.The tumor-specific upregulation of other activation markers (CD40L, CD107a, PD1) was only found in a subset of patients.
Surprisingly, tumor-specific activation was rarely accompanied by the production of IFN-γ, TNF-α or IL-2, while these cytokines were abundantly expressed by expanded NSCLC-derived TILs. This suggests that tumor-reactive 4-1BB positive T cells produce another yet to be defined cytokine profile. To define the tumor microenvironment and its effects on TILs, we are currently correlating the tumor reactivity with a comparative analysis of lymphoid infiltrates to the corresponding healthy kidney tissue. In conclusion, expanded T cells from RCC are tumor reactive as evidenced by 4-1BB upregulation, but the TIL expansion conditions may require further optimization. RCC is thus a conceivable candidate for the application of TIL therapy.

Combined immune stimulation with IL-15 and CD40 results in profound anti-tumour effects in pancreatic cancer

J. R. M. Van Audenaerde[1,2], *B. von Scheidt*[2], *A. Unsworth*[2], *E. Marcq*[1], *A. Oliver*[2], *J. De Waele*[1], *G. Roeyen*[3], *C. Y. Slaney*[2], *P. K. Darcy*[2], *M. Peeters*[1,4], *M. H. Kershaw*[2], *E. L. Smits*[1,5];
[1]*Center For Oncological Research, University of Antwerp, Wilrijk, Belgium,* [2]*Cancer Immunotherapy and Immune Innovation Laboratory, Peter MacCallum Cancer Centre, Melbourne, Australia,* [3]*Dept of Hepatobiliary, Endocrine and Transplantation Surgery, Antwerp University Hospital, Antwerp, Belgium,* [4]*Dept of Oncology and Multidisciplinary Oncological Centre Antwerp, Antwerp University Hospital, Antwerp, Belgium,* [5]*Center for Cell Therapy and Regenerative Medicine, Antwerp University Hospital, Antwerp, Belgium.*

Background: Pancreatic cancer (PC) is the 3rd deadliest cancer worldwide with the lowest 5-year survival of all cancers. Therapeutic improvements have barely been made over the last decade. Within the tumour microenvironment, tackling the stromal shield is needed to overcome treatment resistance. CD40 stimulation has already demonstrated moderate anti-tumour responses in PC, including some anti-stroma effects. We have shown that interleukin (IL)-15 stimulated NK cells are capable of tackling both tumour as well as the surrounding desmoplastic stroma. Therefore, we explored a novel combination immunotherapy consisting of an agonistic anti-CD40 monoclonal antibody and IL-15 in two mouse models of PC.
Methods: C57BL/6 mice bearing subcutaneous Panc02 or KPC tumours were treated over a two-week period with IL-15 and/or anti-CD40. Tumour kinetics and survival were monitored. Experiments depleting different immune cell populations were performed. Re-challenge experiments were executed to check immune memory induction. Tumour infiltrating lymphocytes are being characterised using flow cytometry and immunohistochemistry.
Results: Combination treatment of IL-15 and anti-CD40 caused a distinct reduction of tumour growth rates in comparison with single agent treatments. Mice receiving the combination treatment showed significantly increased survival, with 60-80% of the mice being completely tumour free. Depletion studies revealed both CD8+ T cells and NK cells are mechanistically involved in the anti-tumour effect of this novel treatment. Re-challenge experiments also showed that immune memory was induced. Flow cytometry experiments and immunohistochemistry experiments are being performed to provide more details on the phenotype of the tumour infiltrating lymphocytes and their spatial distribution within the tumour.

P.B1.02.20

Induction of immunogenic cell death by innovative antitumoral platinum (II) compounds

M. Wantz[1], *N. Chekkat*[1], *M. Bouché*[2], *G. Dahm*[2], *B. Frisch*[1], *S. Bellemin-Laponnaz*[2], *S. Fournel*[1];
[1]*Faculty of Pharmacy, Illkirch Cédex, France,* [2]*IPCMS, Strasbourg Cédex 2, France.*

Some cancer treatments like chemotherapeutic agents (anthracyclines, platinum derivatives,…) are able to activate the antitumor immune response by inducing a particular cell death: the immunogenic cell death (ICD). This process is characterized by the exposition of the endoplasmic reticulum chaperone calreticulin (CRT) at the cell surface as well as the release of ATP and non-histone chromatin-binding protein high mobility group box 1 (HMGB1) which serve as immunostimulatory damage-associated molecular patterns (DAMPs) and increase the antitumor immune response. We focused on *N*-heterocyclic carbene platinum complexes associated with polyethyleneimine, a transfection agent, to create multivalent cationic platinum compounds (NHC-Pt(II)-PEI) that induce apoptosis *in vitro* and *in vivo* in xenograft immunodeficient mouse model[1].
To evaluate the potential implication of the immune response on the NHC-Pt(II)-PEI *in vivo* effect, immunocompetent mice bearing tumors were treated with platinum particles and the results revealed an antitumor effect of our conjugates, in the same range than the clinical used platinum drug oxaliplatin, but with less side effects. We evaluated if NHC-Pt(II)-PEI were able to induce ICD. First results showed expression of CRT upon NHC-Pt(II)-PEI treatment. We are then evaluating if their association with immune danger signals could enhance this effect.
Altogether our results reveal the possibility of creating Pt(II) derivatives that can be used as chemotherapeutic agents by killing tumor cells and as immunotherapeutic agents by triggering the antitumor immune response.

Macrophages that are major players of tumor immunity, are divided into two subgroups as M1 (pro-inflammatory) and M2 (anti-inflammatory) macrophages. In general, M1 macrophages are potent tumor-fighting cells, whereas M2 macrophages display protumoral functions. ATP-binding Cassette Transporter G1 (ABCG1) promotes cholesterol efflux from cells and regulates intracellular cholesterol homeostasis. We have recently shown that in the absence of ABCG1, macrophages shift from a tumor-promoting M2 phenotype to a tumor-fighting M1 phenotype within the tumor and suppress bladder cancer growth in vivo. The molecular mechanism through which ABCG1-deficiency shifts macrophages to an M1 phenotype is not known. AMP-activated protein kinase is a master regulator of energy metabolism. In macrophages, AMPK also regulates M1/M2 polarization and activation of AMPK promotes macrophage polarization to an M2 phenotype. Herein, we show that Abcg1-/- bone marrow-derived macrophages display reduced levels of AMPK activation at baseline and also after stimulation with LPS/IFNγ (M1 stimulus) or IL4 (M2 stimulus). Moreover, while Abcg1-/- macrophages stimulated with LPS/IFNγ have increased TNFα production compared to WT macrophages, after treatment with the AMPK activator AICAR, the TNFα production of Abcg1-/- and WT macrophages were comparable. Our data suggest that the M1 bias of Abcg1-/- macrophages is mediated through AMPK signaling pathway. These findings not only deepen our mechanistic understanding of the M1/M2 switch in macrophages, but have the potential to open up new immunotherapeutic approaches for the treatment of cancer.

Adoptive cell transfer following personalized cancer vaccination elicits newly detectable neoantigen-specific T-cell responses in ovarian cancer patients

V. Bianchi[1], *S. Bobisse*[1], *B. J. Stevenson*[2], *L. Kandalaft*[1], *A. Harari*[1], *G. Coukos*[1];
[1]*Ludwig Institute for Cancer Research, Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, Lausanne, Switzerland.*

Private tumor neo-antigens derived from non-synonymous somatic point mutations can be immunogenic and are becoming highly attractive targets for tailored mutanome-based immunotherapies. A pilot study conducted by Kandalaft and colleagues, has shown that a personalized vaccination strategy in advanced ovarian cancer patients is feasible and safe, and induces a broad antitumor response including T-cell reactivities against private mutated neo-epitopes (Kandalaft et al., 2013; Tanyi et al. 2018). Patients who developed antitumor T-cell responses following vaccination but failed to achieve a complete remission (n=12), were enrolled in a second part of the trial involving lympho-depletion and adoptive cell transfer (ACT) of autologous vaccine-primed *ex vivo* co-stimulated T-cells (Kandalaft et al., 2013). To investigate whether ACT provided a boost to the cancer vaccine treatment, we performed a longitudinal screening of neo-epitope specific T-cells in the peripheral blood of vaccinated patients who received T-cell infusion. Of interest several (n=6) $CD8^+$ T-cell reactivities to private nonsynonymous mutations (neoepitopes) were newly detected only upon ACT in the blood of 4 out of 11 patients. Furthermore, increased progression-free survival was associated with the *de novo* detection of neoepitope-specific T-cell responses after ACT. We are now in the process of further dissecting the frequency of neoantigen-specific T-cell populations in the T-cell infusion products of patients undergoing ACT. Tracking the origin, expansion and persistence of neo-antigen specific T-cell clonotypes upon infusion, will help elucidate whether ACT of *ex vivo* co-stimulated T-cells following personalized vaccination is an effective way to further mobilize T-cell reactivities against the patient's mutanome.

Interferons synergize with either TLRs or CD40-induced signaling to efficiently render macrophages tumoricidal *in vitro*

P. F. Christopoulos[1], *A. Lunde*[1], *E. Müller*[1], *T. A. Theodossiou*[2], *I. Øynebråten*[1], *A. Corthay*[1];
[1]*Tumor Immunology Lab, Department of Pathology, Rikshospitalet, Oslo University Hospital, Oslo, Norway,* [2]*Department of Radiation Biology, Institute for Cancer Research, Radium Hospital, Oslo University Hospital, Oslo, Norway.*

Introduction: TAMs represent a main component of the tumor-infiltrating immune cells and therefore re/polarization into their anti-tumor M1 phenotype has raised great interest in cancer immunotherapy. IFNγ and/or LPS have been described as the typical inducers of the classical M1 activation, however less is known about the effect of other molecules or TLR ligands on macrophages activation.
Methods: LPS, Pam3CSK4, IFNγ, IFNβ and sCD40L were used alone or in combinations to activate mouse BMDM. Growth inhibition and/or apoptosis of LLC and MOPC315 cells were investigated using co-culture *in vitro* assays. Production of NO and cytokines, as well as, other phenotypic properties of polarized BMDM were also analyzed.
Results: We found that IFNγ induced growth inhibition and apoptosis of cancer cells only when it was used in combination with TLR agonists or sCD40L. Similarly, IFNβ also synergized with TLR-ligands for induction of cancer cell growth inhibition. In addition, combinational treatments synergistically upregulated NO, as well as TNFα and IL-12 production in BMDM, whereas IL-10 secretion was suppressed. Furthermore, activated BMDM upregulate CD38, CD40, CD80/86, MHCI/II and PD-L1 in different expression patterns depending on the applied stimuli. The mitochondrial respiration was suppressed upon activation and to a greatest extent following combinational treatments. Finally, apoptosis of macrophages was not greatly affected by activation.
Conclusions: Herein we have shown that TLR agonists, sCD40L and/or interferons promote distinct functional and phenotypic properties in so-called M1 macrophages. We conclude that activation of more than one signaling pathway is required to efficiently induce macrophage tumoricidal *in vitro*.

P.B1.03.04

Astragaloside II Exerted Anti-Tumor Immunological Effect through Regulating CD45

w. Chunping;
Yunnan University of Traditional Chinese Medicine, Kunming, China.

object: This paper was designed to assess the anti-tumor immunological effect and reveal the molecular mechanism on Astragaloside II exhibit the anti-tumor immunological effect via regulating regulating CD45 .
Method: The H22 tumor-bearing mice was established . Mice were divided into three groups including, Model group ,Astragaloside II group and Astragaloside II+Anti-CD45 Ab group.After 10 days of intragastric administration, the tumor tissue were isolated to assess the anti-tumor immunological effect of Astragaloside II, The lymphocyte cells proliferation from H22 tumor-bearing mice was detected by MTT method. The mRNA expression of Th1 cytokine,Th2 cytokine and transcript factor T-bet were examined by q-PCR analysis.Surface marker,Treg and Th1 intracellular cytokines(IFN-γ) were detected by flow cytometry.

Result: The tumor weight,tumor diameter and tumor volume in Astragaloside II group are more small than model group($P < 0.05$). Astragaloside II treatment significantly enhance the lymphocyte proliferation activity from H22 tumor-bearing mice in response to ConA,increase the proportion of $CD44^+CD62L^-$ effector T cells, up-regulated the transcriptional expression in Th1 and Th2,including IFN-γ,IL-2,IL-4 and T-bet.Meanwhile,Astragaloside II treatment also markedly increase IFN-γ expression in CD4+T cells and down-regulated T regulatory cell expression.Furthermore,anti-mouse CD45 Ab treatment intensely blocked the anti-tumor immunological effect and lymphocyte proliferation activity which induced by Astragaloside.Compared with Astragaloside II group,IL-2,IFN-γ, IL-4 and T-bet mRNA expression is decreased in Astragaloside II+Anti-CD45 Ab group.Anti-mouse CD45 Ab treatment intensely down-regulated IFN-γ expression in CD4+T cells without significantly influencing Treg cells and $CD44^+CD62L^-$ effector T cells.
Conclusion: we hypothesis that activating CD45 protein tyrosine phosphatase may be involved in anti-tumor immunological effect of Astragaloside II.

P.B1.03.05
Targeting human skin DC using melanoma specific multivalent glyco-nanomers to enhance anti-tumor immune responses

***S. Duinkerken**, S. T. Schetters, H. Kalay, M. Ambrosini, J. J. Garcia-Vallejo, Y. van Kooyk;*
VUmc, Amsterdam, Netherlands.

Human skin dendritic cell (DC) subsets are actively explored for use in anti-cancer vaccination strategies because of their easy accessibility. Targeting epidermal Langerhans cells (LCs) or dermal $CD1a^+$, $CD14^+$, and $CD141^+$ DCs individually has shown enhanced (cross-) presentation of tumor-associated antigens (TAA), inducing tumor specific $CD4^+$ and $CD8^+$ T cells, yet not enough for effective cancer regression in humans. We hypothesize, that simultaneous targeting of multiple DC subsets might give superior responses *in vivo*. We designed multivalent glyco-nanomers which showed increased $CD8^+$ T cell responses compared to single peptides *in vivo*, showing the potential for use of multivalent CLR targeting moieties to induce anti-tumor T cell responses. To verify targeting capabilities of these nanomers specifically to human skin DCs a human skin explant model was used. Multivalent glyco-nanomers containing gp100 MHCI and II epitopes were coupled to the common DC-SIGN/Langerin ligand Le^y, thereby targeting both LCs and dermal DCs (dDCs). We show increased uptake by LCs, $CD14^+$ and $CD1a^+$ dDCs *in situ* which, surprisingly, was not mirrored with increased *in vitro* $CD8^+$ T cell activation. To ensure proper T cell activation we combined the multivalent nanomers with the PRR agonists MPLA (TLR4) and MDP (NOD2). We show an altered skin environmental milieu when MPLA and MDP-nanomers are injected *in situ* in human skin and enhanced *in vivo* $CD8^+$ T cell responses in B6 mice. In conclusion, we designed tumor specific multivalent glyco-nanomers which can target both CLR and PRR on multiple human skin DC to induce anti-tumor immune responses.

P.B1.03.06
Reduced DNAM expression and impaired function of cytokine-secreting and cytotoxic NK cells in tumor draining lymph nodes in non small cell lung cancer

*E. Cetin Aktas[1], A. Turna[2], **F. Esen**[3,1], A. Engin[1], M. Agkoc[4], G. Deniz[1];*
[1]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey, [2]Istanbul University, Cerrahpasa Medical School, Department of Thoracic Surgery, Istanbul., Turkey, [3]Istanbul Medeniyet University School of Medicine, Department of Ophthalmology, Istanbul, Turkey, [4]Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey.

Natural killer (NK) cells have important functions in antitumoral immunity and have been shown to have impaired functions in cancer patients. The aim of this study was to evaluate phenotyping of NK cells in tumor draining lymph nodes of non-small cell lung cancer (NSCLC).
Five NSCLC lung cancer patients undergoing preoperative mediastinal staging by video-assisted mediastinoscopic lymphadenectomy were included in this study. Peripheral blood mononuclear cells were isolated from tumor draining lymph nodes and peripheral blood. Activator and inhibitory receptors, immune checkpoint molecule expressions were analyzed in NK cell subsets. Cytotoxic capacity and cytokine secretion of NK cells were also analyzed.
The ratio of cytotoxic $CD16^{bright}CD56^{dim}$ (p=0.008) and $CD16^{bright}CD56^-$ NK cells (p=0.03) were significantly diminished in lymph nodes, while there was no difference for cytokine-secreting NK cells (p=0.22). IL-10 secreting NK cells were significantly increased (p=0.02), while IFN-γ (p=0.03) and TNF-α (p=0.03) secreting $CD16^-CD56^{dim/bright}$ cells were significantly decreased in lymph nodes, representing a regulatory phenotype. Percentages of $CD16^{bright}CD69^+$ cells (p=0.047) and granzyme expression of $CD16^{bright}$ cells in unstimulated and K562 stimulated conditions (p=0.016 and p=0.008) were significantly lower in lymph nodes, while there was no statistically significant difference for CD107a degranulation (p=0.20 and p=0.88). DNAM expression in the lymph nodes were significantly lower in both groups (p=0.008).
Tumor responding immune cells reduced DNAM expression of both cytotoxic and cytokine secreting NK cells, that might lead regulatory or suppressive phenotype of these cells to impair antitumoral immune responses.

P.B1.03.07
Exosome based immunotherapy to induce antigen-specific humoral and cellular immunity and mediate long-term memory in vivo

***X. Hu**, G. Gucluler, R. Veerman, P. Larssen, S. Gabrielsson;*
Karolinska Institutet, Solna, Sweden.

Exosomes are candidates for cancer immunotherapy due to their capacity to stimulate tumor-specific activity *in vivo*. However, clinical trials using peptide-loaded autologous exosomes have so far only showed moderate T cell responses, suggesting a need for optimization of exosome-induced immunity in humans. We previously demonstrated that induction of antigen-specific $CD8^+$ T cells and anti-tumor responses to whole antigen were independent of major histocompatibility complex (MHC) class I on exosomes. Here, we further investigated humoral and cellular immunity induced by syngeneic and allogeneic exosomes. Both exosomes can enhance antigen-specific $CD8^+$ T cell, follicular helper T cell (Tfh) and antigen-specific antibody responses. Exosome-injected mice demonstrated antigen-specific memory after 4 months. To be noted, mice receiving double allogeneic exosome injections showed highest antibody avidity. Reduced B16mOVA melanoma tumor growth was shown in all exosome-injected groups. Our findings support the application of allogeneic exosomes for therapeutic use in clinical immunotherapy studies.

Ectopically expressed membrane-bound form of IL-9 exerts immune-stimulatory effect on CT26 colon carcinoma cells

*V. Do Thi, **Y. Kim**;*
Department of Biochemistry, College of Natural Sciences, Chungnam National University, Daejeon, Korea, Republic of.

IL-9 is a known T cell growth factor with pleiotropic immunological functions, especially in parasite infection and colitis. However, its role in tumor growth is controversial. In this study, we generated tumor clones expressing the membrane-bound form of IL-9 (MB-IL-9) and investigated their influences on immune system. MB-IL-9 tumor clones showed reduced tumorigenicity but shortened survival accompanied with severe body weight loss in mice. MB-IL-9 expression on tumor cells had no effect on cell proliferation or major histocompatibility complex class I expression in vitro. MB-IL-9 tumor clones were effective in amplifying CD4+ and CD8+ T cells and increasing cytotoxic activity against CT26 cells in vivo. We also observed a prominent reduction in body weights and survival period of mice injected intraperitoneally with MB-IL-9 clones compared with control groups. Ratios of IL-17 to interferon (IFN)-γ in serum level and tumor mass were higher in mice implanted with MB-IL-9 tumor clones than those observed in mice implanted with control cells. These results indicate that the ectopic expression of the MB-IL-9 on tumor cells exerts an immune-stimulatory effect with toxicity. To exploit its benefits as a tumor vaccine, a strategy to control the toxicity of MB-IL-9 tumor clones should be developed.

Immunomonitoring of triple negative breast cancer patients undergoing neoadjuvant therapy (GBG89, Geparnuevo trial)

***C. Massa**[1], A. Mueller[1], A. Schneeweiss[2], C. Hanusch[3], J. Huober[4], M. Untch[5], T. Karn[6], P. Fasching[7], F. Marmé[2], N. Burchardi[8], C. Denkert[9], S. Loibl[8], B. Seliger[1];*
[1]Martin Luther University, Halle (Saale), Germany, [2]Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany, [3]Rotkreuzklinikum Frauenklinik, München, Germany, [4]University of Ulm, Ulm, Germany, [5]HELIOS Klinikum Berlin Buch, Berlin, Germany, [6]University of Frankfurt, Frankfurt, Germany, [7]University Hospital Erlangen, Erlangen, Germany, [8]GBG German Breast Group, Neu-Isenburg, Germany, [9]Charité University Hospital, Berlin, Germany.

The Geparnuevo trial is a randomized, double-blind, multi-center phase II trial of neoadjuvant therapy in patients with early-stage triple negative breast cancer (TNBC) investigating the role of durvalumab, an anti-PD-L1 inhibitor in addition to standard chemotherapy with nab-Paclitaxel followed by Epirubicin plus Cyclophosphamid. In order to determine possible predictive and / or prognostic biomarkers, blood samples were taken before and during the different treatment phases and evaluated by multicolor flow cytometry. Evaluation of the absolute cell count in the whole blood highlighted a mixed behavior of the total leukocytes, whereas there was a statistically significant reduction in the lymphocytes, particularly during the last phase of the treatment. Further dissection into the different immune populations highlighted an almost complete loss of B cells that in some patients was also accompanied by a reduction of NK cells, mostly regarding the $CD16^+$ subset. However, the loss of $CD4^+$ and $CD8^+$ T cells has been less pronounced resulting in an overall enhancement of their percentages within the total lymphocytes. The different populations have also been evaluated for the expression of activation and exhaustion markers, whose behavior will be more deeply evaluated when the clinical outcome and the treatment received by the various patients will be made available. We expect that with such analysis possible biomarkers for the treatment of TNBC patients will be identified thus leading to better patient selection for tumor chemo/immuno combination therapy. The trial and this translational research project was funded by AZ and Celgene, Germany, respectively.

Efficient adjuvants have the potential to trigger both innate and adaptive immune responses simultaneously. Flagellin is a unique pathogen-derived protein, which is recognized by pattern recognition receptors (PRRs) as well as by B-cell and T-cell receptors thus providing an important link between innate and adaptive immunity.
Here, we sought to investigate the potential modulatory effects of flagellin exerted on various cell death processes known to play detrimental roles in regulating the final outcome of various types of immune responses. We proved that the pre-treatment of Jurkat T-cells with flagellin is able to increase the degree of cell death provoked by FAS, TRAIL or TNF-α and concomitantly increases the cytotoxic potential of phytohemagglutinin activated T-lymphocytes. In contrast to these flagellin-mediated effects exerted on the death receptor-induced signalling events, the mitochondrial apoptotic pathway remained unaffected. Furthermore, the cell culture supernatant of wild type *Salmonella enteritidis* bacteria, but not their flagellin deficient variant were able to enhance the Fas-induced cell death. To define the molecular mechanisms mediated by flagellin we were able to detect the upregulation of RIP1-dependent signalling events.
These findings demonstrate that the cooperative action of pattern recognition and the different death receptors are able to initiate the cell death process towards the mobilization of RIP-dependent cell death modalities. This finding highlights the capability of flagellin to act as a potential adjuvant relevant for tumor immunotherapy.
The work is supported by NKFIH-K-125224 and by the GINOP-2.3.2-15-2016-00050 project. The project is co-financed by the European Union and the European Regional Development Fund.

Cytokine nitration boosts myeloid suppressor cell commitment and functions in tumors

A. Agnellini[1], *B. Cali*[1], *A. Predonzani*[2], *G. Toffolo*[2], *G. Arrigoni*[1], *F. Zonta*[3], *L. Albertoni*[4], *C. Mescoli*[4], *I. Marigo*[5], ***B. Molon***[1];
[1]*Department of Biomedical Sciences, University of Padova, Padova, Italy,* [2]*Venetian Institute of Molecular Medicine VIMM, Padova, Italy,* [3]*ShanghaiTech University · Shanghai Institute for Advanced Immunochemical Studies, Shanghai, China,* [4]*Department of Medicine, DIMED, Surgical Pathology and Cytopathology Unit, University of Padua, Padova, Italy,* [5]*Istituto Oncologico Veneto, IOV-IRCCS, Padova, Italy.*

The recruitment of defined immune cell subsets within the locoregional tumor environment significantly influence cancer fate. A strong lymphocytic infiltration associate with good clinical outcome in different human tumors. On the contrary, high frequency of myeloid cells is tightly connected with tumor promotion, metastasis and poor prognosis. Despite the relative profusion of each cell type, the predominant cytokine and chemokine milieu within the tumor microenvironment importantly tips the balance in favor of either anti-tumor immunity or tumor-induced immunosuppression. Notably, the overload of inflammatory reactive species is a common feature of the majority of chronic inflammatory diseases including cancer. Reactive Nitrogen Species (RNS) influence homeostatic properties of several proteins at post-translational level. Indeed, the post-translation modifications (PTM) of proteins represent an important level of regulation that must be deeply investigated in cancer. Our group showed that PTM alter the recruitment of distinct immune subsets within tumor primary lesion thus affecting the efficacy of cancer therapy. We originally focused our analysis on CCL2, though other cytokines and chemokines should be target of such modifications and contribute to shape the immune response. One of the possible candidates is the granulocyte-macrophage colony-stimulating factor (GM-CSF), which is an important regulator of inflammation. Its prominent role as immunomodulatory cytokine has been increasingly considered from different studies linking its deregulation to chronic inflammatory diseases and cancer. Our data indicated that RNS impact on the molecular dynamics and functions of this key cytokine by altering the immune landscape in tumor-bearing hosts.

P.B1.03.13

Direct and indirect effects of various cytokine pretreatment of human peripheral blood mononuclear cells on the proliferation of cervical cancer cells in coculture

M. G. Mujtaba*, T. R. Simpson;*
Florida Gulf Coast University, Fort Myers, United States.

Immunotherapies are increasingly being developed to target certain tumors and cancers. Here, we examine the direct and indirect effects of various cytokine pretreatment of human peripheral blood mononuclear cells (HPBMC) on the proliferation of cervical cancer cells. HPBMC were pretreated with various cytokines, such as IL-12, IL-15, IL-18, and IFNγ, either alone or in combination for 48 hours, after which cells were washed. Washed cells were then either incubated directly with HeLa cells or alone for another 48 hours and their supernatants collected and incubated with HeLa cells. After 48 hours of coculture of HeLa cells with either HPBMC or supernatants, cellular proliferation was measured using the WST-1 proliferation assay kit and absorbance was read at 495nm on a microplate reader. Results show that HeLa cells inhibition required direct contact by HPBMC when cytokine pretreatments involved IL-12 and IL-15. Direct coculture inhibition of proliferation was approximately 54% for IL-12 and 62% for IL-15 pretreatments. On the contrary, IL-18 pre-treated HPBMC cell supernatants had a greater effect on HeLa cell inhibition (40%) than HPBMC directly cocultured with HeLa cells (20%). Both IFNγ pretreated HPBMC (33% inhibition) and their resultant supernatants (23% inhibition) had inhibitory effects on HeLa cell proliferation. At optimal inhibitory concentrations, above cytokine combination pretreatments of HPBMC had no additive or synergistic inhibition of HeLa cell proliferation in the coculture assay. Thus, data from this study increases our understanding of the tumor microenvironment and the effect of certain cytokines on peripheral blood mononuclear cell activity on cancer cells.

P.B1.03.15

Porcine Circovirus Type 2 ORF3 protein induces apoptoses in melanoma cells

M. Teras[1], *A. Rump*[2], *V. Paalme*[2], ***S. Rüütel Boudinot***[2];
[1]*North Estonia Medical Centre, Oncology, Estonia,* [2]*Tallinn University of Technology, Department of Chemistry and Biotechnology, Estonia.*

Background. The current treatment of malignant melanoma is limited by the lack of effective therapeutic approaches, and alternative treatments are needed. Proliferative diseases such as melanoma and other cancers may be treatable by virally-encoded apoptotic proteins that are targeted to rapidly multiplying cells. **Methods.** In the current study, the Porcine circovirus type 2 (PCV2), proapoptotic protein ORF3 was expressed in mouse and human cancer cell lines, and its apoptotic activity assessed. **Results**. Quantitative assessment of the apoptotic cells by flow cytometry showed that apoptotic cell death was significantly increased in ORF3-expressing malignant cells, compared with ORF3 non-expressing cells. Our data show that PCV2 ORF3 induces apoptosis likely in a caspase-independent manner. ORF3 expression causes an increase in abnormal mitosis in B16F10 melanoma cells by interacting with centrosomes and thereby disrupting formation of the mitotic spindle. In addition, we show that ORF3 of PCV2 also exhibits significant anti-tumor effects *in vivo*. Although the expression of regulator of G protein (RGS)-16 by recipient mice inhibited the developement of grafted melanoma *in vivo*, it was not required for the antitumoral activity of ORF3. **Conclusion.** PCV2 ORF3 causes non-bipolar mitosis in rapidly dividing cells and increases the apoptosis of cancer cells. Apoptin might therefore be considered to develop future antitumoral strategies.

P.B1.03.16

Cortisol determines the capability of human acute myeloid leukaemia cells to escape immune surveillance via upregulation of latrophilin expression on genomic level

S. S. Sakhnevych[1], *I. M. Yasinska*[1], *A. M. Bratt*[1], *O. Benlaouer*[1], *W. Fiedler*[2], *Y. Ushkaryov*[1], *V. Sumbayev*[1];
[1]*Medway School of Pharmacy, Chatham Maritime, United Kingdom,* [2]*University Hospital Hamburg-Eppendorf, Hamburg, Germany.*

Introduction. Acute myeloid leukaemia (AML) is a blood and bone marrow cancer, which rapidly develops into a systemic malignancy due to capability of cancer cells to disable anti-cancer immunity. One of the biochemical mechanisms lying in the core of this process is highly upregulated secretion of galectin-9, a tandem protein, which triggers biochemical inactivation of natural killer (NK) cells and killing of cytotoxic T cells. Galectin-9 secretion is mediated by latrophilin 1 (LPHN1), a G-coupled receptor expressed by AML cells but not healthy leukocytes. However, the biochemical machinery which controls these events remains unclear and thus was the aim of this study. **Methodology.** Primary human AML cells, healthy leukocytes and blood plasma from respective donors as well as THP-1 human AML cell line were used to conduct the work. Western blot analysis, ELISA and qRT-PCR were employed as main research instrumental. **Results and Discussion.** Cortisol has significantly upregulated LPHN1 expression in AML cells, but not in primary healthy leukocytes. Importantly, cortisol levels were highly upregulated in blood plasma of AML patients compared to healthy donors. Natural LPHN1 ligand, FLRT3 protein present in human blood plasma in its soluble form was found to facilitate galectin-9 exocytosis in AML cells. **Conclusion.** Our results suggest, that human steroid hormone cortisol normally responsible for regulation of metabolism is used by malignant AML cells to gain capability to disable anti-cancer immunity. In blood plasma of AML patients glucose levels are decreased, which induces biochemical triggering of upregulated cortisol production by hypothalamus and pituitary gland.

Combination therapies to improve DC-based treatment of melanoma

A. Seretis[1], *G. Cappellano*[1], *L. Bellmann*[1], *J. Schachtl-Rieß*[1], *N. Prokopi*[1], *D. Ortner-Tobider*[1], *K. Komenda*[1], *C. H Tripp*[1], *C. E Brinckerhoff*[2], *J. Lühr*[3], *C. Lehmann*[3], *D. Dudziak*[3], *P. Stoitzner*[1];
[1]*Department of Dermatology, Venereology and Allergology, Medical University of Innsbruck, Innsbruck, Austria,* [2]*Departments of Medicine and Biochemistry, Geisel School of Medicine at Dartmouth, Norris Cotton Cancer Center, Lebanon, New Hampshire, United States,* [3]*Department of Dermatology, Laboratory of Dendritic Cell Biology, Friedrich-Alexander University Erlangen-Nürnberg (FAU), University Hospital Erlangen, Erlangen, Germany.*

Dendritic cells (DC) are the most potent antigen-presenting cells of the immune system inducing $CD4^+$ and $CD8^+$ T cell responses. However, the tumor microenvironment actively suppresses anti-tumor immunity. The aim of this project is to develop combination therapies, allowing control of melanoma growth. For this purpose, tumor antigens will be delivered directly to DC by antibody-mediated uptake. These DC-vaccines will be combined with tumor-targeted therapy or immune checkpoint inhibitors to further boost anti-tumor immune responses. For the generation of DC-vaccines, the expression of three melanoma-associated antigens (gp100, trp-2 and MAGE-A2) were examined by RT-PCR in two BRAF mutant melanoma models: the transplantable D4M and the inducible Tyr::CreER;$Braf^{CA}$;$Pten^{lox/lox}$. In the D4M model, we observed low levels of expression which increased under treatment with a BRAF inhibitor-containing diet, while the inducible Tyr::CreER;$Braf^{CA}$;$Pten^{lox/lox}$ model showed high expression levels in tumors compared to healthy skin. We are currently cloning these melanoma antigens into the skin DC targeting antibody, anti-DEC-205. These constructs will be used to deliver the antigens to skin DC and combined with the BRAF inhibitor. So far, we observed that the transplantable D4M melanoma model is very sensitive to BRAF inhibition and develops resistance after prolonged exposure. Moreover, we found that the BRAF inhibitor affects the phenotype and composition of immune cell infiltrate, in D4M tumors. Our ultimate goal is to improve anti-tumor immunity and prevent development of resistance to targeted therapy by combining it with DC-targeting vaccines.

P.B1.03.18

The Tim-3-galectin-9 secretory pathway determines the capability of human acute myeloid leukaemia (AML) cells to escape host immune surveillance

V. V. Sumbayev[1], *I. M. Yasinska*[1], *I. Goncalves Silva*[1], *S. S. Sakhnevych*[1], *E. Fasler-Kan*[2], *B. F. Gibbs*[1], *R. Hussain*[3], *G. Siligardi*[3], *W. Fiedler*[4];
[1]*University of Kent and Greenwich, Chatham Maritime, United Kingdom,* [2]*University Hospital Bern, Inselspital, Bern, Switzerland,* [3]*Diamond Light Source, Didcot, United Kingdom,* [4]*University Medical Centre Hamburg-Eppendorf, Hamburg, Germany.*

Acute myeloid leukemia (AML) is a blood/bone marrow cancer which is a severe and very often a fatal systemic malignancy. Cancerous blood cells are capable of escaping host immune surveillance by inactivating cytotoxic lymphoid cells (natural killer (NK) cells and cytotoxic T lymphocytes (CTLs)). Our work is focused on understanding molecular mechanisms underlying this pathophysiological process. We discovered a fundamental molecular pathway which includes ligand-induced activation of plasma membrane associated receptor latrophilin 1 leading to increased translation and exocytosis of the immune receptor Tim-3 (T cell immunoglobulin and mucin domain containing protein 3) and its ligand galectin-9. This occurs via protein kinase C and mammalian target of rapamycin (mTOR) pathways. Tim-3 is directly involved in galectin-9 secretion and can also be released in a free soluble form. Galectin-9 impairs the anti-cancer activity of NK cells and kills CTLs. Soluble Tim-3 prevents secretion of interleukin-2 (IL-2) required for NK cell/CTL activation as cytotoxic cells. These results were validated in *ex vivo* experiments using primary samples from AML patients. Importantly, activity of this pathway was detected in other types of cancer including breast and colorectal cancer. A fundamental Tim-3/galectin-9 secretory pathway is one of the crucial biochemical mechanisms determining the capability of human AML cells to escape host immune surveillance.

P.B1.03.19

ABCG1 modulates macrophage polarization in human monocyte-derived macrophages

D. Unuvar Purcu[1], *S. Gunalp*[2], *M. Altunay*[2], *G. Baslar*[3], *D. Sag*[3,4];
[1]*Department of Molecular Medicine, Health Sciences Institute, Dokuz Eylul University, Izmir, Turkey,* [2]*Izmir International Biomedicine and Genome Institute, Dokuz Eylul University, Izmir, Turkey,* [3]*Izmir Biomedicine and Genome Center, Izmir, Turkey,* [4]*Department of Medical Biology, School of Medicine, Dokuz Eylul University, Izmir, Turkey.*

The ATP-binding cassette transporter G1 (ABCG1) mediates efflux of cellular cholesterol to high-density lipoprotein (HDL) particles. Recently, we have shown that the absence of ABCG1 inhibits tumour growth in mice by modulating macrophage function within the tumour. In the absence of ABCG1, macrophages shift from a tumour-promoting M2 phenotype to a tumour-fighting M1 phenotype within the tumour and kill tumour cells directly. Conforming a similar tumour fighting potential of ABCG1 in human macrophages is the next crucial step to determine if ABCG1 can be a molecular target in cancer immunotherapy. To this end, we inhibited ABCG1 expression in human peripheral blood monocyte-derived macrophages by RNA interference before the macrophages were polarized to M1 or M2 phenotypes by the stimulation with LPS/IFNγ or IL-4, respectively. The expression of M1 and M2 markers were analysed by qPCR. The inhibition of ABCG1 by siRNA significantly increased the expression of the M1 markers IDO1, CXCL10, CD64 and TNF after LPS/IFNγ stimulation. In contrast, the inhibition of ABCG1 by siRNA significantly reduced the expression of the M2 markers MRC1, TGM2 and CD163 after IL-4 stimulation. Our results indicate that ABCG1-deficiency promotes macrophage polarization to an M1 phenotype in human monocyte-derived macrophages. These findings suggest that ABCG1 in macrophages could be a potential new target to modulate macrophage polarization for cancer immunotherapy.

Identification of high affinity TCRs directed against lineage-specific antigens expressed by solid tumors

R. A. van Amerongen*, R. S. Hagedoorn, M. G. Kester, M. van der Meent, D. Remst, D. M. van der Steen, S. Tuit, P. A. van Veelen, F. Falkenburg, M. H. Heemskerk;
Leiden University Medical Center, Leiden, Netherlands.*

Targeting lineage-specific antigens by T-cell receptor (TCR)-based therapies is an interesting option for solid tumor types that often require a complete resection of the organ. Examples are late stage prostate and ovarian cancer. These lineage-specific antigens should be expressed in both tumor tissues and the healthy counterpart. Hypothetically a more homogeneous expression of lineage-specific antigens in the target population can be expected, compared with tumor-associated targets that are mostly heterogeneously expressed. We have selected a group of lineage-specific antigens per tumor type, using publically available RNAseq databases of both healthy (HPA/GTEx) and tumor samples (TCGA). Examples of prostate lineage-specific genes included in this study are kallikrein-2, -3 and -4. To identify potential T-cell epitopes from these lineage-specific genes, peptide elution experiments were performed on resected tumors, tumor cell lines or transduced cell lines. Peptides binding in different common HLA molecules were selected, synthesised and confirmed, and peptide-MHC (pMHC) multimers were produced. In PBMCs of HLA-typed individuals these pMHC multimers were used to enrich for peptide-specific $CD8^+$ T-cells. We aim to identify potent high affinity T-cells by searching within the allo-HLA repertoire. Initially, over 3000 pMHC multimer positive $CD8^+$ T-cells were collected via single-cell sorting. T-cell clones that specifically recognized peptide loaded target cells, as well as target cells expressing endogenously processed antigen, were selected for further screenings. Using cell panels consisting of different healthy and malignant cell types, safety and efficacy screenings were conducted. Altogether, promising lineage-specific T-cell clones were identified, recognizing both tumor cell lines and primary tumor material.

P.B1.03.21

Adoptive T cell transfer combined with DC vaccination in patients with metastatic melanoma

S. L. Wickström[1], *T. Lövgren*[1], *M. Wolodarski*[1], *U. Edbäck*[1], *E. Martell*[2], *K. Markland*[1], *M. Nyström*[1], *A. Lundqvist*[1], *H. Jacobsson*[2], *J. Hansson*[1], *G. Masucci*[1], *R. Tell*[1], *I. Poschke*[3], *J. Mattsson*[1], *R. Kiessling*[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Karolinska Univeritets sjukhuset, Stockholm, Sweden,* [3]*German Cancer Research Center, Heidelberg, Germany.*

Adoptive T-cell therapy (ACT) has been reported to induce clinical responses in up to 70% of stage IV melanoma patients. The aim of the MAT02 trial is to investigate the effect of adoptive transfer of autologous, tumor infiltrating lymphocytes (TIL) with or without autologous dendritic cell (DC) vaccination in patients with advanced melanoma. The anti-tumor response will be evaluated and the transferred T cells will be characterized in regard to phenotype and function. This study is a single center, open-label, two-armed, phase I trial. Five patients are assigned to each cohort (A or B) and receive ACT of autologous TIL without (A) or with (B) autologous tumor loaded DC i.c. Radiological evaluation is performed four weeks after the last DC administration. Cohort A: patients received only TIL has been completed and the treatment had limited expected toxicity. All treated patients showed a mixed response or stable disease. However, these responses were not durable. Cohort B: received the combined treatment of TIL and DC-vaccine, three patients have completed the treatment, 29-33 billion TIL and were administered five DC-vaccinations. All 3 patients responded; one with a complete response which is still ongoing (> 15 mo). Two patients showed a partial response, one with a long lasting response (> 24 mo) and one with a short response. We expect to include another two patients before the summer of 2018. Adoptive T cell therapy combined with DC-vaccination is safe and can result in complete clinical response in patients who have failed on checkpoint therapy.

P.B1.04.01

Media evaluation for production and expansion of anti-CD19 chimeric antigen receptor (CAR) T cells

R. Alnabhan[1,2]*, J. Mattsson*[3,4]*, M. Uhlin*[1,4]*, I. Magalhaes*[3]*;*
[1]Division of Surgery, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden, [2]King Abdullah International Medical Research Center, Riyadh, Saudi Arabia, [3]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden, [4]Department of Clinical Immunology and Transfusion Medicine, Karolinska University Hospital, Stockholm, Sweden.

The use of CD19 chimeric antigen receptor (CAR) T cells to treat B cell malignancies has been showing beneficial clinical outcomes. The production of CD19 CAR T cells usually involves serum supplementation. Currently, multiple manufacturers provide serum-free media that can be used without serum supplementation. Therefore, it becomes important to evaluate the production of CD19 CAR T cells with and without serum supplementation. Methods: T cells from buffy coats were cultured in AIM-V and TexMACS supplemented with 5% human serum (A5% and TM5%), and in TM without serum. Cells were activated with OKT3 and expanded in IL-2. Viral transduction was performed by spinoculation in RetroNectin-coated plates. We evaluated CD19 CAR T cell viability, expansion, transduction rate, phenotype and cytotoxicity. Results: CD19 CAR T cells expanded in A5% and TM5% showed significantly better viability and higher fold expansion than cells expanded in TM. TM promoted the expansion of $CD8^+$T cells and effector phenotype of CD19 CAR T cells. The transduction rate and the cytotoxicity were comparable between the different media. TM and TM5% promoted higher frequency of $CD107a^+$cells, while A5% promoted higher frequency of $IL\text{-}2^+$and $IL\text{-}17^+$ cells. CD19 CAR exhibited co-expression of exhaustion markers including; $TIM\text{-}3^+LAG\text{-}3^+$ and/or $TIM\text{-}3^+PD\text{-}1^+$. Conclusion: Our results indicate that the addition of serum promotes improved CD19 CAR T cells expansion and viability *in vitro*. Different culture media promoted different phenotypes of CD19 CAR T cells, which warrants further assessment in clinical settings. Overall, culture medium is a key factor that impacts CD19 CAR T cell.

P.B1.04.02

Development and preclinical testing of simultaneous dual engagement CARs (SiDECARs) against Acute Myeloid Leukemia

I. E. Balabanov*, H. M. Van Santen;*
Center for Molecular Biology "Severo Ochoa", Madrid, Spain.

Introduction: The use of immunotherapy in the treatment of cancer has provided clear benefits for patients. Still, exploitation of its full potential is hampered by, amongst other reasons, the severe side effects that can be caused by therapy-induced immune responses against healthy tissues of the patient. In the case of adoptive cell therapy with T cells, expressing chimeric antigen receptors (CARs) that recognize tumor-associated antigens, these off-tumor on-target effects are mainly due to the paucity of truly tumor-specific antigens. One way to improve tumor recognition capabilities of T cells is to generate CARs that require binding of two different ligands to initiate T cell activation.
Materials & Methods: We have generated bispecific CARs targeting two AML-associated antigens by appending ScFv-chains, recognizing these antigens, to the TCR. These receptors were designed with different intracellular signaling chains with the aim to find a balance between ligand binding affinity and intracellular signaling capacity, in order to promote optimal dual recognition-dependent T cell activation.
Results: cDNAs encoding the AML-specific antibodies were cloned and ScFv were successfully generated. The proposed CAR constructs were created through seamless cloning techniques and expressed in mouse and human primary T cells and T cell lines. Their capacities to induce T cell activation were investigated and compared using different human AML cell lines as targets.
Conclusions: This approach could be applied to other types of cancer.
This project is being funded by the Horizon 2020 program MSCA-ITN-2016 of the European Union with grant agreement GA721358 (ENACTI^{2}NG).

P.B1.04.03

Increased antigen loading in synthetic peptide vaccines - is more better?

T. R. Cooney[1]*, G. F. Painter*[1]*, I. F. Hermans*[2]*, G. F. Walker*[3]*;*
[1]Ferrier Research Institute, Victoria University of Wellington, Wellington, New Zealand, [2]Malaghan Institute of Medical Research, Wellington, New Zealand, [3]University of Otago, Dunedin, New Zealand.

Vaccines that generate T cell responses can be used to treat non-communicable diseases such as cancer. Peptide vaccines have considerable advantages compared to protein or whole cell based alternatives as they are highly defined, possess a good safety profile and are more amenable to optimisation. A major limitation of peptide vaccines is their lack of immunogenicity, however, this can be overcome through the incorporation of immune stimulants (i.e. vaccine adjuvants). Vaccine immunogenicity can be further increased via the chemical conjugation of a peptide to an adjuvant such as those which activate invariant natural killer T (iNKT) cells. Subunit vaccine designs which are limited to a 1:1 molar ratio of antigen:adjuvant ratio are not considered to be optimal with most vaccine formulations containing a higher ratio of peptide antigen compared to the adjuvant. To investigate the importance of high antigen loading we have employed a dendrimer scaffold which can be synthesised at a multi-generational level, to provide either 2, 4, 8, 16 or more antigen attachment sites branching from a singular adjuvant. Utilisation of a multi-generational branched dendrimer scaffold will enable investigation towards the hypothesis that higher antigen loading will produce more efficacious vaccines.

P.B1.04.04

Conventional $CD4^+$ T cells present bacterial antigens to induce cytotoxic and memory $CD8^+$ T cell responses.

A. Cruz-Adalia*, G. Ramirez Santiago, J. Osuna, M. Torres Torresano, E. Veiga;*
CNB/CSIC, Madrid, Spain.

Bacterial phagocytosis and antigen cross-presentation to activate $CD8^+$ T cells are principal functions of professional antigen presenting cells. However, conventional $CD4^+$ T cells also capture and kill bacteria from infected dendritic cells in a process termed transphagocytosis (also known as transinfection). Here, we show that transphagocytic T cells present bacterial antigens to naive $CD8^+$ T cells, which proliferate and become cytotoxic in response. $CD4^+$ T-cell-mediated antigen presentation also occurs in vivo in the course of infection, and induces the generation of central memory $CD8^+$ T cells with low PD-1 expression. Moreover, transphagocytic $CD4^+$ T cells induce protective anti-tumour immune responses by priming $CD8^+$ T cells, highlighting the potential of $CD4^+$ T cells as a tool for cancer immunotherapy.

P.B1.04.05

Intracellular localization of the negative checkpoint regulator VISTA in Antigen Presenting Cells

L. Dübbel[1]*, K. W. Koch*[1]*, N. H. Meyer*[2]*;*
[1]Biochemistry, Department of Neuroscience, University of Oldenburg, Oldenburg, Germany, [2]Dermatology and Allergology, Department of Human Medicine, University of Oldenburg, Oldenburg, Germany.

In the recent past, blocking of the negative checkpoint regulators *Programmed Death-1* (PD-1) and *Cytotoxic T-lymphocyte Antigen-4* (CTLA-4) showed groundbreaking results in the immunotherapy of cancer.
The negative checkpoint regulator *V-domain immunoglobulin (Ig)-containing suppressor of T-cell activation* (VISTA) is a new potential target for cancer immunotherapy. In mice, the anti-VISTA antibody treatment is not only increasing tumor specific T-cells in the periphery, but also the infiltration, proliferation and effector function of tumor reactive T-cells in the tumor microenvironment. Consequently, an anti-VISTA antibody was recently approved for a phase I clinical trial.
The surface expression pattern of VISTA is clearly distinct from other negative checkpoint regulators. Intriguingly, VISTA is expressed on both, T-cells and Antigen Presenting Cells, with very high expression on tumor-infiltrating immune cells. Since model negative checkpoint regulators are exclusively expressed on T-cells the function of VISTA on Antigen Presenting Cells remains unknown.
We thus investigated the expression of VISTA on murine *bone marrow derived macrophages* (BMDM) and human monocyte-derived macrophages. Particularly, we analyzed the localization of VISTA in different types of vesicles using immunofluorescence microscopy. In addition, we isolated different cell fractions and organelles to analyze the subcellular localization of VISTA in Antigen Presenting Cells.
Our results show that VISTA co-localizes with several vesicle markers (SNAP-25, CD71, Perforin) and is released to the cell surface upon stimulation. A similar mechanism has been previously suggested for CTLA-4.
Overall, we conclude that VISTA storage in vesicles allows a fast response of APCs to immunogenic stimuli.

P.B1.04.06

Nanobodies as tools for targeting of Adeno-associated viruses to target-expressing cells

A. Eichhoff[1], *T. Eden*[1], *F. Haag*[1], *S. Adriouch*[2], *F. Koch-Nolte*[1];
[1]*Institute of Immunology, UKE, Hamburg, Germany,* [2]*Institute of Medicine and Pharmacy, Inserm U1234, Rouen, France.*

Adeno-associated viruses (AAVs) are widely used as vectors in gene and tumor therapy to treat various diseases. A limiting factor for successfull gene delivery without side effects is the broad tropism of AAV serotypes, i.e. the parallel infection of several tissues and cell types.
Here, we show that Nanobodies - the single binding domain of camelid heavy chain antibodies - can be used as ligands to target AAVs to specific cells. Nanobodies provide high specificity and stability, and their small size allows easy reformatting as fusion proteins.
The ectoenzymes CD38 and CD296 and the P2X7 ion channel were evaluated as target receptors for AAVs. In one strategy, the membrane protein-specific nanobody was genetically inserted into an exposed surface loop of the viral capsid protein VP1 of AAV2^{RA} (a variant containing two mutations of arginines to alanines that inhibit binding to HSPG). The presentation of the nanobody on the viral capsid resulted in specific transduction of cells expressing the target with GFP-encoding AAVs.
As a second strategy, the membrane protein-specific nanobody was genetically fused via a flexible peptide linker to an AAV1/2 dual-reactive nanobody, thereby generating bispecific nanobody-based adaptor proteins. These adaptors strongly and specifically enhanced the transduction of cells expressing CD38, CD296, or P2X7 by both AAV1 and AAV2^{RA}.
These results provide proof of principle for nanobody-based strategies to enhance the cell specificity of AAVs and provide a basis for new approaches to optimize Adeno-associated viral vectors for gene and tumor therapy.

P.B1.04.07

Regulation of the NK cells melanoma cytotoxic cross talk by nanotechnology assisted p53 reactivation

c. garofalo[1], *M. Naddeo*[2], *V. Ventura*[1,3], *L. Izzo*[4], *G. Selivanova*[5], *D. Pappalardo*[2], *E. Carbone*[1,5];
[1]*Tumor Immunology and Immunopathology Laboratory, Department of Experimental and Clinical Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy., catanzaro, Italy,* [2]*Department of Science and Technology, University of Sannio, via dei Mulini 59/A, 82100 Benevento, Italy., Benevento, Italy., Italy,* [3]*Department of Health Sciences, University "Magna Græcia" of Catanzaro, Catanzaro, Italy, Catanzaro, Italy,* [4]*Department of Biotechnology and Life Science, University of Insubria, via J. H. Dunant, 3, 21100 Varese - Italy, Varese Italy, Italy,* [5]*Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, 17177, Stockholm, Sweden., Stockholm, Sweden.*

Introduction: PRIMA-MET and RITA are small molecules able to restore p53 function and induce tumor cells apoptosis. We and others demonstrated that these molecules enhance the NK cell-mediated recognition of solid tumors by promoting the expression of NKG2D ligands on tumor cell surface. To improve the pharmacological effect of these compounds on tumor cells, and increase their solubility and transport efficiency in the body fluids,we analyzed a panel of biocompatible polymers for their capability to form nanoparticles able to deliver a drug cargo inside tumor cell lines. We found that novel designed FITC-conjugated $mPEG_{2K}$-$(PD,LLA)_2$ was able to efficiently deliver paclitaxel anti-cancer drug inducing tumor cell death and we decide to use it as carrier for p53 reactivating small molecules (PRIMA-1MET and RITA)
Materials and Methods: Primary melanoma cells were treated with FITC-labeled PRIMA-1MET-loaded nanoparticles and analysed for the expression of NK activating/inhibitory molecules by FACS.
Results: Our preliminary data showed that FITC-nanoparticles loaded with PRIMA-1MET were detected in the melanoma cytoplasm after 6 days of treatment. Moreover, the treatment increased MICA while it reduced the PD-L1 expression on melanoma cells.
A new formulation of FITC-nanoparticles loaded with RITA has been generated.
Conclusions: The new formulation of PRIMA-1MET goes into the melanoma cells and change their immune phenotype.

Virus specific T lymphocyte expansion for adoptive immunotherapy

M. Grau-Vorster[1,2,3], *M. López-Montañés*[1,2], *A. del Mazo-Barbara*[1,2], *S. Querol*[1,2], *J. Vives*[1,2,3], *I. Oliver-Vila*[1,2], *F. Rudilla*[1,2];
[1]*Blood and Tissue Bank, Barcelona, Spain,* [2]*Vall d'Hebron Research Institute, Barcelona, Spain,* [3]*Autonomous University of Barcelona, Barcelona, Spain.*

Adoptive immunotherapy with virus-specific T lymphocytes (VST) can prevent immunodeficient patients from virus reactivation or *de novo* infection. However, this treatment has several limitations, such as HLA-compatibility restriction, high costs and time required in the production of personalised medicines. These limitations can be overcome by the generation of a third-party VST bank through large-scale expansion compliant with Good Manufacturing Practice (GMP) standards. Cytomegalovirus (CMV) peptides were used to stimulate lymphocytes specifically against these antigens. Readouts after expansion included cell counting, purity, in terms of $CD8^+$ and $CD4^+$, and specificity (interferon gamma (IFNγ) expression). Moreover, product characterisation through immunophenotype, ELISPOT, degranulation, cytotoxicity and alloreactivity assays were performed. Physiological VST stimulus was tested, consisting of CMV pp65 peptide-pulsed autologous dendritic cells (DCs) derived from monocytes. Furthermore, anti-CD3+anti-CD28 antibodies were added in order to enhance VST proliferation. The combination of cytokines IL-2+IL-7+IL-15 in a G-Rex cell culture system resulted in optimum conditions for VST expansion. The use of DCs for VST activation and the addition of anti-CD3+anti-CD28 in the presence of IL-2 resulted in greater than 40-fold expansion at day 14 and >17% of specificity was achieved. After a purification step based on Cytokine Capture System (Miltenyi Biotec) 90% purity of VST was obtained. A GMP scalable process and with high values of VST was successfully defined. The phenotypic analysis as well as the functionality and safety of the final product have been tested. A further improvement to the approach would consider specificity for other viruses.

P.B1.04.09

Anti-tumoral potential of a granulysin-containing protein product directed against the carcinoembryonic antigen*

R. Ibáñez[1], *P. Guerrero*[1], *S. Al-Wasaby*[1], *R. Navarro*[2], *D. de Miguel*[1], *O. Gonzalo*[1], *B. Conde*[1], *L. Martínez-Lostao*[3], *R. Hurtado-Guerrero*[4], *L. Sanz*[2], *A. Anel*[1];
[1]*University of Zaragoza, Zaragoza, Spain,* [2]*University Hospital "Puerta de Hierro", Majadahonda, Spain,* [3]*Clinical University Hospital "Lozano Blesa", Zaragoza, Spain,* [4]*Institute for Biocomputation and Physics of Complex Systems (BIFI), Zaragoza, Spain.*

Introduction: Granulysin is a protein present in the granules of human CTLs and NK cells, with cytolytic activity against microbes and tumors. Previous work from our group demonstrated the *in vivo* antitumoral activity of intratumoral injection of recombinant granulysin in two animal models of tumor development, breast adenocarcinoma and multiple myeloma. In the present work we have developed a granulysin-containing protein product directed against the carcinoembryonic antigen (CEA), commonly expressed in colon adenocarcinomas. Material and Methods: 1) Recombinant granulysin or the protein product were tested against cells negative for CEA expression (Jurkat), or on CEA^+ cells (HT-29, SW1222, MKN45 or HeLa-CEA) and cell death was analyzed by annexin-V staining and 7-AAD incorporation. 2) Granulysin and the protein product were tested as a treatment in *in vivo* models of tumor development, based in subcutaneous injection of $3x10^6$ colon carcinoma HT-29 cells or HeLa-CEA transfected cells in groups of immunodeficient athymic mice. In the HT-29 model, injections were performed intratumorally, and in the HeLa-CEA model, injections were performed systemically (intraperitoneal). Results: We demonstrated that the cytotoxicity of the protein product against several CEA^+ cell lines *in vitro* was higher than that of granulysin alone. After intratumoral injection, both granulysin and the protein product were able to inhibit HT-29 tumoral growth more than 60%, demonstrating the *in vivo* bioactivity of the protein product. Finally, the protein product demonstrated a higher *in vivo* therapeutic effect against tumors derived from HeLa-CEA cells than granulysin alone after systemic administration. *The "protein product" is under patent tramitation

P.B1.04.10

Humanized heavy chain antibodies based on CD38-specific nanobodies effectively inhibit tumor growth in a systemic human lymphoma xenograft model

J. Hambach, L. Schriewer, N. Schuster, B. Albrecht, K. Petry, D. Aytan, J. Röckendorf, P. Bannas, ***F. Koch-Nolte****;
University Medical Center Hamburg, Hamburg, Germany.*

The cell surface ecto-enzyme CD38 is a target for the treatment of hematological malignancies. Nanobodies derived from camelid heavy chain antibodies are highly soluble and can bind to epitopes that are not accessible for conventional antibodies. Other advantages of nanobodies include their better tissue penetration *in vivo*, and the facile construction of bi- or multi-specific biologicals by genetic fusion (1). We have generated humanized heavy chain antibodies by fusion of CD38-specific nanobodies to the hinge and Fc-domains of wild type and engineered human IgG1. Some of these heavy chain antibodies mediate potent complement dependent cytotoxicity (CDC) and antibody-dependent cellular cytotoxicity (ADCC) of CD38-expressing tumor cell lines in vitro. In vivo some of the heavy chain antibodies reduced the growth of systemic CA46 lymphomas in tumor-bearing SCID mice more effectively than daratumuab, the benchmark conventional human IgG1 in the clinic.(1) Bannas P, Hambach J, Koch-Nolte F. 2017. Nanobodies and Nanobody-Based Human Heavy Chain Antibodies As Antitumor Therapeutics. Front Immunol. 8:1603.

P.B1.04.11

Enforced expression of a constitutively active form of GSK3β as a novel treatment to combat melanoma through facilitation of dendritic cell differentiation and activation

M. Lopez Gonzalez[1], *R. van de Ven*[1], *D. Oosterhoff*[1], *J. Jan Lindenberg*[1], *H. de Haan*[1], *W. Dong*[2], *V. W. van Beusechem*[1], *T. D. de Gruijl*[1];
[1]*Cancer Center Amsterdam, Amsterdam, Netherlands,* [2]*ORCA Therapeutics BV, Amsterdam, Netherlands.*

Even though immune checkpoint blockade has increased the overall survival of melanoma patients considerably, not all patients respond to this treatment, in part due to a lack of T-cell infiltration in the tumor fields. Activation of the *Wnt signaling* pathway has been identified as a molecular mechanism underlying this lack of immune infiltration, resulting in a lack of cross-presenting dendritic cells (DCs), which in turn are vital for the chemo-attraction and activation of tumor-infiltrating T-cells. β-catenin levels can be directly regulated by glycogen synthase-3-beta (GSK3β), an enzyme involved in various signaling pathways. When GSK3β is activated it will phosphorylate β-catenin which will lead to its inactivation and degradation.
Here, we report that modulation of GKS3β at the level of DCs plays a key role in their differentiation and maturation, and that overexpression of the constitutively active form of GKS3β (CA.GSK3β) renders DCs refractory to the suppressive effect of IL-10, an important suppressive factor released by metastatic melanoma, and of melanoma-derived supernatants. Moreover, the inhibition of GKS3β in melanoma cells increases their suppressive effect on monocyte-to-dendritic cell differentiation. Conversely, the enforced over-expression of CA.GSK3β reduces this suppressive effect and drives DC development to a type-1 T-cell-activating phenotype.
Based on our findings, we hypothesize that the enforced expression of CA.GSK3β at the melanoma tumor site may enhance the infiltration and activation of DC and T-cells and thereby render previously resistant tumors sensitive to immune checkpoint blockade.

P.B1.04.12

Use of alpha technology to identify novel small molecules that specifically inhibit LAG-3 binding to its ligand HLA-DR

G. H. Mason[1], *B. J. MacLachlan*[1], *A. Greenshields Watson*[1], *F. Triebel*[2], *D. K. Cole*[1,3], *A. Godkin*[1];
[1]*Division of Infection & Immunity, Cardiff, United Kingdom,* [2]*Immutep, Orsay, France,* [3]*Immunocore Ltd, Abingdon, United Kingdom.*

Introduction: $CD4^+$ helper T-cells express a series of activating and inhibiting co-receptors. These play a role in both autoimmunity and cancer immunity. Immune checkpoint inhibitors (ICI) which target molecules mediating inhibition (e.g. PD1, CTLA-4) may result in enhanced anti-tumour immunity. Lymphocyte activation gene-3 (LAG-3) is a negative regulator of T-cells that has not so far been successfully targeted by monoclonal antibodies. LAG-3^+ T-cells within tumours have been shown to be immunosuppressive and are associated with poor prognosis. As an alternative to expensive antibody based therapies, we conducted a small molecule library screen to identity lead compounds which may interfere with the interaction of LAG-3 with its ligand HLA class II.
Materials and Methods: Alpha technology, a bead based assay for the detection of protein:protein interactions (PPI), was used to screen a 50,000 compound library against i) LAG-3-HLA II ii) irrelevant control PPI using TCR:pHLA.
Results: 50 compounds which specifically block the interaction between LAG-3 and HLA II have been identified as true assay hits which block the LAG-3-HLA II interaction without blocking an irrelevant PPI.
Conclusions: Having identified hit compounds, these compounds are being tested using a LAG-3 expressing reporter cell line. Generation of a novel LAG-3-HLA II inhibitor, will enable us to learn more about the role of LAG-3 in disease setting, and aid the development of novel therapeutics.

P.B1.04.13

B cell lineage-specific transcription coactivator BOB1 is indispensable for multiple myeloma cell survival and allows for superior TCR-based targeted therapy

R. M. Reijmers, *A. D. Meringa, L. Jahn, F. Falkenburg, M. H. Heemskerk;*
Leiden University Medical Center, Leiden, Netherlands.

Although still incurable, much progress has been made in the treatment of multiple myeloma (MM). Recent advances in immunotherapy have contributed substantially, of which the most promising, T cells modified to express a chimeric antigen receptor (CAR) directed against B cell maturation antigen (BCMA). Another approach is introducing a transgenic T cell receptor (TCR) into cytotoxic T cells. Recently, for MM, we successfully demonstrated *in vivo* efficacy of a transgenic TCR targeting the transcription coactivator octamer binding protein-1 (BOB1) in the context of HLA-B*07.02. BOB1 is a B cell lineage specific protein that is highly expressed in all B cell malignancies, including MM. Like rituximab (anti-CD20) treatment, targeting BOB1 will only affect the B cell lineage, which makes it attractive for immunotherapy with high *on*-target and low *off*-tumor effects. This prompted us to further explore the significance of BOB1 in MM. To this end, we applied CRISPR/Cas9 to disrupt BOB1 expression in several MM cell lines. Remarkably, upon single-cell sorting and DNA sequencing, all targeted clones revealed in-frame deletions only. We are currently extending these findings to other B cell malignancies and study the functionality of the in-frame mutated BOB1 variants on target gene expression, and study the effect on *in vitro* and *in vivo* growth. Together, these data suggest that BOB1 is indispensable for myeloma cell survival, which identifies BOB1 as a superior target for TCR-based immunotherapy. This work was financially supported by Bellicum Pharmaceuticals.

P.B1.04.14

Identifying immunological properties of natural products for the treatment of chemoresistant tumors and bacterial pathogens

L. Richter[1], *M. Frank*[2], *P. Proksch*[2], *S. Scheu*[1];
[1]*Heinrich Heine University, Institute of Medical Microbiology and Hospital Hygiene, Duesseldorf, Germany,* [2]*Heinrich Heine University, Institute of Pharmaceutical Biology and Biotechnology, Duesseldorf, Germany.*

Introduction: The most abundant human diseases worldwide include cancer and bacterial infections. To overcome the development of resistances against cytostatics and antibiotics, there is a rising need to find new drugs. Natural products comprise many untested highly bioactive molecules inspiring medical research. We are looking for compounds that modulate immune effector functions and additionally target tumors and pathogens, thus reducing the risk of resistances. Material and methods: A library with 240 natural products derived from endophytic fungi and marine sponges undergoes different screenings to determine promising compounds. After having completed cytotoxicity screenings, we are currently using an IL-12p40 fluorescence reporter mouse line to test selected natural products for their ability to induce or enhance expression of IL-12 in macrophages or dendritic cells via flow cytometry and ELISA. The thus identified immune activating compounds will be further interrogated in T cell activation assays for their potential to promote T cell priming by dendritic cells. Results: We have identified 41 natural products that are non-toxic to immune cells but simultaneously toxic to tumor cells or pathogens. For application of the aforementioned IL-12p40 assay, cell culture and FACS staining conditions have been successfully established and multifunctional natural products will be screened for immune activation. Conclusions: Promising multifunctional, immune activating natural products will further be biochemically optimized for immune modulatory effectivity and tested in *in vivo* tumor and infection mouse models. This work is funded by the German Research Foundation (DFG).

P.B1.04.15

Human γδT cells: Presentation Of Tumour Antigens And Induction Of Anti-Tumour Immunity

T. Rus[1], *M. Eberl*[1,2], *B. Moser*[1,2];
[1]*Cardiff university, School of medicine, Cardiff, United Kingdom,* [2]*Systems Immunity Research Institute, Cardiff, United Kingdom.*

An important discovery that activated human blood γδT cells behave as professional antigen-presenting cells (γδT-APCs) has highlighted their potential use as cellular vaccines. γδT-APCs are ideal candidate for immunotherapy as they are non-MHC-restricted and they do not mount unwanted/unpredicted cross-reactivities in patients. They are capable of inducing potent antigen-specific and MHC-restricted responses that may boost anti-tumour cytotoxic T cell responses. Lastly, they can be generated in large numbers ($>10^9$) *in vitro* from small blood samples and predominantly secrete proinflammatory cytokines (IFNγ, TNFα), which may help overcome immune inhibitory conditions frequently associated with tumours. It has been shown that γδT-APCs can excellently process microbial antigens (influenza, CMV, Mtb), including peptides, whole proteins and cell extracts, and induce strong responses in responder αβT cells. This study focuses on the ability of γδT-APCs to process and present tumour antigens, including NY-ESO-1 and 5T4, which are frequently expressed in malignant melanomas and breast cancer but not in healthy tissue.
This is accomplished through the production and purification of recombinant protein from *E.coli*, and antigen-specific CD8+ T cells from PBMC in an autologous system. These are then used to examine the functionality of γδT-APCs in *in vitro* APC assays. Demonstration that γδT-APCs are capable of inducing strong tumour-specific CD4+ and CD8+ αβT cell responses is a prerequisite for carrying our first-in-man clinical trials. Further work will include localisation and generation of γδT-APCs from cancer tissues, as well as the generation of a mouse immunotherapy model to test the benefits of γδT-APCs as a cellular vaccine.

P.B1.04.16

PD-1 blockade impairs the anti-tumor activity of innate immune cells stimulated with TLR9 agonist

C. Storti[1], *M. Sommariva*[1], *M. De Cesare*[2], *E. Tagliabue*[3], *A. Balsari*[1,3], *L. Sfondrini*[1];
[1]*Dipartimento di Scienze Biomediche per la Salute, Università degli Studi di Milano, Milan, Italy,* [2]*Molecular Pharmacology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [3]*Molecular Targeting Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.*

Introduction: TLR agonists are known to activate innate immune cells and can exert anti-tumor activity. We previously reported that locoregional administration of CpG-ODN, synthetic TLR9 agonist, inhibited IGROV-1 human ovarian cancer cell growth in athymic nude mice, preclinical model devoid of T lymphocytes in which anti-tumor immune response is mediated only by innate immune system. PD-1 receptor is expressed by activated T lymphocytes and also by innate immune cells. Interaction of PD-1 with PD-L1 or -2 blunts immune response, but specific antibodies blocking PD-1 can re-activate it. Therefore, combinations of TLRs therapies with anti-PD-1 antibody may be a promising new therapeutic strategy.
Methods: Nude mice were intraperitoneally xenografted with IGROV-1 cells and locally treated with CpG-ODN in combination with anti-PD-1 antibody. Macrophages were depleted by liposomes-containing clodronate. Immunocompetent mice injected with B16 melanoma and 4T1 breast cancer cells were treated as above.
Results: CpG-ODN/anti-PD-1 antibody combination in IGROV-1-injected mice was found to be less efficacious than CpG-ODN alone, independently from the treatment schedules and anti-PD-1 clone used. The same combination in B16- or 4T1-injected immunocompetent mice did not reveal a similar effect. Administration of anti-PD-1 antibody immediately after IGROV-1 tumor injection determined tumor growth acceleration. Immunohistochemical analysis showed an increase of $Arg1^+$ intratumoral macrophages in anti-PD-1 treated group. Macrophage depletion restored CpG-ODN antitumor effect when combined with anti-PD-1 antibody.
Conclusion: Our results suggest that blocking PD-1 pathway reduced the therapeutic efficacy of CpG-ODN probably due to an effect probably mediated by macrophages.

P.B1.04.17

Estimation of antitumor effect of chemoimmunotherapy with methotrexate nanoconjugates and dendritic cell-based vaccines in MC38 murine colon carcinoma model

A. Szczygieł, *N. Anger, K. Węgierek, J. Mierzejewska, J. Rossowska, T. Gościczyński, M. Świtalska, E. Pajtasz-Piasecka;*
Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wrocław, Poland.

Nanoconjugates of methotrexate (MTX) and hydroxyethyl starch (HES) are a new type of therapeutic compounds formed from certified drugs widely used in medicine. Conjugation of MTX with HES prolongs the half-life of MTX and reduces its side effects. In order to enhance the therapeutic effect, we combined MTX-HES nanoconjugate with bone marrow-derived dendritic cells (BM-DCs), which are considered to be capable to activate the immune system in the host.
To determine the antitumor effect of chemoimmunotherapy, mice with subcutaneously growing MC38 tumor intravenously received MTX or MTX-HES and three days later, immunotherapy started (peritumoral injections of mature BM-DCs). To evaluate the changes in percentage of tumor infiltrating lymphocytes and myeloid cells, three days after chemotherapy or seven days after immunotherapy, tumors were collected for multiparametric flow cytometry analyses.
On the 3rd day after chemotherapy in MTX-HES-group the highest percentage of $CD4^+$ and $CD8^+$ T cells infiltrating tumor tissue was observed, moreover in both groups the percentage of Tregs was drastically decreased. Supplementing therapy with BM-DC-vaccines intensified this effect, additionally an increase in the percentage of NK cells was also noticed. Infiltration of leukocytes were enhanced only after chemoimmunotherapy, moreover application of BM-DC-vaccines resulted in reduction of percentage of myeloid cells with suppressor activity.
Concluding, therapy with nanoconjugates and BM-DCs-vaccines resulted in efficient response against growing tumor. These findings demonstrate that methotrexate-nanoconjugate immunomodulates the antitumor response and this effect was beneficial for generation of proper immune response by dendritic cells.
The study was funded by National Science Centre, Poland (project no.2015/19/N/NZ6/02908).

P.B1.04.18

Sodium stibogluconate in conjunction with CD47-SIRPαcheckpoint blockade enables rituximab-mediated killing of B lymphoma cells by neutrophils

D. J. van Rees[1], *M. van Houdt*[1], *A. Tool*[1], *P. Verkuijlen*[1], *K. Schornagel*[1], *K. Franke*[1], *T. W. Kuijpers*[1,2], *T. K. van den Berg*[1,3], *H. L. Matlung*[1];
[1]*Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [2]*Emma Children's Hospital, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [3]*Department of Molecular Cell Biology and Immunology, VU medical center, Amsterdam, Netherlands.*

Rituximab (Rmab) is used as a first-line treatment for CD20-expressing B cell malignancies. It is believed to act by a combination of direct and immune-mediated effects, including complement- and immune cell- dependent mechanisms. However, neutrophils, the most abundant effector cells mediating antibody-dependent cellular cytotoxicity (ADCC) are incapable of killing Rmab-opsonized B lymphoma cells. Instead, Rmab triggers neutrophil trogocytosis of CD20-containing plasma membrane fragments of the target cells, which is believed to render the tumor cells resistant against further Rmab-dependent destruction. Interestingly, we found previously that neutrophils exert an entirely novel type of cytotoxicity against antibody-opsonized solid cancer cells, designated *trogoptosis*, which actually involves a trogocytic process. Here, we demonstrate that the lack of cytotoxicity of neutrophils towards Rmab-opsonized B lymphoblastoid cells is not due to an inherent defect of neutrophils to destroy such target cells, but rather to intrinsic properties of the CD20-Rmab complex. Furthermore, we present evidence that a combination of CD47-SIRPα checkpoint blockade and the tyrosine phosphatase inhibitor sodium stibogluconate (SSG) are able to overcome the neutrophil defect to effectively kill B lymphoma cells in the presence of Rmab. This provides opportunities for improving the clinical efficacy of Rmab treatment in cancer.

P.B1.04.19

The supernatant of immature dendritic cells mediates RIP1-dependent apoptosis

Z. Varga, *E. Jakab-Racz, A. Szabo, E. Rajnavolgyi, G. Koncz;*
Department of Immunology, University of Debrecen, Debrecen, Hungary.

Dendritic cells (DCs) are known to engulf dead cells continuously and present antigenic fragments derived from infected cells and tumor antigens thus having the capacity of triggering naïve $CD8^+$ T cells. The cross-priming process has been known as a unique route to initiate classical T cell responses. *In vitro* generated moDCs have also been demonstrated to induce apoptosis in target cells.
We provide evidence here that supernatants of activated immature moDCs activated by PRR agonist (LPS, poly (I:C) or Cl-075) induces cell death on Jurkat cells. In contrast, the supernatant of mature DCs were less cytotoxic, which may effect on the adoptive DC therapies. TNF:Fc fusion protein inhibited the cytotoxic activity of DCs in contrary to Fas and TRAIL antagonists, suggesting it is a TNF dependent, but Fas and TRAIL independent process. In contrary to cytotoxic T cell-mediated killing, secreted vesicles from culture supernatants of moDC were not able to generate cell death. To define the molecular mechanisms of DC-mediated signaling we were able to detect RIP1-dependent cell death. Pretreatment of target cells with a pancaspase inhibitor (zVad) completely blocked moDC triggered apoptosis, but necroptosis inhibitor (nec-1) did not prevent this cell death.
In summary, our results indicate that the supernatant of immature dendritic cells induces RIP1-dependent apoptosis, which may be relevant for tumor immunotherapy broaden the plethora of cytotoxic mechanisms acting against tumoric cells.
The work is supported by NKFIH-K-125224 and by the GINOP-2.3.2-15-2016-00050 project. The project is co-financed by the European Union and the European Regional Development Fund.

P.B1.05.01

From mono- to bivalent: increasing affinity of EGFR-specific target modules results in enhanced anti-tumor properties of the UniCAR system

S. Albert[1], *C. Arndt*[2], *S. Koristka*[2], *N. Berndt*[2], *R. Bergmann*[2], *A. Feldmann*[2], *M. Bachmann*[1,2,3];
[1]*University Cancer Center Dresden, Dresden, Germany,* [2]*Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Institute of Radiopharmaceutical Cancer Research, Dresden, Germany,* [3]*German Cancer Consortium (DKTK), partner site Dresden and German Cancer Research Center (DKFZ), Heidelberg, Germany.*

Introduction: Despite improvement of conventional cancer therapies, treatment of epithelial tumors needs to be further optimized. Especially chimeric antigen receptor (CAR)-modified T cells possess a tremendous immunotherapeutic potential. However, due to the risk of serious side effects and the lack of efficient control mechanisms, we established the switchable modular UniCAR system. This system is composed of two distinct components, T cells expressing a universal CAR (UniCAR) and exchangeable tumor-specific target modules (TMs). Based on the modular structure, engrafted T cells are inert in the absence of TMs and only switched on in their presence.
Materials and Methods: For redirection of UniCAR T cells to epithelial tumors, we recently generated a monovalent nanobody-based α-EGFR TM. After expression in CHO cells, the construct mediated an antigen-specific tumor cell lysis. To analyze whether the functionality can be improved by increasing the affinity, a bivalent α-EGFR-EGFR TM was established and compared to the monovalent counterpart.
Results: Due to raising the number of binding sites, the bivalent TM shows an increased avidity, higher levels of released pro-inflammatory cytokines and an improved killing capability *in vitro* and *in vivo*. Nevertheless, cells with an EGFR density comparable to physiological numbers of EGFR are not eliminated and, therefore, destruction of healthy tissues is rather unlikely.
Conclusions: Summing up, increasing the avidity of the TM enhances its functionality.

P.B1.05.02

Testing monoclonal antibodies blocking TGF-β1 production from human GARP/TGF-β1 complexes in mutant mice expressing a humanized form of Garp

***C. Bertrand**;*
de Duve Institute, Brussels, Belgium.

Regulatory T cells (Tregs) are important contributors to immunosuppression in tumors. Based on our previous work, we believe that TGF-β1 is a major player in Treg-mediated immunosuppression. We showed that Tregs activate TGF-β1 through a mechanism that implies transmembrane protein GARP and can be inhibited with blocking anti-GARP antibodies, which could thus serve as drugs to increase anti-tumor immune responses.
Our blocking antibodies bind h(uman) GARP, but not m(urine) GARP. We thus generated mice expressing a humanized version of Garp (*mGarp*$_{Hu137\text{-}139}$ mice) that can be bound by the blocking anti-hGARP antibodies.
In this project, our main objective is to assess the activity and toxicity of blocking anti-hGARP antibodies in preclinical models of cancer in *mGarp*$_{Hu137\text{-}139}$ mice.
Generation of *mGarp*$_{Hu137\text{-}139}$ mice was performed by subcontractors in two genetic backgrounds, namely C57BL/6 and DBA/2. Homozygous mutant mice were born to Mendelian ratios from heterozygous couples, and showed no gross anomaly after birth.
We show that the *mGarp*$_{Hu137\text{-}139}$ mutation does not affect the expression pattern of the *Garp* gene in the genetically manipulated mice, by comparison to wild-type littermates. Flow cytometry and qPCR analysis of various organs (thymus, blood, spleens, bone marrows, lymph nodes) indicate normal hematopoietic cell development and numbers. No signs of auto-immunity or general T cell activation is observed in mutant mice.
We verified that Tregs from mutant *mGarp*$_{Hu137\text{-}139}$ mice were able to produce active TGF-β1 upon *in vitro* stimulation, and that this production could be blocked with the blocking anti-hGARP antibodies.

P.B1.05.03

Towards a clinical grade CD137-based isolation and expansion of neoantigen-specific T-cells for tailored cancer adoptive cell therapies

***V. Bianchi**, S. Bobisse, R. Genolet, L. Kandalaft, G. Coukos, A. Harari;*
Ludwig Institute for Cancer Research, Lausanne, Switzerland.

Mounting evidence suggests that neoantigens tumor neo-antigens derived from non-synonymous somatic mutations represent ideal candidates to target with T-cell mediated immunotherapies. The selective isolation of low frequency neoantigen-specific T-cells in patients' TIL (Tumor Infiltrating Lymphocyte) and PBMC (Peripheral Blood Mononuclear Cell) bulk populations represents one of the major challenges in the development of personally tailored cancer T-cell therapies. A surface marker uniformly upregulated upon activation would facilitate the isolation of neoantigen-specific T-cells when cognate peptide-HLA multimers are not. The TNFR family member CD137 has been well characterized as a specific marker of TCR-induced activation of conventional CD8+ (and CD4+) T-cells. Following antigen-specific stimulation, CD137 expression on CD8+ T-cells peaks at 20-24h, therefore allowing the detection of viable T-cells displaying reactivity to the epitope of interest. Within the framework of our translational neoantigen discovery platform, we are in the process of developing a clinical-grade strategy for the *ex vivo* isolation and expansion of viable neoantigen-specific T-cells based on CD137 expression and flow-cytometric separation from patients' TIL and/or blood samples. The protocol is currently being validated on healthy donors PBMC samples with known viral and tumor T-cell reactivities and, in close collaboration with the Process Development team at CTE (Lausanne), will be performed with clinical grade compliant materials and reagents. By enriching for neoantigen-specific T-cells prior to infusion, it may be possible to improve the overall response rate achieved so far by unselected adoptive T-cell therapies.

P.B1.05.04

Preclinical Safety, Pharmacokinetics and Pharmacodynamics of BION-1301, a first-in-class antibody Targeting APRIL for the Treatment of Multiple Myeloma

***J. Dulos**;*
Aduro Biotech Europe, Oss, Netherlands.

BION-1301 is a first-in-class humanized antibody targeting APRIL (TNFSF13). A single-dose non-human primate (NHP) study administering intravenous BION-1301at 0.3, 3 and 30 mg/kg dose levels yielded PK parameters typical for IgG4 class antibodies and an absence of tolerability issues. PD analysis showed a statistically significant reduction in total IgA and IgM in a dose-dependent fashion. Consistent with previous observations in hAPRIL transgenic mice, BION-1301 reduced TNP-specific IgA and IgM in NHP in a dose-dependent fashion. Using a weekly dosing regimen, a 4-week repeat-dose toxicity study was conducted at 10, 30 and 100 mg/kg, demonstrated that BION-1301 had no effect on vital organs and other toxicology related factors examined at any dose level up to 100mg/kg. Chronic exposure to BION-1301 led to significantly reduced levels of IgA, IgG and IgM observed at all dose levels. To determine target engagement of BION-1301, quantitative assays were developed to detect free APRIL and BION-1301. BION-1301 reduced free APRIL levels in serum in a dose-dependent manner following single and multiple dose administrations. Using a MABEL approach, PK/PD modeling informed a proposed human starting dose of 50 mg. In summary, BION-1301 showed no toxicity in NHP and binding of APRIL resulted in decreased IgA, IgG and IgM levels. PK and target engagement biomarkers predicted the first-in-human dose using PK/PD pharmacometric modeling. BION-1301, which was shown preclinically to inhibit MM proliferation, survival, and drug resistance and reversed an immune suppressive phenotype, is being evaluated in previously treated MM patients in an ongoing Phase 1/2 clinical trial.

P.B1.05.05

Synergistic killing of glioblastoma stem-like cells by monoclonal antibody 8B6 specific for O-acetyl-GD2 and temozolomide

***S. Fougeray**;*
CRCINA - INSERM U1232, Nantes, France.

Introduction: Glioblastoma multiforme (GBM) is the most deadly primary brain tumors. Therapeutic options are limited and there is no cure. Moreover, almost all patient develop recurrent tumors, which are generally more aggressive. GBM recurrence is related to the presence of highly tumorigenic GBM cells, the glioblastoma stem-like cells (GSC). GSC are resistant to standard of care glioblastoma therapy consisting of radiotherapy and temozolomide (TMZ). As such, sensitizing GSC to the current standard of care will potentially improve its therapeutic impact.
Materials and methods: We first evaluated the O-acetyl-GD2 (OAcGD2) expression on GSC by flow cytometry. Next, we characterized the effects of anti-OAcGD2 monoclonal antibody 8B6 + TMZ combination on tumor cell viability, using an MTT assay and *in vivo* in an orthotopic GBM xenograft mice model.
Results: Here we found that OAcGD2 ganglioside is expressed on GSC. We further demonstrated that 8B6 + TMZ synergistically inhibited glioblastoma cell proliferation and compromised GSC survival *in vitro*. These findings correlated with longer therapeutic response evidence *in vivo*. Mechanistically, we evidenced that 8B6 oncosis-like properties increased cytotoxic drug uptake into GBM cells. As a result, 8B6 + TMZ combination induced significantly increased DNA damages and tumor cell death than either 8B6 or TMZ monotherapy.
Conclusion: Taken together, our data provides a mechanistic rationale for anti-OAcGD2 monoclonal antibodies as chemosensitizing agents to improve the response of GBM to TMZ.
Disclosure: JF, SFa and SB are designed as inventor of pending patents covering cancer immunotherapy targeting O-acetyl-GD2.

P.B1.05.06

Assessment of HER2 amplification in paired tumoural/non-tumoural gastric adenocarcinoma samples by reliable molecular biology methods

***I. Juarez**[1], J. F. Toro-Fernandez[1], A. Gutierrez[2], A. Blazquez[2], E. Ovejero[2], I. Lasa[2], A. Lopez[2], R. Gomez[2], J. M. Martin-Villa[1];*
[1]Universidad Complutense de Madrid, Dpt. of Immunology, Madrid, Spain, [2]Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Madrid, Spain.

Gastric cancer is the fifth most common malignancy, and the third cause of death by cancer in the world (survival rate below 30%). There are no specific biomarkers for this disease, and so the therapeutic approach consists of the resection of the tumour and adjuvant chemo-radiotherapy.
HER2 (Human epithelial growth factor receptor 2) is a tyrosine-kinase receptor whose genetic amplification and overexpression is a common malignant trait in breast cancer. This gives way to the treatment with Trastuzumab, a specific antibody that recognizes the HER2 malignant cells and gives patients a better predictive value. Some works have found that HER2 overexpression is not specific of breast cancer, but could also play a role in gastric adenocarcinoma.
40 samples from gastric adenocarcinoma patients were obtained at Hospital Universitario Principe de Asturias (Madrid). As positive control, DNA from cell-lines SKBR-3 and BT-474 was used.
HER2 genetic-amplification was measured by differential PCR (dPCR) for HER2 and IFN-γ, run the samples in a 3% agarose gel and calculated the bands densitometry. In addition, qPCR for the same genes was also done. In both cases, HER2-amplification was determined by measuring the HER2/IFN-γ signal ratio.
A cut-off point was established using 26 controls and confirmed HER2 amplification in 25% of gastric cancer patients by both DNA-based methods. Results were confirmed by IHC. These results suggest that HER2-positive patients are not a scarce in gastric adenocarcinoma and overexpression ought to be assessed by more than one method. For these patients, Trastuzumab might become a good therapeutic approach.

P.B1.05.07

Depletion of CAR-expressing lymphocytes using autologous anti-CAR-engrafted T cells

S. Koristka[1], *P. Ziller-Walter*[2], *A. Feldmann*[1], *C. Arndt*[1], *S. Albert*[2], *G. Ehninger*[3,4,5], *M. Bornhäuser*[3,4,5], *M. Bachmann*[1,2,4];
[1]*Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany,* [2]*Tumor Immunology, UniversityCancerCenter (UCC) `Carl Gustav Carus' Technische Universität Dresden, Dresden, Germany,* [3]*Medical Clinic and Policlinic I, University Hospital `Carl Gustav Carus' Technische Universität Dresden, Dresden, Germany,* [4]*German Cancer Consortium (DKTK), partner site Dresden and German Cancer Research Center (DKFZ), Heidelberg, Germany,* [5]*National Center for Tumor Diseases (NCT), `Carl Gustav Carus' Technische Universität Dresden, Dresden, Germany.*

Adoptive transfer of chimeric antigen receptor (CAR) T cells represents one of the fastest growing areas in cancer immunotherapy. Albeit gene-modified cells have demonstrated unparalleled antitumor efficiency in B cell malignancies, highly potent CAR T cells can cause severe and partly life-threatening side effects including cytokine release syndrome, neurological toxicity and off-target effects. Hence, there is an increasing demand for developing effective approaches to selectively ablate gene-modified cells *in vivo*.
Previously, we described an epitope tag (E-tag) derived from the human nuclear protein La that is incorporated into the extracellular domain of CARs and accessible by an anti-La monoclonal antibody (mAb). Based on this mAb, we generated a novel CAR construct for specific binding and depletion of E-tag-expressing CAR T cells.
We demonstrate that anti-E-tag-redirected T cells selectively eliminate CAR T cells that extracellularly express the E-tag whilst CAR T cells lacking this tag are not attacked. Interestingly, T cell killing is reciprocal and occurs in dependence of an intracellular signaling domain. Our studies further indicate that T cells expressing high CAR levels are more efficiently depleted than T cells with low CAR expression. Besides, $CD4^+$ and $CD8^+$ target cells are equally well eliminated by both $CD4^+$ and $CD8^+$ effector T cells.
Overall, we provide an approach for specific and efficient depletion of overactive CAR T cells in case patients experience severe side effects. The E-tag can be incorporated into all CARs irrespective of the targeted tumor antigen and represents a promising tool to improve safety of cell-based immunotherapies.

Peripheral blood immune profiling to predict response to PD-1 checkpoint blockade in patients with advanced non-small cell lung cancer

S. Lopez-Lastra[1,2], *T. Le Bourgeois*[1,3], *F. Bidard*[2,3,4], *S. Amigorena*[1,2], *O. Lantz*[1,2], *E. Romano*[1,2,3];
[1]*Center of Cancer Immunotherapy, Institut Curie, PSL Research University, Paris, France,* [2]*INSERM U932, PSL Research University, Institut Curie, Paris & St. Cloud, France,* [3]*Department of Oncology, Institut Curie, Paris & St. Cloud, France,* [4]*Université Versailles Saint-Quentin-en-Yvelines & Université Paris-Saclay, Saint Cloud, France.*

Introduction: Immune checkpoint inhibitors have remarkably improved the natural history of patients with non-small cell lung cancer (NSCLC), with improved clinical responses and overall survival compared to standard therapy. However, over 80% of unselected NSCLC patients do not respond, highlighting the need of theranostic biomarker discovery. In a cohort of NCSLC patients treated with anti-PD-1-blockade, we investigated blood immune parameters at baseline and patient characteristics as potential theranostic biomarkers. **Methods**: Thirty-four patients with locally advanced/metastatic NSCLC received either nivolumab or pembrolizumab as ≥ 2 line treatment in a prospective study at the Institut Curie. Peripheral blood mononuclear cells and serum were analyzed at baseline and correlated with outcome parameters based on immune-related RECIST criteria. **Results**: Baseline $CD3^+/CD14^+$ratio was the strongest predictive biomarker with patients achieving progression free survival (PFS) ≥4 months showing an average ratio of 1.91 vs 1.11 in patients with PFS ≤4 months (p=0,003). We found a strong positive correlation between the proportion of HLA-$DR^{hi}CD14^+$monocytes and the PFS (r=0,471), with objective responders showing higher CD86 expression, suggesting an improved antigen-presenting capacity. In addition, patients with a PFS ≥4 months, displayed higher proportions of $CCR7^-CD45RA^-$ effector memory $CD8^+$T cells and regulatory $CD4^+$T cells suggesting pre-existing adaptive immune responses. In line with previous reports, our results confirm the association of baseline serum albumin with clinical outcome in NSCLC, with levels ≥ 3.9 g/dL significantly associated with improved PFS (p=0,026).
Conclusions: Our study identifies promising, immune-related, theranostic biomarkers in NSCLC patients treated with PD-1 blockade.

P.B1.05.09

Dual CAR antiHER2-CD137 and anti-MUC1-CD3: a proposal of immunotherapy against anti-HER2 breast cancer

B. Marzal[1], *S. Betriu-Mendez*[1], *V. Ortiz-Maldonado*[2], *A. Boronat*[1], *J. Yagüe*[1], *M. Juan*[1,3], *A. Prat*[4];
[1]*Hospital Clínic - Servei d'Immunologia CDB, Barcelona, Spain,* [2]*Hospital Clínic - Servei d'Hematologia, ICMHO, Barcelona, Spain,* [3]*Plataforma d'Immunoteràpia HClínic-HSJD, Barcelona, Spain,* [4]*Hospital Clínic - Servei d'Oncologia, ICMHO, Barcelona, Spain.*

Introduction: Chimeric antigen receptors (CARs) are a new promising antitumoral immunotherapy. Despite great results in the treatment of hematologic malignancies, in solid tumors there are still some great challenges to overcome, being to avoid on-target off-tumor-effects one of the main aspects to improve. In our project we propose a novel dual CAR for the treatment of HER2+ breast cancer targeting ErbB2 (HER2) and Mucin-1 (MUC1). We present here some preclinical steps of this proposal.
Methodology and Results: After synthetizing scFv-HER2 and scFv-MUC1, we construct individuals CARs (CAR-HER2 and CAR-MUC1) with scFv sequence and 4-1BB/CD3ζ intracellular signaling domains. Delivering them into human T cells by lentiviral transduction for each CAR, we tested their specific and powerful. Dual CAR was also synthesized dissociating co-stimulatory domains: scFv-HER2 with 4-1BB and scFv-MUC1 with CD3ζ. We evaluate the specificity, functionality, and safety by comparing cytotoxicity in co-culturing with SK-BR3 and T-47D breast cancer cell lines.
Conclusions: The creation of a dual CAR to fight against breast cancer HER2+ is feasible and it is a new promising proposal for the treatment of HER2+ breast cancer tumors.
Study mainly supported by Fundación Eugenio Rodrigez Pascual PI044185 and partially by projects PI13/0676 and PIE13/033, integrated in the Plan Nacional de I+D+I (ISCIII - Subdirección General de Evaluación y Fomento de la Investigación Sanitaria - and FEDER).

P.B1.05.10

A high throughput approach for the parallel identification of TCRs recognizing multiple antigens with clinical relevance for the treatment of B cell malignancies

M. H. Meeuwsen, *C. Kweekel, L. Jahn, D. M. van der Steen, R. S. Hagedoorn, M. G. Kester, M. Griffioen, P. A. van Veelen, F. Falkenburg, M. H. Heemskerk;*
LUMC, Leiden, Netherlands.

CAR T-cell therapies for the treatment of B-cell malignancies have shown great promise in clinical trials. However, antigen negative escape variants can cause disease relapse and therefore additional therapies are needed. To increase the number of potential targets we propose a TCR-based approach to target both intracellular and extracellular proteins. Illumina HT-12 microarray data was used to select 31 target genes expressed in B-cell malignancies but not in healthy tissues other than B-cells. To broaden to scope of TCR gene therapy beyond HLA-A*02, peptides presented in HLA-A*01, A*24, B*08 or B*35 were selected. Elution of HLA-presented peptides and mass spectrometry was used, which led to the identification of 19 target genes derived peptides presented in one of the HLA-alleles of interest. Peptide-HLA tetramers were used to single cell sort tetramer+ CD8+ T-cells from healthy donor PBMCs. Donors were negative for the HLA alleles of interest to allow identification of high affinity T-cells from the allo-HLA repertoire. In total 12.300 T-cells were single-cell sorted of which 62 T-cell clones recognized one of the candidate peptides. Of these 62 T-cell clones 23 were potent enough to recognize endogenously processed and presented peptide by target gene and HLA transduced k562 cells. For safety reasons only 9 T-cell clones were selected that specifically recognized the candidate epitope without recognizing other HLA-peptide combinations. Finally 3 T-cell clones specific for two different targets effectively recognized malignant B-cells. The TCRs of these clones could be promising candidates for TCR gene transfer therapy to treat B-cell malignancies.

P.B1.05.11

z-Movi: A high throughput cell-cell avidity screening and sorting acoustic force based technology

W. Scheper[1], ***E. Merino Rodriguez***[2], *R. Braster*[2], *G. Sitters*[2], *F. Oswald*[2], *R. Driessen*[2], *T. Schumacher*[2], *A. Candelli*[2];
[1]*The Netherlands Cancer Insitute, Amsterdam, Netherlands,* [2]*LUMICKS, Amsterdam, Netherlands.*

Adoptive cell therapy can be an effective treatment option in a proportion of cancer patients. Nevertheless, the clinical efficacy of such therapies is likely limited by a lack of tools to quantitatively select and sort the most potently tumor-reactive immune cells at high throughput. Here, we developed a novel platform that uses acoustic force manipulation to query the interaction strengths of cells with their cognate binding partners. This technology, based on acoustic forces, is a lab-on-a-chip assay that allows the assessment of thousands of cell-cell interactions in parallel. Moreover, this technology provides an accurate, label-free method to isolate cells based on their avidity to specific targets, such as (tumor) cells as well as proteins, peptides, and viruses. As a proof of concept, we validated our technology by analyzing the functional avidity of T-cells towards tumor cells and found that it permits the separation of tumor-specific T-cells from non-specific bystander T-cells. These data demonstrate the potential of this platform in profiling T cell-tumor cell interaction and pave the way to quantitative cell-cell avidity studies as well as a selection of patient-specific immune effector cells or immune receptors for therapeutic use.

P.B1.05.12

HLA DP as a transmembrane anchor for chimeric TCR dimers to improve TCR transgenic therapies

L. T. Morton, *R. Hagedoorn, D. Remst, T. Jonkman, F. Falkenburg, M. H. Heemskerk;*
Leiden University Medical Centre, Leiden, Netherlands.

Ex-vivo introduction of tumour-reactive T-cell receptors (TCRs) into patient-derived T-cells result in redirected T-cell responses towards tumours. TCRαβ expression depends on formation of the CD3 signalling complex via non-covalent interactions within the transmembrane (TM) domains. Competition between endogenous TCR and introduced TCR for binding to the CD3 signalling complex, has been shown to interfere with introduced-TCR expression, thereby reducing future therapeutic efficacy. To remove competition, chimeric TCR dimers (cTD) were designed to incorporate TM domains from type I heterodimeric TM proteins, linked to the intracellular signalling domains of CD3ζ.

We hypothesised cTDs would demonstrate CD3-independent expression of introduced-TCR and allow for improved antigen-specific T-cell responses against tumour targets. Here, cTDs were engineered to incorporate 1) the extracellular domains of TCRαβ, specific for B-cell antigen BOB1, 2) the TM domains of HLA-DPαβ and 3) the intracellular CD3ζ signalling motifs (BOB1-DP-3z). Firstly, BOB1-DP-3z was expressed in $TCR^{neg}CD3^{pos}$ Jurkat-76 cell lines and demonstrated BOB1-specific pMHC-tetramer binding at the cell surface. Furthermore, in contrast to wild-type BOB1-TCR, BOB1-DP-3z expressing Jurkat-76 cells did not show surface expression of CD3, demonstrating CD3-independent expression of cTD. Next, BOB1-DP-3z was expressed in primary CD8 T-cells and co-cultured with BOB1-expressing tumour-target cells. Despite demonstrating BOB1-specific pMHC-tetramer binding, BOB1-DP-3z expressing CD8 T-cells were unable to produce functional T-cell responses against tumour targets. Inclusion of CD28 intracellular signalling motifs also did not prompt functional T-cell responses against tumour targets. In conclusion, in the context of the BOB1-specific TCR, HLA-DP appeared to be unsuitable as a TM anchor for functional TCR expression.

P.B1.05.13
Novel method for the manufacture of CAR-T-cells: Effects of different cytokines in culture media on the phenotype of CAR-T-cells

***J. Musil**, P. Ptáčková, P. Otáhal, P. Gabriel, M. Kroutilová, Š. Něměčková;*
IHBT, Prague, Czech Republic.

Current manufacture of clinical CAR-T-cells is primary based on lentiviral/retroviral transduction of CD3/CD28 activated T-cells and subsequent cultivation in the presence of IL2. This well-established approach, however has few weak points such as that it induces polyclonal T-cells activation resulting in low frequency of transduced T-cells and that the anti-CD3/CD28 activation is supra-physiological and modifies the differentiation of T-cells. Recently, alternative methods for efficient T-cells expansion were developed which are based on T-cell stimulation with antigen followed by cultivation in the presence of cytokines IL4 and IL7. We present a novel method of manufacturing CD19+ CAR-T-cell by electroporation of plasmid DNA followed by cultivation in the presence of cytokines IL2, IL4, IL7 and/or IL21 without any additional artificial T-cell activation step. This method leads to a spontaneous activation of transfected T-cells probably through recognition of endogenously present B cells, which results in overall CAR19+ cell yield (>90% CAR+) surpassing the standard methods. Cultivation of CAR19 T cells in the presence of IL4 and IL7 preferentially expands CD4+ CAR19 T-cells. Addition of IL2 or IL21 into this cytokine cocktail enhances expansion of CD8+ CAR19 T cells. However, IL21 preferentially expands CD8+ central memory T-cells. Furthermore, it enhances expression of costimulatory molecules CD28 and CD27 on CD8+ CAR-T-Cells and decreases expression of inhibitory receptors. This project is supported by grant NV15-34498A of the Ministry of Health, Czech Republic and by the European Regional Development Fund and OP RDE, Ministry of Education, Youth and Sports of the Czech Republic (project AIIHHP: CZ.02.1.01/0.0/0.0/16_025/0007428).

P.B1.05.14
Devising a dual chimeric antigen receptor system to prevent on-target off-tumor effect of engineered T cells

***T. Peters**[1], V. Gudipati[1], O. Dushek[2], M. Hudecek[3], J. B. Huppa[1];*
[1]Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria, [2]Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom, [3]Medizinische Klinik und Poliklinik II, Universitätsklinikum Würzburg, Würzburg, Germany.

CAR-T cell therapies have shown to be potent tools in the fight against cancer as validated by the recent FDA approval of two such therapies against B cell malignancies. However, a complication associated with all current CAR designs is limited tumor-specificity due to the non-existence of tumor-specific antigens for the CAR to act upon. As a consequence, CAR-T cells attack invariably healthy tissue. To overcome this impediment, we are devising a logic gate CAR-T cell system based on the combinatorial recognition of at least two antigens, which we expect to confer sufficient discriminatory power for cancer therapy with much reduced off-target toxicity. To this end we co-express in addition to the tumor-associated antigen-specific CAR a second CAR with inhibitory properties (iCAR) binding to a surface antigen exclusively present on healthy tissue to be protected from CAR-T-cell attack. For proof of concept and system optimization we derive the iCAR from the well characterized high affinity 1G4 TCR, which targets HLA-A201/NY-ESO-1 as model antigen and which can be precisely fine-tuned through the use of NY-ESO-1-derived altered peptide ligands within an affinity spectrum covering 6 orders of magnitude. Tumor-specificity, killing capacity and intracellular signaling characteristics will be assayed through (i) conventional immunological assays and (ii) a preclinical molecular imaging platform, which involves the use of protein-functionalized planar supported lipid bilayers serving as target cell surrogate in combination with advanced microscopy affording single molecule resolution. This project is funded by the Marie Sklodowska-Curie action EN-ACTI²NG program, from the European Commission.

P.B1.05.15
Increasing CAR T-cell efficacy in prostate cancer with an immunocytokine targeted to the tumour microenvironment

***E. Runbeck**, J. Maher, S. Papa;*
King's College London, London, United Kingdom.

Chimeric Antigen Receptor (CAR) T cell therapy received landmark FDA approvals for haematological indications in 2017. Solid tumours raise many challenges and anticipated breakthroughs remain elusive. Prostate cancer (PCa) is a highly prevalent disease with a significant unmet need in the advanced setting. The Prostate Specific Membrane Antigen (PSMA) CAR P28ζ has established *in vitro* and *in vivo* efficacy in PCa models but has not met expectations in clinical studies highlighting the need for strategies to enhance efficacy. We have co-expressed the chimeric cytokine receptor 4αβ (consisting of the interleukin-4 (IL-4) receptor alpha in series with the IL-2/15 receptor beta), with P28ζ (4P28ζ). In response to IL-4, 4αβ delivers an IL-2/15 signal in the CAR-T cell. Fibroblast Activation Protein (FAP) is a stromally expressed trans-membrane enzyme found in the stroma of epithelial tumours and healing wounds. We hypothesised that a FAP specific IL-4 immunocytokine would enhance 4P28ζ proliferation, survival and cytotoxicity in the tumour microenvironment. FAP-specific hybridomas were screened for FAP specificity. Single chain variable fragments (scFvs) from clones B1 and C11 were cloned into the IgG1 heavy chain expression vector with a positive control scFv ESC11 and a derivative ESC11 immunocytokine. Screening for FAP specificity was undertaken. PCa cell lines (PC3-LN3, DU145) we engineered to express PSMA, firefly luciferase and the tdTomato reporter genes. Embryonic fibroblasts (MRC5), which naturally express FAP, were transduced with the far-red mNeptune reporter gene. Co- culture ratios for PCa:MRC5 were established *in vitro* and *in vivo* for the functional testing of anti-FAP-IL4 efficacy.

P.B1.05.16
Effect of N-deglycosylation on the immunogenic and antitumor properties of hemocyanins in mammals.

***M. Salazar**[1], J. M. Jiménez[1], J. Villar[1], M. Rivera[2], M. Báez[2], A. Manubens[3], M. I. Becker[1,3];*
[1]Fundación Ciencia y Tecnología para el Desarrollo (FUCITED), Santiago, Chile, [2]Facultad de Ciencias Químicas y Farmacéuticas, Universidad de Chile, Santiago, Chile, [3]Biosonda S.A, Santiago, Chile.

Mollusk hemocyanins from *Concholepas concholepas* (CCH), *Fisurella latimarginata* (FLH) and *Megathura crenulata* (KLH) are glycoproteins widely used as carriers, adjuvants, and non-specific immunostimulants in cancer because they bias towards Th1 immunity. Hemocyanins are oligomeric glycoproteins (4-8 MDa), with complex didecameric structures and heterogeneous glycosylations, mainly mannose-rich N-glycans. We have demonstrated that murine antigen presenting cells incorporate hemocyanins through mannose-recognizing C-type lectin receptors (CLRs), such as Mannose Receptor (MR) and Dectin-2. However, the role of N-glycans on the immunologic properties of these proteins has not been compressively demonstrated.
We hypothesized that enzymatic N-deglycosylation of hemocyanins decreases their immunogenic and antitumor effects in mammals.
Hemocyanins were enzymatically and chemically deglycosylated, by treatment with peptide:N-glycosydase-F and sodium periodate, respectively. Biochemical analyses showed structural modifications in N-deglycosylated hemocyanins, and the presence of residual fucose-rich glycans. ELISA analyses showed a decreased binding of deglycosylated hemocyanins to chimeric receptors MR-Fc and Dectin-2-Fc. The humoral and antitumor responses were explored in the B16F10 murine melanoma model, in which mice were primed with native and N-deglycosylated hemocyanins. After 14 days, mice were challenged with melanoma cells and underwent intralesional immunotherapy. Tumor volume was higher in mice treated with N-deglycosylated KLH, compared with native KLH, while no differences were observed with N-deglycosylated CCH and FLH. The specific serum antibody titer, measured by ELISA, showed a decreased humoral response in groups immunized with N-deglycosylated hemocyanins. These results suggest that N-glycosylations of hemocyanins play a role in their structure, immunogenicity, and would contribute to their antitumor potential.

P.B1.05.17
Characterization of MSLN CAR T-cells in an ovarian cancer model

***E. Schoutrop**[1], I. Magalhaes[1], I. El Serafi[1], Y. Zhao[2], M. Hassan[2], J. Mattsson[1];*
[1]Karolinska Institute - Department of Oncology-Pathology, Stockholm, Sweden, [2]Karolinska Institute - Department of Laboratory Medicine, Stockholm, Sweden.

Chimeric antigen receptor (CAR) T-cells are engineered to target surface antigen with the specificity of a monoclonal antibody combined with full activation of T cell effector functions. Mesothelin (MSLN) is an attractive target for CAR T-cell immunotherapy in ovarian cancer, with 60-65% of the ovarian tumors being MSLN+. Here we compare two 2nd generation MSLN directed CAR constructs containing different co-signaling domains (MSLN-CD28z and MSLN-4-1BBz) and evaluate if MSLN CAR T-cells can effectively attack ovarian cancer *in-vitro* and *in-vivo* using an orthotopic mouse model. RD114 packaging cell lines were used for the production of γ-retroviral vectors encoding for MSLN-CD28z-CAR, MSLN-4-1BBz-CAR, MSLN, or GFP-Luciferase. Healthy donor (HD) PBMCs were transduced with MSLN-CD28z and MSLN-4-1BBz γ-retroviral vectors to generate MSLN CAR T-cells. The human ovarian cancer cell line, Ovcar-3, was used as target following transduction with MSLN and GFP-Luciferase γ-retroviral vectors.

Successful generation of MSLN-CD28z and MSLN-4-1BBz CAR T-cells from HD PBMCs was established. The newly generated MSLN-CD28z and MSLN-4-1BBz CAR T-cells showed killing capacity *in-vitro.* Stable transduction of Ovcar-3 cells with MSLN and GFP-Luciferase vector constructs was achieved. The techniques required for MSLN CAR T-cell generation were established, as were the techniques for ovarian cancer cell transduction with MSLN and GFP-Luciferase. The latter will allow for monitoring of tumor engraftment and killing by MSLN CAR T-cells *in-vivo* in the future orthotropic mouse model.

P.B1.05.18

Dual-specific T cells and an indirect vaccine eradicate large solid tumors

C. Y. Slaney[1,2], *B. von Scheidt*[1,2], *A. S. Unsworth*[1,2], *J. A. Westwood*[1,2], *A. J. Davenport*[1,2], *A. Ali*[1,2], *S. Mardiana*[1,2], *P. A. Beavis*[1,2], *D. C. Tscharke*[3], *S. A. Rosenberg*[4], *N. P. Restifo*[4], *P. Neeson*[1,2], *P. K. Darcy*[1,2], *M. H. Kershaw*[1,2];

While immunotherapy can eliminate substantial burdens of some leukaemias, the ultimate challenge remains the eradication of large solid tumors and metastases for most cancers. Here we generate dual-specific T cells expressing a chimeric antigen receptor (CAR) specific for Her2 and a TCR specific for the melanocyte protein (gp100). Injection of T cells, together with a vaccine that contains a recombinant vaccinia virus expressing gp100, induced durable complete remission of a variety of Her2$^+$ tumors and established metastases, some in excess of 150 mm^2, in immunocompetent mice expressing Her2 in normal tissues. Tumor destruction occurred rapidly over seven days and was associated with an extensive infiltrate of T cells. Mice that had rejected tumors were resistant to rechallenge with the same Her2$^+$ tumor cells, indicating the formation of immune memory. Furthermore, we have established methods to transduce dual-specific T cells from human peripheral blood with both a TCR specific for gp100 and a CAR for Her2. From as little as 1 ml of human buffy coat, we could generate sufficient numbers of cells for a course of treatment for a patient. The stimulation of gp100 through TCR enhanced the human dual-specific CAR T cell proliferation, secretion of IFN-γ and killing of Her2$^+$ human cancer cells *in vitro.* These characteristics were identified to be important for eradicating tumors in the mouse models. Taken together, our data provide valuable information for the development of CAR T cell therapies for patients with solid cancers and evidence for pursuing a phase I clinical trial.

P.B1.05.19

Combination therapy of CAR-NK cells and anti-PD-1 antibody displays potent efficacy against late-stage Glioblastoma and induces protective antitumor immunity

F. Strassheimer[1], *C. Zhang*[2,3], *I. C. Mildenberger*[1], *P. N. Harter*[4,3], *T. Tonn*[5], *J. P. Steinbach*[1,3], *W. S. Wels*[2,3], *M. C. Burger*[1,3];

Introduction: Checkpoint inhibitors as well as adoptive cell therapy hold great promise for cancer treatment and promising treatment responses have already been demonstrated in different cancer indications. Glioblastoma (GBM) is the most common and aggressive primary brain tumor. Standard therapy prolongs life expectancy only by months. Analysis of the GBM tumor microenvironment (TME) indicates elevated suppressive leukocyte infiltration. While the surrounding brain is HER2-negative, GBM tumors are frequently HER2-positive, suggesting HER2 as a promising target for adoptive immunotherapy. Indeed, previous results show efficacy of CAR-NK cells (NK-92/5.28.z) targeted to HER2 in mouse glioma models at early stages of tumor development.
Materials and Methods: The murine glioma cell line GL261 was transfected with HER2. Tumor cells were implanted subcutaneously into C57BL/6 mice and treated either with HER2-specific NK-92/5.28.z, parental NK-92 cells, or in combination with anti-PD-1. Effects on tumor growth and survival were determined, and lymphocyte infiltration and immunosuppressive TME were characterized by flow cytometry.
Results: Combined treatment with NK-92/5.28.z cells and anti-PD-1 resulted in tumor regression and long-term survival of late-stage tumor bearing mice. Analysis of TME showed enhanced cytotoxic lymphocyte infiltration after treatment.
Conclusion: These data demonstrate enhanced efficacy of a combination of NK-92/5.28.z cells with checkpoint inhibitors in advanced tumors. Checkpoint inhibition possibly induces a cytotoxic rather than immunosuppressive TME, leading to a primed immune system. Thus, combination therapy may be a promising treatment goal for a clinical phase I/II study.

P.B1.05.20

Establishment and Application of a Panel of PBMC Humanized Mouse Tumor Models in Immuno-Oncology and Targeted Cancer Immunotherapy

L. Zhang[1], *Y. Jin*[1], *H. Wu*[1], *F. Chen*[1], *L. Zhao*[1], *X. An*[1], *W. Tan*[2], *X. Fu*[2], *M. Qiao*[1], *Q. Shi*[1], *W. Yang*[1];
[1]*Crown Bioscience, San Diego, United States,* [2]*Taicang Blood Center, Taicang, China.*

Monoclonal antibodies and checkpoint blocking approaches have achieved remarkable clinical success in cancer immunotherapy. Alongside the success of anti-PD-1 and anti-PD-L1 antibodies (such as Keytruda® and Tecentriq®), two bispecific antibodies, catumaxomab and blinatumomab have been approved to treat cancer patients, and many more bispecific antibodies are currently in preclinical or clinical development. To meet the increasing market needs for fast, reliable, and cost effective mouse tumor model systems, we have developed a panel of PBMC humanized tumor models - the MiXeno™ platform. MiXeno models can be used for a broad spectrum of applications in I/O drug discovery, including targeted cancer immunotherapy. To validate MiXeno models for targeted cancer immunotherapy, gene expression and mutation status was profiled across the CrownBio collection of over 200 xenograft models. Specific xenograft models were selected based on their tumor antigen or gene expression levels. Models which overexpressed a variety of tumor antigens (e.g. EGFR, CD47, Braf, PD-L1, etc.) were used to develop specific MiXeno tumor models via inoculation into PBMC-humanized immunocompromised mice. Reconstitution of human immune components with human PBMCs in these tumor-bearing mice provides a useful tool to evaluate targeted immunotherapeutics including bispecific T cell engagers. Graft versus host disease (GvHD) in these models can be managed by optimizing immune cell reconstitution and tumor cell engraftment. Several models from the resulting MiXeno platform have been validated using standard of care immuno-oncology drugs and characterized by immunophenotyping. Further studies are needed to expand the model collection and to extend platform applications in the I/0 space.

Influence of ionizing radiation on bispecific antibody-redirected T cells

C. Arndt[1], *D. Lindner*[2], *S. Koristka*[1], *A. Feldmann*[1], *N. Berndt*[3], *R. Bergmann*[1], *S. Albert*[2], *A. Ehninger*[4], *G. Ehninger*[5,6,3], *J. Steinbach*[1,3,6], *M. Bachmann*[1,2,3];
[1]*Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Institute of Radiopharmaceutical Cancer Research, Dresden, Germany,* [2]*UniversityCancerCenter (UCC) 'Carl Gustav Carus' TU Dresden, Tumor Immunology, Dresden, Germany,* [3]*German Cancer Consortium (DKTK), partner site Dresden; and German Cancer Research Center (DKFZ), Heidelberg, Germany,* [4]*GEMoaB Monoclonals GmbH, Dresden, Germany,* [5]*Medical Clinic and Policlinic I, University Hospital Carl Gustav Carus Dresden, Dresden, Germany,* [6]*National Center for Tumor Diseases (NCT), Dresden, 'Carl Gustav Carus' TU Dresden, Dresden, Germany.*

Introduction: Ionizing radiation not only leads to tumor cell killing via direct mechanisms, but also has positive modulating effects on the immune system. Consequently, combination of radio- and immunotherapy for treatment of cancer patients might improve clinical outcomes. Bispecific antibodies (bsAb) binding simultaneously CD3 and a tumor-associated antigen represent promising immunotherapeutic tools. As T cells are highly radiosensitive, we questioned, whether they could still be redirected via bsAb for efficient tumor cell killing after exposure to photonic radiation in context of combinatorial therapy.
Materials and Methods: By using a CD3-PSCA bsAb, the effect of γ-radiation on redirected T cells was examined on the example of prostate cancer. Therefore, T cells exposed to doses of 2-50Gy were cultured with PC3-PSCA cells in the presence or absence of the bsAb. Afterwards T cell proliferation, cytokine release and tumor cell lysis were analyzed.
Results: The CD3-PSCA bsAb engaged γ-irradiated T cells as good as unexposed T cells resulting in an efficient tumor cell lysis. However, high doses (30-50Gy) led to a slight decrease in anti-tumor cytotoxicity. Secretion of TNF, IFN-γ and IL-2 was enhanced after exposure of T cells to 2-20Gy in a bsAb-dependent manner, while proliferation and 5dsurvival was already impaired at doses ≥4Gy.
Conclusion: γ-irradiated T cells still exert a high anti-tumor reactivity upon bsAb-mediated cross-linkage. Thus, combination with radiotherapy is a feasible and promising approach. As ionizing radiation also promotes lymphocyte infiltration via indirect mechanisms, local reduction of T cell numbers due to radiation-induced cell cycle block might be compensated.

Introduction: Immunotherapy targeting GD2 in combination with IL-2 and isotretinoïn has emerged as a promising intervention for patients with neuroblastoma. The primary anti-GD2 antibody mechanism of action is based on antibody-dependent cell cytotoxicity induced by NK cells. However, a third of patient presents immunotherapy failure. One reason is the tumor microenvironment, which potentially inhibits optimal anti-tumor response. In this context, elucidation of the potential mechanisms of response merits consideration. Here we evidence by which isotretinoïn induces tumor immunotherapy escape.
Methods: We evaluated the anti-neuroblastoma response using isotretinoïn and anti-O-acetyl GD2 antibody 8B6 in the syngeneic NXS2 neuroblastoma model. Next, we studied the immune modulation induced by isotretinoïn. To this end, we studied the immune cell infiltrate composition and the immune checkpoint inhibitor PD1-L expression in NXS2 tumor in each treatment group by flow cytometry. Results: Treatment with isotretinoïn + 8B6 antibody outperformed treatments with either isotretinoïn or 8B6 antibody used as monotherapy. This effect was correlated with an increased percentage of NK cells in the tumor compared to controls. Isotretinoïn treatment also up-regulated the expression of PD1-L immune checkpoint inhibitor on the tumor cells.
Conclusion: In the isotretinoïn + 8B6 treated mice, the increase of tumor-infiltrating NK cells could contribute to potent 8B6 therapeutic efficacy. However, a better understanding of the cellular and the molecular changes following isotretinoïn is necessary to understand resistance mechanisms to anti-ganglioside immunotherapy in patients with neuroblastoma.
Disclosure: SFa and SB are designed as inventor of pending patents covering cancer immunotherapy targeting O-acetyl-GD2.

Retargeting T-cell cytotoxicity to a unique sialylated epitope on CD43 present in acute myeloid leukemia and melanoma

L. Bartels[1], *G. de Jong*[1], *M. Gillissen*[1], *E. Yasuda*[2], *V. Kattler*[2], *C. Bru*[2], *C. Fatmawati*[2], *A. Bakker*[2], *P. M. van Helden*[2], *J. Villaudy*[2], *M. D. Hazenberg*[3], *H. Spits*[1], *K. Wagner*[2];
[1]*AIMM Therapeutics & Academic Medical Center, Amsterdam, Netherlands,* [2]*AIMM Therapeutics, Amsterdam, Netherlands,* [3]*Academic Medical Center, Amsterdam, Netherlands.*

Introduction: From the B cells of an acute myeloid leukemia (AML) patient in long-term remission, we obtained the antibody AT1413. AT1413 binds a unique sialylated epitope on CD43 present in AML and other cancers, CD43s, and may be an interesting candidate for a bispecific T-cell engaging antibody (bTCE).
bTCEs are powerful, clinically validated tools to induce T-cell cytotoxicity independent of the T-cell receptor specificity by simultaneously binding a cancer surface antigen and CD3ε.
Methods: Using site-specific, chemo-enzymatic linkage, we attached an antibody fragment targeting CD3ε to an AT1413 variant unable to interact with Fc-receptors to generate AT1413 bTCE.
The capacity of AT1413 bTCE to induce tumor cell lysis was assessed in a T-cell cytotoxicity assay; T-cell activation marker upregulation and proliferation were monitored. AT1413 bTCE was tested *in vivo,* in two mouse models, one co-injected with human PBMC, the other engrafted with a human immune system (HIS) at birth.
Results: *In vitro*, AT1413 bTCE potently induced T-cell mediated lysis of different CD43s-expressing AML cell lines, primary AML blasts and melanoma cells. Endothelial cells with detectable, but low binding of AT1413 remained unaffected. T-cell activation and proliferation were observed only in the presence of target-expressing cells. I*n vivo* testing of AT1413 bTCE (2 mg/kg, biweekly) revealed potent AML tumor growth inhibition of 89-99 % compared with a control bTCE. In the HIS-model, normal human hematopoietic cells remained present in AT1413 bTCE treated mice.
Conclusion: Our results suggest that AT1413 bTCE, which recruits T cells to CD43s-expressing tumor cells, has therapeutic potential.

P.B1.06.04

Tumor eradication through CD47 blockage and immune response induction using cancer targeted immunogene therapy

M. Billerhart[1], *M. Schönhofer*[1], *S. Eckmann*[1], *A. Kassem*[1], *W. Polzer*[1], *M. Anton*[2], *J. Maier*[1], *A. Taschauer*[1], *H. Sami*[1], *M. Ogris*[1];
[1]*Laboratory of MacroMolecular Cancer Therapeutics (MMCT), Department of Pharmaceutical Chemistry, Centre of Pharmaceutical Sciences, University of Vienna, Vienna, Austria,* [2]*Institute of Experimental Oncology and Therapy Research and Institute of Molecular Immunology, Klinikum rechts der Isar, Technische Universität München, Munich, Germany.*

The overexpression of CD47 correlates with dismal prognosis in a broad range of cancers, since the interaction of CD47 with its ligand SIRPα (on macrophages and dendritic cells) prevents cancer cell eradication. Antibodies have been evaluated in advanced clinical trials for both blocking CD47 and triggering of antibody directed cytotoxicity. Unfortunately, their systemic application causes side effects like anemia, as CD47 is also abundantly expressed on non-malignant cells including erythrocytes.
Our approach of cancer targeted immunogene therapy circumvents these side effects by triggering the expression of CD47 blocking proteins within tumor cells.
We have cloned a plasmid vector encoding for the secreted fusion protein SIRPα-Fc consisting of the high affinity CD47 binding protein CV1 fused to a human IgG1 Fc part. After transient transfection of tumor cell lines we could demonstrate secretion of SIRPα-Fc, CD47 binding and -blockage on CD47 overexpressing cells. A potent bystander effect was demonstrated when transferring SIRPα-Fc containing supernatant from transfected cells to CD47 positive recipient tumor cells.
SIRPα-Fc transfected and luciferase-marked human MDA-MB-231 triple negative breast cancer cells were implanted orthotopically into SCID mice and tumor growth rate was evaluated by bioluminescence imaging (BLI). Here, the BLI tumor cell signal of SIRPα-Fc transfected cells strongly decreased when compared to controls.
In summary, we could demonstrate that the tumor-restricted secretion of the high affinity CD47 binder SIRPα-Fc is a potential gene therapy approach to prevent side effects in non-target organs, while unleashing the full antitumoral potential of CD47 blockade and immune activation.

Siglec-15 is a rapidly internalized cell-surface antigen expressed by acute myeloid leukemia cells

H. Cao[1], *A. Neerincx*[2], *B. de Bono*[3], *U. Lakner*[4], *C. Huntington*[5], *J. Elvin*[5], *E. Gudgin*[6], *C. Pridans*[6], *B. Huntly*[6], *J. Trowsdale*[2], *A. D. Barrows*[7];
[1]*Institute of Medical Sciences, Aberdeen, United Kingdom,* [2]*Immunology Division, Pathology Department, University of Cambridge, Cambridge, United Kingdom,* [3]*Auckland Bioengineering Institute, University of Auckland, Auckland, New Zealand,* [4]*Medical Faculty, University of Tuebingen, Tuebingen, Germany,* [5]*MedImmune, Milstein Building, Granta Park, Cambridge, United Kingdom,* [6]*Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom,* [7]*Department of Pathology and Immunology, Washington University School of Medicine, St Louis, United States.*

Acute Myeloid Leukemia (AML) is a clinically heterogeneous disease that is difficult to treat due to the lack of consistently expressed specific target cell antigens. Toxin-conjugated anti-Siglec-3 (also known as CD33) antibody may provide a useful therapeutic tool. However, CD33 is not expressed by all AML cells. Siglec-15 can be distinguished from other Siglec family members by its divergent amino acid sequence, genomic location and evolutionary conservation from mammals to fish. We raised a monoclonal antibody, A9E8, specific for Siglec-15 using phage display. A9E8 detected cell-surface expression of Siglec-15 protein on leukemic cell lines of the myeloid lineage as well as on donor blasts from AML patients. Sub-populations of $CD33^+$ and $CD33^-$ blasts from nine of twelve AML donors exhibited high cell-surface Siglec-15 expression. In contrast, there was minimal expression of Siglec-15 on the surface of peripheral blood leukocytes from healthy donors, suggesting Siglec-15 may have significant therapeutic advantage over targeting CD33. Upon binding to Siglec-15, A9E8 was rapidly internalized ($t_{1/2}$, 180sec) from the cell-surface of K562 cells. Therefore, antibodies to Siglec-15 may hold therapeutic potential for a subset of $CD33^+$ and $CD33^-$ AMLs.

P.B1.06.06

DC-SIGN is an uptake receptor for melanoma-derived autophagosomes in human dendritic cells

T. T. H. Eisden[1,2], *C. M. Ribeiro*[2], *R. Van de Ven*[1], *T. D. de Gruijl*[1], *T. B. Geijtenbeek*[2];
[1]*Department Medical Oncology, VU University Medical Center, Amsterdam, Netherlands,* [2]*Department of Experimental Immunology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

Cross-presentation of tumor-associated antigens (TAAs) by dendritic cells (DCs) is critical for the induction of anti-melanoma cytotoxic T cells. However, melanoma-derived TAAs contribute to an immune suppressed tumor microenvironment and thereby halt DC maturation. We hypothesize that melanoma-derived autophagosomes contain a broader spectrum of TAAs as well as damage associated molecular patterns that could potentially break tolerance and induce anti-tumor T-cell responses.
We isolated autophagosomes from the human melanoma cell line SK-MEL-28 by mild sonication followed by differential centrifugation. Immunoblotting analysis showed that the isolated fraction was positive for the autophagosomal markers LC3-II, Atg5 and Atg16L1. Furthermore, high-resolution flow cytometry analysis confirmed enrichment for LC3-II positive vesicles. To determine the autophagosome binding receptors, isolated autophagosomes were labelled with a fluorescent dye and subsequently targeted to monocyte-derived DCs. Notably, blocking experiments showed that the C-type lectin receptor DC-SIGN is involved in the binding and uptake of the autophagosomes by DCs. Binding experiments in DC-SIGN-transfectants corroborated the role of DC-SIGN as an autophagosome targeting receptor. Furthermore, DCs incubated with autophagosomes upregulated the maturation markers CD80, CD86, CD40 and CD70, which suggest that melanoma-derived autophagosomes are immunogenic. In addition, our preliminary data show that these autophagosomes may have the potential to evoke an anti-melanoma cytotoxic T cell response.

Introduction: Radiation is a common therapy for solid tumors. Unfortunately there is a high risk for the outgrowth of radioresistant tumor cells against which only limited treatment options exist. We challenged the idea whether or not chimeric antigen receptor (CAR) engineered T lymphocytes could be used as an adjuvant immunotherapy in combination with radiotherapy. Recently, we have established switchable universal CARs (UniCARs) that bind to a short peptide epitope (E5B9) which does not exist on the surface of living cells. UniCAR T cells are exclusively redirected to tumor cells in the presence of a target module (TM) that exhibits the E5B9 epitope and binds to a tumor associated antigen (TAA) on the tumor cell surface.
Materials and Methods: We used different radioresistant sublines of the head and neck cancer cell line Cal33. Gene expression data for certain TAAs were confirmed by flow cytometry. TMs against potential targets were created from the variable domains of monoclonal antibodies, cloned in lentiviral vectors and purified from supernatants of permanently TM producing 3T3 cells. UniCAR T cells were generated by lentiviral transduction.
Results: Radioresistant Cal33 cell lines expressed PSCA, EGFR and CD98. UniCAR TMs were created against these TAAs. Armed with these TMs UniCAR T cells efficiently killed radioresistant Cal33 cells *in vitro* and *in vivo*.
Conclusions: Radioresistant tumor cells can efficiently be killed by redirecting UniCAR T cells against PSCA, CD98 and EGFR and thus resistance to radiotherapy can be overcome by immunotherapy based on the UniCAR technology to these targets.

Utilising TAPBPR to increase tumour immunogenicity

T. Ilca*, A. Neerincx, M. Wills, M. de la Roche, L. H. Boyle;*
University of Cambridge, Cambridge, United Kingdom.

As the best clinical responses to immunotherapy are often observed in patients with highest mutational burden and neoantigen presentation, the ability to boost presentation of immunogenic peptides on major histocompatibility complex class I (MHC I) molecules has the potential to improve immunotherapy efficacy. We have recently revealed that the tapasin-related molecule TAPBPR functions as an MHC class I peptide exchange catalyst. Although TAPBPR usually resides intracellularly, here we explored whether extracellular TAPBPR can be utilised to enhance the loading of immunogenic peptides on MHC class I molecules expressed on the surface of cells. We reveal that both plasma membrane-expressed TAPBPR as well as its ectodomain alone, added exogenously to cells, can function as peptide exchange catalysts on surface MHC I molecules. We can utilise these two forms of TAPBPR to display both tumour antigens and viral peptides on human MHC I molecules expressed on tumour cells and consequently induce T cell receptor engagement and killing of tumours by cytotoxic T lymphocytes. Our findings highlight a potential therapeutic application of TAPBPR in increasing the immunogenicity of tumours.

Background: Monoclonal anti-tumor antibody treatments could be considered as one of the most successful therapeutic strategies. Their major mechanism of action is the induction of an antibody-dependent cell-mediated cytotoxicity (ADCC) and antibody-dependent cell-mediated phagocytosis (ADCP). Our previous *in vitro* studies showed that IgG4 can drive M2a macrophages to an immunoregulatory phenotype. In the light of these data we hypothesized that IgG1 and IgG4 isotypes may differentially polarize tumor-associated macrophages (TAM), thereby impacting the quality of ADCC and ADCP against tumor cells. Methods: *In vitro*, monocyte-derived macrophages (MDMs) or monocyte differentiated cell line (U937) were treated with M-CSF and IL-4/IL-13 (M2a) to induce a M2-like polarization. A431 and Caco-2 tumor cell lines were used to test the anti-EGFR IgG1 or IgG4 mediated ADCC and ADCP with polarized U937 or MDM as effector cells. The analyses were performed by FACS and microscope immunofluorescence. Results: Our preliminary data demonstrate that treatment with IgG1 or IgG4 anti-EGFR influenced ADCC and ADCP activities by macrophages, resulting in a modulation of the killing effect of high EGFR expressing A431 cells compared to low EGFR expression Caco-2. Conclusion: Our results indicate that the specific use of IgG1 or IgG4 monoclonal anti-tumor antibody treatments may critically influence treatment outcome by modulating ADCC and ADCP mediated macrophage response. We propose that the understanding of interaction of specific anti-tumor IgG subclasses with Fc-gamma receptors expressed by TAM will help to better predict the outcome of anti-cancer immunotherapies. Supported in part by Austrian Science Fund FWF projects SFB F4606-B28 to EJJ

Chimeric antigen receptor (CAR) have shown impressive treating responses against CD19+ B-lymphoproliferative malignancies. To make available this treatment to our patients, we develop our "own CART19-cells" (ARI-001) based on A3B1 anti-CD19 antibody, followed by CD8 hinge/transmembrane region, 4-1BB and CD3z signaling domains. Preclinical studies [*in vitro* we show that ARI-0001 were highly active (cytotoxicity, secretion of cytokines and proliferation) + *in mouse*, ARI-0001 were able to control disease progression in a NSG xenograph B-ALL mice. After reaching all pre-specified acceptance criteria, the Spanish Agency of Medicines approved our IND and also our first pilot clinical trial (*NCT03144583; EudraCT: 2016-002972-29*) on May/2017, being the first phase-I fully academic European clinical trial with CARTs. Until now (April 2018), we have recruited 21 patients with: 17 patients with acute lymphoblastic leukemia (B-ALL), 3 patients with Non-Hodgkin B-cell lymphoma and 1 patient with chronic lymphocytic leukemia. We successfully prepared ARI-0001 cells in all patients, although 3 patients required two procedures (3/24 [12.5%] production failure). After 8-10 days of culture, 1,275 x10^6 cells (range, 230-2500x10^6) were obtained as median value. The median percentage of ARI-0001 in infusible product was 28.85% (range, 20.4-72.3). After patient's conditioning, we infused 0.5-5x10^6 ARI-0001/kg to 17 patients. In all infused patients, ARI-0001 cells were observed in peripheral blood together with B-cell aplasia; no uncontrolled severe events were obtained. Preliminary data about efficacy show levels of response similar to other CART19s currently being used in clinic. *Authors were supported in their works by projects PI13/00676, PICI14/00122 and PIE/00033*

P.B1.06.11

MISTRG: improved human immune system mouse model to test transplantable T cell therapy against solid tumors

J. J. Karrich[1], *R. de Groot*[1], *K. J. Hartemink*[2], *J. B. Haanen*[2], *M. C. Wolkers*[1], *D. Amsen*[1];
[1]*Sanquin Reserch, Amsterdam, Netherlands,* [2]*Netherlands Cancer Institute, Amsterdam, Netherlands.*

Transfusion of *in-vitro* expanded T cells isolated from tumors (Tumor-Infiltrating lymphocytes or TILs), back into patients is a promising form of therapy for yet untreatable types of cancer, such as melanoma. Although significant progress has been achieved in optimizing in-vitro TIL cultures, many parameters affecting T cell responses against tumors cannot be approximated *in-vitro*. Therefore, we aim to establish and characterize a human immune system mouse model to study TIL responses to tumors in vivo. To this end, we are using the newly developed "MISTRG" mouse model, which allows superior development of a human immune system, which includes both lymphocytes as well as functional myeloid and NK cells at close to physiological levels. Importantly, these mice allow establishment of human tumors that are histologically similar to human tumors in terms of vascularization and infiltration of myeloid cells.

This model therefore more reliably mimics human tumors than traditional models using NSG mice. **We will use this new model to engraft patient-derived non-small cell lung carcinoma (NSCLC) tumor cells and subsequently test *ex-vivo* expanded TILs in an autologous setup.** To do so, tumor cells are isolated isolated directly from patient biopsies and expanded *ex-vivo* as organoid culture, cell line culture, or *in-vivo* in a xenograft model. We will use this model to study parameters that determine the outcome of TIL therapy and to develop and test different treatment modalities.

Anti-CD19 immunotherapy based on CAR-T and bispecific antibodies significantly increased the efficiency of refractory leukemia treatment. However, it also brought a new challenge such as increasing frequency of CD19-negative relapses including lineage differentiation switching. Minimal residual disease (MRD) diagnostics is the tool which allow to reveal the risk of relapse by leukemic cells concentration measurement right after therapy. The most common method for MRD diagnostics is flow cytometry which, however, have significant limitations due to target surface markers loss during immunotherapy. Here we present marker expression independent method for MRD monitoring based on high-throughput sequencing (HTS) of clonal rearrangements of T- and B-cell receptors loci.
Leukemia-specific rearrangements were identified by analysis of their frequencies in sequenced amplicons obtained in multiplex PCRs with primers for vast majority of rearranged TCR and BCR loci. MRD monitoring was performed by HTS-based detection of previously identified rearrangements in samples after therapy and subsequent quantitative analysis using statistical principal of digital PCR.
The developed method was tested on cohort of 20 patients received standard chemotherapy. Over 100 clonal rearrangements were detected in initial samples in total. All identified rearrangements were used for subsequent MRD monitoring. Obtained MRD results were highly concordant with ones detected by flow cytometry. The pilot MRD monitoring by developed method after immunotherapy was performed for four patients. All these cases were MRD negative.
Being highly accurate and sensitive, HTS of rearranged TCR/BCR loci is most promising alternative of flow cytometry for MRD diagnostics in leukemia immunotherapy. Funds: RSF grants №17-75-10113, №18-14-00244.

Allogeneic plasmacytoid dendritic cells (pDC) from partly HLA-matched healthy donors may represent a promising alternative to conventional DC as anti-tumor vaccine. Recently, GMP-compliant isolation of pDC precursors from peripheral blood became possible, so that their clinical application appears within reach. In our current study, we tested a GMP-compliant positive selection kit to isolate BDCA-4$^+$ pDC from leukapheresis products collected from 26 unstimulated healthy donors. After isolation, pDC precursors can be activated and matured within 24-48 hours. On average, we retrieved 4.4x10^6 pDC from ~1.9x10^9 total PBMC. Purity was 95.9%, viability 94.5%. Extrapolated to the size of a full leukapheresis product, it is possible to isolate >20x10^6 viable pDC precursors. After pulsing pDC with K562 lysate, followed by TLR-stimulation, we tested the capacity of pDC to generate cytotoxic T cells via CFSE staining, intracellular IFN-γ staining, and a Europium-based cytotoxicity assay. We observed that maturation of pDC consists of a biphasic activation process. During phase 1, immature pDC expressed high levels of proteases and few costimulatory molecules. Confocal microscopy demonstrated that only in this phase pDC can take up antigens from K562 lysates. In phase 2, antigen-loaded pDC matured by TLR ligands downmodulated proteases, but upregulated costimulatory molecules and MHC/peptide complexes. Mature pDC induced IFN-γ expression and proliferation of allogeneic CD8$^+$ cytotoxic T cells. Moreover, after expansion in the presence of K562 lysate-pulsed pDC, cytotoxic T cells were able to kill K562 cells. Our study indicates that GMP-compliant generation of pDC as allogeneic anti-tumor vaccine is feasible.

Evaluation of TfR1 as a suitable receptor for intracellular drug delivery via an antibody drug conjugate.

A. Laroche[1], *R. Melhem*[1], *M. Pugnière*[1], *C. Martin*[2], *N. Joubert*[2], *C. Larbouret*[1], *A. Pèlegrin*[1], *M. Poul*[1];
[1]*IRCM - U1194, Montpellier, France,* [2]*GICC CNRS UMR. 7292, Tours, France.*

Transferrin receptor 1 (TfR1) is a cell surface receptor overexpressed in various cancers. TfR1 provides iron to cells for their metabolic activity by mediating the internalization of iron loaded transferrin (holo-Tf). Our lab has recently generated an internalizing anti-TfR1 antibody (H7) that blocks holo-Tf internalization and deprives efficiently cancer cells from iron. H7 treatment led to cell death in lymphoma and leukemia cell models and to S-phase blockade in pancreatic adenocarcinoma (PDAC) cells models, *in vitro*. To enhance its toxic activity, H7 was now conjugated to the microtubule inhibitor monomethyl auristatin F (MMAF).
Methods: The anti-TfR1 H7 was conjugated to auristatin F with a non-cleavable linker to obtain an antibody drug conjugate (ADC). Negative controls anti-CD20 rituximab was obtained the same way. The anti-CD30 ADC brentuximab vedotin was used as a positive control for its activity on Karpas lymphoma cell line. ADC activity was measured by MTS assay.
Results: H7-MMAF was more potent at reducing CD30 positive lymphoma Karpas cell line viability *in vitro* than the reference anti-CD30 ADC brentuximab vedotin. (2H7-MMAF highly reduced BxPC3 and CFPAC PDAC cell lines viability *in vitro* compared to the naked antibody H7. These data suggest that TfR1 is suitable receptor for microtubule inhibitor intracellular delivery in cancer. H7-ADC iron deprivation intrinsic activity likely combines to microtubule inhibitor to kill cancer cells. Toxicity assessment of H7-MMAF on normal cells will be crucial for further development.

P.B1.06.15

CD20 and CD37 antibodies cooperatively induce killing of malignant B-cells through complement-dependent cytotoxicity

S. C. Oostindie[1,2], *H. van der Horst*[3], *M. A. Lindorfer*[4], *E. M. Cook*[4], *C. S. Zent*[5], *M. E. Chamuleau*[3], *E. C. Breij*[3], *T. Mutis*[3], *F. J. Beurskens*[1], *P. W. Parren*[2], *R. P. Taylor*[4];
[1]*Genmab, Utrecht, Netherlands,* [2]*Leiden University Medical Center, Leiden, Netherlands,* [3]*VU University Medical Center, Amsterdam, Netherlands,* [4]*University of Virginia School of Medicine, Charlottesville, United States,* [5]*University of Rochester Medical Center, New York, United States.*

In recent years, B-cell malignancies have been successfully targeted with anti-CD20 monoclonal antibodies (mAbs). Another interesting B-cell target is CD37, targeting of which by therapeutic antibodies is currently undergoing clinical evaluation. While known CD20 antibodies can employ complement-dependent cytotoxicity (CDC) as an efficient effector mechanism, currently known CD37 antibodies are poor inducers of CDC. Antibody engineering and drug combination studies are promising strategies to enhance antibody mediated effector functions. For example, CDC efficacy can be improved by introducing single point mutations in the Fc domain that enhance intermolecular Fc-Fc interactions between IgG molecules after cell surface antigen binding, thereby facilitating IgG hexamer formation. In this study, we explored whether introducing such a hexamerization-enhancing mutation into CD37-targeting mAbs could potentiate CDC in malignant B-cells, and whether CDC could further be enhanced by combinations of CD37 and CD20 mAbs. Interestingly, introducing a hexamerization-enhancing mutation into CD37 mAbs resulted in enhanced CDC of tumor B-cells. More striking, combinations of hexamerization-enhanced CD20 and CD37 mAbs showed superior CDC *ex vivo* in tumor cells obtained from patients with B-cell malignancies, compared to the single agents alone. Furthermore, in depth analysis into the mechanism behind enhanced CDC activity demonstrated that, upon target binding, CD20 and CD37 antibodies co-localized on the cell surface and substantially enhanced C1q binding and recruitment, indicating more efficient activation of complement components. These results provide a rationale for antibody combinations to enhance CDC, and provide new mechanistic insights into cooperative interactions between antibody molecules leading to highly efficient CDC activity.

P.B1.06.16

Efficacy of ex-vivo PD-1 blockade in cervical tumor-draining lymph nodes is related to a CD8$^+$ T-cell subset with high levels of immune checkpoints and superior poly-functional effector functions

J. Rotman[1,2], *A. M. Heeren*[1,2], *A. S. Stam*[1,3], *N. Pocorni*[1], *C. H. Mom*[4,2], *M. C. G. Bleeker*[5], *J. van der Velden*[4,2], *H. J. Zijlmans*[6,2], *G. G. Kenter*[2], *E. S. Jordanova*[1,2], *T. D. de Gruijl*[1,3];
[1]*Cancer Center Amsterdam, Amsterdam, Netherlands,* [2]*Center for Gynecologic Oncology Amsterdam (CGOA), Amsterdam, Netherlands,* [3]*Department of Medical Oncology, VUmc, Amsterdam, Netherlands,* [4]*Academic Medical Center (AMC), Amsterdam, Netherlands,* [5]*Department of Pathology, VUmc, Amsterdam, Netherlands,* [6]*Netherlands Cancer Institute, Amsterdam, Netherlands.*

Introduction: An important prognostic factor in cervical cancer (CxCa) is lymph node metastasis. High and interrelated rates of Tregs and PD-L1-positive macrophages in metastatic tumor-draining lymph nodes (TDLN) previously pointed to the applicability of PD-(L)1 blockade to halt metastatic spread. Here, we show the ex-vivo efficacy of PD-1 blockade in CxCa primary tumors (PT) and TDLN and relate it to the presence of a specific CD8$^+$ effector T-cell subset.
Materials & Methods: The effect of anti-PD-1 on T-cell reactivity against the HPV16 E6 oncoprotein in TDLN (n=12) and PT (n=7) single cell suspensions was assessed after 10 days in-vitro culture by IFNγ Elispot read-out. Multicolor flowcytometric analysis of T-cells in TDLN (n=23) and PT (n=10) was also performed.

Results: Consistently enhanced T-cell responses to HPV16 E6 upon PD-1 blockade were observed in all tested metastatic TDLN, but remarkably only in 1/4 HPV16$^+$ PT. Extensive flowcytometric analysis revealed a selective and significant correlation between the ex-vivo efficacy of PD-1 blockade and frequencies of CD8$^+$CD25$^+$FoxP3$^+$ T-cells. This subset was characterized by an effector phenotype with elevated expression levels of PD-1, CTLA4, TIM3 and LAG3 checkpoints, but, rather than exhausted, was shown upon activation to express higher levels of Granzyme-B and effector cytokines as compared to its CD8$^+$FoxP3- counterparts.
Conclusion: These data support the earlier reports of a "poised" HPV-specific T-cell repertoire in TDLN and show them to be valid targets for PD-1 blockade. Moreover, they point to CD8$^+$CD25$^+$FoxP3$^+$ T-cells as likely therapeutic target, which may also serve as predictive biomarker.

P.B1.06.17
Modular design of a trispecific T-cell engager antibody (TriTE) for dual targeting of colorectal cancer

*A. Tapia[1], R. Navarro[1], M. Compte[1], A. Erce[1], M. Zonca[1], L. Alvarez-Vallina[2], **L. Sanz**[1];*
[1]Molecular Immunology Unit, Hospital Puerta de Hierro, Majadahonda, Spain, [2]Immunotherapy and Cell Engineering Laboratory, Department of Engineering, Aarhus University, Aarhus, Denmark.

Introduction: *Biespecific T cell Engager*s (BiTE) are engineered antibody constructs composed of an anti-CD3 single-chain variable fragment (scFv) linked to an anti-tumor-associated antigen (TAA) scFv. To minimize the risk of "on-target/off-tumor" effects, we propose a dual-targeting approach with trispecific tandem antibodies recognizing simultaneously two different TAA. As a proof of concept we have designed a *trispecific T-cell engager* (TriTE) directed against epidermal growth factor receptor (EGFR), carcinoembryonic antigen (CEA) and CD3 for colorectal cancer immunotherapy.
Materials and Methods: To generate the TriTE, an anti-EGFR and an anti-CEA single-domain VHH were cloned N-terminal and C-terminal, respectively, to an anti-CD3 scFv in the FLAG-tagged expression vector pCR3.1. Human 293T cells were transfected and conditioned medium was analyzed by Western blot, ELISA and FACS. EGFR/CD3 and CEA/CD3 bispecific light T-cell engagers (LiTE) were also generated to compare the functional activity of the three constructs.
Results: Western blot analysis demonstrated that LiTE and TriTE were secreted and the migration patterns were consistent with the predicted molecular weight (43 and 57 kDa, respectively). As shown by ELISA, the TriTE was able to bind simultaneously plastic-immobilized CEA and EGFR. Moreover, it efficiently recognized the cognate antigens of the three parental antibodies on the cell surface as assessed by flow cytometry.
Conclusions: To our knowledge, the TriTE is the first trispecific antibody simultaneously targeting two TAA and CD3 to redirect specifically T cell responses against colorectal cancer cells. This strategy opens the door for a new class of promising immunomodulatory antibodies in oncology.

P.B1.06.18
Targeted tumour treatment using polymer drug delivery systems

***M. Sirova**[1], B. Rihova[1], P. Chytil[2], M. Tavares[2], O. Lidicky[3], T. Etrych[3];*
[1]Inst. of Microbiology ASCR, Prague 4, Czech Republic, [2]Inst. of Macromolecular Chemistry ASCR, Prague 6, Czech Republic, [3]Inst. of Macromolecular Chemistry ASCR, Prague 4, Czech Republic.

Polymer-bound cytotoxic drugs represent a potential strategy of an effective tumour-targeted therapy devoid of serious side effects. Biocompatible polymer carrier ensures prolonged circulation of the drug in inactive form, its tumor-specific accumulation and controlled release in the target tissue. Water-soluble *N*-(2-hydroxypropyl)methacrylamide (HPMA) is one of the most promising drug carriers. Treatment of murine syngeneic tumours with HPMA-based conjugate of doxorubicin resulted in stronger infiltration of the treated tumours with immune cells , as compared with free doxorubicin. The infiltrates contained more CD8$^+$ effector cells than the infiltrate of Dox-treated tumours. The T cells expressed elevated levels of PD-1, indicating a possible advantage of using checkpoint inhibition. These data conform with our previous results documenting that, upon treatment with the polymer cytotoxic drugs but not with free drugs, a complete regression of the tumours can be achieved, associated with long-lasting tumour resistance, chiefly mediated by CD8$^+$ T cells. Indeed, the host immune system is co-responsible for the curative effect of the HPMA-based cytotoxic drugs. The same drug delivery system also proved good performance when delivering agents, which could reduce suppressing activity of myeloid-derived suppressor cells (MDSC), thereby potentiating the effect of polymer-bound cytotoxic drugs. Supported by projects 17-08084S and 16-28600A.

P.B1.06.19
Chondroitin sulfate proteoglycan 4 (CSPG4) as an immune target in induced drug tolerant melanoma cells (IDTCs)

***K. Uranowska**[1,2], T. Kalic[1,2], K. Karapandža[1], I. Ellinger[2], H. Breiteneder[2], H. Schaider[3], C. Hafner[1];*
[1]Department of Dermatology, Karl Landsteiner University of Health Sciences, St. Pölten, Austria, [2]Institute of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria, [3]Dermatology Research Centre, The University of Queensland Diamantina Institute, Translational Research Institute, The University of Queensland, Brisbane, Australia.

Acquired resistance to PLX4032, a selective inhibitor of mutant BRAF, remains the major obstacle in treating patients with metastatic melanoma. Induced drug-tolerant cells (IDTCs), characterized by an increase in CD271 expression, constitute a state preceding permanent drug-resistance. Chondroitin sulfate proteoglycan 4 (CSPG4) is a multifunctional transmembrane proteoglycan, involved in spreading, migration and invasion of melanoma. We hypothesize that targeting CSPG4 on IDTCs with anti-CSPG4-antibodies may delay or prevent the development of acquired drug-resistance by simultaneous interference of multiple signaling pathways.
BRAF-mutant CSPG4-positive and negative melanoma cells were exposed to PLX4032 in order to generate IDTCs. CD271 expression was monitored as a marker of IDTCs by flow cytometry. Morphological changes were analyzed by bright-field microscopy. CSPG4 expression on melanoma cells before, during and after exposure to PLX4032 was evaluated by FACS and immunofluorescence microscopy.
Exposing BRAF-mutant cells to PLX4032 led to IDTCs, which were characterized by elevated CD271 expression compared to non-treated cells and by morphological changes. A lower mean fluorescence intensity of the CSPG4 signal was found in IDTCs (1594.6±28.7) compared to untreated cells (2829.5±73.9). IF microscopy confirmed a decreased amount of CSPG4 on the IDTCs cell surfaces.
These results might indicate that the inhibition of mutant BRAF influences the expression of CSPG4. This provides the basis for further investigation of the use of CSPG4 as a potential immune target in IDTCs and gives the rationale for studying the role of CSPG4 in the development of permanent drug-resistance in melanoma cells.

P.B1.06.20
Induction of cytotoxic T cell antitumor activity by combined chemo-immunotherapy with methotrexate nanoconjugates and dendritic cell-based vaccines in mice bearing MC38 colon carcinoma

***K. Węgierek**, A. Szczygieł, N. Anger, J. Mierzejewska, J. Rossowska, T. Goszczyński, M. Świtalska, E. Pajtasz-Piasecka;*
Ludwik Hirszfeld Institute of Immunology and Experimental Therapy Polish Academy of Sciences, Wrocław, Poland.

Conjugation of methotrexate and hydroxyethyl starch (MTX-HES) is an innovative solution for prolongation of MTX half-life, reduction of its side effects and enhancing of its antitumor activity. In order to improve MTX-HES therapeutic effect, we performed *in vivo* experiments in which the chemotherapy was supplemented with bone marrow-derived dendritic cell (BM-DCs). Initially, mice with subcutaneously growing MC38 tumors received intravenously one dose of MTX or MTX-HES. On the 3rd day of chemotherapy, BM-DCs were added (in peritumoral injections, in three consecutive weeks). Mice were sacrificed three days after chemotherapy or seven days after the last injection of BM-DC, and antitumor activity of splenocytes was evaluated in *ex vivo* analyses. Chemotherapy with MTX-HES resulted in increased percentage of CD8$^+$ T cells among splenocytes, and their tumor specific-cytotoxicity compared to control- and MTX-group. This effect was intensified when the chemotherapy was supplemented with dendritic cell-based vaccines. The treatment with MTX-HES and BM-DCs increased the percentage of CD8$^+$CD107a$^+$ cells. Moreover, gathered data indicated that therapy using a combination of MTX-HES with BM-DC-vaccines was markedly effective in generation of cytotoxic T cell antitumor activity. Taken together, novel MTX-HES nanoconjugate is able to modulate the antitumor response more effectively than MTX. Meanwhile, its combination with cellular vaccines can improve both therapeutic effects and specific cytotoxic activity of splenocytes. The study was funded by National Science Centre, Poland (project no. 2015/19/N/NZ6/02908).

Targeting gangliosides-containing liposomes to human CD169+ antigen presenting cells to induce anti-tumor immune responses

***A. J. Affandi**[1], J. Grabowska[1], M. Lopez Venegas[1], K. Olesek[1], A. Barbaria[1], P. Mulder[1], M. Ambrosini[1], J. Stöckl[2], G. Storm[3], Y. van Kooyk[1], J. M. den Haan[1];*
[1]VUmc, Amsterdam, Netherlands, [2]Institute of Immunology, Vienna, Austria, [3]Utrecht University, Utrecht, Netherlands.

Pancreatic cancer forms a major cause of cancer related deaths with a very short mean overall survival of just 6-12 months. Our previous work has already demonstrated that CD169+ macrophages can stimulate superior immune responses. Using liposomes containing CD169-binding gangliosides, we hypothesized that these liposomes could be used to target and deliver antigens to human CD169+ antigen-presenting-cells (APCs). We observed that liposomes containing GM3, GD3, GM1, GD1a, GT1b, could efficiently bind and were taken up by CD169-overexpressing THP1 cells and human monocyte-derived dendritic cells (moDCs). moDC liposome binding and uptake could be further enhanced by IFN-α-induced CD169 upregulation, and blocked using neutralizing α-CD169 antibody.

Furthermore, ganglioside-containing liposome were taken up by human peripheral blood CD169+ monocytes, CD169+CD123+ and CD169+CD11c+ DCs, and splenic macrophages. The levels of uptake were associated with CD169 expression. Our ongoing experiments will evaluate the uptake and the intracellular trafficking of ganglioside-containing liposomes using imaging flow cytometry. To conclude, several ganglioside-containing liposomes bind to human CD169 and could potentially be used to target CD169+ APCs. Future studies will focus on whether these liposomes can be used to induce pancreatic tumor antigen-specific T cell responses.

Introduction: Head and neck cancer is a leading cause of cancer related deaths accounting for approximately 3% of all cancer related mortalities in the US. Currently, there is no cure for the advanced squamous cell carcinoma of the head and neck (SCCHN) thus development of efficacious therapies is urgently needed. To test whether vaccine-induced immunity inhibits tumor growth, we investigated efficacy of a tumor membrane-based vaccine immunotherapy in a murine SCC (SCC VII) model.
Materials and Methods: The SCC VII tumors grown subcutaneously in C3H/HeJ mice were harvested to generate tumor membrane vesicles (TMVs). TMVs were then protein transferred with glycolipid-anchored immunostimulatory molecules GPI-B7.1 and GPI-IL-12 to generate the TMV vaccine. Mice were vaccinated with TMV vaccine either before (prophylactic) or after SCC VII tumor cell challenge (therapeutic) and tumor growth was monitored every 3 days. Survival was then assessed using a Kaplan-Meier survival curve and significance determined using a Log-rank test for comparison analysis.
Results: SCC VII cells express MHC I, CD44, CD47 and respond to IFNγ in vitro. The TMV vaccine inhibited tumor growth and improved the survival of mice challenged with SCC VII tumor cells. Further, TMV vaccination induced Th1 cytokine response in vivo.
Conclusions: These observations suggest that tumor tissue-based vaccines can be harnessed to develop an effective immunotherapy for squamous cell carcinoma of the head and neck.
Funding: Supported by Head and Neck SPORE pilot funding from Emory Winship Cancer Institute.

DNA prime-peptide boost immunizations maximize circulating and resident memory CD8⁺ T cells responses against a melanoma-associated self-antigen.

P. Caceres-Morgado*, F. Galvez-Cancino, X. Diaz, E. Menares, S. Hidalgo, O. Chovar, J. Saavedra, A. Lladser;*
Fundación Ciencia & Vida, Santiago (Ñuñoa), Chile.

Memory CD8⁺ T cell responses can mediate long-lasting protection against cancers. Emerging evidence indicates that effective anti-tumor protection requires coordinated action of both tissue-resident and circulating memory CD8⁺ T cells. However, clinically applicable vaccination strategies that efficiently establish both types of responses against tumor-associated self-antigens remain largely unexplored and are expected to strongly protect against tumors. Here we demonstrate that intradermal vaccination using a DNA prime-peptide boost strategy induces strong CD8⁺ T cell effector responses against a model of melanoma-associated self-antigen GP100 in mice, as compared to DNA and peptide prime and the other immunization regimens. These responses were characterized by a high proportion of memory precursor (KLRG1- CD127+) cells expressing CXCR3. At the memory phase, DNA prime-peptide boost lead to enhanced circulating and skin resident memory (Trm) CD8⁺ T cells. Trm cells accumulated at both vaccinated and distant sites, and displayed elevated expression of PD-1 and low expression of Lag3 and KLRG1. Interestingly, *in vivo* stimulation with H-2 Db-restricted $GP100_{(25\text{-}33)}$ peptide leads to the production of high levels of IFN-γ by Trm cells. Current efforts of this project seek to demonstrate that prime and boost vaccination strategies designed to maximize resident and circulating memory CD8⁺ T cell responses achieve potent protection against primary and disseminated melanoma.

CD169⁺ macrophages and the development of anti-cancer vaccines

D. van Dinther[1], *J. Grabowska*[1], *A. J. Affandi*[1], *M. Lopez Venegas*[1], *A. Barbaria*[1], *H. Veninga*[1], *E. Borg*[1], *L. Hoogterp*[1], *K. Olesek*[1], *H. Kalay*[1], *M. Ambrosini*[1], *G. Storm*[2], *Y. van Kooyk*[1], ***J. M. M. den Haan***[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Utrecht University, Utrecht, Netherlands.*

CD169-expressing macrophages are present in lymphoid organs at the site of antigen entrance and are essential in the activation of innate as well as adaptive immune responses. Our aim is to target tumor antigens to these CD169+ macrophages for the activation of anti-cancer immune responses and have investigated two approaches. First, using antiCD169 antibody-antigen conjugates we have shown that CD169+ macrophages present antigen to B cells and stimulate strong germinal center B cell and antibody responses. Furthermore, antigens targeted to CD169+ macrophages were transferred to cross-presenting dendritic cells and this led to strong cytotoxic and helper T cell responses. Both (melanoma) peptide as well as protein antigen targeting to CD169 resulted in strong primary and recall immune responses and protective immunity against melanoma outgrowth in mice. Second, we used liposomes containing CD169-binding ganglioside ligands to target antigens to CD169+ antigen presenting cells in mice and man. These liposomes specifically bound to CD169+ macrophages in mice and led to B and T cell responses against antigen present in the liposome. In addition, CD169 ligand-containing liposomes bound to human monocyte-derived dendritic cells and peripheral blood CD169+ dendritic cells and will be further evaluated for their capacity to stimulate T cell responses. In conclusion, different approaches to target tumor antigens to CD169+ antigen presenting cells demonstrate a strong capacity to stimulate immune responses and should be further explored as a vaccination strategy for cancer.

P.B1.07.05

Tumor derived microvesicles enhance crossprocessing ability of clinical grade dendritic cells

M. Dionisi*, C. De Archangelis, F. Battisti, H. Rahimi Koshkaki, I. G. Zizzari, C. Napoletano, C. Albano, I. Ruscito, M. Nuti, A. Rughetti;*
"Sapienza" University of Rome, Department of Experimental Medicine, Rome, Italy.

Introduction: Manufacturing clinical grade Dendritic Cells (DCs) represents a critical step in antitumor vaccination strategies. Indeed, DC performance is affected by clinical grade culture conditions. Thus, the design of immunogens enhancing antigen presentation of Clinical Grade DCs (cgDCs) is mandatory. Tumor-derived microvesicles (T-MVs) trigger protective anti-tumor immune responses by delivering tumor antigen repertoire and activatory signals to DCs. T-MVs modulate DC phagosomal alkalinization allowing cross-presentation of tumor glycosylated antigens such as MUC1. Here we show that phagosomal performance of cgDCs is altered (low pH, reduced phagocytosis) and that T-MVs uptake counteracts phagosomal acidification of cgDCs, restoring MUC1 antigen cross-processing.
Methods: cgDCs generated in X-Vivo medium and standard DCs (sDCs) grown in RPMI+10%FCS were pulsed with soluble recombinant MUC1 glycoprotein (rMUC1) or T-MVs carrying MUC1. Phagosomal pH and phagocytosis were assessed by flow cytometry, "chasing" DCs with 3µm FITC/FluoProbes647 coupled microbeads. Internalization and cross-processing of the MUC1 carried by T-MVs or rMUC1 were evaluated by immunofluorescence, employing HLA I and II compartment markers.
Results: cgDCs, compared to sDCs, displayed a more acidic phagosomal pH and a decreased phagocytosis. cgDCs also were less efficient in the internalization of soluble rMUC1 glycoprotein and internalized antigen was blocked in HLA class II compartment. Pulsing cgDCs with T-MVs, an increase in antigen up-take and MUC1 translocation in HLA class I compartment were observed. Indeed, T-MVs up-take triggers an early phagosomal alkalinization in cgDCs allowing MUC1 cross-processing.
Conclusions: T-MVs are able to reprogram DC antigen presenting machinery and represent optimal cell-free based immunogens for clinical use.

P.B1.07.06

Generation of multiepitope cancer vaccines based on large combinatorial libraries of survivin-derived mutant epitopes

A. N. Domínguez-Romero*, M. E. Munguia-Zamudio, F. Martínez-Cortés, K. Manoutcharian;*
Instituto de Investigaciones Biomédicas, México CDMX, Mexico.

Introduction: Immune tolerance is the main challenge in the field of cancer vaccines, therefore, mutated versions of a wild-type epitope of tumor-associated antigens represent a promising pathway for these vaccines. A novel vaccine approach has been developed by our research group based on the generation of a new class of vaccine immunogens, called Variable Epitope Libraries (VELs) bearing combinatorial libraries of mutated versions of wild-type immunodominant epitopes of cytotoxic T lymphocytes. Previously, we demonstrated statistically significant tumor growth inhibition in BALB/c mice immunized with the VELs based on a $survivin_{66\text{-}74}$ immunodominant epitope. Now, we used larger regions of survivin (40-45 amino acid long) to generate the VELs as multiepitope vaccines.
Materials and Methods: These VELs were expressed at high copy numbers on recombinant M13 bacteriophages as peptides linked to the cpVIII phage protein by Phage Display. A 4T1 murine breast cancer model was used. The VEL vaccines were applied in therapeutic treatment studies and administered as a single intravenous injection.Results: Our preliminary data showed that a single dose of the survivin-based VEL vaccine significantly decreased tumor growth and lung metastasis. Also, a significant reduction of MDSC cells in the lungs and tumor infiltration by CD8 T lymphocytes were observed. Conclusions: This study provides the feasibility of the generation of VEL-based vaccine immunogens as an alternative approach for the construction of cancer epitope vaccines.
Acknowledgments: Funding provided by DGAPA-UNAM (IN205216). A. Domínguez-Romero is a recipient of a scholarship from CONACyT and Posgrado en Ciencias Biológicas, UNAM.

Using combinatorial peptide libraries to design super-agonists for improved cancer immunotherapy

S. A. E. Galloway[1], *G. Dolton*[1], *B. Szomolay*[1], *A. Wall*[1], *V. Bianchi*[1], *M. Attaf*[1], *P. J. Rizkallah*[1], *M. Donia*[2], *I. M. Svane*[2], *P. Thor Straten*[2], *C. Rius*[1], *A. Fuller*[1], *A. K. Sewell*[1];
[1]*Cardiff University, Cardiff, United Kingdom,* [2]*Centre for Cancer Immune Therapy, Copenhagen, Denmark.*

The use of peptide vaccines for the treatment of melanoma has been a largely unsuccessful endeavour. Generally, peptides derived from tumour associated antigens (TAA) are poorly immunogenic and unable to elicit a substantial CD8 T-cell response capable of mediating effective tumour regression. Here, we demonstrate that combinatorial peptide library (CPL) screens are an important tool to design agonist peptides capable of improving the CD8 T-cell response to a commonly overexpressed TAA, melan-A.
Combinatorial peptide library (CPL) screening of key CD8 T-cell clones, isolated from a patient who successfully underwent tumour infiltrating lymphocyte (TIL) therapy, revealed preferred amino acid residues at each position in the cognate peptide, leading to the selection of a panel of 10 potential agonist peptides.
Testing of candidate peptides using polyclonal T-cell populations and a panel of melan-A specific T-cell clones highlighted 2 dominant agonist peptides. The chosen peptides elicited superior expansion of wild type pMHC-tetramer-positive CD8 T-cells from polyclonal T-cell populations compared to the wild-type peptide in ten HLA A2+ donors tested. ^{51}Cr release assays demonstrated that CD8 T-cells primed with agonist peptides could effectively kill melanoma tumour cells.
Polymorphonuclear cells (PBMC) from patients with melanoma will now be used to assess whether agonist peptides can improve CD8 T-cell responses to autologous tumour. This study highlights the use of CPL screening technology to design superior peptides capable of enhancing the CD8 T-cell response to melanoma.

Increased expression of adenosine in the tumor microenvironment is markedly related to the overexpression of its molecular producer, CD73. It has been demonstrated that overexpression of CD73 facilitates the tumor growth, angiogenesis, and metastasis processes. Regarding the importance of angiogenesis in tumor development and spreading, we decided to assign the anti-angiogenic effects of CD73 suppression, both in vitro and in vivo. We used chitosan lactate (ChLa) nanoparticles (NPs) to deliver CD73 specific siRNA into cancer cells. Our results showed that treatment of 4T1 cells with CD73-specific siRNA loaded NPs led to potent inhibition of cell proliferation and cell cycle arrest which was associated with partial apoptosis induction, in vitro. This growth arrest was correlated with downregulation of angiogenesis-related molecules including VEGF-A, VEGF-R2, IL-6, and TGF-β. In addition, silencing CD73 could effectively suppress the migration and invasion capacity of tumor cells. Moreover, administration of NPs loaded with CD73-siRNA into 4T1 breast cancer bearing mice led to arrested tumor growth and increased mice survival time which was associated with downregulation of the mRNA expression levels of angiogenesis (VEGF-A, VEGF-R2, VE-Cadherin, and CD31) and lymphangiogenesis (VEGF-C and LYVE-1) related factors in the tumor tissues. Furthermore, the expression of angiogenesis promoting factors IL-6, TGF-β, STAT3, HIF-1α, and COX2 was decreased after CD73 suppression in mice. These results indicate that suppression of tumor development by downregulation of CD73 is in part related to angiogenesis arrest. These findings imply a promising strategy for inhibition tumor growth accompanied by suppression of angiogenesis process.

Evaluation of GM3-containing liposomes for antigen targeting to splenic CD169+ macrophages to induce anti-cancer immunity

J. Grabowska[1], *D. van Dinther*[1], *K. Olesek*[1], *L. Hoogterp*[1], *M. Ambrosini*[1], *P. R. Crocker*[2], *G. Storm*[3], *Y. van Kooyk*[1], *J. M. den Haan*[1];
[1]*VUmc, Amsterdam, Netherlands,* [2]*University of Dundee, Dundee, United Kingdom,* [3]*Utrecht University, Utrecht, Netherlands.*

Liposomes are an attractive antigen delivery system and have been successfully used for vaccination strategies. We previously have shown that antibody-mediated antigen (Ag) targeting to CD169+ macrophages stimulates superior Ag-specific CD8 T cell responses. CD169, also known as sialoadhesin or siglec-1, is a sialic-acid binding lectin which has been described to bind to ganglioside GM3. Here we tested GM3-containing liposomes for their binding and uptake by murine CD169+ macrophages and their capacity to induce immune responses. As expected, CD169+ macrophages strongly and specifically bound GM3 liposomes, while macrophages from sialoadhesin knock-in mice bearing a mutation in the CD169 ligand binding pocket were incapable of binding GM3 liposomes. After intravenous administration, GM3/ovalbumin-containing liposomes specifically bound to CD169+ macrophages in a sialic acid dependent manner and stimulated ovalbumin-specific CD8 and CD4 T cell and B cell responses. Surprisingly, liposomes without GM3 also stimulated immune responses, while not binding to CD169+ macrophages. In our current studies we will also evaluate liposomes that contain the ganglioside GM1, that does not bind CD169, for their capacity to evoke an immune response. In future studies we will determine the efficacy of GM3 liposomes to target tumor antigens to CD169+ macrophages in order to induce anti-cancer immune responses.

P.B1.07.10

Photochemical internalization as a novel strategy to realize therapeutic cancer peptide vaccination

M. Haug[1,2,3], *G. Brede*[2], *M. Håkerud*[4], *A. Nedberg*[4], *O. A. Gederaas*[2], *V. T. Edwards*[4,5], *T. H. Flo*[1,2,6], *P. K. Selbo*[4], *A. Høgset*[5], *Ø. Halaas*[2];
[1]*Centre of Molecular Inflammation Research, NTNU, Trondheim, Norway,* [2]*Department of Clinical and Molecular Medicine, NTNU, Trondheim, Norway,* [3]*Department of Infection, St. Olavs University Hospital, Trondheim, Norway,* [4]*Department of Radiation Biology, Oslo University Hospital, Oslo, Norway,* [5]*PCI Biotech AS, Oslo, Norway,* [6]*5Centre for Molecular Medicine Norway, Nordic EMBL Partnership, University of Oslo, Oslo, Norway.*

Effective priming and activation of tumor-specific CD8+ cytotoxic T lymphocytes (CTLs) is crucial for realizing the potential of therapeutic cancer vaccination. This requires cytosolic antigens that feed into the MHC class I presentation pathway, which is not efficiently achieved with most current vaccination technologies. Photochemical internalization (PCI) provides an emerging technology to route endocytosed material to the cytosol of cells, based on light-induced disruption of endosomal membranes using a photosensitizing compound. Here we investigated the potential of PCI as a novel, minimally invasive and well-tolerated vaccination technology to induce priming of cancer-specific CTL responses to peptide antigens.
We show that PCI effectively promotes delivery of peptide antigens to the cytosol of antigen presenting cells *in vitro*. This resulted in a 30-fold increase in MHC class I/peptide complex formation and surface presentation, and a subsequent 30-100-fold more efficient activation of antigen-specific CTLs compared to using the peptide alone. The effect was found to be highly dependent on the dose of the PCI treatment, where optimal doses promoted maturation of immature dendritic cells, thus also providing an adjuvant effect.
The effect of PCI was confirmed *in vivo* by the successful induction of antigen-specific CTL responses to cancer antigens in C57BL/6 mice following intradermal peptide vaccination using PCI technology. We thus show new and strong evidence that PCI technology holds great potential as a novel strategy for improving the outcome of peptide vaccines aimed at triggering cancer-specific CD8+ CTL responses.

P.B1.07.11

Discovery of immunogenic neoantigens for peptide vaccination approaches in murine colorectal cancer.

B. J. Hos;
IHB, LUMC, Leiden, Netherlands.

Recent developments have shown that effectiveness of therapy with checkpoint-blocking antibodies correlates with the expansion and invigoration of neo-antigen specific T cells. Alongside, peptide-based vaccines targeting onco-viral antigens have shown to be effective inducers of T cell responses related to reduction of HPV-induced pre-malignancies. This suggests that peptide-based vaccination targeting neoantigens is a viable immunotherapeutic strategy.
A major limitation for broad application of peptide-based vaccinations is the characterization of cancer-specific epitopes that is required for personalized approaches. The process of epitope identification is yet not trivial. Here we describe the process in a murine colorectal cancer model to identify immunogenic epitopes for peptide vaccination.
DNA and RNA analysis revealed the expression of several thousand mutations. Prediction and ranking of MHC class I binding peptides containing mutations with NetMHC4.0 limited this number to several hundred high- and moderate-affinity peptides. An immunogenicity test of 57 selected high-affinity peptides (based on the type of amino-acid substitution) revealed a large percentage of peptides induced CD8- and CD4-specific responses. However, ex vivo restimulation and subsequent readout of splenocytes from anti-PD-L1 treated and tumor-regressed mice, showed specific responses to a limited number of three peptides. Strong responses were observed to a novel mutated peptide sequence. Mass spectrometry could confirm the expression and presentation of this epitope, but not the other two.
Our approach was successful in the characterization of immunogenic and relevant epitopes. Further research is now needed to improve effectivity in therapeutic vaccinations.

P.B1.07.12

Identifying the role of microRNAs in MDS with particular focus on the contribution of immune cells

A. Kindermann[1], *F. Heidel*[2], *H. Kielstein*[1], *D. Quandt*[1];
[1]*Department of Anatomy and Cell Biology, Martin Luther University Halle-Wittenberg, Germany,* [2]*Department of Hematology and Medical Oncology, Friedrich-Schiller University Jena, Germany.*

Introduction: Myelodysplastic syndromes (MDS) are clonal hematopoietic neoplasia characterized by peripheral cytopenia with defective hematopoiesis and variable tendency to evolve into acute leukemia. MicroRNAs are known to be tight regulators of normal hematopoiesis but also to be dysregulated in various types of cancer and therefore are targets of current therapeutic approaches. MiR-34a is differentially expressed in MDS but the molecular mechanism remains elusive. Altered microRNA expression can evolve from and affect all different cell types that constitute the stem cell niche. **Methods:** Allogeneic tumor-T cell co-culture assays with myeloid leukemic as well as MDS cell lines could be successfully established. By the use of Viromer transfection we were able to overexpress miR-34a using mimics in primary human T cells and leukemic cell lines as determined by qPCR. Differential bone marrow cell sorting for early hematopoietic stem cells (CD34+, lin neg, CD38 neg), committed stem cells as well as T cells will allow the generation of distinct microRNA profiles. **Results:** Overexpression of miR-34a did not alter subsequent proliferative behaviour of polyclonal activated T cells. Tumor-T cell co-culture assays with altered miR-34a expression on the tumor site did not yet give conclusive results of an impact on T cell activation. The FACS sorting strategy for differential bone marrow cells could be established and high quality RNA from 100 cells could be isolated. **Conclusion:** MiR-34a seems not to contribute primarily to T cell-tumor communication. The role of this microRNA for myeloid progenitor survival, proliferation and differentiation will be investigated in ongoing experiments.

P.B1.07.13

Dendritic cells pulsed with tumor cells killed by high hydrostatic pressure are effective as prostate cancer immunotherapy using clinically relevant murine models

R. Mikyskova[1], *I. Stěpanek*[1], *I. Truxova*[2], *I. Moserová*[2], *J. Fučikova*[3,2], *I. Kanchev*[1], *J. Bartůňková*[3,2], *R. Spisek*[3], *M. Reinis*[1];
[1]*Institute of Molecular Genetics AS CR, v.v.i., Prague 4, Czech Republic,* [2]*SOTIO, Prague 7, Czech Republic,* [3]*2nd Faculty of Medicine and University Hospital Motol, Charles University, Prague 5, Czech Republic.*

High hydrostatic pressure (HHP) has been proved to induce immunogenic cell death of cancer cells and dendritic cell (DC)-based vaccines pulsed with HHP-inactivated tumor cells have recently been shown to be a promising tool for immunotherapy. In this study, we analyzed their therapeutic efficacy in clinically relevant settings, such as chemoimmunotherapy, surgical minimal residual tumour disease and, finally, in the orthotopic transgenic adenocarcinoma of the mouse prostate (TRAMP) model, which mimics well humans carcinoma as it develops and progresses through all stages of carcinogenesis similarly as in humans. DC-based vaccines pulsed with the HHP-inactivated tumour cells combined with docetaxel (DTX) chemotherapy inhibited growth of both TRAMP-C2 and TC-1 tumors. Administration of these vaccines after the surgical removal of tumors slowed down the growth of tumour recurrences. Finally, pulsed DC-based vaccines were also effective in reducing prostate cancer growth in the TRAMP model when used alone or in the combination with docetaxel. Although we did not observe any additive or synergic effects of chemoimmunotherapy on the tumor growth, the combination of DTX and pulsed dendritic cells resulted in significantly lower tumour cells proliferation (detected by Ki67 staining) in growing tumors. Collectively, our results indicate that the DC-based vaccines pulsed with HHP-inactivated tumor cells represent a suitable tool for immunotherapy, particularly with regard to the findings that poorly immunogenic TRAMP-C2 tumors were susceptible to this treatment modality. This work was supported by research grants provided by SOTIO a.s. and by Academy of Sciences of the Czech Republic (RVO 68378050).

The *in vitro* melanoma tumor microenvironment conditions macrophages to an immunosuppressive M2-like phenotype, which is reversible by lipopolysaccharide and interferon-gamma

I. Milenova[1], *M. Lopez Gonzalez*[2], *T. Brachtlova*[2], *R. van de Ven*[1], *W. Dong*[3], *V. W. van Beusechem*[2], *T. de Gruijl*[2];
[1]*Vrije Universiteit Medical Center/ORCA Therapeutics, Amsterdam, Netherlands,* [2]*Vrije Universiteit Medical Center, Amsterdam, Netherlands,* [3]*ORCA Therapeutics, Amsterdam, Netherlands.*

The melanoma tumor microenvironment is conditioned to skew infiltrating monocytes to M2-like macrophages. These M2-like macrophages promote growth and invasion of tumor cells. We are exploring the use of oncolytic adenoviruses to enhance the efficacy of immunotherapy and induce favorable M1-like polarization.
In order to study macrophage polarization in the tumor microenvironment, human melanoma cell lines were co-cultured *in vitro* with $CD14^+$ monocytes. Lipopolysaccharide (LPS) and interferon (IFN)-gamma were added to the co-culture to assess M1 polarization, and the effect of the oncolytic adenovirus ORCA-010, which is modified to facilitate improved spread in tumor cells, was studied.
We show that the melanoma cells strongly induce an M2-like macrophage phenotype (CD14+/CD163+/CD80-/CD86-/PD-L1+) *in vitro*. Whereas addition of ORCA-010 led to upregulation of CD163, the combination of LPS and IFN-gamma proved able to negate these effects and induce an M1-like phenotype (CD14-/CD163-/CD80+/CD86+/PD-L1++). These findings demonstrate the feasibility of M1 skewing in the face of melanoma-induced immune suppression.
Next, the macrophage polarizing effects of various clinically applicable immune modulatory agents will be studied. In the B16-OVA melanoma model we are investigating the effects of the combined administration of ORCA-010, a p38-MAPK inhibitor and anti-PD-1. We have observed *in vitro* inhibition of p38 signaling to skew monocyte differentiation away from a melanoma-imposed immunosuppressive M2-like phenotype. We hypothesize that this will result in increased T cell infiltration and activation at the tumor site, thus increasing the efficacy of PD-1 checkpoint blockade.
This work is supported by the European Union Horizon2020 ITN-EID grant 643130 “VIRION”.

***Are you my MAIT?*- Investigating the role of MAIT cells in Colorectal-Liver Metastases**

R. M. Millen[1], *S. Roth*[2], *P. Beavis*[2], *B. Thomson*[3], *S. Banting*[4], *B. Knowles*[1], *J. Kelly*[5], *N. A. Gherardin*[6], *D. Godfrey*[6], *K. Visvanathan*[4], *R. G. Ramsay*[2];
[1]*Peter MacCallum Cancer Centre/St. Vincent’s Hospital, Melbourne, VIC, Australia,* [2]*Peter MacCallum Cancer Centre, Melbourne, VIC, Australia,* [3]*Peter MacCallum Cancer Centre/ Royal Melbourne Hospital, Melbourne, VIC, Australia,* [4]*St. Vincent’s Hospital, Melbourne, VIC, Australia,* [5]*The Fiona Elsey Cancer Research Institute, Ballarat, VIC, Australia,* [6]*Peter Doherty Institute, Melbourne, VIC, Australia.*

Background: Stage-IV Colorectal Cancer (CRC) involves metastasis to the liver. Cytotoxic CD8+ T-cells play a critical role in cancer; serving as a key prognostic marker for the Galon-Immunoscore™
Mucosal-Associated Invariant T-cells (MAITs) are a recently described subset of T-cells that co-express CD8, and are important in controlling bacterial infections. MAITs are highly abundant in the liver comprising up to 40% of T-cells. The role of MAITs in solid tumours is starting to emerge and it’s likely they are included with CD8+ cells when defining Tumour Infiltrating Lymphocytes (TILs). MAIT cells may be prognostic and may be a novel immune-therapeutic target.
Methods: Recruit 40 patients with colorectal-liver metastasis and investigate the role of MAIT cells in the tumour, normal liver and peripheral blood by flow cytometry. Assess function using tumour cell killing assays, developed in our lab, with patient-derived tumouroid cultures.
Results: We have recruited 25 patients with liver mets and documented MAITs in the tumour; surrounding liver tissue and PBMCs. MAIT cell frequency is decreased in the tumour compared to the surrounding tissue. However, MAITs have a high expression of PD-1 in the tumour, indicating potential response to immune checkpoint blockade (ICB). We have preliminary data demonstrating that autologous MAIT cells have effector function when co-cultured with patient-derived tumouroids *in vitro.*
Conclusions: MAITs are decreased in the tumour, with high PD-1 expression and may be ideal targets for ICB. These intriguing results warrant further investigation to determine their direct or indirect role of MAIT cells in tumour immunity.

P.B1.07.16

Virus like particle vaccine targeting xCT protein in preclinical breast cancer models

V. Rolih[1], *E. Bolli*[1], *L. Conti*[1], *J. M. Christen*[2], *J. Caldeira*[2], *F. Pericle*[2], *F. Cavallo*[1];
[1]*University of Turin, Turin, Italy,* [2]*Agilvax Inc., Albuquerque, United States.*

Cancer stem cells (CSCs) are involved in the resistance mechanism to traditional radio- and chemo-therapies. They represent a reservoir for relapse and metastatic evolution.
The cystine-glutamate antiporter xCT (SLC7A11) has been identified as over-expressed on the cell surface of breast CSC (BCSC) and essential for their resistance to common cytotoxic therapies. xCT expression is restricted to a few normal cell types, in particular neurons and subset of macrophages. In breast cancer patients, high levels of xCT mRNA and protein correlate with significant reduction in distal metastases-free and overall survival. Thus, xCT could be an ideal oncoantigen for immunotherapy. We have developed an innovative vaccine based on a virus-like-particle (VLP) technology targeting the xCT protein for breast cancer treatment.
Immunization with our VLPs elicited a strong antibody response against xCT and these antibodies affected BCSC function and biology *in vitro*. We studied the effect of our vaccine on metastasis formation in two different settings: as a preventive model in BALB/c mice injected with Her2+ TUBO cells and as a therapeutic model in BALB/c mice injected with triple negative 4T1 cells. For both protocols, treated mice had a significant reduction in lung metastases compared to controls.
These data show that our VLP vaccine can inhibit xCT activity, impact CSC biology and significantly reduce metastatic progression in preclinical models. We are studying the association of our VLPs vaccine with anti-PD-1 monoclonal antibody therapy. In the future, we would like to translate this combinatorial approach to the clinical settings.

P.B1.07.17

Selection of tumor cells in the cultivation stage, suitable for the development of a vaccine against urothelial cancer

T. Slavyanskaya[1], *S. Salnikova*[2];
[1]*Peoples Friendship University of Russia (RUDN University), MOSCOW, Russian Federation,* [2]*FSBI Clinical Hospital №1 of the Presidential Affairs Management of the Russian Federation, MOSCOW, Russian Federation.*

Introduction: The development of vaccines for urothelial carcinoma (UCV) covers many aspects necessary for its standardization. Materials and Methods: We assayed UC samples from 25 patients aged 37-82. Cultivation of UC cells (UCC) was performed on growth media DMEM/F12. Evaluation of viability (V) was performed every 24 h for 6 days. Tumor disaggregation was performed by means of 2 methods: automatic mechanic and enzymatic methods. Cancer-testicular antigens (CTA) expression was evaluated at FACS Canto II device. Software package SPSS 23.0 for Windows was used. Results: V of UCC in a 1st day exposure at a temperature (T) 0^0C was fall down on 7.14±0.7%, at +4°C on 3.3±0.4% , at +8°C on 11,8±1.5% (p≤0.05). From 2 to 6 days V was decreased on 9.0±1.9% and on 66.7±4.7%, respectively. V of the UCC during the mechanical disaggregation was significantly higher than 81,8±6% (p≤0.05) compared to the enzymatic method: 28,4±3,3% or 55,6±4,9%, depending of UC forms. In UCC cultures CTA expression was detected frequently: MAGE-70%; BAGE-30%; GAGE-40%; NY-ESO-1-50%. At early passages quantity of UCC, expressing CTA, amounted to 78.0% (p<0.05). While expression of CTA at UCC more, than 30 passages, was significantly lower - 28.2±4.6% (p<0.05). Conclusions: It was worked out optimal parameters for preservation of viability of CUC in the process of cultivation, transportation and storage. UCC with high frequency of CTA expression may be used for preparation of UCV.
The publication has been prepared with the support of the "RUDN University Program 5-100".

Genetic mutations of tumor cells depending on the clinical forms of urothelial cancer

T. Slavyanskaya[1], *S. Salnikova*[2];
[1]*Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation,* [2]*2FSBI Clinical Hospital №1 of the Presidential Affairs Management of the Russian Federation, Moscow, Russian Federation.*

Introduction: The objective of the work is to perform comparative study of genetic mutations and expression of cancer-testicular antigens (CTA) in case of different forms of UC. Materials and Methods: The tumor specimens (TS) of UC were studied in 54 patients aged 37-82 with muscular invasive (MIF, TS-75%) and muscular non-invasive (MNIF, TS-25%) forms. Expression of CTA was assessed by FlowCytometry method. We used the package of statistical software SPSS 23.0 for Windows. Results: It was established, that all researched TS had cytogenetic changes: deletion of 9 chromosome (Ch) - 66.7%, absence of Y Ch (50%) and monosomy of 13 Ch (33.3%). In rare cases changes in 1,3,7 Ch, monosomy of 17 Ch, trisomy of 7 Ch were detected. In case of prolonged passaging in a part of cultures, significant increase of the number of genetic changes in a form of division of previously homogeneous population into subclones differing in ploidy (up to 56 Ch) and quantity of changed Ch is observed. Certain correlation of these changes to decrease of CTA expression (GAGE, BAGE, MAGE, NY-ESO-1) (p<0.05) was established. Conclusions: Thus, in MNIF UC CTA expression is significantly lower, than in case of MIF. Particular cultures in the course of multiple transits preserved cytogenetic profile and consistent CTA expression, which makes them promising for preparation of antitumor vaccine in case of UC. *The publication has been prepared with the support of the "RUDN University Program 5-100".*

Immunisation with a synthetic vaccine consisting of a tumour-associated MUC1-glycopeptide conjugated to Tetanus Toxoid significantly reduced breast tumour growth

N. Stergiou[1], *N. Gaidzik*[2], *A. Heimes*[3], *S. Dietzen*[1], *P. Besenius*[2], *J. Jäkel*[4], *W. Brenner*[3], *M. Schmidt*[3], *H. Kunz*[2], *E. Schmitt*[1];
[1]*Institute of Immunology, Mainz, Germany,* [2]*Institute of Organic Chemistry, Mainz, Germany,* [3]*Departement of Obstetrics and Women's Health, Mainz, Germany,* [4]*Institute of Pathology, Mainz, Germany.*

Immunisation against strongly expressed tumour-associated endogenous antigens is considered to be an attractive strategy for the induction of a curative immune response concomitant with a long lasting immunological memory. The mucin MUC1 is a very promising tumour antigen, as its tumour-associated form significantly differs from the glycoprotein form expressed on healthy cells. Due to aberrant glycosylation in tumour cells, the specific peptide epitopes in its backbone are accessible and can be bound by antibodies induced by vaccination. Breast cancer patients develop *per se* only low levels of T cells and antibodies recognizing tumour-associated MUC1 and clinical trials with tumour-associated MUC1 gained unsatisfactory therapeutic effects indicating urgent need to improve humoral immunity against this tumour entity. Herein, we demonstrate that preventive vaccination against tumour-associated human MUC1 results in strong specific humoral immune responses, in a marked slowdown of tumour progression and in an increased survival of breast tumour-bearing mice. For preventive vaccination, we used a synthetic vaccine containing a specific tumour-associated glycopeptide structure of human MUC1 coupled to Tetanus Toxoid. The glycopeptide consists of a 22mer huMUC1 peptide with two immune dominant regions (PDTR and GSTA), glycosylated with the sialylated carbohydrate ST_N on serine-17. PyMT and human MUC1-double transgenic mice expressing human tumour-associated MUC1 on breast tumour tissue served as a preclinical breast cancer model.

Tumor vaccination: chitosan nanoparticles to improve the antigen uptake by dendritic cells for an enhanced tumor-directed immune response

E. Winter[1], *O. Helm*[1], *M. Lettau*[2], *J. Heidland*[3], *R. Scherließ*[3], *F. Walter*[1], *S. Sebens*[1];
[1]*Institute of Experimental Cancer Research, Christian-Albrechts-University (CAU) Kiel and University Hospital of Schleswig-Holstein (UKSH) Campus Kiel, Kiel, Germany,* [2]*Institute of Immunology, Christian-Albrechts-University (CAU) Kiel and University Hospital of Schleswig-Holstein (UKSH) Campus Kiel, Kiel, Germany,* [3]*Department of Pharmaceutics and Biopharmaceutics, Christian-Albrechts-University (CAU) Kiel, Kiel, Germany.*

Tumor vaccination is a promising approach for treatment of tumor diseases.
Dendritic cells (DCs) play a key role in the initiation of an anti-tumor immune response. They present endocytosed tumor antigens via cross-presentation on major histocompatibility complex class I molecules thereby activating CD8+ cytotoxic T lymphocytes.
However, convincing results from studies on solid tumors are still missing. One reason might be an inefficient antigen uptake by DCs.
The aim of this study was to assess the suitability of chitosan nanoparticles (CNPs) for improving the antigen uptake by different antigen presenting cells to further enhance tumor-directed immune responses. CNPs can be used as carriers for noninvasive drug delivery, such as nasal or pulmonary administration.
Hence, the uptake of FITC-conjugated CNPs of different sizes by human DCs or macrophages was analyzed by flow cytometry revealing a high uptake rate by DCs and a less efficient uptake by macrophages. Furthermore, to confirm intracellular CNP-localization in DCs, ImageStream® analysis was performed showing a high internalization rate of nanoparticles.
In order to further investigate the suitability for inhalation, target specificity of CNPs was studied. Nanoparticle uptake analyzed in DCs, which were cocultured with human lung epithelial cells H441, showed CNP-uptake by both cell types. Current studies investigate the uptake of antigen loaded CNPs in cocultured DCs and whether this leads to potent T cell activation.
Overall, these data indicate that CNPs are efficiently internalized in DCs supporting their suitability as vehicles to improve antigen uptake by human DCs.

Natural compounds as modulators of regulatory T cell function for the treatment of cancer

F. Al-Naimi, *L. Thoele, J. Bartel, M. Guderian, M. Swallow, L. Almeida, T. Sparwasser;*
Institute of Infection Immunology, TWINCORE, Centre for Experimental and Clinical Infection Research, Hanover, Germany.

Regulatory T cells (Tregs) play a major role in maintaining the immune homeostasis of the host. However, their increased frequency observed in tumor patients and murine tumor models is associated with poor prognosis and inhibited therapy response rates. Therefore, their manipulation is still a major focus of current research. In recent projects we could show that natural compounds derived from micro-organismal secondary metabolites can influence the function of immune cells, especially T cells. In this project we identified a new additional compound that shows promising potential to inhibit regulatory T cells. First data indicated that this compound inhibits the differentiation of Tregs *in vitro* by dampening the levels of FoxP3 protein, but not FoxP3 mRNA levels. Moreover, the compound did not impair the expression of IFNγ in Th1 polarized CD4 T cells *in vitro*. Furthermore, *in vivo* experiments showed that the therapeutic application of this substance during the early stages of B16 melanoma development in mice reduced the tumor growth rate, decreased Treg frequencies in the tumor-infiltrating lymphocyte (TILs) population and increased the CD8/Treg ratio in the TILs. Besides, RNA microarray analysis of iTregs treated with the compound further supports the idea that the compound regulates FoxP3 on a posttranscriptional or even posttranslational level. Moreover, first human data in *in vitro* induced Tregs from healthy donors cultured in the presence of the compound showed a decrease of FoxP3 protein levels. Therefore, we propose that this new compound has promising immunomodulating capacity on Tregs useful for immunotherapy of melanoma.

CD74, with its two leucine based endosomal sorting signals that binds AP1 and AP2 adaptors was first found to be an essential partner for the proper trafficking of MHC II and efficient antigen loading. The trimeric CD74 delays furthermore endosomal maturation and is essential for forming the peptide loading compartment. CD74 has endosomal membrane fusion properties independent of Rab5, PI3 kinase and EEA1 and I will discuss how this property can be exploited to study maturation, endosomal fusion, fission and endosomal membrane kinetics after tyrosine kinase receptor activation. Interestingly, CD74 has been found to interact with several molecules including MHCI and can be used as a vector for simultaneously increasing both MHCI and MHCII mediated immune responses towards specific antigens and is ready to be tested in clinical therapeutic DC based cancer immunotherapy. <!--EndFragment-->

Therapeutic vaccination protocols aiming to improve adaptive immune responses present a promising anti-tumor therapy. However, T cell mediated effector functions are often counteracted by regulatory T cells (T_{regs}) and myeloid-derived suppressor cells (MDSCs).
Here, we studied therapeutic vaccination in two different mouse tumor models, B16-OVA (melanoma) and MC38-CEA (colorectal carcinoma).
Combined application of the TLR9-ligand CpG and the NKT-ligand α-GalCer induced potent anti-tumor responses in only a subpopulation of mice. Non-responders had equal levels of T_{regs}, $CD4^+$ and $CD8^+$ T cells, B cells and NK cells but elevated levels of $CD11b^+$ $MHC\text{-}II^-$ $Ly\text{-}6G^-$ $Ly\text{-}6C^{high}$ monocytic MDSCs (M-MDSCs). On a per cell basis, M-MDSCs from responders and non-responders were equal suppressive towards T cells. To overcome M-MDSC mediated suppression, concurrent and time-delayed injection of all-trans-retinoic-acid (atRA) was tested, a treatment previously reported to reduce M-MDSC numbers. Strikingly, only 3d time-delayed but not concurrent administration of atRA reduced tumor growth and improved overall survival. M-MDSCs up-regulated MHC class II, cross-presented antigens and lost their suppressive effect towards T cells. In contrast, simultaneous treatment with atRA reduced the beneficial effects of therapeutic vaccination and did not lead to MHC class II expression. Similarly, MDSCs from human colorectal carcinoma patients failed to up-regulate HLA-DR after TLR stimulation *in vitro* when atRA was present.
We hypothesize, treatment with atRA abrogates functional and phenotypic plasticity of myeloid cells. Therefore, timing of atRA administration should be carefully considered in therapeutic vaccination protocols to prolong a TLR-induced pro-inflammatory myeloid phenotype and to reduce immune suppression mediated by MDSCs.

Sensitive identification and advanced profiling of neoantigen-specific T cells in cancer patients

S. Bobisse[1], *R. Genolet*[1], *B. J. Stevenson*[2], ***V. Bianchi***[1], *V. Zoete*[2], *D. Gfeller*[1], *L. Kandalaft*[1], *G. Coukos*[1], *A. Harari*[1];
[1]*Ludwig Institute for Cancer Research, Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, Lausanne, Switzerland.*

Neoantigens arise from tumor nonsynonymous somatic mutations and can generate immunogenic peptides (neo-epitopes) bound to HLA molecules. Mounting evidence suggests that neoantigens represent ideal tumor-specific candidates to target with personalized T-cell mediated immunotherapies or vaccines and several studies indeed demonstrated their clinical relevance. However, feasibility in low mutational load tumor types such as ovarian cancer remains unknown. Using highly sensitive assays to detect and profile neo-epitope specific circulating and tumor-infiltrating (TILs) $CD8^+$ T cells allowed prompt identification of oligoclonal and polyfunctional such cells from most immunotherapy-naïve patients with advanced epithelial ovarian cancer. Neo-epitope recognition was discordant between circulating T cells and TILs, and was more likely to be found among TILs, which displayed higher functional avidity and unique TCRs with higher predicted affinity than their blood counterparts. Of interest, the relative functional avidity of neoepitope-specific TILs correlated significantly with their intratumoral frequency. Our results imply that identification of neo-epitope specific $CD8^+$ T cells is achievable even in tumors with relatively low number of somatic mutations, and neo-epitope validation in TILs extends opportunities for mutanome-based personalized immunotherapies to such tumors.

P.B1.08.05
HLA ligandomics feeds a pipeline of soluble T cell receptor-based immunotherapies

F. Capuano, *G. Mommen, R. Carreira, D. Lowne, M. Cundell, A. Powlesland;*
Immunocore Ltd, Abingdon, United Kingdom.

Introduction: HLA complexes on cell surfaces can present cancer-associated peptides to the immune system, representing valuable targets for cancer immunotherapy. Immunocore identifies tumour-specific HLA peptides, generates peptide-specific T cell clones and engineers T cell receptors (TCRs) into potent soluble immunotherapeutics.
Materials and Methods: Immortalized cancer cells and tumour tissues are homogenised in lysis buffer and HLA complexes captured from the supernatant by affinity purification using HLA-restriction specific antibodies. HLA peptides eluted under acidic conditions are separated by reverse phase liquid chromatography and analysed by mass spectrometry. Fully validated target peptides are used to clonally expand HLA-peptide specific T cells. Isolated TCRs are engineered into soluble molecules (mTCRs) whose affinity towards target peptide:HLA is enhanced using phage display technology.
Results: Our HLA peptidomic workflow combines novel biochemical techniques with high resolution mass spectrometry, data integration from multiple instruments and multiple search algorithms to maximise the depth of the HLA ligandome (up to 400,000 unique HLA-A*02 peptides identified). Our immune-activating therapeutics (ImmTAC™) generated by coupling high-affinity mTCRs with an anti-CD3 scFv domain redirect polyclonal T cell responses toward cancer cells. Our current lead candidate, IMCgp100, has entered pivotal monotherapy trials for treatment of patients with metastatic uveal melanoma. Additionally, Immunocore in collaboration with MedImmune/AstraZeneca is conducting a trial in cutaneous melanoma patients exploring the combination of IMCgp100 with checkpoint inhibition, including Imfinzi® (durvalumab) and tremelimumab.
Conclusions: Our peptidomics workflow enables the identification of HLA-presented peptides to support the successful design of TCR-based immunotherapeutics for cancer treatment.

P.B1.08.06
ERAP1 controls the engagement of human NK cell receptor KIR3DL1 by its specific ligand HLA-B51

M. Compagnone[1], *V. D'Alicandro*[1], *P. Guasp*[2], *L. Cifaldi*[1], *P. Romania*[1], *G. Zicchedda*[1], *V. Lucarini*[1], *O. Melaiu*[1], *D. Pende*[3], *J. A. López de Castro*[2], *D. Fruci*[1];

The activity of natural killer (NK) cells is tightly regulated by inhibitory and activating receptors. Inhibitory killer immunoglobulin-like receptors (iKIRs) survey the surface of target cells by monitoring the expression of HLA class I (HLA-I) molecules. The interaction of iKIRs with HLA-I molecules is sensitive to the sequence of peptides bound to HLA-I molecules, suggesting that NK-cell activation may be regulated by a change in the repertoire of peptide. Recently, we have demonstrated that genetic or pharmacological inhibition of ERAP1, a key component of the antigen processing, on tumor cells perturbs the engagement of NK cell inhibitory receptors by their specific ligands, enhancing the NK-mediated killing. These results indicate that modulation of ERAP1 can be exploited as a novel tool to improve the efficacy of NK-based approaches for cancer immunotherapy.
To identify the HLA-I/KIR combinations most affected by ERAP1 inhibition, HLA-I-negative 721.221 cells transfected with a panel of KIR ligands (HLA-A2, -B51, -Cw3, -Cw4 and -Cw7) were stably silenced for ERAP1 expression and tested for their ability to induce NK-cell degranulation. HLA-I surface expression did not substantially change following ERAP1 inhibition. Conversely, CD107a expression was significantly upregulated on NK cells following stimulation with ERAP1-deficient 721.221-B51 cells as compared with control cells. This increase was particularly evident in the NK cell subset expressing the single KIR3DL1, and directly related to the functional level of this receptor. Overall, these results identify KIR3DL1/HLA-B51 as one of the most sensitive combinations to ERAP1 inhibition rendering tumor cells more susceptible to NK-mediated killing.

Role of CD27/CD70 deficiency in the cell-mediated immune control of the Epstein Barr virus

***Y. Deng**, B. Chatterjee, C. Münz;*
Experimental Immunology, Zurich, Switzerland.

Introduction: Epstein Barr virus (EBV) is one of the most successful pathogens in the human population, persistently infecting more than 90% of adult individuals. It was discovered as the first human tumor virus contributes to 1-2% of all cancers in the world. Primary immunodeficiencies that predispose for EBV induced tumors and uncontrolled virus infection, have identified molecules in the differentiation, co-stimulation and effector function of cytotoxic lymphocytes. In this project, we are assessing CD27 immunodeficiency in EBV specific immune control and investigating which immune compartment(s) are compromised in the absence of CD27/CD70 co-stimulatory signal.
Material and Methods: To mimic the CD27 deficiency, anti-CD27 blocking and depletion antibodies were used to study the function of this pathway in EBV infection using T cell proliferation and killing assays *in vitro*. By reconstituting human immune system in mouse, the human-tropic EBV infection was able to be modeled *in vivo*. Conditions with/without CD27 injection were compared in terms of the EBV viral load and tumor incidence. In addition, the functionality of T and NK cells and cytokine production were monitored by flow cytometer.
Results: An impaired proliferation of T cells was observed due to the blocking effect of CD27 antibodies after 7 days of incubation. In vivo study showed depletion of $CD27^+$ cells in mice led to significant higher EBV viral loads and a slightly increased incidence of tumorigenesis
Conclusions: Overall, $CD27^+$ cells play a protective role in mediating EBV associated immune responses in humanized mice.

P.B1.08.08

Combination of Trastuzumab and Pertuzumab binding site mimotopes together with anti-PD1 immune checkpoint as a novel anti-Her-2/neu multi-level vaccine

*J. Tobias[1], **M. Drinic**[1], K. Baier[1], K. Ambroz[1], C. C. Zielinski[2], U. Wiedermann[1];*
[1]Institute of Specific Prophylaxis and Tropical Medicine, Center for Pathophysiology, Infectiology and Immunology, Medical University Vienna, Vienna, Austria, [2]Division of Oncology, General Hospital Vienna,, Vienna, Austria.

Extracellular subdomains of Her-2/neu is overexpressed in 20-25% of breast and gastric cancers. Combination of the mAbs Trastuzumab and Pertuzumab has synergistically resulted in a significant improvement in clinical outcomes of patients with Her-2/neu-positive metastatic breast cancer. However active immunotherapy, unlike application of mAbs, provides advantages like induction of humoral, cellular and memory responses and anti-tumor activity. The first generation of our B cell multi-peptide anti-Her-2/neu vaccine, containing three single peptides conjugated to virosomes, was recently improved to its second generation by fusing the peptides into a hybrid peptide (P467) which after conjugation to CRM197 and together with the adjuvant Montanide led to induction of strong humoral and Th1-biased cellular responses with antitumor activity. To broaden the number of biologically active epitopes in the vaccine, its third generation has recently been developed by including the binding site epitopes (mimotopes) of Trastuzumab and Pertuzumab, which in combination with P467 have shown to induce polyclonal humoral and cellular responses. Combinational therapy of cancer vaccines and immune checkpoint inhibitors has been suggested to synergistically enhance antitumor immune responses. When immunizing mice with P467-CRM-Montanide combined with anti-mouse PD-1 mAb vaccination, we have seen generally elevated cellular responses compared to unvaccinated mice. The third generation of our anti-Her2/neu vaccine combined with an immune checkpoint inhibitor is now being evaluated *in vivo* and may result in an effective novel multi-level vaccine against Her-2/neu overexpressing cancer entities. The study is granted by Imugene Limited, Australia, and Medical University of Vienna.

LIGHT/LTβR signaling regulates self-renewal and differentiation of hematopoietic and leukemia stem cells

***S. Hoepner**[1], R. Radpour[1], M. Amrein[1], C. Riether[1], G. Baerlocher[2], A. Ochsenbein[1];*
[1]Inselspital, Bern University Hospital/Dept. Medical Oncology/Tumor Immunology, DBMR, University of Bern, Bern, Switzerland, [2]Inselspital, Bern University Hospital, Department of Hematology, Bern, Switzerland.

Introduction: Hematopoietic stem cells (HSC) are responsible to replenish all blood cell lineages. The balance between self-renewal, proliferation and quiescence is tightly regulated to ensure the maintenance of the stem cell pool but also guarantee rapid adaptation in response to hematopoietic stress. Likewise, the balance of self-renewal and differentiation is critical in the pathology of hematopoietic malignancies. Here we show that lymphotoxin-beta receptor (LTβR), a member of the TNF superfamily, and its ligand TNFSF14 (LIGHT) play an important role in HSC and leukemic stem cell (LSC) regulation. LIGHT/LTβR signaling maintains stem cell quiescence, promotes symmetric division and thereby contributes to HSC and LSC self-renewal.
Material and Methods: To study LIGHT/LTβR signaling, we performed serial competitive repopulation assays by using hematopoietic stem and progenitor cells (HSPCs) from *Ltbr* KO, *Light* KO and C57/BL6 (WT) mice and analyzed cell cycle activity, cell viability and cell division. In a second approach we analyzed LTβR signaling in HSCs after induction of genotoxic stress. Therefore, 5-Fluoracil (5-FU), a therapeutic agent which is known to activate HSCs, was administered into *Ltbr* KO and WT mice. Moreover, we investigated LIGHT/LTβR signaling in human HSPCs.
Results: *Ltbr* deficiency on murine HSCs and LSCs resulted in enhanced proliferation, asymmetric division and a reduced stem cell pool. LTβR signaling was induced by LIGHT in an autocrine manner. Moreover, *LTBR* deficiency affected the stemness of human HSPCs.
Conclusion: LIGHT/LTβR signaling is a novel player in HSC and LSC self-renewal, which potentially provide a new strategy to eliminate LSCs.

P.B1.08.10

Pancreatic and colon cancer stem cells evade NK cell effector function through PCNA-NKp44 interaction

***J. D. Malaer**, P. A. Mathew;*
UNT Health Science Center, Fort Worth, United States.

Introduction: NK cells participate in the innate immune response against infection and cancer without prior sensitization. NK cell function depends on a balance of signals transmitted from activating and inhibitory receptors interacting with ligands on the surface of cells. Cancer cells may evade NK-mediated killing by expressing ligands for inhibitory receptors. Proliferating cell nuclear antigen (PCNA) associates with HLA I and forms the inhibitory ligand for NKp44, resulting in the inhibition of NK function. Cancer stem cells (CSC), a unique subset of tumor cells, possess a stem-cell-like phenotype and are thought to facilitate metastasis by escaping NK cell effector function.
Materials and Methods: Pancreatic (Panc-1) and colon (HCT 116) cancer cells were labeled with antibodies against PCNA, CD44, and CD133 and surface expression was determined by flow cytometry. Cells were labeled and sorted for surface PCNA expression via FACS; NANOG, SOX2, and Oct-4 were analyzed by qRT-PCR from sorted cells. Target cells were blocked with anti-PCNA or control antibodies and a chromium release killing assay was performed.
Results: In both cell lines, cell surface PCNA is associated with co-expression of CD44 and CD133 as well as increased CSC transcription factor expression. Blocking the interaction of NKp44 and PCNA enhanced the specific lysis of cells by NK cells.
Conclusions: Collectively these data demonstrate that surface PCNA is a marker of pancreatic and colon CSC. Our research implicates that blocking NKp44-PCNA interaction may provide a novel immunotherapeutic target for pancreatic and colon cancer stem cells and prevent metastasis.

P.B1.08.11

Neoadjuvant therapy with attenuated Salmonella improves outcome of dacarbazine treated melanoma bearing mice

*S. Chilibroste, A. E. Mónaco, M. Vola, C. I. Agorio, J. A. Chabalgoity, **M. Moreno**;*
Universidad de la República, Montevideo, Uruguay.

Melanoma is a severe form of skin cancer with high incidence rate. After 30 years of use, d*acarbazine* (DTIC)-based chemotherapy continues to be the standard of care for most patients with metastatic melanoma. In this work, we evaluate the potential of *Salmonella enterica* serovar Typhimurim, LVR01 (*aroC*), as neoadjuvant therapy in melanoma-bearing mice undergoing chemotherapy. C57BL/6 mice were subcutaneously inoculated with B16F1 melanoma cells. When tumors were palpable, *S*. Typhimurium LVR01 ($1x10^6$ CFU) was intratumorally injected. At the following day, chemotherapy treatment consisting in daily intraperitoneally application of 150 mg/kg/doses DTIC was started and continued for 3 days. Neoadjuvant LVR01 administration in chemotherapy-treated mice retarded tumor growth and prolonged overall survival compared to control and monotherapy-treated animals. Importantly, Salmonella treatment was well tolerated by mice undergoing chemotherapy, with less than 10% of weight loss. This combined approach increased expressions of ccl2, ccl5, cxcl9 and cxcl10 mRNA levels in the tumor microenviroment, accompanied by tumor infiltrating neutrophils and cytotoxic lymphocytes with augmented activated status. Chemotherapy therapy induced a drastic reduction of secondary lymphoid organ size. Salmonella neoadjuvant treatment partially rescued absolute cell numbers in these compartments, and activated effector NK and CD8 T cells. In conclusion, *Salmonella* immunotherapy could be safely used in individuals under chemotherapy treatment. This therapeutic approach induces activation of cytotoxic lymphocytes, resulting in longer survival. The use of attenuated *Salmonella* as a non-specific active immunotherapy in combination with standard chemotherapy could be considered as an interesting therapeutic strategy with close clinical application for patients with melanoma.

P.B1.08.12

Anti-CD137 antibodies enhance Daratumumab efficacy against multiple myeloma increasing ADCC effect in an immunodeficient mouse model reconstituted with human NK cells

M. C. Ochoa[1,2,3], *E. Perez-Ruiz*[4], *A. Zabaleta*[5,2,3], *P. Berraondo*[6,2,3], *L. Minute*[6,2], *I. Rodriguez*[1], *A. López*[1,3], *S. Garasa*[6], *A. Azpilikueta*[6], *C. Molina*[6], *M. F. Sanmamed*[6], *A. Muntasell*[7], *B. Paiva*[6], *J. San Miguel*[1,3], *M. Lopez-Botet*[7,8], *I. Melero*[1,6,3];
[1]*Clínica Universidad de Navarra, Pamplona, Spain,* [2]*Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Pamplona, Spain,* [3]*Navarra Institute for Health Research (IDISNA), Pamplona, Spain,* [4]*Division of Medical Oncology, Hospital Costa del Sol, Marbella, Spain,* [5]*Centro de Investigacion Medica Aplicada (CIMA), Pamplona, Spain,* [6]*Centro de Investigación Médica Aplicada (CIMA), Pamplona, Spain,* [7]*Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain,* [8]*University Pompeu Fabra (UPF), Barcelona, Spain.*

Daratumumab is an anti-CD38 mAb approved for multiple myeloma treatment. Antibody-dependent cellular cytotoxicity (ADCC) mediated by NK cells and macrophages is one of the mechanisms of action proposed for this drug. Preclinical data have shown that the anti-CD137 agonist antibody Urelumab increases NK-mediated ADCC effect exerted by other mAbs used in oncology, such as Rituximab, Cetuximab and Trastuzumab, and clinical trials combining Urelumab and Rituximab or Cetuximab are ongoing. Freshly isolated human NK cells from healthy volunteers do not express CD137 on the membrane, but CD137 is induced when the NK cells are co-cultured with a Daratumumab-coated $CD38^+$ multiple myeloma-derived cell lines (MM1S or KMS28BM). Moreover, NK cells from multiple myeloma patient bone marrows treated *ex-vivo* with Daratumumab also up-regulate CD137 expression. Daratumumab addition to co-cultures of NK cells and MM1S or KMS28BM increases tumor cell death. However, cytotoxicity is not increased by the addition of Urelumab either in short-term (4h) or medium-term (18h) experiments. To study if Urelumab increases Daratumumab-mediated ADCC activity *in vivo,* we set up a tumor model based on the i.v. administration of a luciferase-transfected MM1S cell line, human NK cells and Daratumumab to immuno-deficient NSG mice. In this model, i.v. administration of Urelumab 24h after Daratumumab retarded the tumor growth and prolonged mice survival. P.B1.08.13

The Wiskott-Aldrich syndrome protein regulates antigen processing and presentation by dendritic cells to activate cytotoxic T cells

M. Oliveira[1], *M. Baptista*[2], *L. Westerberg*[1];
[1]*Karolinska Institutet, Solna, Sweden,* [2]*Institute for Virology and Immunobiology, Würzburg, Germany.*

One promising cancer therapeutic today is to teach the patient's own immune system to kill tumor cells. Specialized dendritic cells (DCs) can take up exogenous antigen, such as tumor antigens, and present peptides on MHC class I molecules to activate $CD8^+$ cytotoxic T cells in a process called cross-presentation. Here, we examined the role of the actin regulator Wiskott-Aldrich syndrome protein (WASp) in antigen sorting in DCs. We found that specific deletion of WASp in DCs led to marked expansion of $CD8^+$ T cells. Mechanistically, we found that WASp-deficient DCs induced increased cross-presentation to $CD8^+$ T cells by activating Rac2 that maintained a near neutral pH of phagosomes. This allowed escape of antigen to the cytosol and loading on MHC class I molecules. To address if WASp directly reduced cross-presentation in DCs, we placed back WASp in bone marrow-derived DCs from WASp-deficient mice using Amaxa transfection. WASp-deficient DCs transfected with wildtype WASp induced decreased proliferation of $CD8^+$ T cells, suggesting that antigen sorting is regulated by WASp. To address if we could use our findings to target antigen sorting in wildtype DCs, we used small molecule inhibitors for actin regulators such as WASp. We have identified one inhibitor that induced increased cross-presentation by wildtype DCs. We treated DCs with this inhibitor during antigen sorting *ex vivo* and injected the DCs into mice. We found that inhibitor-treated DCs induced higher proliferation of antigen-specific $CD8^+$ T cells *in vivo*. Our data suggests that direct target of actin regulators may enhance DC-mediated immunotherapy.

Using tumour origins to identify peptide vaccine targets in two independent contagious cancers

R. Owen[1], *A. Gastaldello*[1], *S. Ramarathinam*[2], *A. Bailey*[1], *P. Skipp*[1], *T. Elliott*[1], *A. W. Purcell*[2], *H. V. Siddle*[1];
[1]*University of Southampton, Southampton, United Kingdom,* [2]*Monash University, Melbourne, Australia.*

The Tasmanian devil harbours two distinct transmissible cancers, Devil facial tumour (DFT) 1 and 2. Both are spread by transmission of cells between individuals, threatening a vulnerable species. As these cancers are allografts, Major Histocompatibility Complex (MHC) and bound peptides are key to developing vaccine strategies. DFT1 originated in a Schwann cell, but the cellular origin of DFT2 is unknown. Here we identify the cellular origin of DFT2 and characterise the immunopeptidomes of DFT1 and DFT2 to identify antigenic peptides. Peptides from MHC class I were isolated in triplicate for each cell line using a devil anti-B_2m antibody. Mass spectrometry was used to sequence peptides and generate whole cell proteomes for DFT1-IFNγ, DFT2 and devil fibroblast cell lines. Peptides were identified by searching spectra against custom Tasmanian devil databases using PEAKS. Gene ontology analysis was performed. DFT2 and DFT1 are enriched for similar nervous system processes. DFT2 expresses proteins associated with glial development and myelin components. Between 2243 and 6373 potential MHC class I peptides were identified for each cell line with a length preference for 9mers. We identified 61 and 55 peptides unique to DFT1-IFNγ and DFT2. The immunopeptidomes of two contagious cancers will be used for vaccine design and to identify the binding motifs of MHC alleles expressed by DFT1 and DFT2. Our data suggests that DFT2 is of a myelin competent glial cell lineage and bears remarkable resemblance to DFT1, a finding significant for both vaccine design and fundamental understanding of transmissible cancers. The Leverhulme Trust (RPG-2015-203)

P.B1.08.15

Development of a novel *in vitro* screening method for cancer immunotherapy using genetically modified NK-92 cells: Dissection of NK cell-tumor cell interactions

D. Ozkazanc Unsal[1,2], *E. Celik*[1,2], *M. Chrobok*[3,4], *B. Erman*[1,2], *E. Alici*[3,4], *A. D. Duru*[3], *T. Sutlu*[1,2];
[1]*Nanotechnology Research and Application Center, Sabancı University, İstanbul, Turkey,* [2]*Faculty of Engineering and Natural Sciences, Sabancı University, İstanbul, Turkey,* [3]*NSU Cell Therapy Institute, Nova Southeastern University, Fort Lauderdale, United States,* [4]*Center for Hematology and Regenerative Medicine, Karolinska Institutet, Stockholm, Sweden.*

NK cell-mediated lysis relies on a balance between several activating and inhibitory receptors that either promote or dampen the killing upon receptor-ligand interactions. Here, we propose to develop a screening method based on the genetic modification of NK cells upregulating a single receptor at a time. As both the character of the tumor cell population and phenotypic status of NK cells differ among patients, such a tool will be instrumental in developing patient-tailored cancer immunotherapy approaches.
Genes coding for 20 different NK cell surface receptors were lentiviral vector backbones for genetic modification of NK-92 cells. New cell lines, each overexpressing a specific receptor, were subjected to phenotyping and assessment of effector functions. The use of a colorimetric substrate for Granzyme B activity allowed us to optimize an easy-to-use screening tool to identify targets of NK cell-tumor interactions on a color-based fashion. Degranulation against K562 cell line showed significantly higher cytotoxicity especially in CRACC, DNAM-1, NKG2D transduced NK-92 cells compared to wildtype and backbone controls. Lentiviral genetic modifications did not disrupt or hamper cytotoxicity of NK-92 cells but rather induced enhaced cytolysis against specific tumor ligands.
A novel *in vitro* screening tool can be established on genetically modified NK-92 cells expressing different activating receptors. It has the potential to be a standardized protocol to identify patient-specific targets for NK cell-based cancer immunotherapy.
*This research is supported by the Scientific and Technological Research Council of Turkey (TUBITAK) grant 114Z861.

P.B1.08.16

Evaluation of intravenous immunoglobulin use analyzed in relation to diagnostic evidence levels

D. Garcia-Cuesta[1], *M. Vilches-Moreno*[1], *A. Salguero-Olid*[2], *M. San Jose*[1], ***A. Sampalo***[1];
[1]*UGC Hematology, Immunology and Genetics. Hospital Puerta del Mar., Cádiz, Spain,* [2]*UGC Hospital Pharmacy. Hospital Puerta del Mar., Cádiz, Spain.*

Aim: To evaluate clinical indication of intravenous immunoglobulin (IGIV) in the last year in our hospital in relation of based guideline of immunoglobulin Therapy. Evidence category and strength of recommendation was indicated.
Method: IGIV treatment was prescribed for 145 patients (76 male/ 69 female; median age 43± (range 5 moths - 90 years). Clinical data, evidence category (EC) and strength of recommendation (SC) for indications. Data was evaluated in relation to 2016 update of the Consensus Document of the American Academy of Allergy, Asthma and Immunology.
Results: IGIV were prescribed in 71 patients (49%) for **indications definitively benefit** : 19 ,Primary immune deficiencies(IIb/B) 27 Immune thrombocytopenic purpura (Ia/A), 12 Guillain Barré Syndrome (IIb/B), 4 Kawasaki disease (Ia/A), 6 Chronic desmyelinizating polyneuropathy (1a/A), 3 Multifocal motor neuropathy. IVIG were prescribed in 58 patients (40%) for **indications probably benefit** : 14 secondary immune deficiencies (IV/D) 21 Miastenia gravis (Ib/B, 1 dertomyositis (IIa/B) (1), 1 relapsing remitting multiple sclerosis (Ia/A), 8 Intractable childhood epilepsy (1a/B), 1 acute disseminated encephalomyelitis, 2 post hematopoietic cell transplantation (IV/B), 7 antibody mediated rejection (IV, D), 3 highly sensitized patients for renal transplantation (IV,D). IVIG were prescribed for **indications that may provide benefit** in 8 cases (5.5%): 2 autoimmune blistering skin disease (1a/A), 3 severe resistant atopic dermatitis, 1 severe asthma. IVIG were prescribed for **indications with no clinical evidence of benefit** in 8 (5.5%) patients.
Conclusions: Data demonstrate an appropriate use of immunoglobulin. Uses in which no clear effective benefit was demonstrated might be avoided.

P.B1.08.17

Acute pharmacologic degradation of a stable antigen enhances its direct presentation on MHC class I molecules

*S. C. Moser[1], J. S. Voerman[1], D. L. Buckley[2], G. E. Winter[3], **C. Schliehe**[1];*
[1]Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [2]Department for Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria.

Bifunctional degraders, also referred to as proteolysis-targeting chimeras (PROTACs), are a recently developed class of small molecules. They were designed to specifically target endogenous proteins for ubiquitin/proteasome-dependent degradation and to thereby interfere with pathological mechanisms of diseases, including cancer. In this study, we hypothesized that this process of acute pharmacologic protein degradation might increase the direct MHC class I presentation of degraded targets. By studying this question, we contribute to an ongoing discussion about the origin of peptides feeding the MHC class I presentation pathway. Two scenarios have been postulated: peptides can either be derived from homeostatic turnover of mature proteins and/or from short-lived defective ribosomal products (DRiPs), but currently, it is still unclear to what ratio and efficiency both pathways contribute to the overall MHC class I presentation. We therefore generated the intrinsically stable model antigen GFP-S8L-F12 that was susceptible to acute pharmacologic degradation *via* the previously described degradation tag (dTAG) system. Using different murine cell lines, we show here that the bifunctional molecule dTAG-7 induced rapid proteasome-dependent degradation of GFP-S8L-F12 and simultaneously increased its direct presentation on MHC class I molecules. Using a doxycycline-inducible setting, we could further show that the stable, mature antigen was the major source of peptides presented in our system. This study is, to our knowledge, the first to investigate targeted pharmacologic protein degradation in the context of antigen presentation and our data point toward future applications by strategically combining therapies using bifunctional degraders with their stimulating effect on direct MHC class I presentation.

P.B1.08.18

Antitumor activity of Gastropodan hemocyanins in murine model of colon carcinoma

*E. Stoyanova[1], I. Manoylov[1], N. Mihaylova[1], K. Idakieva[2], **A. I. Tchorbanov**[1];*
[1]Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria, [2]Institute of Organic Chemistry, Bulgarian Academy of Sciences, Sofia, Bulgaria.

Introduction: The hemocyanins (Hcs) are oligomeric copper-containing glycoproteins that function as oxygen carriers in the hemolymph of several molluscs and arthropods. Molluscan Hcs have been studied intensively for many years as very promising class of anti-cancer therapeutic, generating strong humoral and cellular immune response. A possible mechanism for their antitumor effect is the presence of cross-reactive epitopes between the carbohydrate content of the hemocyanin molecule and tumor-associated carbohydrate antigens, which are characteristic for different types of cancer. Materials and Methods: The Hcs were isolated from marine snail *Rapana thomasiana* (RtH) and the terrestrial snail *Helix pomatia* (HpH). Murine colon carcinoma cell line C-26 was used for animal administration and solid tumor establishment. Flow cytometry was performed for phenotyping of spleen and tumor suspensions and an apoptosis assay. The levels of cytokines and anti-C-26 antibodies were quantified by ELISA. Results: The Hcs exhibited strong *in vivo* anti-cancer and anti-proliferative effects in the developed murine model of colon carcinoma. We observed a significant increase of the spleens in non-treated C-26-bearing mice compared to Hcs treated. The immunization with RtH and HpH prolonged the survival of treated animals, improve humoral anti-cancer response and moderate the manifestation of C-26 carcinoma symptoms as tumor growth, splenomegaly and lung metastasis appearance. Conclusions: Hemocyanins are used so far for therapy of superficial bladder cancer and murine melanoma models. Our findings demonstrate a potential anti-cancer effect of hemocyanins on a murine model of colon carcinoma suggesting their use for immunotherapy of different types of cancer.

P.B1.08.19

Efficacy of generating immunogenic fast dendritic cells *in vitro* depend on the phenotype and early cytokines production by monocytes

*B. Pavlovic[1], **S. Tomic**[2], J. Djokic[3], D. Mihajlovic[4], D. Vucevic[4], M. Colic[2];*
[1]Pharmaceutical Faculty, University in Belgrade, Belgrade, Serbia, [2]Institute for the Application of Nuclear Energy, Belgrade, Serbia, [3]Laboratory for molecular microbiology, Institute for Molecular Genetics and Genetical Engineering, University in Belgrade, Belgrade, Serbia, [4]Medical Faculty of the Military Medical Academy, University of Defence, Belgrade, Serbia.

Cancer immunotherapy based on fast dendritic cells (fDC) is a promising and physiologically more relevant approach. However, not all donors respond well to fast DC protocol, leading to differentiation of potentially tolerogenic fDC, which may be deleterious for cancer treatment. Out of 10 donors tested in this work, we identified 4 whose monocytes do not generate immunogenic DC after 24h differentiation with granulocyte-macrophage colony stimulating factor and IL-4, followed by 48h stimulation with Poly (I:C). Non-responder fDC displayed high CD14 expression, low CD1a and costimulatory molecules expression, and low IL-12p70/TGF-β production ratio. Additionally, non-responder fDC displayed a weaker allostimulatory capacity, and a higher potential to induce alloreactive $CD4^+CD25^{hi}FoxP3^{hi}$ T regulatory cells, compared to responder fDC. These properties of non-responder fDC correlated positively with the expression of CD16 and the production of IL-6 and IL-1β early in cultures, and negatively with the expression of CD36 and CD69 and IL-8 production by the precursor monocytes. The blocking IL-6R with tocilizumab during the differentiation of non-responder monocytes into fDC, improved significantly the immunogenic phenotype and functions of fDC, and diminished their capacity to induce Tregs due to down-regulated expression of PD-1L and ILT-3. Our results stress out the importance of careful monitoring of cell cultures for identification of potential non-responder monocytes, and suggest timely actions toward increasing the immunogenic potential of fDC for cancer immunotherapy.

P.B1.09 Tumor vaccination principles and Immunotherapy - Part 9

P.B1.09.01

Cancer vaccines: Designing synthetic long peptides to improve presentation of selected class I and class II T cell epitopes by dendritic cells.

***C. Rabu**[1,2,3], L. Rangan[4,5], O. Adotevi[4,5], N. Labarrière[1,3], F. Lang[1,2,3];*
[1]INSERM U1232, Nantes, France, [2]Université de Nantes, Nantes, France, [3]Labex IGO, Nantes, France, [4]INSERM U1098, Besancon, France, [5]EFS Bourgogne France-Comté, Besancon, France.

Numerous class I and II T cell epitopes from tumor antigens have been characterized and exploited in vaccination protocols. Relying solely on short class I epitopes failed to elicit strong clinical responses while the simultaneous recruitment of CD4 T cells greatly enhanced vaccine efficacy. Thus, recent trials use synthetic long peptides (SLP) to activate both CD4 and CD8 T cells. The long peptides used consisted mainly in a mix of extended class I epitopes requiring DC internalisation for presentation and containing undefined class II epitopes. However, on native tumor antigens, the immunodominant epitopes can be either separated by hundreds of amino acids or on the contrary, overlap which could impair their processing efficiency.
Our strategy is to bring together a defined CD4 class II epitope to a defined CD8 class I epitope, joining them with a cathepsin-sensitive linker to increase its intracellular processing by DC.
As model antigens, we used MELOE-1 and MelanA/Mart1 widely expressed in melanoma and containing immunodominant epitopes. We tested a wide serie of short linkers (4 to 6 aa) selected for potential cathepsin sensitivity. We observed up to hundred fold differences in cross-presentation efficiency while classical class II presentation was less affected. We also confirmed that optimized SLP are more efficient than native antigen to expand specific CD8 T lymphocytes from whole PBMC in vitro. In a humanized mouse model, we show that immunization with optimized SLP tends to increase crosspresentation in vivo.
The selection of an optimized linker in the design of SLP vaccines should significantly increase the efficacy of therapeutic vaccination in cancer patients.

P.B1.09.02

Listeria based nanovaccines as therapeutic vaccines in cancer

***C. Alvarez-Dominguez**[1], H. Teran-Navarro[1], R. Calderon-Gonzalez[1], D. Salcines-Cuevas[1], J. Freire[2], J. Gomez-Roman[2], A. Garcia-Castaño[2], F. Rivera-Herrera[2], S. Yañez-Diaz[2];*
[1]Instituto de Investigación Marqués de Valdecilla, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain.

Dendritic cell-based (DC-based) vaccines are promising immunotherapies for cancer. However, several factors, such as the lack of efficient targeted delivery and the sources and types of DCs, have limited the efficacy of DCs and their clinical potential. We propose an alternative nanotechnology-based vaccine platform with antibacterial prophylactic abilities that uses gold glyconanoparticles coupled to listeriolysin O 91-99 peptide (GNP-LLO91-99), which acts as a novel adjuvant for cancer therapy as well as therapeutic vaccine for cutaneous melanoma acting as a novel immunotherapy. GNP-LLO91-99, exhibited dual anti-tumour activities, namely, the inhibition of tumour migration and growth and adjuvant activity for recruiting and activating DCs, including those from melanoma patients. GNP-LLO91-99 nanoparticles caused tumour apoptosis and induced antigen- and melanoma-specific cytotoxic Th1 responses ($P \leq 0.5$). They also cause tumour complete remission and survival improvement. GNP-LLO_{91-99} nanovaccines presented superior tumour rejection and survival benefits, when combined with anti-PD-1 or anti-CTLA-4 checkpoint inhibitors, predicting an improvement of these immunotherapies action. Studies with monocyte-derived DCs of patients with stage IIIB melanoma confirmed the ability of GNP-LLO_{91-99} nanovaccines to complement the action of check point inhibitors, not only reducing cell-death markers expression on DCs, but also potentiating DC antigen-presentation and production of Th1-Th12 cytokines. We propose that GNP-LLO_{91-99} nanovaccines function as immune stimulators and immune effectors and serve as safe cancer therapies, alone or in combination with other immunotherapies.

P.B1.09.03

Functional study of tumor infiltrating lymphocytes in a breast cancer patient: an approach to personalized medicine

A. Aran[1], *M. Bernuz*[1], *V. Peg*[2], *C. Bernadó*[2], *E. Zamora*[2], *J. Soberino*[3], *J. Pérez*[3], *E. Holgado*[4], *J. Arribas*[2], *J. Cortés*[4,3,2], *M. Martí*[1];
[1]*Universitat Autònoma de Barcelona, Bellaterra, Spain,* [2]*Vall d'Hebron Institute of Oncology, Barcelona, Spain,* [3]*Instituto Oncológico Baselga - Quirón Hospital, Barcelona, Spain,* [4]*Ramón y Cajal University Hospital, Madrid, Spain.*

Breast cancer is the most common of women cancers. Triple-negative BC (TNBC), negative for estrogen and progesterone receptor and HER-2 genes, represent a clinical challenge because they do not respond to endocrine therapy or other targeted agents. Studying of tumor infiltrating lymphocytes (TILs) is a promising field because of their good correlation with patient survival, especially those with high CD8/Treg ratio.
We have studied TILs from a TNBC patient to characterize the immune response. TILs were obtained from a core biopsy that was cut in serial slices and cultured. Molecular and functional phenotype of TILs was studied by immunostaining of TILs, cytokine release and suppression assays, all analyzed by flow cytometry. TCRs from TILs, before and after expansions, have been sequenced in order to find if there are monoclonal expansions.
TILs were a mixture of populations in all cultures, different CD8/CD4 ratios were observed related with their location on the biopsy. This different distribution of CTLs and CD4 TILs also affected the immune mediators detected in the supernatant, i.e. higher presence of cytotoxicity-related proteins Granzyme B and IFNγ in cultures with CTLs dominance. No cytokine profile could be defined on cultures with predominant CD4 T cells. TILs were expanded in vitro and tested in standard regulation assays. Cultures with predominant CTLs showed less capacity of inhibiting alloreactive proliferation compared with CD4 T cell cultures.
We have observed a heterogeneous distribution of TILs in the biopsy that may be useful to select the appropriate T cells to design tailored approaches to TNBC treatment.

P.B1.09.04

Heterologous prime-boost vaccination protects from Epstein-Barr virus antigen-expressing lymphomas

J. Rühl[1], *C. Citterio*[1], *C. Leung*[2], *C. Münz*[1];
[1]*Institute of Experimental Immunology, University of Zurich, Zurich, Switzerland,* [2]*Nuffield Department of Medicine, Ludwig Institute for Cancer Research, University of Oxford, Oxford, United Kingdom.*

Epstein-Barr virus (EBV) is a γ-herpesvirus that preferentially infects B cells and establishes life-long chronic infection in more than 90% of the adult human population worldwide. The virus-host balance is mainly sustained by T-cell responses, which are able to control the infection asymptomatically. However, when T-cell immune control fails, EBV is associated with a number of human malignancies such as Burkitt's lymphoma, Hodgkin's lymphoma and nasopharyngeal carcinoma. EBV is one of the predominant tumor viruses in humans, but so far no therapeutic or prophylactic vaccination against this transforming pathogen is available. We demonstrate that heterologous prime-boost vaccination with the nuclear antigen 1 of EBV (EBNA1) either targeted to the DEC205 receptor on dendritic cells or expressed from a recombinant modified vaccinia virus Ankara (MVA) vector improves priming of antigen-specific $CD4^+$ T-cell help. $CD4^+$ T-cell help supports the expansion and maintenance of EBNA1-specific $CD8^+$ T cells that are most efficiently primed by recombinant adenoviruses that encode EBNA1. These combined $CD4^+$ and $CD8^+$ T-cell responses protect from EBNA1-expressing T cell lymphomas and B cell lymphoproliferations that emerge spontaneously after EBNA1 expression. Especially the heterologous EBNA1-expressing adenovirus, boosted by EBNA1-encoding MVA vaccination demonstrated protection as prophylactic and therapeutic treatment of the respective lymphoma challenges. Therefore, we propose that such heterologous prime-boost vaccinations should be further explored for clinical development against EBV-associated malignancies as well as symptomatic primary EBV infection.

P.B1.09.05

Live cell imaging of lytic granule motility in anti-ErbB2 CAR NK cells and FcR NK cells plus Herceptin towards ErbB2+ breast cancer cells

N. Wotschel[1,2,3], *J. Eitler*[1,2,3], *T. Müller-Reichert*[4], *M. Gerlach*[5], *W. Wels*[6,7], *T. Tonn*[1,2,3], *H. G. Klingemann*[8];
[1]*Experimental Transfusion Medicine, Medizinische Fakultät Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany,* [2]*Institute for Transfusion Medicine Dresden, German Red Cross Blood Donation Service North-East, Dresden, Germany,* [3]*German Cancer Consortium (DKTK), Partner Site Dresden, Dresden, Germany,* [4]*Structural Cell Biology Group, Experimental Center, Medizinische Fakultät Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany,* [5]*Structural Cell Biology Group, Experimental Center, Medical Faculty Carl Gustav Carus, University of Technology, Dresden, Germany,* [6]*Institute for Tumor Biology and Experimental Therapy, Georg-Speyer-Haus, Frankfurt am Main, Germany,* [7]*German Cancer Consortium (DKTK), Partner Site Frankfurt/Mainz, Frankfurt am Main, Germany,* [8]*Nantkwest Inc., Culver City, United States.*

Upon encountering a susceptible target, NK cells mediate directed cytotoxicity by exocytosis of lytic effector molecules such as perforin and granzymes. The steps leading to NK cell granule exocytosis are highly regulated. Granule exocytosis is preceded by convergence of granules to the microtubule organizing center (MTOC) and subsequent polarization of the MTOC and granules to the immunological synapse (IS). In case of antibody-dependent cell-mediated cytotoxicity (ADCC), it has been shown that signaling through the Fc receptor is critical to polarize MTOC and granules to the IS with otherwise resistant targets. Here we used spinning disk confocal microscopy for live cell imaging to analyze granule-mediated NK cell cytotoxicity in ErbB2-targeted CAR expressing NK-92 cells (NK-92/5.28.z) and research-grade high affinity FcR expressing NK-92 cells plus Herceptin™ towards ErbB2-positive breast cancer cells (MDA-MB-453), which are resistant to parental NK-92. Interestingly, unmodified NK-92 cells in combination with MDA-MB-453 cells showed granule convergence to the MTOC, but failed to polarize MTOC and granules to the IS. In contrast, retargeting by either CAR or mAb/FcR towards the ErbB2 antigen on MDA-MB-453 enabled granule polarization to the IS resulting in highly effective cytotoxicity. Granule polarization was rapid in both the ErbB2 and high affinity FcR expressing NK-92 cells after cell-cell contact was initiated (3 and 9 minutes respectively). These observations suggest that retargeting of NK-92 cells by either transgenic CAR or high affinity FcR expression in combination with tumor-specific antibodies confers tumor cell lysis by enabling the otherwise impaired MTOC and granule polarization to the IS which resembles the physiological exocytosis cascade observed in naturally occurring ADCC.

P.B1.09.06

Activation of phosphorylation of STAT3 by farnesoid X receptor accelerates the migration of NSCLC cell induced by lung fibroblast

H. JIANG, *X. Liu;*
RENJI HOSPITAL, SCHOOL OF MEDICINE, SHANGHAI JIAO TONG UNIVERSITY, SHANGHAI, China.

Objective: We aimed to study that whether the bile acid nuclear receptor (FXR) played a role in the complex dynamic interaction between cancer associated fibroblasts (CAFs) and lung cancer cells. **Materials and methods:** Human lung cancer cells (A549 cells) were co-cultured with lung fibroblasts (HPF cells) for 48 hours in vitro. The expression of proteins, the migration abilities and the levels of cytokines were detected by western blot assay, the transwell migration assay and cytokines antibody arrays respectively. **Results:** Western blot results showed that the expression of FXR and STAT3 phosphorylation (at Tyr705) in the A549 cells increased in the co-culture system. The transwell migration assay showed that the cell migration ability in the A549 cells was also improved compared with the control group ($P<0.001$). Meanwhile, the levels of some cytokines such as TNF RII, IL-17B and RGM-B were significantly up-regulated in the co-culture supernatant ($P<0.05$). The levels of TNF RII, IL-17B and RGM-B increased 18.2, 11.3 and 8.7 times as high as the controls respectively. However, these effects could be reversed by silencing FXR with si-RNA in A549 cells ($P<0.05$). **Conclusion:** FXR accelerates to the migration of NSCLC induced by lung fibroblast-tumor cells interaction though STAT3 signaling pathway.

Neutral sphingomyelinase 2 heightens anti-melanoma immune response and synergizes with immune checkpoint inhibitors

A. Montfort[1], *F. Bertrand*[1], *J. Rochotte*[1], *J. Gilhodes*[2], *T. Filleron*[2], *C. Imbert*[1], *M. Tosolini*[3], *C. Clarke*[4], *F. Dufour*[5], *O. Micheau*[5], *M. Record*[1], *P. Cordelier*[1], *S. Sylvente-Poirot*[1], *N. Therville*[1], *N. Andrieu-Abadie*[1], *T. Levade*[6], *Y. Hannun*[4], *H. Benoist*[6], *C. Colacios*[6], *B. Ségui*[6];
[1]*INSERM U1037, CRCT, Toulouse, France,* [2]*Institut Universitaire du Cancer (IUCT), Toulouse, France,* [3]*INSERM U1037, Toulouse, France,* [4]*Stony Brook University, Stony Brook, NY 11794, United States,* [5]*INSERM UMR866, Dijon, France,* [6]*INSERM U1037, CRCT, Université Toulouse III, Toulouse, France.*

Background: Neutral sphingomyelinase 2 (nSMase2) belongs to a network of sphingolipid-metabolizing enzymes. More specifically, it catalyses the hydrolysis of sphingomyelin into ceramide, a bioactive lipid considered as an anti-oncometabolite. **Results:** Gene expression analyses from melanoma tumours of the TCGA dataset revealed the gene coding for nSMase2, *SMPD3*, was expressed at lower levels in metastases as compared to primary masses. Moreover, high levels of the transcript coding for nSMase2 in tumour biopsies were associated with better overall survival for advanced melanoma patients. In the mouse B16 melanoma model, which displays low levels of nSMase2, overexpression of this enzyme did not affect cell growth under 2D or 3D culture conditions, however it decreased tumour growth *in vivo*. Surprisingly, nSMase2 overexpression increased the infiltration of tumours by CD8+ T cells and the nSMase2-dependent delayed tumour growth was abolished in CD8 KO mice. Mechanistically, increased nSMase2 activity led melanoma cells to secrete exosomes enriched for the immunogenic miR155, thus favouring dendritic cell activation and anti-melanoma CD8+ T cell responses *in vivo*. Finally, increased nSMase2 activity in tumours synergized with anti-PD-1 therapy to abolish melanoma growth *in vivo*. **Conclusion:** Our work highlights a new role for the sphingolipid metabolism in the modulation of the immune microenvironment of melanoma by malignant cells.

P.B1.09.08

Use of primary T cells for delivery of mRNA encoded immunotoxins

R. Eggers[1], *A. Philippi*[1,2], *M. O. Altmeyer*[1], *F. Breinig*[3], *M. J. Schmitt*[3];
[1]*Environmental Safety Group, Korea Institute of Science and Technology (KIST) Europe, 66123 Saarbrücken, Germany,* [2]*BioNTech AG, 55131 Mainz, Germany,* [3]*Department of Biosciences, Molecular and Cell Biology and Center of Human and Molecular Biology (ZHMB), Saarland University, 66123 Saarbrücken, Germany.*

In cancer therapy, immune cells can be used as delivery platform for highly toxic compounds like immunotoxins in order to reduce their side effects. Here we investigated the potential of human primary T cells to deliver immunotoxins. T cells were engineered by transient transfection with immunotoxin encoding mRNA. The recombinant toxin, secreted by T cells, was expected to cause an increased efficiency in adoptive T cell therapy. Therefore two *Pseudomonas exotoxin* A-based immunotoxin constructs (e23-PE38 and VEGF-PE38) were designed. *Ex vivo* activated, primary T cells were transfected with *in vitro* synthesized mRNA, coding for e23-PE38 and VEGF-PE38. Successful expression and secretion of the immunotoxin were shown by Westernblot and Sandwich-ELISA analyses. WST-1 assay revealed that immunotoxin expression impaired the viability of transfected T cells. Nevertheless, *in vitro* toxicity tests showed that immunotoxin expressing T cells were able to perform residual effector functions, mediated by HEA125xOKT3 bispecific antibody. An additional effect of the immunotoxin was not observed. It was possible to restore impaired viability and reduced proliferation of transfected T cells by expressing an attenuated version of VEGF-PE38. MALDI-TOF analysis revealed that the immunotoxin was partially translocated into the endoplasmic reticulum.
By expressing mRNA encoded immunotoxins in T cells, we were able to demonstrate the potential of T cells for mRNA-mediated drug delivery. Therefore mRNA mediated protein expression might be a promising tool for T cell mediated drug delivery.

P.B1.09.10

The effect of vitamin E on the function and frequency of myeloid-derived suppressor cells in an experimental breast cancer model

Y. Vojgani, *S. Habibi, J. Hadjati, M. Vojgani;*
Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Background: Vitamin E has been shown to have strong anti-carcinogenic properties, including antioxidant and apoptotic characteristics, making it appealing candidate for cancer therapy. On the other hand, among the tumor immunosuppressive components, it has been shown myeloid derived suppressor cells (MDSCs) have remarkable ability to suppress anti-tumor immunity through multiple mechanisms. The aim of current study was to assess whether the alpha-tocopherol succinate can alleviate MDSCs-mediated immunosuppression in vitro and in an experimental breast cancer model. **Material and Methods:** After assessing the effect of α-tocopherol succinate on MDSC viability and gene expression in vitro, mice were challenged with $7x10^5$ 4T1 murine breast adenocarcinoma cell line. After 5 days, tumor-bearing mice were intraperitoneally injected with vitamin E (5mg/kg) or DMSO/Tween (vitamin E solvent) at one day interval for a total of five times. After isolation of MDSCs from the spleen and tumor tissue, MDSCs frequency, nitric oxide (NO) production and gene expression analysis were performed by flow cytometry and quantitative RT PCR respectively. **Results:** Based on our experiments, vitamin E diminished tumor growth rate in tumor bearing mice but it had no effect on the percentage of CD11b+ Gr-1+ MDSCs in the spleen and tumor tissues in tumor-bearing mice. Q-PCR showed that α-tocopherol succinate reduced iNOS, Arginase and indoleamine-pyrrole 2,3-dioxygenase (IDO) gene expression in isolated MDSCs. **Conclusion:** According to our data, vitamin E has not effect on MDSCs frequency in tumor bearing mice however it may modulate their functions through decreasing MDSC expression of immunosuppression-related genes *in vitro.*

P.B1.09.11

Unbiased identification of CD4⁺T-cell epitopes using novel MHC-based chimeric receptors.

J. Kisielow, *F. Obermair, M. Kopf;*
Institute of Molecular Health Sciences, ETH, Zürich, Switzerland.

αβT-cell receptors(TCRs) bind peptide-major histocompatibility complexes(pMHC) with low affinity, posing a considerable challenge for direct identification of αβT-cell cognate peptides (epitopes). Here, we describe a platform for the discovery of MHC class-II presented epitopes, based on screening of engineered reporter cells expressing novel pMHC-TCR (MCR) hybrid molecules carrying cDNA-derived peptides. This technology identifies natural epitopes of CD4 T-cells in an unbiased and efficient manner and allows detailed analysis of TCR cross-reactivity providing recognition patterns on top of discrete epitopes. We identify cognate peptides of virus- and tumor-specific T-cells in mouse disease models and present a proof-of-concept for human T-cells. Furthermore, we show that vaccination with a peptide naturally recognized by TILs can efficiently protect from tumor challenge. Thus, the MCR technology holds promise for basic research and clinical applications allowing personalized identification of T cell antigens in patients.

P.B1.09.12

Memory CD8 T cell inflation promotes tissue-residency

E. T. I. van der Gracht[1], *A. N. Yilmaz*[1], *S. van Duikeren*[1], *P. Klenerman*[2], *F. Koning*[1], *R. Arens*[1];
[1]*LUMC, Leiden, Netherlands,* [2]*University of Oxford, Oxford, United Kingdom.*

Memory T cell inflation is a phenomenon occurring upon infection with certain chronic viruses that is characterized by the maintenance of large populations of circulating antigen-specific memory CD8+ T cells with an effector-memory-like phenotype. Whether memory T cell inflation is related to the formation and maintenance of tissue-resident memory (TRM) T cells is not known. Here we studied the induction and maintenance of CD8+ TRM T cells upon immunization with adenoviral vectors modified to elicit memory T cell inflation. Mice immunized with different doses of adenovirus encoding full-length HPV E7 protein or the immunodominant epitope from E7 protein elicited E7-specific memory inflation in a dose-dependent manner. Interestingly, E7-specific CD8+ TRM T cells were generated and maintained for months in multiple organs after vaccination, and the numbers of these CD8+ TRM T cells associated with memory inflation. The vaccine-induced CD8+ T cell responses conferred long-term protection in a mouse model of HPV-induced carcinoma, and this protection depended on the development of CD8+ TRM T cells. Moreover, this formation of CD8+ TRM T cells could be enhanced by temporal targeting costimulatory interactions early after immunization. Together, these data suggest that the induction of tissue-residency is linked to the memory inflation, and can be enhanced by targeting costimulation.

P.B1.09.13

The *Taenia crassiceps*-derived immunomodulatory peptide GK-1 controls tumor growth by promoting tumor-specific CD8 T cell infiltration and effector function

N. Rodriguez Rodriguez[1,2], *J. Cervantes*[2], *F. Rosetti*[1], *J. C. Crispin*[1], *G. Fragoso*[2], *E. Sciutto*[2];
[1]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico,* [2]*Instituto de Investigaciones Biomedicas, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.*

GK-1 is a synthetic 18 amino acid-peptide, originally derived from *Taenia crassiceps,* that has shown immunomodulatory properties in several immunization models. Our group and others demonstrated that GK-1 administration decreases tumor burden and metastasis, while improving survival in mouse models of cancer. Such a result was ascribed to GK-1 influence on antigen presenting cells (APC).
To further dissect the immunomodulatory properties of GK-1, T cell-deficient mice previously subcutaneously injected with ovalbumin (OVA)-expressing B16-F0 melanoma cells were weekly intravenously given GK-1. Contrary to results obtained with T-cell immunosufficient mice, where GK-1 demonstrated antitumor properties, administration of GK-1 neither prevented tumor development nor increased survival, indicating that T cells are required for GK-1 antitumor effect.
The capacity of GK-1 to promote tumor-specific T cell responses was evaluated by transferring OT-I $CD8^+$ T cells specific for OVA into mice that received B16-OVA cells. GK-1 significantly decreased tumor incidence and size compared to control individuals, regardless of co-administration of OVA. This was associated with increased numbers of tumor-infiltrating OT-I cells, and a higher proportion of cells able to proliferate and produce IFN-γ upon antigen encounter. Tumor-associated dendritic cells displayed elevated CD86 expression and OVA presentation. Interestingly, GK-1 administration to mice transferred with OVA-specific $CD4^+$ T lymphocytes was unable to reduce tumor development, despite in vitro results demonstrating that GK-1 indirectly stimulates $CD4^+$ cell, but not $CD8^+$ cell, proliferation by activating APC.
In conclusion, GK-1 reduces tumor establishment and growth. $CD8^+$ lymphocytes are necessary to mediate this effect, while $CD4^+$ cells probably act as relays transferring the GK-1-induced stimulation of APCs to $CD8^+$ lymphocytes.

P.B1.09.14

In situ delivery of allogeneic natural killer cell (NK) combined with Cetuximab in liver metastases of gastrointestinal carcinoma: A phase I clinical trial

O. Adotévi, Y. Godet, ***J. Galaine****, Z. Lakkis, I. Idirene, J. Certoux, M. Jary, R. Loyon, C. Laheurte, S. Kim, A. Dormoy, F. Pouthier, C. Barisien, F. Fein, P. Tiberghien, X. Pivot, S. Valmary-Degano, C. Ferrand, P. Morel, E. Delabrousse, C. Borg;*
UMR1098, BESANCON, France.

Despite successful introduction of NK-based cellular therapy in the treatment of myeloid leukemia, the potential use of NK alloreactivity in solid malignancies is still elusive.
We performed a phase I clinical trial to assess the safety and efficacy of *in situ* delivery of allogeneic NK cells combined with cetuximab in liver metastasis of gastrointestinal origin. The conditioning chemotherapy was administrated before the allogeneic NK cells injection via hepatic artery. Three escalating doses were tested (3.10^6, 8.10^6 and 12.10^6 NK cells/kg) following by a high-dose interleukin-2 (IL-2). Cetuximab was administered intravenously every week for 7 weeks. Nine patients with liver metastases of colorectal or pancreatic cancers were included, three per dose level. Hepatic artery injection was successfully performed in all patients with no report of dose-limiting toxicity. Two patients had febrile aplasia requiring a short-term antibiotherapy. Grade 3/4 anemia and thrombopenia were also observed related to the chemotherapy.

Objective clinical responses were documented in 3 patients and among them 2 occurred in patients injected with cell products harboring two KIR ligand mismatches and one in a patient with one KIR ligand mismatch. Immune monitoring revealed that most patients presented an increase but transient of IL-15 and IL-7 cytokines levels one week after chemotherapy. Furthermore, a high expansion of FoxP3$^+$regulatory T cells and PD-1$^+$ T cells was observed in all patients, related to IL-2 administration. Our results demonstrated that combining allogeneic NK cells transfer via intra-hepatic artery, cetuximab and a high-dose IL-2 is feasible, well tolerated and may result in clinical responses.

P.B1.09.15

Antigen presentation to CD169$^+$macrophages: translation to the human situation and coparison to DC-SIGN targeting

M. López-Venegas[1], *A. Barbaria*[1], *K. Olesek*[1], *L. Hoogterp*[1], *M. Ambrosini*[1], *H. Kalay*[1], *G. Storm*[2], *E. Puchhammer-Stöckl*[3], *Y. van Kooyk*[1], *J. den Haan*[1];
[1]Amsterdam UMC, Amsterdam, Netherlands, [2]Utrecht University, Utrecht, Netherlands, [3]Medical University of Vienna, Vienna, Austria.

Dendritic Cell Specific Intercellular adhesion molecule-3-Grabbing Non-integrin (DC-SIGN) and CD169/Sialic acid binding immunoglobulin type lectin I (siglec-1), are lectin receptors expressed by macrophages in secondary lymphoid organs and are implicated in antigen uptake. Our aim is to compare the efficacy of these lectin receptors with regard to antigen uptake and cross-presentation by monocyte-derived DCs (moDCs).
Fluorescent DC-SIGN and CD169-specific antibodies or liposomes containing the DC-SIGN and CD169 specific ligands Lewis Y and monosialodihexosylganglioside (GM3) were used to target gp100 melanoma antigen to moDCs. Binding and uptake of our targeting strategies was investigated by flow cytometry, while imaging flow cytometry was employed to study antigen routing. The determination of gp100 cross-presentation was assessed by coculturing targeted moDCs with gp100 specific HLA-A201-restricted T cells and analyzing IFNγ production. Our preliminary data show that liposome and antibody targeting of gp100 to DCSIGN and CD169 lead to effective binding, but also suggests that DCSIGN and CD169 lectin receptors may have a differential capacity to endocytose and to stimulate cross-presentation of antigens. Our studies will help to determine which lectin receptor is the most efficient to target antigens to for the activation of anti-melanoma T cell responses.

P.B1.09.16

Robust GMP manufacturing process with IL-2, fibronectin and anti-CD16 antibodies generates highly active human NK cell batches for cancer immunotherapy

K. Bröker[1], *U. Schumacher*[2], *R. Pörtner*[3], *H. Hoffmeister*[4], *E. Sinelnikov*[4], *S. Lüth*[1], *W. Dammermann*[1];
[1]Brandenburg Medical School, Brandenburg a. d. Havel, Germany, [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [3]Hamburg University of Technology, Hamburg, Germany, [4]Zellwerk GmbH – HiPer-Group, Oberkrämer, Germany.

Introduction: NK cells are innate immune cells crucial for killing of infected and malignant cells. They are able to fight circulating tumor cells thereby preventing metastases formation which account for approximately 90% of all cancer-deaths. Thus, NK cells became interesting candidates for cancer immunotherapy and *ex vivo* manipulation and expansion of highly potent NK cells for adoptive transfer in patients an aim of paramount importance.
Methods: Human, CD3$^+$ T cell-depleted PBMCs were expanded in a fibronectin and anti-CD16 antibody-coated bioreactor in presence of IL-2 following GMP guidelines. Cells were analyzed for NK cell purity, expression of different chemokine receptors, cell adhesion molecules, activating receptors and death ligands as well as IFNγ production using flow cytometry. Further, cytotoxicity towards different tumor cell lines was assessed via LDH assays and flow cytometry-based degranulation assays.
Results: Upon expansion NK cell purity reached 85 to 96%. The cells showed expression of the chemokine receptors CXCR3, CXCR4 and CCR7 and the cell adhesion molecules L-selectin, LFA-1 and VLA-4. Further, they expressed the activating receptors NKp30, NKp44, NKp46, NKG2D, DNAM-1 and CD16, the death ligands Fas and TRAIL and produced IFNγ. NK cells showed cytotoxicity towards the tumor cell lines K562, PaCa5061, GC5830 and SKOV3.
Conclusion: We describe a novel approach for *ex vivo* NK cell expansion generating a set of highly potent NK cells which represent promising candidates for cancer immunotherapy. The GMP manufacturing process allows the use of these cells in clinical trials, i.e. adoptive NK cell transfer in patients.

P.B1.09.17

TNFa blockade overcomes resistance to anti-PD-1 in experimental melanoma

A. Montfort[1], *F. Bertrand*[1], *E. Marcheteau*[1], *C. Imbert*[1], *J. Gilhodes*[2], *T. Filleron*[2], *P. Rochaix*[2], *N. Andrieu-Abadie*[1], *T. Levade*[1,3], *N. Meyer*[1,3,4], *C. Colacios*[1,3], *B. Ségui*[1,3];
[1]INSERM U1037, CRCT, Toulouse, France, [2]Institut Universitaire du Cancer (IUCT), Toulouse, France, [3]Université Toulouse III, Toulouse, France, [4]CHU Purpan, Toulouse, France.

Anti-PD1 therapy has significantly improved the care of melanoma patients. However, about 40 to 70% of them do not display optimal response to treatment and responders often relapse and/or experience mild to severe immune related adverse events (irAEs). While anti-Tumor Necrosis Factor α (TNF) antibodies were successfully used in the clinic to help control irAEs, their impact on the anti-cancer immune response remained unknown. Our pre-clinical studies demonstrated that blocking the TNF/TNFR1 pathway potentiated the CD8$^+$-dependent anti-melanoma immune response in mouse. Moreover, blocking the TNF/TNFR1 pathway synergized with anti-PD1 treatment to impair tumor growth in mouse. In this context, we found anti-TNF prevented the anti-PD1 dependent upregulation of TIM-3 on T cells as well as activation-induced cell death thus favoring CD8$^+$ T cell accumulation in tumors. These results lead our team to take part to a phase 1b clinical trial aiming at evaluating the safety and tolerance of combining immune checkpoint inhibitors (ICI) to anti-TNF by metastatic melanoma patients (TICIMEL: NCT03293784).

P.B1.09.18

A non-small cell lung cancer (NSCLC) mouse model for improved preclinical validation of immune therapies

M. Kruchem;
Institut for Translationale Immunology, Mainz, Germany.

Introduction: Lung cancer has an overall dismal prognosis and only when diagnosed early, surgery and ablative therapies may offer a cure. Checkpoint inhibitors are a first good alternative treatment option promoting objective response rates and in some cases complete tumour remission. The failure of established treatment strategies and the therapeutic benefit of immune therapies highlight the need for additional research with tractable models.
Methods: For preclinical testing of immune therapies, we have generated a mouse model containing a conditional gene switch that sets off oncogenic K-Ras12V and inactivates p53 in lung progenitor (BASC), AT2 and Clara cells. This SKP model also contains two conditional reporter genes (EYFP and lacZ) to trace transformed lung cancer cells. Finally, we established several lung cancer cell lines from primary SKP tumours.
Results: Tamoxifen (TAM) injection in SKP mice resulted in reproducible lung tumor progression and the co-expression of EYFP and lacZ reporter genes. The specific expression of reporter genes in malignant cells allowed to exactly quantify the therapeutic benefit of different therapies/immune therapies. Injection of tumor-derived cell lines demonstrated that these cells metastasize to the brain, the peritoneum and the liver.
Conclusion: With the autochthonous SKP model and its metastasized SKP cell line derivatives any experimental immune therapy can be tested in an adequate and reliable preclinical setting. Co-expression of the two reporter genes differentiates between transformed tumor cells and non-malignant tumor-constituting cells thus allows to study the effect of different therapies for malignant tumor cells and non-transformed bystander cells.

P.B2.01 Environmental regulation anti-tumor responses - Part 1

P.B2.01.01

Assessment of promoter hypermethylation in tissue and blood of non-small cell lung cancer patients and association with survival

A. Ali, *P. Sohal, K. Upadhyay, A. Mohan, K. Madan, K. Luthra, S. Kumar, W. Rafi, R. Guleria;*
All India Institute of Medical Sciences, New Delhi, India.

Background Gene silencing by aberrant promoter hypermethylation is common in lung cancer and is an initiating event in its development. **Aim** To compare promoter hypermethylation frequency in serum and tissue of lung cancer patients with disease controls. Cyclin-dependent kinase inhibitor 2A (p16), a tumor suppressor gene, plays an important role in cell cycle regulation. O6 methylguanine DNA methyltransferase (*MGMT*) gene encoded protein is essential for genome stability **Method** 95 newly diagnosed untreated advance stage lung cancer patients and 50 cancer free matched controls were studied. Bisulfite modification of tissue and serum DNA was done; modified DNA was used as a template for methylation specific PCR analysis.
Survival was assessed for one year. **Results** Of 95 patients, 82% were non-small cell lung cancer (34% squamous cell carcinoma, 34% non-small cell lung cancer and 14% adenocarcinoma) and 18% were small cell lung cancer. Biopsy revealed that tissue of 89% and 75% of lung cancer patients and 85% and 52% of controls had promoter hypermethylated for MGMT (p=0.35) and p16 **(p<0.001)** gene, respectively. In serum, 33% and 49% of lung cancer patients and 28% and 43% controls were positive for MGMT and p16 gene**.** No significant correlation was found between survival and clinicopathological parameters. **Conclusion** High methylation frequency of p16 gene in tissue biopsy may be linked with early stages of carcinogenesis. Appropriate follow-up is required for confirmation of this finding.

Implication of matrix metalloproteinases 9/2 and nitric oxide in the development of breast cancer: correlation with clinicopathological parameters

M. Amri[1], *A. Kouchkar*[2], *N. Benzidane*[2], *C. Touil-Boukoffa*[1];
[1]*University USTHB, Faculty of Biological Sciences, Laboratory of Cellular and Molecular Biology, Algiers, Algeria,* [2]*Department of anatomic-pathology, Centre Pierre and Marie Curie, Algiers, Algeria.*

Introduction: Many studies have demonstrated that nitric oxide (NO) plays a significant role in the multistep processing of carcinogenesis in breast cancer patients. These steps involve many inflammatory mediators like matrix metalloproteinases, in particular MMP 9 and 2. Thus, the aim of the present study was to investigate the activity levels of MMP9/2 and NO in breast cancer patients. **Methods:** MMP activities were assessed by a zymographic analysis in the sera of 125 patients carrying breast tumors and 20 healthy subjects as well as 63 breast tumors. Moreover, NO activity was investigated in the same samples by an enzymatic method. The results obtained were then correlated with the clinicopathological parameters. Moreover, immuno-histochemical staining was performed to analyze the tissue expression of CD68 (marker of infiltrating macrophages), uNOS (universal NO synthases), and NFkB. **Results:** The activities of MMPs and NO increased significantly in breast cancer patients compared with control subjects. Moreover, these activities were higher in patients with malignant tumors than in those with benign tumors both in sera and biopsy. They also correlate with tumors' size, type, stage, metastasis, and tissue expression of uNOS, CD68 and NFkB. **Conclusion:** Our results showed an association between high activities of MMPs (particularly MMP9) and NO and the development of breast malignant tumors. Interestingly, the serum MMP and NO level reflect the tissue levels. These findings suggest that serum levels of these molecules may be useful marker in monitoring breast carcinoma patients.

Notch and Aiolos transcription factors in B CLL

J. Skelin[1], *L. Milkovic*[1], *I. Feliciello*[2], *B. Jelic Puskaric*[3], *M. Matulic*[4], *I. Kardum-Skelin*[3], *D. Radic-Kristo*[5], ***M. Antica***[1];
[1]*Ruđjer Bošković Institute, Zagreb, Croatia,* [2]*Dipartimento di Medicina Clinica e Chirurgia, Universita' degli Studi di Napoli Federico II, Napoli, Italy,* [3]*Department of Clinical Cytology and Cytogenetics, Merkur Univesity Hospital, Zagreb, Croatia,* [4]*University of Zagreb, Faculty of Science, Zagreb, Croatia,* [5]*School of Medicine, University of Osijek, Zagreb, Croatia.*

B-cell chronic lymphocytic leukaemia (B-CLL) is characterized by increasing accumulation of monoclonal lymphocytes. The leukemic clone is characterised by simultaneous expression of the CD5 antigen together with specific B-cell antigens CD19, CD20 and CD23. We used this feature of the abnormal B-cell clone expressing $CD5^+CD19^+$ and characterised the individual cell groups within the sample at the transcriptional and protein level in order to study the aberrant developmental stages of the B cells in this disease regarding the roles of Ikaros transcription factor Aiolos, the Notch signalling pathway and its target genes Hes and Deltex. We also established a coculture system with the Delta-like ligand transfected OP9 cells which is mandatory for T cell development in order to explore the activation potential of the Notch receptors we found expressed also by B-CLL cells. Although well explored in T-cell acute lymphoblastic leukaemia, the Notch specific pathway involvement in B-CLL has been contradictory so far. In addition to Notch, we and others have previously shown that a member of the Ikaros family of zinc -finger proteins, Aiolos has a very high expression in B-CLL lymphocytes and there is evidence supporting its role in the survival of other leukaemic B cells. We analysed these genes simultaneously and tested apoptosis regulation by Notch activation on co-cultures of the malignant clone on the OP9DLL1 cell line.

Relation between dendritic cells and regulatory T cells in mammary neoplasm in dogs

P. H. L. Bertolo*, M. C. Rosolem, M. B. Conceição, P. R. Moreira, R. O. Vasconcelos;*
Sao Paulo State University (UNESP), Jaboticabal, Sao Paulo, Brazil.

Introduction - The malignant mammary tumors have several ways of evading the immune system, including the modulation of dendritic cells (DCs), by interfering with their maturation, resulting in inefficient presentation of antigens to T cells and consequent induction of immunological tolerance. Therefore, this study aimed to evaluate the relationship between DCs and regulatory T cells (Treg) in the simple type canine mammary carcinomas, using the immunohistochemical technique. Methods - Ten samples of mammary gland without tumor (G1) and 40 samples of mammary neoplasms (G2: adenomas, G3: papillary carcinomas, G4: tubular carcinomas and G5: solid carcinomas) were submitted to immunodetection of Treg cells (FOXP3+), CD4 and CD8 T cells, MHC-II, myeloid DCs (immature and mature), cytokines TGF-β, IL10, Indoleamine 2,3-dioxygenase (IDO) and chemokine receptors (CCR6 and CCR7). Results - Most of the cells, cytokines and immunological receptors showed positive correlation within the tumor population and controls evaluated, mainly on the fixed effect "age" that had high positive correlation with the tumor size and with CCR6. It was observed that there was a relationship between immature / mature myeloid DCs and Treg cells, as well as TGFβ and IL-10, and the IDO enzyme showed a marked presence in the malignant samples. Conclusion - Immunodetection of CCR6 and CCR7 occurred mainly in the most aggressive tumors, where CCR6 had a high relation with older patients and with larger tumors, which, in the end, may reflect that the aging of the immune system may be more of a pro- tumor.

Cytotoxic and helper T- and innate lymphoid cell subsets in myelodysplastic syndromes

M. Boy[1,2], *A. Celia*[1,2], *J. Villemonteix*[1,2], *G. Henry*[1], *L. Amable*[1], *L. Comba*[1], *J. Klibi*[1], *A. Lim*[1], *H. Yssel*[3], *A. Caignard*[1], *K. Benlagha*[1], *J. Di Santo*[4], *P. Fenaux*[1,2], *L. Adès*[1,2], *A. Toubert*[1,2], *N. Dulphy*[1,2];
[1]*UMRS-1160 INSERM, Hôpital Saint-Louis, Centre Hayem, Paris, France,* [2]*Université Paris Diderot, Sorbonne Paris Cité, Hôpital St. Louis, Paris, France,* [3]*U1135 INSERM, Hôpital Pitié-Salpêtrière, Département d'Immunologie, Paris, France,* [4]*U1223 INSERM, Institut Pasteur, Département d'Immunologie,, Paris, France.*

Introduction: Myelodysplastic syndrome (MDS) is a group of heterogeneous clonal disorders arising in the bone marrow (BM). MDS evolution is dominated by the risk of progression into acute myeloid leukemia. In addition, 10 to 30% of MDS patients present autoimmune disorders (AID).
We hypothesized that MDS could lead to perturbations in cytotoxic and cytokine-producing lymphocyte subsets, including Natural Killer (NK) cell, Innate Lymphoid Cells (ILCs) and T cells. These functional deficiencies could be associated with inefficient immunosurveillance and AID.
Materials and Methods: Expressions of activation markers, chemokine receptors, and regulatory molecules were determined by flow-cytometry in order to evaluate phenotypic and functional perturbations of T-cells, NK-cells and ILCs in peripheral blood samples from MDS patients, as compared to healthy controls, using conventional and non-supervised analytical methods. Quantitative PCR was used to investigate the expression of lymphocyte subset-specific transcription factors (T-bet, Eomes, Gata-3, RORγt), and functional markers (perforin, IFN-γ).
Results: A reduction in the percentage of circulating ILC subsets was observed in patients, as compared to healthy controls. The NK-cell phenotype showed alterations in the expression of activating and inhibitory receptors. Moreover, perturbations in the distribution of the various T lymphocyte subsets and in the expression of immune checkpoint molecules were observed.
Conclusions: Altogether, these results are in favor of a profound perturbation in the frequency of peripheral blood lymphocyte subsets in MDS patients. The data warrant to further analyze the impact of the BM microenvironment in MDS on the lymphoid phenotype, as well as to determine its association with AID.

P.B2.01.06

Shared CCR7-CCL19 pathway in NK and melanoma cells marks the clinical progression and suggests a new immune escape strategy in melanoma patients

C. M. Cristiani[1], *V. Ventura*[1], *A. Turdo*[2], *T. Apuzzo*[2], *M. Capone*[3], *G. Madonna*[3], *D. Mallardo*[3], *C. Garofalo*[1], *E. Selinger*[1], *E. Simeone*[3], *A. M. Grimaldi*[3], *C. Coracò*[4], *E. Staaf*[5], *R. Tallerico*[1], *G. del Zotto*[6], *E. Gulletta*[1], *A. Moretta*[7], *K. Kärre*[5], *M. Todaro*[2], *P. A. Ascierto*[3], *E. Carbone*[1];
[1]*University "Magna Graecia" of Catanzaro, Catanzaro, Italy,* [2]*University of Palermo, Palermo, Italy,* [3]*Istituto Nazionale Tumori Fondazione "G. Pascale", Naples, Italy,* [4]*Istituto Nazionale Tumori Fondazione, Naples, Italy,* [5]*Karolinska Institutet, Stockholm, Sweden,* [6]*Istituto Giannina Gaslini, Genoa, Italy,* [7]*University of Genoa, Genoa, Italy.*

Introduction. Changes within the immune response that can be associated to and can mark melanoma clinical progression are poorly investigated. Here, we identified selective changes in NK cells repertoire and serum cytokine pathological perturbation characterizing the transition from stage III to stage IV. The potential role of CCR7-CCL19 axis in metastatic process was dissected as well.
Materials and Methods. PBMCs from healthy donors and melanoma patients were characterized for their immune profile and activation status. Their sera as well as melanoma cells supernatants were characterized for cytokines/chemokines content. Melanoma primary cells and cancer stem cells (CSCs) were analyzed for CCR7 and NK immunomodulatory ligands expression, as well as for their susceptibility to NK cells cytotoxicity.
Results. The frequency of $CCR7^+CD56^{bright}$ NK cells reached its peak in stage IV melanoma patients, together with the serum levels of CCL19. CCL19 serum concentration may derive from the ectopic production by melanoma cells, since it was detectable in melanoma cells supernatants but not in those from other tumors cells. A small cell subpopulation within primary melanoma cells selectively co-expressed CCR7, PD-L1 and Galectin-9 and was characterized by low levels of MHC class I molecules. This phenotype was shared by melanoma CSCs, which were highly susceptible to NK cells-mediated killing.
Conclusions. The accumulation of tumor produced CCL19 in the blood may promote the selective blood metastatic spread of the $CCR7^+$PD-$L1^+$Gal-9^+HLA-class I^{low} melanoma CSCs and subvert the tumor immune response by preventing $CD56^{bright}$ NK cells migration in sentinel lymph nodes.

P.B2.01.07

The influence of short-term and long-term ibrutinib treatment on the HLA-DR expression on leukemic and T cells in chronic lymphocytic leukemia

G. Gabcova[1], *Z. Mikulkova*[1], *G. Manukyan*[2], *T. Papajik*[3], *P. Turcsanyi*[3], *R. Fillerova*[1], *T. Dyskova*[1], *V. Smotkova Kraiczova*[1], *S. Zehnalova*[4], *P. Gajdos*[4], *R. Urbanova*[3], *M. Kudelka*[4], *E. Kriegova*[1];
[1]*Department of Immunology Faculty of Medicine and Dentistry Palacky University, Olomouc, Czech Republic,* [2]*Laboratory of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia,* [3]*Department of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic,* [4]*Department of Computer Science, Faculty of Electrical Engineering and Computer Science, VSB-Technical University of Ostrava, Ostrava, Czech Republic.*

There is the first evidence about the changes in the kinetics of B cell antigen receptor (BCR) internalization of neoplastic cells in chronic lymphocytic leukemia (CLL) after the short-term and long-term administration of ibrutinib. We aimed to assess the influence of short-term and long-term ibrutinib treatment on the HLA-DR expression on CLL and T cells.
The immunophenotyping of CLL and immune cells in peripheral blood was performed in 16 high-risk CLL patients treated with ibrutinib. Early after ibrutinib administration, the HLA-DR expression on CLL cells reduced (P=0.019), accompanied by an increase in CLL cell counts in peripheral blood (P=0.001). *In vivo* reduction in the HLA-DR expression was confirmed by *in vitro* culturing of CLL cells with ibrutinib at protein and mRNA levels (P<0.01). The decrease in HLA-DR on CLL cells after the first month was followed by the gradual increase of its expression by the 12th month (P=0.016).
The one-month follow-up resulted in elevated absolute counts of CD4+ (P=0.002) and CD8+ (P<0.001) cells as well as CD4+ and CD8+ cells bearing HLA-DR (P<0.01).
The long-term administration of ibrutinib was associated with increased numbers of CD4+ bearing HLA-DR (P=0.047), along with a trend to higher CD4+ and CD8+ absolute cell counts in the majority of patients. Our results provide the first evidence of the time-dependent immunomodulatory effect of ibrutinib on CLL and T cells. The clinical consequences of time-dependent changes in HLA-DR expression in ibrutinib treated patients deserve further investigation. **Grant support:** MZ ČR VES16-32339A, IGA UP_2018_016, MH CZ-DRO (FNOL, 00098892)

P.B2.01.08

Using multi-parameter analysis to dissect the systemic immune landscape of breast cancer patients

H. Garner[1,2], *M. Brüggemann*[1,2], *K. Vrijland*[1,2], *C. Hau*[1,2], *M. Kok*[1], *K. E. De Visser*[1,2];
[1]*Netherlands Cancer Institute, Amsterdam, Netherlands,* [2]*Oncode Institute, Amsterdam, Netherlands.*

Metastatic breast cancer remains the principal cause of death for breast cancer patients. Whilst strategies for treating the primary tumour have markedly improved, our ability to prevent or treat metastasis remains considerably less effective. It is now widely accepted that the tumour microenvironment plays a critical role in determining tumour biology. However, tumour-induced perturbations to the host reach far beyond the tumour microenvironment, evoking systemic changes that remain relatively underexplored.
In this project, we set out to extensively characterise the systemic immune landscape of breast cancer patients of different molecular subtypes and at differing disease stages compared to age- and sex-matched healthy controls. By employing multi-parameter flow cytometry analysis in conjunction with unbiased clustering and dimension reductionality techniques we are able to characterise the systemic immune landscape at a single cell level.
Preliminary findings show that advanced, metastatic triple negative breast cancer (TNBC) patients have considerably expanded neutrophil frequency and these neutrophils appear more homogeneous compared to healthy controls. Furthermore, TNBC patients have considerably reduced frequency of circulating lymphocytes yet these lymphocytes show an increased propensity to produce IL-17 and increased expression of the immune checkpoint receptor PD1. This analysis technique will allow us to generate a systemic immune "fingerprint" of different breast cancer molecular subtypes and different disease stages.

P.B2.01.09

Ig-like transcript 2 (ILT2) suppresses T cell function in chronic lymphocytic leukemia

S. Gonzalez, *S. Lorenzo-Herrero, C. Sordo-Bahamonde, A. López-Soto, A. González-Rodríguez, Á. R. Payer, M. Villa-Álvarez;*
Universidad de Oviedo. IUOPA, Oviedo, Spain.

Introduction: Chronic lymphocytic leukemia (CLL) is a heterogeneous and incurable disease characterized by malignant B cell accumulation and a profound immune dysregulation. T-cell dysfunction is caused by signaling mediated by inhibitory receptors such as PD-1 and CTLA-4. In this study, we describe the role of a novel inhibitory receptor, Ig-like transcript 2 (ILT2), in the pathogenesis of CLL by mediating T-cell exhaustion.
Materials and Methods: Surface expression of ILT2 and its ligands was analyzed in different lymphocyte subsets obtained from 52 patients with CLL and 20 healthy donors by flow cytometry. The role of ILT2 in T-cell function (activation, proliferation and cytokine production) was determined *in vitro* by using an ILT2-blocking antibody.
Results: In CLL, ILT2 expression was markedly decreased in leukemic cells and upregulated in CD4 and CD8 T lymphocytes, especially in those patients with bad prognostic features, such as chromosome 11q deletion. Moreover, the expression of ILT2 ligand was profoundly dysregulated on leukemic cells. ILT2 expression was associated with the suppression of the effector function of T cells and ILT2 blockade restored their activation and proliferation without affecting B cells. Further, ILT2 blockade increased IL-2 production and downregulated the production of cytokines that promote the survival of leukemic cells, such as IFN-γ.
Conclusions: Expression of ILT2 and its ligands is deeply dysregulated in patients with CLL. Our data suggest that ILT2 blockade may restore T cell activation, proliferation and cytokine production, suggesting that ILT2 may be a new potential therapeutic target for the treatment of patients with CLL.

P.B2.01.10

Changes in rat microglia metabolic profile after treatment with doxorubicin and its complex with C_{60} fullerene *in vitro*

Y. Hurmach, *S. Prylutska, M. Rudyk, K. Stepura, Y. Maiboroda, O. Shuliak, D. Hladun, S. Stepanenko, V. Svyatetska, Y. Prylutskyy, L. Skivka;*
Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

Microglia are resident CNS macrophage-like cells involved in neuroimmunity. Also they are the predominant immune cell infiltrating brain neoplasms, such as glioblastoma. Preclinical studies suggest that doxorubicin (Dox) had a strong antineoplastic activity against gliomas. Dox conjugated to nanoparticles demonsrtates enhanced anti-cancer activity through the mechanisms including tumor-associated microglia targeting. The aim of the work was to evaluate the effect of Dox in complex with C_{60} fullerene on metabolic profile of rat microglia *in vitro*. Microglial cells from adult Wistar rats were treated with C_{60} fullerene, Dox, and C_{60} + Dox complex for 30 min. Metabolic profile of microglial cells was characterized by the arginine metabolism as well as by the phagocytosis and reactive oxygen species (ROS) generation. Treatment of microglial cells with with C_{60} + Dox complex resulted in increased reactive nitrogen species generation. Meanwhile, phagocyte arginase activity remained unchanged after the treatment. It indicates pro-inflammatory shift of microglia arginine metabolism. ROS production by microglial cells treated with C_{60} + Dox complex was 2 times higher than that in untreated cells and 1.5 times higher than that after treatment with Dox used alone. Phagocytosis of microglial cells treated with Dox was 2.5 times higher than that in untreated cells and 3 times higher than that after treatment with C_{60} + Dox complex. Complexation of Dox with C_{60} fullerene potentiates its modulatory effect on microglia metabolic profile.

P.B2.01.11

Sall4 oncogene is an immunogenic antigen presented in various HLA-DR contexts.

m. kroemer[1,2], *L. Spehner*[1], *M. Ben khelil*[1], *P. Letondal-Mercier*[1], *L. Boullerot*[1], *Y. Godet*[1], *O. Adotévi*[1,2], *C. Borg*[1,2];
[1]*EFS/BFC/UMR1098, Besançon, France,* [2]*CHRU Besançon, Besançon, France.*

Purpose: To investigate the immunoprevalence of SALL4-derived peptides in healthy volunteers and cancer patients. Experimental Design: A multistep approach including prediction algorithms was used to design *in silico* SALL4-derived peptides theoretically able to bind on common HLA-DR and HLA-A/B molecules. The presence of T-cell responses after a long term T-cell assay (28 days) against SALL4 was monitored in 14 healthy donors and the presence of T-cell responses after a short term T-cell assay (10 days) was monitored in 67 cancer patients using IFN-γ ELISPOT assay. A T-cell clone specific for the immunoprevalent A18K-derived peptide was isolated, characterized and used as a tool to characterize the natural processing of A18K. Results: A SALL4 specific T-cell repertoire was present in healthy donors (8/14) and cancer patients (29/67) after short term T-cell assay. We further identified two immunoprevalant SALL4-derived peptides, R18A and A18K, which bind MHC-class II. In parallel, an A18K specific Th1 clone recognized monocyte derived Dendritic Cell (moDC) loaded with SALL4 containing cell lysate. The level of IFN-γ secreted by specific T-cell clone was greater in presence of moDC loaded with SALL4 containing cell lysate (49.23 ± 14.02%) than with moDC alone (18.03 ± 3.072%) (p= 0.0477)
Conclusion: These results show for the first time immunogenicity of SALL4 oncogenic protein-derived peptides, especially A18K and R18A peptides and make them potential targets for personalized medicine. Thus, SALL4 possess major characteristics of a tumor antigen.

P.B2.01.12

Modulation of pulmonary microbiota by antibiotic or probiotic aerosol therapy: a new strategy to promote immunosurveillance against lung metastases

V. Le Noci[1], *S. Guglielmetti*[2], *S. Arioli*[2], *C. Camisaschi*[3], *M. Sommariva*[4], *C. Storti*[1], *A. Balsari*[1,4], *E. Tagliabue*[1], *L. Sfondrini*[4];
[1]*Molecular Targeting Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [2]*Dipartimento di Scienze degli Alimenti, Nutrizione e Ambiente (DeFENS), Università degli Studi di Milano, Milan, Italy,* [3]*Immunotherapy Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [4]*Dipartimento di Scienze Biomediche per la Salute, Università degli Studi di Milano, Milan, Italy.*

Immunological tolerance in the lung microenvironment is essential to control inflammation in response to inhaled particulates, but it also creates a permissive milieu for the setting of lung metastasis. Since the lung microbiota is implicated in pulmonary tolerance, we explored whether its manipulation via antibiotics or probiotics aerosolization in C57BL/6 mice limits melanoma metastasis by subverting local immune suppression and boosting immune responses. Here, we show that in lungs of vancomycin/neomycin aerosolized mice a decrease in bacterial load was associated to a reduction in regulatory T cells (Tregs). Moreover, the enhanced activation of lung T and NK cells paralleled the significant reduction of lung metastases in mice aerosolized with antibiotics and intravenously injected with melanoma B16 cells. Reduction of lung metastases also occurred in lung transplanted with bacteria isolated from the bronchoalveolar lavage of antibiotic-treated mice (*Morganella morganii, Campylobacter* sp); likewise, transplantation of bacteria isolated from untreated mice (*Paenibacillus glucanolyticus, Bacillus clausii)* attenuated the anti-metastatic effects of antibiotics. Aerosolized probiotic *Lactobacillus rhamnosus*, a human commensal bacterium, strongly limited B16 metastases implantation and promoted immune activation as well. Furthermore, probiotics or antibiotics improved the therapeutic effects of dacarbazine, a chemotherapeutic agent used in metastatic melanoma patients, in advanced B16 metastases-bearing mice. Our results reveal for the first time that the balance of immunostimulatory and immunosuppressive commensal bacteria in lungs is relevant in creating an immunological permissive milieu for metastatization. Thus, targeting lung microbiota via probiotic or antibiotic aerosolization represent a new therapy to prevent metastases and enhance the response to chemotherapy.

P.B2.01.13

IgG subclass switching and clonal expansion in human colorectal cancer

R. Liu*, Q. Zhang, H. Liu;*
Institute of Gastroenterology and the Sixth Affiliated Hospital, Guangzhou, China.

B lymphocytes play an important role in the maintenance of intestinal homeostasis. However, the subsets and roles of B lymphocytes in human colorectal cancer are not clear. Here, we found that B cells showed a lymphatic-like distribution in the steady state but a disorganized distribution pattern in human colorectal cancer tissue. These results led us to suspect that the change in distribution pattern may affect B cell differentiation and development. Our further study showed that IgM^+ and IgA^+ B cell subsets skewed to IgG^+ B cell subsets in tumor microenviroment. Consistent with this, tumor-infiltrating B cells featured shorter complementarity-determining (CDR3) regions compared with B cells isolated from normal tissues. More importantly, we also detected higher IgG4 levels in the plasma of colorectal cancer patients compared with healthy donors , suggesting that B cell subsets change in tissues can be reflected in the patient's body fluids. Evidence for antibody class switching and antibody maturation in human colorectal cancer, support the involvement of B cells in human colorectal cancer immunity.

P.B2.01.15

Serum chemokine profiling reveals candidate biomarkers for recurrence and immune infiltration in ovarian cancer

A. Mlynska[1], *G. Salciuniene*[1], *K. Zilionyte*[1], *B. Intaite*[1], *A. Barakauskiene*[2], *V. Pasukoniene*[1];
[1]*National Cancer Institute, Vilnius, Lithuania,* [2]*Vilnius University, Vilnius, Lithuania.*

The management of advanced ovarian cancer is challenging due to the high frequency of recurrence, often associated with the development of resistance to platinum-based chemotherapy. Molecular analyses revealed the complexity of ovarian cancer with particular emphasis on the immune system that may contribute to disease progression and response to treatment. Chemokines orchestrate the cross-talk between cancer and immune cells, and therefore present as potential biomarkers, reflecting the tumor microenvironment. We examined a panel of circulating CC and CXC chemokines in the serum of 40 high-grade ovarian cancer patients prior to primary surgery. We also analyzed the level of immune infiltration in tumors.The preoperative levels of chemokines differ between patients. Elevated levels of circulating CXCL4+CCL20+CXCL1 combination can discriminate patients with shorter recurrence-free and overall survival. Serum CCL17 has a potential to select platinum-resistant tumors. In half of the patients, we detected the presence of intratumoral lymphocytes, as well as high expression of T cell response-associated genes. Circulating CXCL9+CXCL10 combination can distinguish immune-infiltrated tumors that are more likely to recur. Our results suggest that profiling of circulating chemokines in ovarian cancer patients may provide valuable information regarding tumor chemosensitivity and immune infiltration. We show that combinations have better prognostic utility than single chemokines and may serve as patient stratification tools.

P.B2.01.16

Diverse functions of CR3 (CD11b/CD18) and CR4 (CD11c/CD18) β_2-integrins expressed by human B lymphocytes

Z. Nagy-Baló[1], *S. Lukácsi*[1,2], *B. Mácsik-Valent*[1,2], *Z. Bajtay*[1,2], *A. Erdei*[1,2];
[1]*Department of Immunology, Eötvös Loránd University, Budapest, Hungary,* [2]*MTA-ELTE Immunology Research Group, Eötvös Loránd University, Budapest, Hungary.*

CR3 and CR4 are known for long to participate in adhesion and migration of myeloid cells. The expression and function of these β_2-integrins on human B lymphocytes however, has not been extensively studied yet.
Investigating the CD11b and CD11c expressing human B cell line BJAB we found that blocking CR4 with a CD11c specific antibody, a significant, up to 50 % reduction of adhesion could be observed on fibrinogen coated surface, in contrast to the effect of the anti-CD11b antibody. Therefore CR4 dominates adhesion of B cells over CR3, showing a division of labour of these two β_2-integrins, similarly to that observed previously in the case of myeloid cells (Sándor et al., PloSOne, 2016). Employing cells of the Daudi line we found that blocking of either receptor decreases the migration towards SDF-1α by 30-40 %. Our current experiments include also B cells isolated from tonsils, which express CR4 upon stimulation by PMA.
Further, we analysed the function of these two receptors on B cells of chronic lymphocytic leukaemia (CLL) patients expressing varying levels of CR3 and CR4, since adhesion and migration are important for survival of these malignant cells. Our ongoing experiments show that these receptors participate in both functions also on CLL B cells at different scales depending on the level of expression. We also found that inhibition of adhesion by blocking with PLL-PEG lowers the rate of proliferation of CLL B cells triggered by different stimuli.

P.B2.01.17

Exploring the effects of tetraspanin CD37-deficiency on metabolic signaling during B-cell lymphomagenesis

R. Peeters[1], *A. Hoekstra*[2], *R. Stienstra*[3], *C. Berkers*[2], *E. Jansen*[1], *A. Van Spriel*[1];
[1]*Department of Tumor Immunology, RIMLS, Radboudumc, Nijmegen, Netherlands,* [2]*Department of Biochemistry and Cell Biology, University of Utrecht, Utrecht, Netherlands,* [3]*Department of Internal Medicince, Radboudumc, Nijmegen, Netherlands.*

Introduction: Immune cells employ a metabolic state that fits their specific needs. These needs fluctuate throughout their lifespan. Metabolic alterations are induced by intracellular and extracellular signals that are coordinated by membrane receptors. Abnormal composition of these receptors can have drastic effects on cell faith. The tetraspanin superfamily of 4-transmembrane proteins controls membrane protein organization. Absence of the immune-specific tetraspanin CD37, results in spontaneous B-cell lymphoma development in mice. Importantly, diffuse large B-cell lymphoma (DLBCL) patients lacking CD37 on tumor cells have a significantly worse prognosis. CD37 controls the activity of Akt kinase which plays a central role in metabolic regulation and cell survival. We therefore set out to establish the effects of CD37-deficiency on the metabolic faith of healthy B-cells and its potential role in lymphomagenesis.
Objective: Provide more insight into the metabolic pathways underlying CD37 function in healthy B cells and during lymphomagenesis, potentially finding modes of clinical intervention.
Methods: Metabolite abundance in WT and $CD37^{-/-}$ of human B-cell lines and primary murine B-cells was assessed with mass spectrometry (MS). The metabolic analyzer Seahorse XF96 was used to directly measure oxidative phosphorylation (OXPHOS) and glycolysis activity in live cells. Furthermore, mitochondrial phenotyping of B-cells was carried out using confocal microscopy.
Results: Preliminary results indicate that B-cells without CD37 display lower metabolic activity. WT cells contain higher absolute levels of OXPHOS-, and glycolysis-associated metabolites. Furthermore, WT B-cells portray higher oxygen consumption and extracellular acidification, indicating more active OXHPHOS and glycolysis respectively.

*Introduction*Tumor-infiltrating lymphocytes (TILs) are correlated to prognosis of several kinds of cancer. Most studies focused on T cells, while the role of tumor-associated B cells (TABs) has only recently gained more attention. TABs contain subpopulations with distinct functions, potentially promoting or inhibiting immune responses. This study provides a detailed analysis of TABs in gastro-esophageal adenocarcinoma (EAC).*Methods*Single cell suspensions of tumor samples (n=54), mucosa (n=43), lymph nodes (n=42) and peripheral blood mononuclear cells (PBMC, n=88) of EAC and PBMC of healthy controls (n=20) were studied by flow cytometry.
A panel of 34 tumor-associated antigens (TAAs) expressed in EAC was identified based on public databases and TCGA data to analyze tumor-specific B cell responses using a LUMINEX™bead assay and flow cytometry. Spatial distribution of TABs was analyzed by confocal immunofluorescence-microscopy.ResultsB cells were elevated in primary tumor samples compared to PBMCs of gastric cancer patients or normal mucosa. Subset-analyses of TILs revealed increased proportions of differentiated and activated B cells and enrichment for follicular T helper cells. TABs were organized in tertiary lymphoid structures (TLS) at the invasive tumor margin. Structural analyses of TLS and the detection of tumor-specific antibodies against one or more TAAs in 48.1% of analyzed serum samples underline presence of anti-tumor B cell responses in EAC. B cells were decreased in tumors with expression of Programmed Death Ligand 1 or impaired HLA-I expression.ConclusionsAnti-tumor B cell responses are an additional and underestimated aspect of EAC. These results are of immediate translational relevance to emerging immunotherapies.

P.B2.01.19

Evaluation of serum iron in tumorigenesis and malignancy of ovarian cancer

N. TOUNSI[1], *A. Benyelles-Boufennara*[2], *B. Djerdjouri*[3];
[1]University of sciences and technology Houari Boumedienne, Alger, Algeria, [2]Department of Department of Pathological anatomy, Public Health Center Pierre and Marie Curie, Mustapha Bacha Hospital (Algiers, Algeria)., Algiers, Algeria, [3]University of sciences and technology Houari Boumedienne, Algiers, Algeria.

Introduction: Ovarian cancer is a lethal malignancy that recorded in 2012, 238719 new cases and caused 151917 deaths, worldwide. It represents the fifth most common women cancer in Algeria, with a worse prognosis for more than 66% of new cases 821 deaths in 2012.
The goal of our study was to evaluate the contribution of serum iron in Algerian ovarian cancer patient's progression.
Materials and Methods: Hematoxylin and eosin (H&E)-stained sections of ovarian tumors were examined for diagnosis (benign or malignant tumor) and staging. Sera from 40 ovarian tumor patients before treatment and 30 controls were sampled and used for seric iron and CA-125 evaluation.
Results: H&E stained sections of ovarian cancer showed that among the 40 patients, 30 are malignant tumor and 10 benign tumor. The 30 malignant tumor displayed 2 patients in stage 1, 12 patients in stage 2, 11 patients in stage 3 and 5 patients in stage 4.
Iron levels decreased by 17% ($p < 0.05$) while CA-125 increased by 98% ($p < 0.001$) in malignant ovarian cancer patients, compared to healthy individuals. NO significant correlation were shown between seric iron and CA-125 levels (r= 0.2879, $p > 0.05$). Despite the altered iron levels, it was not significantly associated to tumoral stage progression (r= 0.1265, $p > 0.05$).
Conclusion: Our preliminary data suggests that seric iron cannot be taken as supportive biomarkers for the diagnosis of ovarian cancer but may partially emphasizes the iron microenvironment enrichment for ovarian cancer initiation.

SERUM AND URINARY LEVELS OF CD222 IN CANCER DISEASES: ORIGIN AND DIAGNOSTIC VALUE

K. Vičíková[1], *E. Petrovčíková*[1], *P. Maňka*[2], *J. Drach*[3], *H. Stockinger*[4], *V. Leksa*[1];
[1]Institute of Molecular Biology, Bratislava, Slovakia, [2]BSP Sizar s.r.o, Bratislava, Slovakia, [3]University Hospital Vienna, Department of Medicine I, Vienna, Austria, [4]Institute for Hygiene and Applied Immunology, Center for Pathophysiology, Infectology and Immunology, Medical University in Vienna, Vienna, Austria.

The mannose 6-phosphate/insulin-like growth factor 2 receptor (CD222, M6P/IGF2R) is a multifunctional transmembrane type I receptor, mostly localized intracellularly, less on the surface of all types of mammalian cells. It is known both to transport lysosomal enzymes through their mannose 6-phosphate moieties and to internalize extracellular ligands like insulin-like growth factor 2 or plasminogen. CD222 is involved in regulation of cell proliferation, migration, T cell activation, and apoptosis. Soluble CD222 has been found in higher concentrations in sera of liver disease patients. In this study, we analysed the level of CD222 present in body fluids, namely in serum and urine, of cancer patients. We found significantly elevated levels of soluble CD222 in sera of cancer patients compared to healthy controls irrespective of the type of disease. The urine CD222 levels were increased specifically in breast cancer and multiple myeloma. In contrast to serum, CD222 was present within CD222-positive exosomes in urine pointing to different origins of CD222 present in various human body fluids. Based on this work, we propose serum soluble CD222 as a general biomarker for tumorigenesis.

P.B2.01.21

Study of the biological effects of lactoferrin on the prostate cancer cells with varying sensitivity to hormonal therapy

T. Zadvornyi, *N. Lukianova, V. Chekhun;*
RE Kavetsky Institute of Experimental Pathology, Oncology and Radiobiology, NAS of Ukraine, Kyiv, Kyiv, Ukraine.

Introduction. Correction of prostate cancer (PCa) hormone resistance is one of the top research directions of biology exploration of this localization. One of the perspective approaches is the search of low-toxic substances that increase treatment efficacy.
Aim: to investigate biological effects of lactoferrin (LF) and to find out the possibility of its use to reduce the malignancy degree of human PCa cells by modifying their phenotype.
Materials and methods: The hormone-sensitive (LNCaP) and hormone-independent (DU-145) human PCa cell lines were cultured with an exogenous LF. The expression levels of ER, PR, Her2/neu, Ki-67, E- and N-cadherin, were monitored by immunohistochemical analysis. The levels of miRNAs were assessed, using q-PCR. The invasive activity of the cells was examined using a standard invasive test according to the manufacturer's instructions.
Results. We established that cultivation of human PCa cell lines with exogenous LF resulted in lowering of steroid hormone receptor expression (ERa and PR). The decrease in the expression of the Ki-67 under the influence of exogenous LF was observed in both cell lines. Also, we established the decrease of invasive activity - by 40% and 30% in DU-145 and LNCaP cell lines, respectively. We found that under the action of exogenous LF there was an increase in the level of expression of oncogenic and oncosuppressive miRNAs in both cell lines.
Conclusions: Thus, we have shown that under the influence of exogenous LF there are changes in phenotypic characteristics and levels of oncogenic and oncosuppressive miRNAs.

P.B2.02 Environmental regulation anti-tumor responses - Part 2

P.B2.02.01

Evaluation of local immune response after silencing of IL-10 or IL-10R expression in MC38 tumors

N. Anger, *A. Szczygieł, K. Węgierek, J. Mierzejewska, M. Napierała, E. Pajtasz-Piasecka, J. Rossowska;*
L. Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wrocław, Poland.

A growing tumor is composed of a variety of cells and factors, which collectively form the tumor microenvironment (TME). One of the cytokines, which is frequently upregulated in cancer is interleukin 10. The majority of reports indicate that IL-10 is a suppressive cytokine with a pro-tumoral effect. However, IL-10 can also enhance the anti-tumor response. The aim of our research was to evaluate the role of IL-10 in MC38 murine colon carcinoma microenvironment through silencing of IL-10 or IL-10R expression.
Mice with subcutaneously growing MC38 tumors were intratumorally inoculated with lentivectors silencing IL-10 or IL-10R expression (shIL-10 LVs or shIL-10R LVs). Characterization of the tumor microenvironment was performed on the 4th and 6th day after LV inoculation. Percentage of tumor infiltrating subpopulations of myeloid and lymphoid cells and their activation stage were evaluated by flow cytometry.
A simultaneous accumulation of CD8$^+$ T cells and PMN-MDSCs was observed in TME on the 4th and 6th days after inoculation with shIL-10 LVs. However, shIL-10R LVs and control LVs induced an antiviral response characterized by high influx of CD8$^+$ T cells into tumor on the 6th day after inoculation.
The gathered data indicates that inoculation with LVs induced a strong antiviral response. This effect seemed to be diminished by reduction of IL-10 in TME. Additionally, the early influx of CD8$^+$ T cells observed on the 4th day after inoculation suggests a CTL-dependent antitumor response.
This work was financed by National Science Centre, Poland (grant no 2014/15/N/NZ4/04817).

P.B2.02.02
Modeling cancer immunomodulation using epithelial organoid cultures

Y. E. Bar-Ephraim[1,2], *K. Kretzschmar*[1,2], *P. Asra*[1,2], *Z. Sebestyen*[3], *J. Kuball*[3], *H. Clevers*[1,2,4];
[1]*Hubrecht Institute, Utrecht, Netherlands,* [2]*Oncode Institute, Utrecht, Netherlands,* [3]*UMC, Utrecht, Netherlands,* [4]*Princess Maxima Center, Utrecht, Netherlands.*

Colorectal carcinoma (CRC) is one of the most prevalent forms of cancer which develops in a multi-step process from lesions in healthy colon tissue. While mutations in cancerous epithelial cells drive the process of tumorigenesis, interaction of the tumor with the immune system and subsequent evasion from immune-mediated destruction is essential for tumor progression.
Epithelial organoids provide a platform which allows culturing of cancerous and healthy epithelium while retaining tissue-of-origin identity over a prolonged culture period. As such, epithelial organoids are a reliable system to model many biological processes, ranging from normal epithelial differentiation to tumor development. Also, tumor-derived organoids have shown potential to be used in patient-specific drug screens, making a critical step towards personalized medicine.
Here, we report a new method to study immune-cancer interactions and assess modulation of the immune response by CRC. We derived organoids from CRC samples and show by transcriptional profiling that organoids maintain differential expression of immune modulatory molecules present in primary tumors. Further, we have set up a co-culture system for organoids and T cells to assess immunoreactivity. Indeed, upon co-culture with TCR transgenic $CD8^+$ T cells, organoid killing and cytokine production by T cells was only observed when co-cultured organoids were pulsed with TCR specific native peptides but not with control peptides. In conclusion, our method presented here allows for investigation of immune cell-tumor interaction in vitro and how immunomodulators can be utilized to stimulate tumor eradication. Implementation of this system may thus lead towards new avenues of patient-specific treatment.

P.B2.02.03
$CD68^+$ cells not implicated in Ncf1-mediated tumor progression

M. Y. Bonner*, R. Holmdahl;*
MIR, Karolinska Institutet, Solna, Sweden.

Cancer is the second leading cause of death globally, according the WHO, with the number of deaths from cancer expected to increase by 70% over the next two decades. The purpose of this study is to advance our understanding in cancer biology and anti-cancer immune response in order to facilitate the development of improved anti-cancer therapies needed to address this concern. Levels of reactive oxygen species (ROS), such as superoxide, hydrogen peroxide are known to increase as premalignant cells evolve into malignant lesions. ROS is also know to play a role in immune response and communication. The aim of our study is identify which immune cell subtype is able to inhibit tumor growth through NOX2-ROS inhibition. A mutation in the Ncf1, component of the NOX2 complex prevents ROS production in B10.Q Ncf1*/* mice. Recent results point to impaired tumor growth in mice with the Ncf1 mutation, in agreement with published studies. Interestingly, when the B10.Q Ncf1*/* mice acquire a functional Ncf1 gene only in $CD68^+$ macrophages, B10.Q Ncf1*/* MN, they also present similarly impaired tumor growth in relation to the wildtype B10.Q mice. We then tested to the potential of $CD11c^+$ cells mediated tumor progression through functional and non-functional Ncf1 molecules. Our results indicate that the potential of $CD11c^+$ lineage involvement in Ncf1 mediated tumor progression in B16F10 melanoma and LLC Lewis lung carcinoma tumor models.

P.B2.02.04
Assessing the role of myeloid cell GCN2 in anti-tumor immune responses

F. Cichon[1], *J. K. Sonner*[1], *K. Deumelandt*[1], *L. Wolf*[1], *E. Green*[1], *W. Wick*[1,2], *M. Platten*[1,3];
[1]*German Cancer Research Center, Heidelberg, Germany,* [2]*Department of Neurology and National Center of Tumor Diseases, Heidelberg, Germany,* [3]*Department of Neurology, University Medical Center Mannheim, Mannheim, Germany.*

Nutrient deprivation is a hallmark of the tumor microenvironment and exerts significant suppressive influence. The tryptophan catabolism has been identified as a central pathway restricting T cell immunity in tumors. In clinical trials inhibitors of the rate-limiting enzyme that mediates tryptophan depletion, indoleamine-2,3-dioxygenase (IDO), have been tested as monotherapy and in combination with checkpoint inhibition without positive results thus far. Based on the identification of the stress kinase general control non-derepressible 2 (GCN2) as a central hub for sensing tryptophan deprivation and mediating downstream effects of the immunoregulatory enzyme IDO, further investigations are required to define the role of immune cell GCN2 in the tumor microenvironment to understand the mechanism of IDO-mediated immunosuppression. We demonstrate that the deletion of GCN2 within the immune compartment promotes resistance to T cell activating immunotherapy (glycoprotein 100 peptide vaccine and immune checkpoint inhibition targeting programmed death-ligand 1) in experimental B16 melanoma in full knock-out mice and bone marrow chimera. Since we have recently reported that T cell GCN2 is dispensable for suppression of B 16 melanoma rejection, we are focussed on the role of myeloid cell GCN2 for anti-tumor immune responses. *In vitro* genetic ablation of *Gcn2* reinforced immunosuppressive capacities of bone-marrow derived macrophages. In addition, *Gcn2* deletion in bone marrow-derived dendritic cells suppressed cytotoxic responses of co-cultured gp100-specific T cells. In conclusion, our results suggest that GCN2 mediated downstream signaling exerts substantial influence on both, efficient antigen presentation and production of immunosuppressive factors and thereby significantly modulates anti-melanoma immune responses during checkpoint Blockade.

CombImmunotherapy: poly(I:C) primes glioblastoma for PD-L1 blockade via lymphocyte attraction and activation

J. De Waele[1], *E. Marcq*[1], *J. Van Audenaerde*[1], *J. Van Loenhout*[1], *C. Deben*[1], *K. Zwaenepoel*[2], *E. Van de Kelft*[3], *D. Van der Planken*[3], *T. Menovsky*[2], *J. Van den Bergh*[1], *Y. Willemen*[1], *P. Pauwels*[1,2], *Z. Berneman*[1,2], *F. Lardon*[1], *M. Peeters*[1,2], *A. Wouters*[1], *E. Smits*[1];
[1]*University of Antwerp, Antwerp, Belgium,* [2]*Antwerp University Hospital, Edegem, Belgium,* [3]*AZ Nikolaas, Sint-Niklaas, Belgium.*

Novel therapies are needed to address to abysmal prognosis of glioblastoma patients. Immunotherapy requires combination strategies to unlock its full potential. Here, we investigated the immunomodulatory capacities of poly(I:C) on glioblastoma cells and its combinatorial potential with programmed death ligand (PD-L) blockade.
Primary human glioblastoma cells were cultured from residual tumour tissue obtained from standard surgery of glioblastoma patients. Phenotyping was performed using flow cytometry (FCM), immunohistochemistry, qRT-PCR and multiplex electrochemiluminescence. Toll-like receptor 3 (TLR3) signalling was inhibited using chloroquine. Lymphocyte migration was studied using a transwell FCM assay, and activation using FCM and ELISA. Additional PD-L1/PD-L2 blockade was evaluated using ELISA and CSFE-labelled T-cell proliferation.
Poly(I:C) stimulated a pro-inflammatory secretome by gliobolastoma cells, including type I interferons (IFN), interleukin-15, reduced transforming growth factor β, and chemokines CXCL9, CXCL10, CCL4 and CCL5. Concomitantly, PD-L1 and PD-L2 expression on glioblastoma cells was stimulated via TLR3 signalling. Poly(I:C)-treated glioblastoma cells doubled $CD8^+$ T-cell attraction, and to a lesser extent $CD4^+$ T cells, in part via ligands for CXCR3 and CCR5, while natural killer cell migration was not affected. Lymphocytes cocultured with poly(I:C)-treated glioblastoma cells showed enhanced activation (CD69, IFN-γ) and cytotoxic potential (CD107a, granzyme B). Additional blockade of PD-L1, but not PD-L2, further propagated this immune activation.
Our results show that poly(I:C) triggers glioblastoma cells to secrete cytokines which attract and activate $CD8^+$ T cells, following which blocking of the elevated tumoural PD-L1 further reinforces immune activation. In conclusion, our data proposes poly(I:C) to strengthen PD-L1 blockade in glioblastoma.

P.B2.02.06
CDK5 involvement in the tumor microenvironment

F. Farina[1,2], *M. Quintavalle*[2], *M. Locati*[1];
[1]*Università degli Studi di Milano, Milano, Italy,* [2]*Istituto Clinico Humanitas, Rozzano, Italy.*

Cyclin-dependent kinase 5 (CDK5) is a serine/threonine kinase belonging to the CDK family. Several works highlighted CDK5 role in cancer progression and invasiveness both in solid tumors and in hematopoietic malignancies. Until now, no previous work described CDK5 role in Tumor Associated Macrophages. To study CDK5's involvement in macrophages polarization, we performed both gain- and loss-of-function studies. Preliminary *in vitro* experiments were performed on THP1 monocytic cell line, differentiated into M0 macrophages. Once differentiated, macrophages polarization was induced after IFNγ (M1) and IL-4 or IL-10 (M2) treatment. Lentiviral overexpression of p35 in M0 macrophages was employed as a gain-of-function model, while lentiviral overexpression of CDK5-specific shRNA was employed as a loss-of-function model. We observed that CDK5 is highly expressed in macrophages at basal level and it is downregulated after inflammatory stimuli. We measured a reduction in CDK5 protein expression after M1 phenotype induction (IFNγ), indicating that CDK5 is necessary for a correct M1 polarization. Conversely, p35 overexpressing macrophages showed a decreased pro-inflammatory gene expression. Therefore, these data suggested a clear CDK5 role in TAMs via a p35/CDK5 activation pathway and possible CDK5 involvement in tumor progression. CDK5 silencing, induced a reduction in podosome formation. These data clarify results obtained in vitro and suggest a possible correlation between p35/CDK5 deregulation and cancer invasion. In addition, CDK5 expression in TAMs might be used as prognostic marker for the outcome evaluation of breast cancer patients. We aim to demonstrate that CDK5 inhibition might be a viable anti-metastatic strategy to treat invasive breast cancer.

P.B2.02.07

CD16^{+}NKG2A^{high} NK cells from Tumor draining lymph nodes correlate with stage in Breast Cancer patients

***A. Frazao**, M. Messaoudene, N. Nunez, E. Piaggio, N. Dulphy, A. Toubert, A. Caignard;*
INSERM, Paris, France.

We characterized the Natural killer (NK) cells that infiltrate tumor draining (TD) lymph nodes (LN), the first site of metastasis of breast cancers (BC). We analyzed by flow cytometry the phenotype of NK cells from TD-LN, (including non-invaded (NI) and metastatic (M)-LN from BC patients) and also NK cells from healthy donor (HD)-LN. First, we show that NK cells from paired NI and M-LN display similar phenotype and M-LN contained low percentages of tumor cells that express ULBP2 and HLA class I molecules. Compared to HD-LN, TD-LN NK cells highly express NCR, NKG2D and NKG2A receptors and characterized by elevated CD62L and CXCR3 expression. TD-LN contained a major compartment of activated CD56^{+}CD16^{+} NKG2A^{high} and these NK cells are prominent in Stage IIIA BC patients. We found that a subset of LN-NK cells express PD-1. TD-LN NK cells degranulate efficiently after co-culture with BC cell lines. Cytokine activated TD-LN NK cells exerted higher lysis of BC cell lines than HD-LN NK cells and preferentially lysed the HLA class-I^{low} PD-L1^{low} MCF-7 BC cell line. The expression of inhibitory receptor NKG2A and checkpoint PD-1 by TD-LN NK cells from BC indicate their potential as targets for immunotherapies using anti-NKG2A and/or anti-PD1 mAbs.

P.B2.02.08

Slan+ monocytes and NK cells contribute to a tumor microenvironment that induces a p21-dependent growth arrest in melanoma cells

***F. Funck**[1,2], J. Pahl[2], A. Cerwenka[2], K. Schäkel[1];*
[1]Dermatology, University Hospital Heidelberg, Heidelberg, Germany, [2]Medical Faculty Mannheim, University Heidelberg, Mannheim, Germany.

The cell types of the immune system orchestrate effective anti-tumor responses and often eliminate malignant cells before primary tumors or metastasis can arise. In the mouse system, it was recently reported that patrolling monocytes initially detect newly formed metastasis and reduce metastatic load by recruiting NK cells. slan^{+} monocytes (slanMo) represent a subset of human CD14^{dim}CD16^{+} monocytes (homolog of patrolling monocytes in mice) and were previously identified in melanoma metastasis. slanMo are capable of initiating anti-tumor responses based on the secretion of proinflammatory cytokines and the interaction with NK cells is highlighted by an IL-12/IFN-γ dependent positive feedback loop that results in high levels of TNF-α and IFN-γ. Here, we address the question whether the cytokine milieu generated by co-culturing these two cell types influences the growth of melanoma cells and can lead to senescence induction. To this end, we incubated melanoma cell lines with supernatants from slanMo/NK co-cultures. Supernatant treatment resulted in a severely reduced proliferation rate, increased Senescence-associated beta-Galactosidase staining, and a senescence phenotype characterized by strong p21 (CDKN1A) upregulation. This phenotype could be abolished by combined TNF-α and IFN-γ neutralization. We provided evidence that NK cells migrate towards activated slan supernatants *in vitro*. In addition, we validated the presence of slanMo in melanoma metastasis prior and after immunotherapy, together supporting a mechanism similar to patrolling monocytes in the mouse system. Our data suggests that slanMo are present in melanoma metastasis and contribute to a pro-inflammatory immune microenvironment that inhibits the growth of melanoma cells. Funded by RTG2099.

P.B2.02.09

Ni(II) complexes with Mannich bases affect viability and proliferation of rat tumor and non-tumor (bone marrow, macrophages, lymphocytes) cells

***M. Glavcheva**[1], T. Zhivkova[1], B. Andonova-Lilova[1], L. Dyakova[2], R. Tudose[3], E. Mosoarca[3], O. Costisor[3], R. Alexandrova[1];*
[1]1Institute of Experimental Morphology, Pathology and Anthropology with Museum, Sofia, Bulgaria, [2]2Institute of Neurobiology, Bulgarian Academy of Sciences, Sofia, Bulgaria, [3]Institute of Chemistry Timisoara of the Romanian Academy, Timisoara, Romania.

In recent years there has been an increasing interest in the antitumor and immunomodulating activities of metals and metal compounds. The aim of the present study was to evaluate the influence of four Ni(II) complexes with ligands containing the antipyrine moiety N,N'-bis(4-antipyrylmethyl)-piperazine (BAMP) or N,N'-tetra-(antipyryl-1-methyl)-1,2-diaminoethane (TAMEN) on viability and proliferation of cultured rat tumor and non-tumor cells. The following cell cultures were used as model systems in our investigations: permanent cell line (LSR-SF-SR) established from transplantable sarcoma in rat induced by Rous sarcoma virus strain Schmidt-Ruppin; primary cultures from tumor growths developed after a s.c. implantation of LSR-SF-SR cells (7.5 x 10^6 cells/animal) in inbred Wistar rats (PRSC) as well as from bone-marrow cells (BMC), peritoneal macrophages (PM) and spleen lymphocytes (SL) of the same tumor bearing animals and healthy rats. The investigations were performed by MTT test, trypan blue dye exclusion technique, double staining with acridine orange and propidium iodide and colony-forming method. The compounds were applied at concentrations of 10, 50, 100 and 200 μg/ml for 24h, 48h and 72h. The results obtained revealed that: i) $Ni_2(BAMP)(CH_3COO)_4$ and $Ni_2(BAMP)(Cl)_4$ are more pronounced cytotoxic agents as compared to $Ni(TAMEN)(ClO_4)_2$ and $Ni(TAMEN)(NCS)_2$ for both tumor and non-tumor cells; ii) BMC are relatively more sensitive to the toxic effects of Ni(II) complexes as compared to the other used cell culture models; iii) Both ligands (BAMP, TAMEN) do not significantly decrease viability and proliferation of the treated tumor and non-tumor cells. The authors gratefully acknowledge the EU Grant BG05M2OP001-2.009-0019-C01 from 02.06.2017.

P.B2.02.10

TGF beta compromises STING-induced IFN alpha/beta production and tumor regression in spontaneous tumors

***M. V. Guérin**[1], F. Regnier[2], J. M. Weiss[3], V. Feuillet[2], L. Vimeux[2], M. Thoreau[2], G. Renault[2], E. Donnadieu[2], A. Trautmann[2], N. Bercovici[2];*
[1]Cochin Institute INSERM U1016 CNRS UMR8104, Univ Paris Descartes, Paris, France, [2]Cochin Institute INSERM U1016 CNRS UMR8104, Univ Paris Descartes, Paris, France, [3]Univ Medical Center Freiburg, Freiburg, Germany.

Background: The rate of tumor growth and the responsiveness to therapies depend not only on intrinsic properties of malignant cells but also on the tumor microenvironment. Here, we examined in which conditions targeting the ubiquitous cytosolic protein STING in spontaneous tumors can trigger the production of type I IFN in the tumor microenvironment, inducing tumor regression. Materials and methods: Mice with spontaneous mammary tumors (MMTV-PyMT) received a single intraperitoneal injection of the STING ligand DMXAA. We examined the evolution of tumor growth and performed a molecular analysis of the tumor and immune infiltrate by flow cytometry, fluorescence imaging and transcriptomics. Results: We show that IFNα/β release that conditioned a swift recruitment of neutrophils, followed by a rise in CD8 T cells and monocytes in transplanted tumors, was impaired at an early stage in tumor cells and immune cells infiltrating spontaneous tumors. One reason is that TGFβ, abundant in such tumors, prevents the phosphorylation of IRF3 following STING stimulation. Blocking TGFβ restored the production of IFNα and facilitated tumor regression in the mammary tumor model. Conclusions: These data highlight that IFNα/β production is crucial to initiate an efficient anti-tumor immune response. We provide evidence for a determinant role of TGFβ in IFNα/β deficient induction in spontaneous tumors. This calls for further development of combined strategies allowing STING-dependent tumor rejection to take place. This work was granted by the Ligue Contre le Cancer Ile de France.

P.B2.02.11

TGFB1 polymorphisms may identify gastric adenocarcinoma patients with high risk of metastasis and lower survival rate

***I. Juarez**[1], A. Gutierrez[2], A. Blazquez[2], E. Ovejero[2], I. Lasa[2], A. Lopez[2], R. Gomez[2], J. M. Martin-Villa[1];*
[1]Universidad Complutense de Madrid, Dpt. of Immunology, Madrid, Spain, [2]Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Madrid, Spain.

Transforming growth factor β 1 (TGF-β1) is a cytokine involved in the development and malignancy of tumours. Several works attribute a dual effect to the cytokine in the cancer evolution depending on its levels and the stage of the disease. TGFB1 gene presents several single nucleotide polymorphisms (SNP), related with TGF-β1 levels.
We analysed four SNPs (rs1800468, rs1800469, rs1800470, rs1800471) in a group of 78 patients with gastric adenocarcinoma to assess the association between the TGFB1 and tumor progression.
Patients were classified as type I, II, III (non-metastatic) or IV (metastatic), according to their TNM stage. Upon DNA isolation, the polymorphisms were genotyped. PBMC were isolated and stimulated with PMA-Ionomicin and TGF-β1 was measured by ELISA. Survival curves analysis was also performed.
rs1800468-G/A genotype was present in 30% of metastatic patients compared to 10.3% of non-metastatic patients (p=0.049, OR=3.17). rs1800469-T/T was absent in metastatic patients, and present in the 19.1% of non-metastatic patients (p=0.03). The combined haplotyped ACTG was present in 15% of the metastatic patients as compared to 3.2% of non-metastatic (p=0.019, OR=7.65). rs1800469-C/C polymorphism yielded a lower expression of TGF-β1 than the C/T or T/T (1.44 and 1.41-fold respectively) variants. Likewise, the rs1800470 T/T polymorphism produced lower TGF-β1 amounts than C/C variant (0.73-fold). Finally, PBMC of rs1800469T/T-rs1800470C/C bearing patients produce higher TGF-β1 upon stimulation (1.4-fold, p=0.025) and have better survival-rates (85.5%) than rs1800469C/C-rs1800470T/T patients (28.1%)
These polymorphisms may us enable to pinpoint metastasis-prone patients, who would need more aggressive therapeutic approaches upon diagnosis.

P.B2.02.12

Impact of photodynamic therapy on the regulation of human immune system in the context of hepatocellular carcinoma

A. Kumar[1], *O. Morales*[1], *B. Leroux*[1,2], *C. Frochot*[3], *S. Mordon*[4], *N. Delhem*[1], *E. Boleslawski*[1];
[1]*Lille Biology Institute, Lille, France,* [2]*INSERM Unit U1189-ONCO THAI, Lille, France,* [3]*LRGP, UMR-CNRS 7274, University of Lorraine, Nancy, France,* [4]*INSERM, U1189-ONCO THAI, Lille, France.*

Introduction: With development in Photodynamic Therapy (PDT), scientists are trying to test the therapy in different cancer models. However, the immunological impact of the therapy is largely unknown. As immune-escape is the major hallmark for proliferating cancers, hence, we aim to evaluate the impact of 5-Aminolevulinic acid (5-ALA) mediated PDT on HCC cell lines: HuH7 (p53 over expression), HepG2 (wild type p53) and Hep3B (partially deleted p53).
Methodology: The expression of Delta-Aminolevulinic Acid Dehydratase (ALAD) and Protoporphyrinogen Oxidase (PPOX) was analyzed through qPCR. The optimal 5-ALA and illumination dosage was determined by treating cells with varying 5-ALA concentration and illumination duration, followed by cellular mitochondrial metabolism analysis. Thereafter, the cells were treated with these PDT parameters, the 'conditioned medium' was recuperated and used to culture cancer cells to analyze the cellular viability and proliferation.
Results: qPCR proves that HCC cell lines express ALAD and PPOX enzymes. Subsequent treatment of the cell lines reveal cancer cell death along with minimal change in proliferation when cultured with PDT treated conditioned media.
Conclusion: The anti-cancer therapy caused cancer cell death with a cell death pattern corresponding to the state of p53, along with an inhibition of cancer cell proliferation suggesting towards cell-cycle checkpoint regulation. Our preliminary studies have also showed that 5-ALA PDT can induce an immune-regulatory microenvironment, while its capability to prompt an immunogenic cell death and the role of cancer secreted exosomes remains to be studied.

P.B2.02.13

Predictive and prognostic value of circulating and tumor-associated NK cells in HER2-positive breast cancer patients treated with neoadjuvant therapy

A. Muntasell[1], *S. Servitja*[2], *F. Rojo*[3], *M. Cabo*[1], *S. Santana*[1], *I. Tusquets*[2], *B. Bermejo*[4], *M. Martinez*[4], *O. Arpi*[1], *M. Martínez-García*[2], *M. Costa-García*[5], *P. Eroles*[4], *I. Vázquez*[6], *L. Serrano*[6], *C. Vilches*[7], *A. Rovira*[2], *A. Lluch*[4], *J. Albanell*[2,5], *M. López-Botet*[1,5];
[1]*Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain,* [2]*Hospital del Mar-CIBERONC, Barcelona, Spain,* [3]*IIS 'Fundación Jiménez Diaz', Madrid, Spain,* [4]*Institute of Health Research INCLIVA, Valencia, Spain,* [5]*University Pompeu Fabra, Barcelona, Spain,* [6]*Hospital del Mar, Barcelona, Spain,* [7]*Instituto de Investigación Sanitaria Puerta de Hierro, Madrid, Spain.*

We investigated the value of distinct NK cell-related variables for predicting pathological complete response (pCR) in primary breast cancer patients undergoing anti-HER2 antibodies (mAbs)-based neoadjuvant treatment.
The immunophenotype of baseline circulating NK cells and the CD16A 158V/F genotype were analysed by multiparametric flow cytometry and PCR in a prospective cohort of patients recruited between 2014 and 2016 (n=64). Tumor-infiltrating NK cell numbers were assessed by double immunohistochemistry (CD56+CD 3-) in diagnostic tumor biopsies from recruited from 2008 to 2016 (n=139). NK cell-related variables were correlated with pCR adjusted for prognostic factors.
CD16A 158V/F genotype was not associated with pCR. Baseline circulating CD57+ NK cells and tumor-infiltrating NK cell numbers respectively showed an inverse and a positive association with pCR (p=0.029 and p<0.0001), independent of clinicopathological factors. Levels of <64% circulating CD57+NK cells and of ≥3 tumor-infiltrating NK cells 50 high-power fields (HPF) predicted pCR [OR 5.52 (95% CI, 1.68-18.058) and OR 44.6 (95% CI, 14.3-138,7), respectively]. In addition, circulating CD57+ and tumor-infiltrating NK cell numbers associated with longer disease-free survival. Of note, circulating CD57+NK cells inversely correlated with tumor-infiltrating NK cell numbers, according to the reduced frequency of CD57+NK cells in tumor-associated immune infiltrates.
Circulating CD57+ and tumor-infiltrating NK cells predict the likelihood of achieving pCR to anti-HER2 mAb-based neoadjuvant treatment. Our data point to the putative importance of tumor-infiltrating NK cells and the fitness of the circulating NK cell repertoire for the efficacy of anti-HER2+ breast cancer neoadjuvant therapies.

The ecto-ATPDase CD39 is involved in the acquisition of the immunoregulatory phenotype by M-CSF-macrophages and ovarian cancer tumor-associated macrophages: Regulatory role of IL-27

L. Papargyris[1], *S. d'Almeida*[1], *G. Kauffenstein*[2], *C. Roy*[2], *L. Basset*[1], *P. Jeannin*[3], *M. Grégoire*[1], *Y. Delneste*[1], *J. Tabiasco*[1];
[1]*INSERM U1232, ANGERS, France,* [2]*INSERM U1083, ANGERS, France,* [3]*INSERM U1232, Laboratoire d'Immunologie et d'Allergologie, CHU Angers, ANGERS, France.*

Objectives: Tumor-associated macrophages (TAM) are immunosuppressive cells that can massively accumulate in the tumor microenvironment (ME). In patients with ovarian cancer (OC), their density is associated with poor prognosis. Targeting mediators that control the generation/differentiation of immunoregulatory macrophages (Mϕ) may represent therapeutic challenge to overcome tumor-associated immunosuppression.
Methods: Our laboratory has previously shown that (i) in vitro monocytes treated with M-CSF or GM-CSF induce the generation of M2 and M1 Mϕ, respectively and (ii) that in vitro differentiated M-CSF-Mϕ are similar to TAM. We analyzed the expression of the membrane ectonucleotidase CD39 in Mϕ subsets and its role in the biology of M-CSF-Mϕ and ovarian cancer TAM.
Results: We observed that $CD14^+$ $CD163^+$ TAM isolated from ovarian cancer patients and that in vitro generated M-CSF-Mϕ express high levels of CD39 compared to M1-type GM-CSF-Mϕ. CD39 hydrolyzes ATP into extracellular adenosine that exhibits potent immunosuppressive properties when signaling through the A2A adenosine receptor. CD39 blockade diminished some of the immunosuppressive functions of $CD163^+$ $CD39^{high}$, such as IL-10 production. We identified the cytokine IL-27, secreted by tumor-infiltrating neutrophils, located close to infiltrating $CD163^+$ Mϕ, as a major rheostat of CD39 expression and, consequently, of the immunoregulatory properties of Mϕ. Accordingly, blocking IL-27 down regulated CD39 and PD-L1 expression and IL-10 secretion by M-CSF-Mϕ.
Conclusions: These data suggest that targeting molecules that maintain the immunosuppressive phenotype of TAM (IL-27-induced CD39, CD115 ligands) could give substantial benefit to the treatment of ovarian cancer.

P.B2.02.15

Carboplatin-cucurbituril complex: antitumour activity with reduced immunotoxicity

N. Knauer[1], ***E. Pashkina***[1], *E. Kovalenko*[2], *A. Aktanova*[3], *A. Ermakov*[3], *V. Kozlov*[1];
[1]*Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation,* [2]*Nikolaev Institute of Inorganic Chemistry, Novosibirsk, Russian Federation,* [3]*Novosibirsk State Medical University, Novosibirsk, Russian Federation.*

Cancer is the leading cause of mortality worldwide. Platinum(II)-based cytostatic drugs are actively used for antitumour therapy. However they have a plenty of side effects such as immunosupression because of their toxicity. This problem can be potentially solved by using nanocarriers for drug delivery which allow to reduce systemic toxicity without loss of efficacy. Cucurbiturils, macrocyclic cavitands, are promising tools for this purpose.
Herein, we study the effect of carboplatin, cucurbit[7]uril and carboplatin-cucurbit[7]uril complex (1:1) on B16 melanoma cells and on the primary culture of peripheral blood mononuclear cells (PBMCs) of healthy volunteers. The cells were cultivated in RPMI 1640 media with 10% of fetal calf serum in presence of drugs under study in concentration 0.01-0.3 mM for 48 h (B16) and 72 h (PBMCs). Cytotoxic effect was evaluated by MTT test, proliferative activity was evaluated using CFSE labeling.
It was found that complex in concentration 0.3 mM exhibits higher toxicity towards tumor cells than carboplatin in the same concentration. At the same time, the complex and carboplatin in concentration 0.3 mM have the equal toxicity towards PBMCs. Furthermore, recently, we have demonstrated that cucurbit[7]uril in concentration 1 mM has proper toxicity towards either tumor cells or PBMCs. Cucurbit[7]uril can also suppress aCD3-induced PBMCs proliferation.
Our findings suggest that cucurbit[7]uril can be a prospective nanocarrier for decreasing the toxicity of cytostatic drugs which also has its own immunomodulative effects.

P.B2.02.16

A lipid mediated paracrine signaling network stimulates tumor associated macrophage development in cancer and metastasis

V. Rai, *R. Ray;*
Institute of Life Sciences, Bhubaneswar-751023 India, Bhubaneswar, India.

Tumor microenvironment consist of dynamic interactions between tumor cells and the surrounding non-transformed cells. Inflammatory cells constitute a major population of the non-transformed cells. Tumor associated macrophages (TAMs), the predominant population of inflammatory cells have major roles in cancer progression and metastasis but the exact stimulus and triggers for the tumor cells-macrophage interaction remains unclear. Autotaxin or lysophospholipaseD (LysoPLD) catalyses the synthesis of lyophosphatidic acid - the smallest phospholipid from lysophosphatidylcholine by its enzymatic action. Autotaxin is implicated in breast cancer, ovarian cancer and many other cancers. Lysophosphatidic acid (LPA) is involved in numerous biological processes encompassing cell growth, cell proliferation, cell migration, cancer and metastasis. LPA effects are mediated on different cell types via its cognate G-protein coupled receptors (GPCRs) or non-receptor pathways.

Our recent study has shown that LPA converts monocytes into macrophages both in mice and humans and has an important role to play with immune cells. Here, we show that cancer cells in tumor growth are associated with tumor associated macrophages via a signature paracrine link. Our studies identify previously unknown signaling link between tumor cells and macrophages. Furthermore, we identify that suppression of this paracrine network can suppress tumor growth. This study suggests that inhibition of this paracrine network may act as a new therapeutic approach to control cancer and metastasis.

P.B2.02.17

Interest of NK cells to counteract resistance to target therapies in melanoma

***L. Rethacker**, A. Frazao, M. Avril, A. Caignard;*
INSERM, Paris, France.

Melanoma incidence is increasing for several decades and metastatic melanoma patients still have a poor prognosis. Since the identification of activating mutations in B-RAF in 50% of melanoma patients treatment with BRAF (vemurafenib) and then BRAF+MEK (cobimetinib) inhibitors is the first line treatment for patients bearing a tumor with a BRAF mutation. Despite high response rates of the development of resistance and relapse after a few months is frequent. To find the best combined treatment, we have investigated how resistance to these inhibitors interferes with melanoma cell immunogenicity to Natural Killer (NK) cells. From 3 BRAF mutated melanoma cell lines, we have generated vemurafenib resistant variants (R). Paired sensible (S) and R cells to vemurafenib displayed similar mutational profile, comparable cell growth kinetics and the growth of R variants is maintained in presence of vemurafenib. We found that the resistance to BRAF is associated to increased immunogenicity to NK cells. First, NK cell activation (degranulation and IFNγ production) is strongly increased in response to R cells. The lysis of R cells by NK cells was significantly increased. Compared to S cell lines, R variants displayed increased expression of NKG2D ligands (MICA, ULBP2), increased Fas, and TRAILR expression. The acquisition of resistance is associated to increased NK immunogenicity, increased TRAIL induced apoptosis. These findings outline the interest of combined target therapies and NK based immunotherapy for melanoma patients.

Utilization of high-frequency irreversible electroporation (H-FIRE) to modulate the tumor microenvironment and promote systemic immune system activation in breast cancer

***V. M. Ringel-Scaia**[1,2], S. L. Coutermarsh-Ott[2], R. M. Brock[1,2], K. E. Huie[2], N. Beitel White[3], M. F. Lorenzo[3], R. V. Davalos[3], I. C. Allen[1,2,4];*
[1]Graduate Program in Translational Biology, Medicine, and Health, Virginia Tech, Blacksburg, United States, [2]Department of Biomedical Sciences and Pathobiology, Virginia-Maryland College of Veterinary Medicine, Blacksburg, United States, [3]School of Biomedical Engineering and Sciences, Virginia Tech-Wake Forest University, Blacksburg, United States, [4]Department of Biomedical Science, Virginia Tech Carilion School of Medicine, Roanoke, United States.

Introduction: Breast cancer is among the most common malignancies in the US; 1 in 8 women will develop invasive breast cancer in her lifetime. Despite promising treatments for breast cancer, there is no cure once metastatic disease has developed. Thus, new therapeutics to address metastases are direly needed. High-frequency irreversible electroporation (H-FIRE) is a particularly novel and emerging therapeutic approach for tumor ablation. This technique utilizes a series of high-frequency bipolar electric pulses applied via electrodes inserted directly into the tumor to induce cancer cell death. Our overarching hypothesis predicts local treatment of the breast tumor with H-FIRE will stimulate both the innate and adaptive immune system, leading to systemic anticancer response and improved survival.
Materials and Methods: We utilized a mouse 4T1 mammary tumor model and applied H-FIRE to the primary tumor. We evaluated changes in the size of the primary tumor after treatment, as well as metastatic burden and gene expression in the primary tumor at the conclusion of the model.
Results: Here, we show H-FIRE treatment of the primary tumor results in near complete ablation and a shift in the tumor microenvironment from immunosuppressive to pro-inflammatory. Local H-FIRE treatment also significantly reduces 4T1 metastases in animals with an intact immune system, indicating increased engagement of a systemic anti-tumor immune response and improved activation of the adaptive immune system.
Conclusions: We anticipate this novel tumor ablation technology will improve conventional treatment strategies and complement emerging immunotherapy approaches targeting primary tumors and metastatic lesions.

P.B2.02.19

Serum pre-inflammatory cytokines TNF-a and IL-6 have higher predictive strength compared to metalloproteases and markers of tumor activity, bone metabolism and cell apoptosis in breast cancer patients with bone metastases.

*A. Notopoulos[1], **A. Sarantopoulos**[2], P. Notopoulos[3], K. Psarras[4], C. Likartsis[1], E. Alevroudis[1], I. Petrou[1], Z. Iconomou[1], G. Meristoudis[1], E. Zaromytidou[1], A. Doumas[5];*
[1]Department of Nuclear Medicine, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece, [2]2nd Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokration GHTH, Thessaloniki, Greece, [3]Neuroinformatics Laboratory, Technological Institute of Central Macedonia, Thessaloniki, Greece, [4]2nd Propedeutical Surgery Department, Aristotle University of Thessaloniki, Hippokration GHTH, Thessaloniki, Greece, [5]2nd Department of Nuclear Medicine, Aristotle University of Thessaloniki, AHEPA University GHTH, Thessaloniki, Greece.

Objective: To evaluate the predictive strength of 32 serum markers in breast cancer patients with bone metastases (BC+BM) under treatment.**Methods**: The serum level of all markers has been determined in 153 BC+BM patients (a) at their enrollment in the study, (b) one month later, and (c) after six months. We created a conventional "scan score" based on the number, size and metabolic activity of BM in the initial bone scintigraphy. Levels of p53, bcl-2, TRAIL, caspase-3, FasL, Fas, MMP-1, MMP-2, TIMP-1, DKK-1, OPG, RANKL, TRAP-5b, BAP and OPN were determined by an ELISA assay, while CEA, CA 15-3, TPA, CA 27.29, CYFRA 21-1, ICTP, PICP, PINP, PIIINP, PTHrP, IGF1, CT, OC, TNFαand IL-6 were assayed by radiometric methods. The clinicopathological characteristics and serum markers were compared among the subgroups identified either on the basis of the scan score (S1, S2, and S3) or of the disease outcome (A1-recession or stability, A2-deterioration). **Results**: S1 score was observed in 81 (52.94%) patients, S2 in 49 (32.03%) patients and S3 in the remaining 23 (15.03%) patients. A1 subgroup included 107 (69.93%) patients and 46 (30.07%) patients belonged to subgroup A2. IL-6, bcl-2 p53, MMP2 and OPG/RANKL ratio efficiently reflected the extent and severity of the initial skeletal involvement. TNFa, IL-6, p53, MMP2, and TRAP had the higher predictive strength being significantly lower in all measurements in patients with subsequent disease remission or stabilization. **Conclusion**: The proinflammatory cytokines IL-6 and TNFa help to predict more accurately BC+BM subgroups' clinical behavior.

Gene expression in correlation to the cancer/testis antigen histone H2A family member B (H2AFB)

*L. I. Ohm, **M. S. Staege**;*
1Department of Surgical and Conservative Paediatrics and Adolescent Medicine, Halle, Germany.

The cancer/testis antigen H2AFB is a non-canonical histone variant of H2A. In our previous studies we observed high expression of H2AFB in Hodgkin lymphoma (HL) cells with very high expression in the chemotherapy resistant cell lines L-1236 and L-428. For further analysis of H2AFB we cloned H2AFB from Hodgkin lymphoma cells into a GFP fusion-protein expression vector. H2AFB-GFP showed an in-homogeneous enrichment in the nucleus of transfected cells. During mitosis H2AFB-GFP appeared to be partly associated with chromatin. H2AFB is known to be associated with transcriptional active chromatin. Therefore, we performed DNA microarray analysis of transgenic cells and identified H2AFB-regulated genes. Microarray data suggest that H2AFB over-expression induces an anti-apoptotic gene expression profile characterized by regulation of genes like programmed cell death protein 4 (PDCD4), BCL2 interacting protein 3 (BNIP3), Bcl-2-associated transcription factor 1 (BCLAF1; all down-regulated by H2AFB-GFP), and protein phosphatase 1 regulatory subunit 13 like (PPP1R13L; up-regulated by H2AFB-GFP). However, analyses of chemotherapy sensitivity showed no difference between H2AFB-transgenic cells in comparison to control cells. Similarly, transgenic expression of H2AFB-GFP had no impact on cell cycle progression. Interestingly, the expression of human endogenous retroviruses (HERV) families K and F is positively correlated with the expression of H2AFB in HL cells. Reactivation of HERV-like sequences in Hodgkin lymphoma has been described before. It seems likely that the high expression of the cancer/testis antigen H2AFB in HL cells and reactivation of endogenous retrovirus-like sequences are induced by a common mechanism leading to relaxation of gene regulation.

P.B2.02.21

The bridge between tumor-associated glycans and the anti-tumor immune response

***A. Zaal**, E. R. Li, J. Lübbers, Y. van Kooyk, S. J. van Vliet;*
VUmc university medical center, Amsterdam, Netherlands.

Many colorectal tumors display alterations in biosynthetic pathways of glycosylation, resulting in increased expression of specific tumor-associated glycan structures. Expression of these altered glycan structures is associated with metastasis and poor prognosis. Antigen presenting cells can recognize tumor-associated glycan structures, including the truncated O-glycan Tn antigen, via specific glycan receptors. Tn-antigen-mediated activation of the MGL receptor on dendritic cells, for example, induced regulatory T cells via the enhanced secretion of IL-10. Although these findings indicate that the expression of tumor-associated glycans modulates the anti-tumor immune response, the impact of these glycans on dendritic cells is still not fully understood. To investigate the impact of tumor-associated glycans on antigen presenting cells, RNA sequencing analysis was performed on human monocyte-derived dendritic cells stimulated with various tumor-associated glycans, including MGL ligands. GO term enrichment analysis of the differently expressed genes upon MGL ligation revealed an enrichment for genes involved in T cell differentiation. In addition, MGL ligation decreased gene expression of enzymes involved in glycolysis.
Since decreased glycolytic activity corresponds with a more regulatory function of antigen presenting cells, these data imply that MGL ligation reduces the anti-tumor immune response. Currently, we are further investigating the effect of MGL activation on metabolic changes in dendritic cells and subsequent T cell activation. Overall, our findings highlight the impact of tumor-associated glycans on anti-tumor immune responses and will increase our understanding of immune regulation by tumor-associated glycans.

P.B2.03.01

HHLA2 (B7H7) is highly expressed in human hepatocellular carcinoma cells and is associated with better patient survival

P. P. Boor[1], *K. Sideras*[1], *K. Biermann*[1], *J. Verheij*[2], *B. Takkenberg*[3], *S. Mancham*[1], *G. Zhou*[1], *Q. Pan*[1], *K. Tran*[1], *U. Beuers*[3], *T. M. van Gulik*[2], *J. N. IJzermans*[1], *M. J. Bruno*[1], *X. Zang*[4], *D. Sprengers*[1], *J. Kwekkeboom*[1];
[1]*ErasmusMC, Rotterdam, Netherlands,* [2]*University of Amsterdam, Amsterdam, Netherlands,* [3]*Tytgat Institute for Liver and Intestinal Research, Amsterdam, Netherlands,* [4]*Albert Einstein College of Medicine, New York, United States.*

Introduction: HHLA2 is a member of the B7-family and is thought to function predominantly as a T-cell co-inhibitory molecule. We assessed the expression of HHLA2 in hepatocellular carcinoma (HCC) and determined its relation to patient survival. Method: Tissue-microarrays with HCC tumors and tumor-free liver (TFL) tissues were immunohistochemically stained with an antibody against HHLA2 (clone: 566.1) and scored as negative, weak, intermediate, or strong expression. FACS-analysis of single cells isolated from freshly isolated tumors was used to further characterize HHLA2 expression. Results: In 27.8% of patients HHLA2-expression was absent on tumor cells, while 15.5% had weak expression, 37.1% had intermediate expression, and 19.6% had strong expression on tumor cells (n=194). Absent or weak tumor expression of HHLA2 was associated with poorer HCC-specific patient survival compared with intermediate or strong HHLA2 expression (average 72 versus 95 months; p=0.002). HHLA2 expression was predictive of HCC-specific survival independent of baseline clinicopathologic characteristics, like liver cirrhosis, alfa-feto protein serum level, tumor size, and number of lesions (HR 0.43; P=0.004). There was no association between HHLA2 expression in TFL tissues and patient survival. FACS analysis showed that HHLA2 was also expressed on $CD19^-$ $BDCA1^+$ myeloid dendritic cells and $CD14^+$ cells in tumors. Conclusion: Tumor cell expression of HHLA2 was observed in most HCC patients and is associated with better HCC-specific survival. HHLA2 expression in tumors may be induced in response to immunologic pressure, which may explain the positive association with prolonged survival.

Introduction: The study of the immune surveillance in the tumour microenvironment is leading to the development of new biomarkers and therapies. This research focuses on analysing *CD5* and *CD6* expression, two lymphocyte surface markers involved in TCR tuning, as potential prognostic biomarkers in resectable stages of Non-Small Cell Lung Cancer (NSCLC).
Materials and Methods:*CD5* and *CD6* gene expression were analysed by RTqPCR in 201 paired fresh frozen tumour and normal tissue samples of resected NSCLC. The Cancer Genome Atlas (TCGA) database was used to obtain an independent validation patient cohort. Prognostic value was assessed by Cox regression and Kaplan-Meier curves (log rank-test), considering significant $p < 0.05$.
Results: Local cohort consisted mainly of men, current or former smokers, with good performance status (PS=0). Patients with higher *CD5* expression had significantly increased overall survival (OS, 53.3 vs NR months, p = 0.011). Multivariate analysis allowed establishment of *CD5* expression as an independent prognostic biomarker for OS in early stages of NSCLC [HR=0.539; 95% CI, 0.329-0.883; p=0.014]. Further survival analysis of 97 patients from TCGA database, containing gene expression data for normal and tumoral tissue samples, confirmed high expression levels for both *CD5* and *CD6* as of prognostic value for relapse-free survival (34.98 vs 75.57 months, p=0.033; 25.31 vs 75.57 months, p=0.020, respectively) and OS (40.49 vs 77.97 months, p=0.038; 39.02 vs 77.97 months, p=0.034, respectively).
Conclusions: The present data support *CD5* expression level as a novel independent prognostic marker in resectable NSCLC.

P.B2.03.03

Identifying a novel role for fractalkine in T cell accumulation in the visceral adipose tissue of obesity-associated cancer patients.

M. J. Conroy[1], *A. Melo Rodriguez*[1], *S. Maher*[1], *S. L. Doyle*[2], *E. Foley*[1], *N. Ravi*[3], *J. V. Reynolds*[3], *A. Long*[1], *J. Lysaght*[1];
[1]*Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland,* [2]*Dublin Institute of Technology, Dublin, Ireland,* [3]*St. James's Hospital, Dublin, Ireland.*

The global health burden of obesity continues to rise, resulting in increased incidence of associated morbidities. We have previously reported the importance of T cells in obesity-associated inflammation and demonstrated their active migration to the visceral adipose tissue (VAT) of patients with the obesity-associated malignancy, oesophageal adenocarcinoma (OAC). Furthermore, we have reported that chemokine receptor antagonism can significantly reduce such T cell migration to the VAT and may have therapeutic potential to ameliorate pathological inflammation in obesity and obesity-associated cancer. Here, we show that the inflammatory chemokine fractalkine (CX3CL1) is enriched in the VAT of OAC patients. Furthermore, our *ex vivo* demonstration of fractalkine-driven migration of OAC-derived T cells, suggests that this chemokine plays a role in T cell recruitment to VAT in OAC. Interestingly, surface expression of the fractalkine receptor CX3CR1 by high expressing circulating $CD8^+$ T cells is endocytosed but not degraded upon encountering fractalkine. We also show that such fractalkine-mediated endocytosis of CX3CR1 is accompanied by enhanced surface expression of ICAM-1 and L-Selectin on peripheral blood-derived $CD8^+$ T cells. Interestingly, our analyses identified these molecules in their soluble form among the most prevalent soluble adhesion molecules in the VAT of OAC patients suggesting that an abundance of fractalkine in VAT serves in T cell adhesion as well as T cell recruitment to this tissue in OAC patients. For the first time, these findings identify fractalkine as a potential therapeutic target to release inflammatory and cytotoxic T cells from the VAT and attenuate obesity-associated inflammation in OAC.

P.B2.03.04

Complete tumor desialylation drives tumor growth through hampered $CD8^+$ T cell cytotoxicity

L. A. M. Cornelissen, *A. Blanas, J. C. Van der Horst, L. Kruijssen, A. Zaal, T. O'Toole, Y. Van Kooyk, S. J. Van Vliet;*
VU University Medical Center, Amsterdam, Netherlands.

The tumor microenvironment is immunosuppressive, allowing tumor cells to escape from immune attack. Tumor cells generally display an aberrant glycosylation profile, amongst others characterized by an overexpression of sialylated structures. Sialic acids (Sias) are recognized by Siglec receptors, most of which are immune inhibitory receptors. Therefore, we hypothesized that Sias play a crucial role in suppressing anti-tumor immunity. Indeed, we have previously shown that Sia^{low} melanoma tumor cells, expressing reduced level of Sias on the cell surface, exhibited delayed *in vivo* growth due to an augmented effector T cell response. However, the role of Sia on other tumor types than melanoma and the effect of complete cancer cell desialylation on the anti-tumor immune response has never been studied. To generate Sia^{neg} glycovariants, we selected the mouse colorectal cancer cell line MC38 and desialylated the cells with the use of CRISPR/Cas9. Interestingly, the MC38-Sia^{neg} tumor cells displayed enhanced growth *in vivo* compared to their mock-transfected counterparts. Strikingly, MC38-Sia^{neg} tumors contained less $CD8^+$ T cells and these $CD8^+$ T cells had a reduced activation state. In an *in vitro* tumor killing assay MC38-Sia^{neg} tumor cells were less efficiently killed by activated cytotoxic T cells. Together our results indicate that a loss of Sias in colorectal cancer hampers $CD8^+$ T cell cytotoxicity. In conclusion, we show for the first time that complete desialylation drives tumor growth, which greatly impacts the design of novel cancer therapeutics aimed at targeting the tumor glycosylation profile.

P.B2.03.05

DNGR-1 as a Dendritic Cell-Specific Checkpoint in Antitumor Immunity

F. J. Cueto[1], *C. del Fresno*[1], *P. Brandi*[1], *A. Combes*[2], *A. R. Sánchez-Paulete*[3], *M. Enamorado*[1], *R. Conde-Garrosa*[1], *I. Melero*[4], *M. F. Krummel*[2], *D. Sancho*[1];
[1]*Spanish National Center for Cardiovascular Research, Madrid, Spain,* [2]*University of California San Francisco, San Francisco, United States,* [3]*Center for Applied Medical Research (CIMA), Pamplona, Spain,* [4]*IdISNA, CIMA and University Clinic, University of Navarra, Pamplona, Spain.*

Classical type 1 dendritic cells (cDC1s) are pivotal to antitumor immunity and their infiltration in tumors associates with better prognosis. DNGR-1 is a dead cell-sensing receptor highly restricted to cDC1s, but its role in antitumor immunity has not been clarified yet. Here, we found that DNGR-1 absence did not affect cross-presentation of tumor-associated antigen, tumor growth or responsiveness to anti-PD-1 treatment. However, Flt3L-expressing B16 melanoma showed delayed tumor growth in DNGR-1-deficient mice. Indeed, treatment of mice with systemic Flt3L in DNGR-1-deficient mice led to improved antitumor immunity. Enhanced antitumor immunity in the absence of DNGR-1 was T cell-dependent and correlated with increased infiltration of cDC1s within B16F10 tumors. Absence or blockade of DNGR-1 in the presence of Flt3L resulted in increased expression of CCR7 on cDC1s but not on cDC2s. These results correlated with the analysis of TCGA data from patients with different cancers, which indicates a strong association between the expression of CCR7 ligands CCL19 and CCL21 with cDC1 infiltration. Our data show that blockade of DNGR-1 signaling promotes cDC1 infiltration within tumors in the presence of Flt3L, suggesting CCR7 upregulation as a potential mechanism.

Exploring the effectsof systemic and local immunity on tumour regression grade in oesophagealadenocarcinoma

***M. R. Dunne**, E. K. Foley, J. V. Reynolds, J. O'Sullivan;*
Trinity Translational Medicine Institute, Dublin, Ireland.

Oesophageal adenocarcinoma (OAC) is an aggressive malignancy, with a 5 year survival of <15%, and incidence is rapidly rising in the Western world. Although multi-modal neoadjuvant chemotherapy and chemoradiotherapy (neo-CT) approaches have significantly improved survival outcome, this only occurs for a minority of patients, and it is currently not possible to predict which patients will respond to treatment.
This study explored the association between 54 circulating immune, vascular and angiogenic markers, and patient response to neo-CT treatment. Serum was taken from n=80 treatment-naive OAC patients levels of circulating markers were quantified using multiplex ELISA technology. Markers assessed encompassed key inflammatory cytokines, chemokines, angiogenic factors and markers of vascular injury. The concentration of circulating markers was compared with tumour regression score (Mandard grade 1-5), collapsed into a 3 tier system.
Levels of CCL4, a chemoattractant for natural killer cells and monocytes, were significantly lower in patients with a poor response to treatment ($p<0.001$), while levels of angiogenic factor Tie-2 were significantly higher in poor responders ($p<0.05$), when compared to patients who experienced complete or partial responses. Future work will compare these circulating marker profiles with other clinical features, e.g. survival time, tumour stage, nodal status and level of immune cell infiltration into tumour biopsies.

P.B2.03.07

Mechanism of the effects of cancer associated fibroblasts on the functional changes observed in T cells

***G. Gunaydin**, D. Guc;*
Hacettepe University Cancer Institute, Ankara, Turkey.

Fibroblasts, turn into cancer associated fibroblasts (CAFs) and myofibroblasts in the tumor microenvironment. Tissue fibroblasts have previously been shown to affect T lymphocyte functions. CAFs were reported to show immunosuppressive effects similar to fibrocytes. They also display similar phenotypic and functional characteristics to the circulating fibrocytes, which were reported to represent a unique MDSC subset. However, studies investigating the underlying mechanisms responsible for such effects of CAFs on T cells are limited in the literature. The scope of this study is to determine the role of tumor stromal fibroblasts on the alterations in T cell effector functions. For this reason, CAFs were isolated from tumors generated by a rat chemical breast carcinoma model.
PBMCs were cocultured with either normal-fibroblasts or CAFs and proliferations of PBMCs were assessed by CFSE assays. Surface and intracellular expressions of immune activation markers of T lymphocytes cocultured with CAFs were analyzed with flow cytometry. Breast cancer associated CAFs were shown to decrease proliferations of splenocytes in cocultures. CAFs also decreased the protein expressions of activation markers of T cells. In addition, splenocytes cocultured with CAFs were found to have decreased expression levels of genes associated with cellular activation and effector functions. The alterations in T cells in terms of gene and protein expression levels have been shown via phenotypical and functional analyses. This study helps elute the mechanisms of the effects of cancer associated fibroblasts on the functional changes observed in T cells in the tumor microenvironment.

V-set and immunoglobulin domain-containing 4 (VSIG4) expressed on macrophages suppressed anti-tumor immune responses in myelodysplastic syndromes

***M. Ishibashi**[1], H. Tamura[2], I. Choi[3], H. Takahashi[1];*
[1]Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan, [2]Department of Hematology and, Nippon Medical School, Tokyo, Japan, [3]Department of Microbiology and Immunology, Inje University College of Medicine, Busan, Korea, Republic of.

Introduction: Myelodysplastic syndromes (MDS) are a group of hematologic malignancies, and MDS blast cells increase clonal proliferation during the disease-progression process, while immune cells in the bone marrow microenvironment become less efficient. V-set and immunoglobulin domain-containing 4 (VSIG4) molecule is a new B7 family related protein and a strong negative regulator of T-cell proliferation. However, the role of VSIG4 in tumors remains unknown. Thus we investigated the expression and functions of VSIG4 in MDS. **Methods:** The expression of VSIG4 was analyzed using flow cytometry (FCM) in MDS cell lines and bone marrow samples from patients. The proliferative potential was examined by BrdU incorporation using FCM. The antibody-dependent cellular cytotoxicity (ADCC) of a natural killer (NK) cell line was determined by measuring LDH activity. The production of IFN-γ from donor T cells was measured in cell culture supernatants using ELISA. **Results:** Cell-surface VSIG4 expression was highly expressed on macrophages, especially tumor-associated macrophages, but not on $CD34^+$ blasts (tumor cells) in patients with MDS and AML transformed from MDS (AL-MDS). Furthermore, high expression of VSIG4 was detected on monoblasts (tumor cells) from patients with chronic myelomonocytic leukemia. $VSIG4^+$ MDS cells had higher proliferative potential than $VSIG4^-$ cells. CD45-mediated ADCC activity of NK cells was inhibited in VISG4-expressing MDS cells in comparison with controls. Moreover, the production of IFN-γ from donor T cells co-cultivated with $VISG4^+$ MDS cells was decreased compared with $VISG4^-$ cells. **Conclusions:** Our results revealed that VSIG4 expressed on macrophages and monoblasts suppresses antitumor immune responses.

P.B2.03.09

Phenotypic and functional analysis of peripheral blood, healthy mucous and tumour lymphoid populations of patients with gastric adenocarcinoma

***I. Juarez**[1], A. Gutierrez-Calvo[2], A. Blazquez[2], E. Ovejero[2], I. Laso[2], A. Lopez[2], R. Gomez[2], J. M. Martin-Villa[1];*
[1]Universidad Complutense de Madrid, Dpt. of Immunology, Madrid, Spain, [2]Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Madrid, Spain.

The presence of infiltrating lymphocytes in the tissue is a good prognostic factor in gastric cancer, although there are few functional data.
We studied PBL, as well as healthy and tumoral mucose lymphocytes (HML/TML) of 6 patients with gastric adenocarcinoma. Tissue explants were grown for 20 days in cDMEM with 1000 U/ml IL-2, and HML and TML were thus obtained.
PBL showed a significant increase in PD-1+ cells in gastric cancer patients compared to controls (27.5% and 11.6%, respectively, $p<0.0001$). No differences were found in the number of CD8+ cells, although CD8 expression was significantly lower in gastric cancer patients' PBL (392.8) compared to controls (625.1; $p=0,0169$). A higher frequency of PD1+ cells were found at a higher frequency in TMLs and HMLs than PBL (52.9% $p<0.01$).
In patients, a large dispersion in TML, but not HML, CD8+ cells were found (27.7%±11.8; 41.8%±3.3). FCM data were confirmed by IHC CD8 staining. These differences may be due to a defect in the IFN-γ mediated CD8 cell recruitment and activation within the tumor environment.
Lymphocytes were stimulated with PMA-ION and the production of IFN-γ was quantified by FCM. In two of the three patients analyzed, detectable amounts of IFN-γ were found, either in PBL-CD8+, HML-CD8+ or HML-CD8+. In the patient in whom no TML-CD8+ were detected, the number of CD8+ cells producing IFN-γ in PBL and LMS is very low (18.1% and 1.9% respectively). These data suggest that intrinsic defects in IFN-mediated activation-γ may limit CD8 cell response in gastric cancer.

P.B2.03.10

Increased *Δ133TP53β* in glioblastoma: an alternative to p53 mutation in promoting brain tumor progression

***M. Kazantseva**[1,2], R. A. Eiholzer[1], S. Mehta[1,2], A. Taha[3], S. Bowie[1], I. Roth[1], J. Zhou[1,3], S. M. Joruiz[4], M. A. Baird[1], N. A. Hung[1], T. L. Slatter[1,2], A. W. Braithwaite[1,2];*
[1]University of Otago, Dunedin, New Zealand, [2]Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand, [3]Southern District Health Board, Dunedin, New Zealand, [4]University of Dundee, Dundee, United Kingdom.

The p53 (*TP53* gene) is a powerful suppressor of cancer. In contrast, the p53 isoform, Δ133p53 is increased in cancers that are more aggressive and those with a poorer response to treatment. As Δ133p53 isoforms have tumor promoting migration and inflammatory properties this study investigated if Δ133p53 contributed to brain tumor (glioblastoma) progression.
The expression of *full-length TP53* and six *TP53* mRNA variants were quantitated by real time-quantitative PCR in 89 glioblastomas and correlated with tumor associated macrophage content, various other immune cell markers and whether the tumors had wild-type or mutant p53. Hypoxic areas in glioblastoma tissue were detected with carbonic anhydrase nine staining and *Δ133TP53β* expression using RNAscope. To determine if Δ133p53β could contribute to the temozolomide resistance and/or promote cell survival in response to oxidative stress, 10.1 cells expressing a murine 'mimic' of Δ133p53 (Δ122p53) were treated with temozolomide or *tert*-butyl hydroperoxide, respectively.
Elevated levels of *Δ133TP53β* mRNA characterized glioblastomas with increased CD163 positive macrophages and wild-type p53. We found *Δ133TP53β* expression was localized to cancer cells in areas with increased hypoxia, and in stromal cells with *CCL2* expression. Tumors with increased *Δ133TP53β* had increased numbers CSF1R and PDL1 positive cells. In addition, cells expressing Δ122p53 were resistant to temozolomide treatment and oxidative stress; suggesting Δ133p53β could reduce the sensitivity to temozolomide and promote cell survival under oxidative stress.
We show elevated *Δ133TP53β* aids tumor progression by promoting an immunosuppressive and chemoresistant environment. This study suggests a role for hypoxia signalling in the regulation of *Δ133TP53β* expression.

P.B2.03.11

In vivo suppression of murine tumour growth through CD8+CTL via activated DCs by sequential administration of alpha-galactosylceramide

H. Kogo[1,2,3]*, M. Shimizu*[1]*, Y. Negishi*[1]*, H. Takahashi*[1]*;*
[1]*Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan,* [2]*Department of Gastrointestinal and Hepato-Biliary-Pancreatic Surgery, Nippon Medical School, Tokyo, Japan,* [3]*Department of Surgery, Kitamurayama Hospital, Yamagata, Japan.*

Tumour immunity is largely attributed the effective priming and activation of tumour-specific class I MHC molecule-restricted CD8+ CTLs. CD205+ DCs can cross-present the epitopes of captured tumour antigens associated with class I MHC molecules alongside co-stimulatory molecules to prime and activate tumour-specific CD8+ CTLs. Immunosuppressive tolerogenic DCs with reduced co-stimulatory molecules may be a cause of impaired CTL induction. Hepa1-6-1 cells were established from the murine hepatoma cell line Hepa1-6; these cells grow continuously after subcutaneous implantationinto syngeneic B6 mice and do not prime CD8+ CTLs. In thisresearch, we show that the growth of ongoing tumours was suppressed by activated CD8+ CTLs with tumour-specific cytotoxicity through the administration of alpha-GalCer, which is a glycolipid known to stimulate iNKT cells and selectively activate CD205+ DCs. Moreover, we demonstrated thatsequential repetitive intraperitoneal inoculation with alpha-GalCer every 48 hours appeared to convert tolerogenic CD205+ DCs into immunogenic DCs with a higher expression of co-stimulatory molecules and a stronger cross-presentation capacity, which primed CTL precursors and induced tumour-specific CD8+ CTLs within the tumour environment without activating iNKT cells. These findings provide a new method for cancer immunotherapy to convert tolerogenic CD205+ DCs within tumours into immunogenic DCs through the sequential administration of an immuno-potent lipid/glycolipid, and then activated immunogenic DCswith sufficient expression of co-stimulatory molecules prime and activate tumour-specific CD8+ CTLs within the tumour to suppress tumour growing.

P.B2.03.12

Abrogation of the immunosuppressive tumor microenvironment in cholangiocarcinoma by targeting PD-1 or GITR

G. Zhou, D. Sprengers, R. Erkens, S. Mancham, M. Doukas, L. Noordam, P. P. Boor, R. W. van Leeuwen, B. Groot Koerkamp, W. G. Polak, J. de Jonge, J. N. IJzermans, M. J. Bruno, ***J. Kwekkeboom****;*
Erasmus MC - University Medical Centre, Rotterdam, Netherlands.

Cholangiocarcinoma (CCA) is an aggressive malignancy of the biliary tract. CCA-patients generally present with advanced disease for which no curative treatment is available. Whether CCA is responsive to immune checkpoint antibody therapy is unknown, and little is known about the tumor immune microenvironment of CCA. We characterized tumor-infiltrating lymphocytes (TIL) isolated from freshly resected CCA tumors, determined their expression of co-signaling molecules, and assessed the effects of targeting these molecules on TIL functions in *ex vivo* assays. TIL contained lower proportions of CD8+ T cells, NKT cells and NK cells and higher proportions of CD4+Foxp3+ regulatory T cells (Treg) than lymphocytes isolated from tumor-free liver tissues (TFL) of the same patients. Immunohistochemistry showed that the majority of CD8+ and CD4+ T cells were sequestered at the tumor margin, while Treg accumulated in the tumors. Tumor-infiltrating CD8+ T cells showed reduced expression of the cytotoxic molecules perforin and granzyme compared to those in TFL and blood.
Co-stimulatory receptor GITR as well as co-inhibitory receptors PD-1 and CTLA4 were over-expressed on tumor-infiltrating T cells compared with T cells in TFL and blood. PD-L1, CD86 and CD80 were expressed on antigen-presenting cells in tumors, but GITR ligand not. Antagonistic targeting of PD-1 with nivolumab or agonistic targeting of GITR with GITR-ligand enhanced granzyme B and effector cytokine production and/or T cell proliferation in *ex vivo* stimulations of TIL with CD3 and CD28 antibodies. **Conclusions:** The tumor microenvironment in CCA is immunosuppressive. PD-1 and GITR are potentially promising targets for immunotherapy of CCA patients.

P.B2.03.13

Bone marrow endothelial cells sustain a tumor-specific CD8$^+$T cell subset with suppressive function in myeloma patients

P. Leone*, G. Di Lernia, D. Giannico, A. G. Solimando, A. Vacca, V. Racanelli;*
University of Bari Medical School, Bari, Italy.

Endothelial cells (EC) line the bone marrow microvasculature and are in close contact with CD8$^+$ T cells that come and go across the permeable capillaries. Because of these intimate interactions, we investigated the capacity of EC to act as antigen-presenting cells (APC) and modulate CD8$^+$ T cell activation and proliferation in bone marrow of patients with multiple myeloma (MM) and monoclonal gammopathy of undetermined significance. We found that EC from MM patients show a phenotype of semi-professional APC given that they express low levels of the co-stimulatory molecules CD40, CD80 and CD86, and of the inducible co-stimulator ligand (ICOSL). In addition, they do not undergo the strong switch from immunoproteasome to standard proteasome subunit expression which is typical of mature professional APC such as dendritic cells. EC can trap and present antigen to CD8$^+$ T cells, stimulating a central memory CD8$^+$ T cell population that expresses Foxp3 and produces high amounts of IL-10 and TGF-β. Another CD8$^+$ T cell population is stimulated by professional APC, produces IFN-γ, and exerts antitumor activity. Thus, two distinct CD8$^+$ T cell populations coexist in the bone marrow of MM patients: the first population is sustained by EC, expresses Foxp3, produces IL-10 and TGF-β, and exerts pro-tumor activity by negatively regulating the second population. This study adds new insight into the role that EC play in MM biology and describes an additional immune regulatory mechanism that inhibits the development of antitumor immunity and may impair the success of cancer immunotherapy.

P.B2.03.14

MESENCHYMAL STROMAL CELL SIALYATION ENHANCES T LYMPHOCYTE IMMUNE SUPPRESSION

K. Lynch[1]*, M. O'Dwyer*[1]*, A. Ryan*[1,2]*, T. Ritter*[1]*;*
[1]*Regenerative Medicine Institute (REMEDI), College of Medicine, Nursing & Health Sciences, National University of Ireland, Galway, Galway, Ireland,* [2]*Discipline of Pharmacology, College of Medicine, Nursing & Health Sciences, National University of Ireland, Galway, Galway, Ireland.*

Introduction: Little is known about the mechanisms of immune modulation mediated by mesenchymal stromal cells (MSC) in the tumour micro-environment (TME). Aberrant glycosylation is a hallmark of cancer cells, playing an important role in tumour progression. Here we sought to investigate if regulation of MSC sialylation alters their ability to inhibit T-cell function in an inflammatory micro-environment, characteristic of the TME.**Methods:**MSC were treated with both tumour necrosis factor alpha (TNF-α) and interleukin 1 beta (IL-1β) (i-MSC) for 72 hours and the sialic acid levels were analysed by flow cytometry. MSC and i-MSC were co-cultured in MSC-lymphocyte co-cultures for 96 hours. T-cell proliferation, activation, death and differentiation were determined by flow cytometry. Both MSC and i-MSC were pre-treated with a sialyltransferase inhibitor (3FaxNeu5Ac) for 72 hours prior to TNF-α and IL-1β stimulation and co-cultured with lymphocytes. **Results:**i-MSC displayed phenotypical changes. i-MSC displayed increased levels of both α2-3/α2-6 linked sialic acid when compared to MSC. i-MSC displayed an enhanced ability to inhibit the proliferation of lymphocytes when compared to MSC alone. i-MSC inhibited the proliferation of stimulated CD4+/CD8+ lymphocytes. Following sialyltransferase inhibition, i-MSC lost the ability to suppress both CD4+/CD8+ lymphocytes resulting in significant restoration of lymphocyte proliferation. Sialic acid expression on the cell surface correlated with both CD4+/CD8+ lymphocyte suppression.**Conclusions:** Our findings confirm that inflammation induces MSC sialylation and enhances their ability to suppress activated lymphocytes. We suggest that understanding the importance of MSC sialylation is likely to lead to the identification of a new molecular target.

P.B2.03.15

Clinical relevance of intratumoral dendritic cells in neuroblastoma

O. Melaiu[1,2]*, M. Chierici*[3]*, V. Lucarini*[1]*, M. Compagnone*[1]*, G. Zicchedda*[1]*, G. Jurman*[3]*, R. Boldrini*[1]*, C. Furlanello*[3]*, F. Locatelli*[1]*, D. Fruci*[1]*;*
[1]*Ospedale Pediatrico Bambino Gesù, Rome, Italy,* [2]*University of Pisa, Pisa, Italy,* [3]*Fondazione Bruno Kessler, Trento, Italy.*

Introduction: The prognostic value of tumor-infiltrating T lymphocytes (TILs) has been demonstrated in several human cancers. Recently, we have shown that TILs have a prognostic value greater than, and independent of the criteria currently used to stage neuroblastoma. We defined an immunoscore based on the presence of different T-cell subsets that associates with favorable clinical outcome in MYCN-amplified tumors. We also demonstrated that the combined PD-L1 and HLA class I tumor cell density represents a novel prognostic biomarker for neuroblastoma patients. Here we sought to further dissect the neuroblastoma microenvironment, evaluating density of infiltrating dendritic cells (iDC), macrophages and NK cells. Moreover, we tested whether immune gene profiling of neuroblastoma could identify novel prognostic and therapeutic targets for these patients.
Methods: *In situ* immunohistochemical staining for CD141, CD163 and NKp46 was assessed in 104 neuroblastoma specimens and correlated with clinical outcome. Gene expression profiling using Nanostring nCounter Immune panel was also performed in 36 neuroblastoma samples. Publically available datasets were used to validate the results.
Results: High density of iDCs, macrophages and NK cells was correlated with the presence of TILs, tumor HLA class I expression and favorable clinical outcome, suggesting their potential role in controlling tumor development. These data were confirmed by gene expression profiling analyses. Clustering analysis revealed the existence of distinct expression profiles in high- and low-risk neuroblastomas.
Conclusions: These results may provide a rationale for improving risk stratification of patients and addressing towards a more targeted therapy.

P.B2.03.16

The balance between activated follicular helper T-cells and follicular regulatory T-cells infiltrating human breast cancer guides anti-tumor immune responses

G. Noel[1], *M. Langouo*[1], *S. Garaud*[1], *G. Van den Eynden*[2], *A. Boisson*[1], *H. Duvillier*[3], *D. Larsimont*[4], *K. Willard-Gallo*[1];
[1]*Molecular Immunology Unit-Institut Jules Bordet-ULB, Bruxelles, Belgium,* [2]*Anatomical Pathology Department-GZA Hospital Sint-Augustinus, Antwerp, Belgium,* [3]*Flow Cytometry Core Facility-Institut Jules Bordet-ULB, Bruxelles, Belgium,* [4]*Anatomical Pathology Department-Institut Jules Bordet-ULB, Bruxelles, Belgium.*

The recent success of immunotherapy highlights the importance of then immune response in cancer treatment. In human breast cancer (BC), tumor infiltrating lymphocytes (TIL) can organize in tertiary lymphoid structures (TLS) in the stroma. We have shown that CXCL13, a B-cell chemoattractant, is involved in TLS formation and associated with positive clinical outcomes. The present study investigated how TLS functionally contributes to immune responses in human BC.
We used fresh primary breast tissues to prepare primary tumor supernatants for immunoglobulin analysis and TIL for flow cytometric analysis and sorting. Matched formalin-fixed paraffin-embedded tissues were used for TIL and TLS scoring and organization.
CXCR5, the CXCL13 receptor, is expressed on infiltrating B-cells, $CD4^+$ T-cells [follicular helper T (Tfh) cells] and interestingly a $CD8^+$ T-cell subpopulation. All of these $CXCR5^+$ TIL co-localize in TLS, but only $ICOS^+PD\text{-}1^+$ Tfh TIL express high levels of *BCL6*, *IL21*, *CXCL13* and *IFNG* mRNA and functionally help B-cell differentiation *in vitro*. $ICOS^+PD\text{-}1^+$ Tfh TIL are also correlated with activated $CD8^+$ TIL in tumor tissues and IgG in tumor supernatants. Follicular regulatory T-cells (Tfr), express GARP, a sign of active TGFβ, within TLS. The Tfh/Tfr ratio is significantly correlated with IgG but also with IgA and IgM production suggesting that the balance between effector and regulatory Tfh TIL influence TLS activities.
Activated $ICOS^+PD\text{-}1^+$ Tfh and $GARP^+$ Tfr TIL are major players in TLS functionality, regulating anti-tumor immune responses and likely playing an important role in the response to immunotherapy.

P.B2.03.17

Stromal cell PD-L1 inhibits CD8 T cell anti-tumour immune response and promotes colon cancer

G. O'Malley[1], *O. Treacy*[1], *K. Lynch*[1], *S. Naicker*[1], *P. Lohan*[1], *P. Dunne*[2], *T. Ritter*[1], *L. J. Egan*[1], ***A. E. Ryan***[1];
[1]*National University of Ireland, Galway, Galway, Ireland,* [2]*Queens University Belfast, Belfast, Ireland.*

Stromal cells of mesenchymal origin reside below the epithelial compartment and provide structural support in the intestine. These intestinal stromal cells interact with both the epithelial cell compartments as well as infiltrating hematopoietic immune cells, however, little is known about their function and phenotype in the inflammatory tumour microenvironment. Using a syngeneic immunogenic colorectal cancer model, we show that TNF-α initiated inflammatory signalling in CT26 colorectal cancer cells selectively induces PD-L1 expression in stromal cells. Stromal cell PD-L1 potentiates enhanced immunosuppression, characterised by inhibition of $CD8^+$ granzyme B-secreting T cells and, consequently, enhanced tumour progression. To confirm a definitive role for stromal cell PD-L1 in the suppression of T cell proliferation and activation, we targeted the PD-1/PD-L1 signalling axis using a monoclonal blocking antibody to the PD-1 receptor. We observed high PD-1 expression on CD4+ and CD8+ T cells and treatment with anti-PD-1 antibody significantly reduced inflammatory tumour conditioned stromal cells ability to suppress the proliferation of CD8+ T cells. Additionally, PD-1 blockade was sufficient to restore lymphocyte activation and cytolytic potential, as measured by IFN-γ, TNF-α and granzyme B secretion. *In vivo*, treatment with anti PD-1 reversed stromal cell-mediated inhibition of CD8+ T cell cytolytic capacity and this was associated with increased tumour volume and invasive potential. We validated these findings in human stromal cells in the inflammatory tumour microenvironment. Collectively these results demonstrate the critical role of the PD-1/PD-L1 signalling axis in the ability of tumour-conditioned stromal cells to inhibit CD8+ T cell mediated anti-tumour immune effector functions

P.B2.03.18

The Model Regarding Participation of the Immune System in Metastatic Spread

D. Sepiashvili;
Oncology Dispensary LTD, Tbilisi, Georgia.

Cancer cells (CC) appearing in a macrophage, may not die because the process of apoptosis is disrupted in them. In the case of "incomplete phagocytosis", concealed in a macrophage CC can move towards the direction of lymphatic capillaries or directly to the blood vessels. The phagocyte with CC freely penetrates into the capillaries, reaches the lymph nodes. CC can multiply in the transport macrophage. After reaching a lymph node, the phagocyte, with incubated CC in it, is dying, insemination of CC occurs in the lymph nodes, and the new cycle is put into action.
The sizes of the microorganisms mainly vary within the range 1 - 4 μm. Most zooblasts have the diameter of 10-20 μm. and rarely are changed more than 2 times beyond this range. The sizes of macrophages equal 20-80 μm. Most researchers, considering the sizes of cells, indicate that the stem cells are much smaller in size, than more complete and highly proliferative cells. It turns out, that the sizes of the microbes and stem cells are of the same kind and comparable.
Macrophages are much more actively phagocytize microobjects with a size of 1-4 μm. Perhaps, with small-sized cancer stem cells, the special "tropism" of macrophages to the latter, is explained. Perhaps, this is the reason for the steady progression of tumor growth.
If this corresponds to reality then our ideas on the mechanisms of progression and dissemination of tumors must undergo serious revision. It is necessary to find the ways immunotherapy of "incomplete phagocytosis".

P.B2.03.19

The effect of radiofrequency ablation on the frequency of CD4+ T cells in patients with inoperable pancreatic cancer

N. Toria[1], *M. Mizandari*[2], *N. Kikodze*[3], *I. Pantsulaia*[3], *N. Janikashvili*[1], *T. Chikovani*[1];
[1]*Department of Immunology, Tbilisi State Medical University, Tbilisi, Georgia,* [2]*Department of Interventional Radiology, Tbilisi State Medical University, Tbilisi, Georgia,* [3]*Institute of Medical Biotechnology, Tbilisi State Medical University, Tbilisi, Georgia.*

Introduction: There is an increased interest in radiofrequency ablation (RFA) as the new type of local thermal ablative therapy for inoperable pancreatic cancer. In addition to cancer eradication, RFA favors tumor antigen release followed by the increase in specific anti-tumor immune response. However, this effect lasts for short time period. We suppose that it will be able to maintain anti-tumor immune response with repeatable RFA. The aim of the study was to explore the impact of repeated intraluminal RFA on the frequency of CD4+ T cells in patients with inoperable pancreatic cancer.
Methods: Patients with inoperable pancreatic cancer underwent three repetitive RFA procedures followed by self-expanding stent placement. Peripheral blood was obtained after one month of each procedure. Healthy age-matched volunteers were used as controls. The percentages of $CD39^+$ cells were separately quantified within $CD4^{low}$ and $CD4^{high}$ populations. Data were acquired on a FacsArray cytometer and analyzed with FlowJo® v7.5.6 software.
Results: Our results demonstrate that the frequency of total circulating $CD4^+$T lymphocytes was comparable between the patients and controls. After one month of RFA procedure, the frequencies of $CD4^{total}$ and $CD4^{+\,low}$ T cells were increased. The percentage of $CD39^+$ cells was decreased after repeated RFA procedure.
Conclusion: It is the first time to study the effect of repetitive ablation on adaptive immune response and may, therefore, uncover an important new target for therapeutic intervention as well as relevant treatment of this disease.
This research was funded by Shota Rustaveli National Science Foundation (Grant №: PhD_F_17_46).

P.B2.03.20

The downregulation of PDCD4 induced by progesterone is mediated by PI3K/ Akt/mTOR signaling pathway in human endometrial cancer cells

W. Zengtao[1], *X. Wang*[1,2];
[1]*Department of Gynecology and Obstetrics, Clinical Medical School, Jinan, China,* [2]*Department of Immunology, School of Basic Medical Sciences, Shandong University, Jinan, China.*

The endometrium is regulated by changing concentrations of ovarian hormones, such as estrogen and progesterone, and shows periodical changes. Apoptosis-related gene *programmed cell death 4* (*Pdcd4*) is identified as a tumor suppressor gene that inhibits neoplastic transformation, tumor progression, and translation. It has been reported that multiple factors participate in regulation of PDCD4 mRNA and protein. This study aims to explore the effect and mechanism of estrogen or progesterone on PDCD4 mRNA and protein expression in human endometrial cancer cells. We demonstrated that progesterone could effectively decrease the expression of PDCD4 protein and PI3K/AKT/mTOR pathway may be involved in the downregulation of PDCD4 protein. In conclusion, these results suggest that the downregulation of PDCD4 induced by progesterone could affect the therapeutic efficacy of progesterone in human endometrial cancer or endometriosis, which may have important implications for progesterone treatment in clinic.

P.B2.03.21

Targeting lysyl oxidase (LOX) favors T cell migration in the tumor stroma

A. NICOLAS-BOLUDA[1,2], *J. Vaquero*[3], *S. Barrin*[1], *C. Kantari-Mimoun*[1], *G. Renault*[1], *A. K. Silva*[2], *L. Fouassier*[3], *F. Gazeau*[2], *E. Donnadieu*[1];
[1]*Institut Cochin, Paris, France,* [2]*Laboratoire Matière et Systèmes Complexes, Paris, France,* [3]*Centre de Recherche Saint-Antoine, Paris, France.*

In the last decade, there has been an intense development of immunotherapeutic strategies boosting T cells with efficient anti-tumor activities. These include the use of monoclonal antibodies against the immunosuppressive surface molecules such as CTLA-4 and PD-1. However, complete and durable responses are only seen in a fraction of cancer patients. One of the determinants in the success of T cell-based immunotherapies lies on the ability of effector T cells to migrate within the tumor and access its specific antigens. Solid tumors are characterized by an aberrant organization of the extracellular matrix (ECM) in the form of highly reticulated and long linear collagen fibers, which has been shown to affect T cells penetration into tumor islets.

There are currently many strategies in development that target tumor ECM including the inhibition of lysyl oxidase, an extracellular copper-dependent enzyme upregulated in many tumors that catalyzes the cross-linking of collagen. Here, using a subcutaneous model of human biliary duct carcinoma (EGI-1) and dynamic imaging on fresh tissue slices, we investigated the consequences of LOX inhibition on the intratumoral migration of T lymphocytes. Our data indicates that LOX inhibition with beta-aminopropionitrile induced a significant decrease in tumor stiffness mapped using shear wave elastography (SWE) that correlates with the increase of the ability of T cell to migrate within the tumor. These experiments support the rationale of combining collagen-degrading strategies with approaches boosting T cells such as anti-PD-1 antibodies.

Novel potential target genes attract the attention on T regulatory cells in malignant mesothelioma

S. Oliveto[1,2], *A. Miluzio*[1], *N. Manfrini*[1], *P. Gruarin*[1], *S. Curti*[1], *L. Mutti*[3], *M. R. Benvenuti*[4], *P. Novellis*[5], *G. Veronesi*[5], *M. Pagani*[1,2], *S. Biffo*[1,2];
[1]*INGM, MILANO, Italy,* [2]*University of Milan, Milan, Italy,* [3]*University of Salford, Manchester, United Kingdom,* [4]*Thoracic Surgery Unit, ASST Spedali Civili, Brescia, Italy,* [5]*Humanitas Clinical and Research Centre, Rozzano, Italy.*

Characterization of tumor infiltrating lymphocytes (TILs) is crucial for understanding the mechanisms of cancer progression and immunotherapy reaction. Blockade of immune checkpoints, such as inhibition of CTLA4 and PD-L1, is the master approach to enhance antitumor immunity. Unfortunately, durable responses fail in most patients, suggesting the persistence of immunosuppressive mechanisms. CD4+CD25+Foxp3+ tumor-infiltrating T regulatory cells (Tregs) are responsible for the suppression of effector T cells and, as a consequence, they favour the tumor in escaping the immune defence. Here we show that Mesothelioma tumors present lymphocyte infiltrates containing proliferating cells. Foxp3+ cells are specifically organized in the infiltrates' periphery andhave extremely high immunosuppressive capabilities. Thus, we isolated intratumoral CD4+ Tregs from surgical chemonaive MPM samples and performed RNA sequencing analysis in order to characterize their molecular signature. Tregs infiltrating MPM upregulated 1) several immune checkpoint genes, such as OX-40, TIGIT and TIM-3, as in other tumors and 2) a specific set of cytokines and citokine receptors. Surprisingly, they expressed also a set of genes never described before which underlines the uniqueness of the immunosuppression in MPM. In order to identify whether immunosuppression is driven by tumor-derived signals, we are now performing topological positioning analysis of Tregs in MPM tumors. Targeting specific Treg cells by manipulating tumor-derived signals may become a novel approach for MPM treatment.

Hodgkin lymphoma secreted factors support differentiation of monocytes into macrophages with enhanced endocytic activity

A. Arlt[1], *F. von Bonin*[1], *T. Pukrop*[2], *J. Wilting*[3], *L. Trümper*[1], *D. Kube*[1];
[1]*Clinic for Hematology and Medical Oncology, Göttingen, Germany,* [2]*Clinic for Internal Medicine III, Regensburg, Germany,* [3]*Institute of Anatomy and Cell Biology, Göttingen, Germany.*

Hodgkin lymphoma (HL) is a hematological malignancy characterized by a rich and complex tumor microenvironment (TME). The malignant Hodgkin-Reed-Sternberg (HRS) cells account for less than 1% of the disease-related cells and are embedded in a reactive background of immune infiltrates. Hence, HRS cells highly depend on signaling cross-talk with non-transformed neighboring cells. Tumor-associated macrophages (TAMs) have been found to promote tumor development by promoting proliferation, angiogenesis and suppressing anti-tumor immune responses. In HL the number of TAMs was found to correlate with poor prognosis. Therefore, the aim of our study is the characterization of interactions between HRS cells and macrophages.
We found that *in vitro* HL cells secrete factors can attract and differentiate primary human monocytes into macrophages. Phenotypic characterization revealed that these macrophages resemble a M2 phenotype with a strong expression of CD206 and adhesion markers. Functional studies further showed that these features are accompanied with an increased endocytosis of CD206 specific targets. Additionally, we observed a high MMP-9 secretion and an altered tumor formation in an *in ovo* xenograft model suggesting a function of HL derived macrophages in matrix remodeling. Furthermore, we identified factors produced by HL cells that mediate the differentiation into this specific M2 type. Taken together our observations support a model in which HRS cells are able to induce monocyte differentiation into M2-related macrophages to rebuild the lymphoma microenvironment. Further molecular and functional studies are in progress to characterize mutual interactions between TAMs and HRS cells more deeply.

P.B2.04.02

Tks4 promotes tumor progression via modulation of the tumor-associated stroma

E. Boldizsár[1], *D. Laoui*[2], *A. Gyöngyösi*[1], *J. Van Ginderachter*[2], *Á. Lányi*[1];
[1]*University of Debrecen, Debrecen, Hungary,* [2]*Vrije Universiteit Brussel, Brussels, Belgium.*

Background: Tks4's (tyrosine kinase substrate with 4 SH3 domains) involvement in the regulation of cell migration, the development of functional podosomes and lamellipodia suggested that it plays a role in tumor progression. However, the function of Tks4 in the regulation of the tumor-associated stroma (TAS) - an essential, rate limiting factor of tumor growth and metastasis - is unknown. **Results:** Here we show that the murine melanoma B16-F10 and Lewis lung carcinoma (LLC) cells injected into Tks4-deficient mice develop significantly smaller tumors compared to those injected into wild-type animals. In addition, in bone marrow transfer experiments, animals that received Tks4-deficient bone marrow developed smaller tumors, strongly suggesting that the immune cells of TAS may be responsible for the observed differences. To identify which immunocyte subsets are affected by the absence of Tks4 LLC were injected into full-body $Tks4^{null}$ mice or mice in which Tks4 was eliminated in lineages expressing lysozyme M, affecting mainly macrophages and neutrophils. We found impaired tumor growth in Tks4-KO animals in both tumor models. Furthermore, the distribution of tumor-associated immune cells, surface marker expression, gene expression and the functional activity of the above cell populations was also influenced by Tks4. **Conclusion:** Tks4 expressed in myeloid lineages has a significant impact on the functional activity of TAS and appears to be a positive regulator of the tumor-associated immunosuppressive stroma. **Grants and fellowships**: Hungarian National Research, Development and Innovation Office (NKFIH, K-109444) (ÁL), EFIS-IL Short-term Fellowship (EB)

P.B2.04.03

The anti-tumor activity of brown adipose tissue: Function of the NLRP3 inflammasome and Caspase 1/11 of fat tissue in the modulation of breast cancer

L. C. Corrêa[1], *L. D. Dourado*[1], *R. A. Almeida*[1], *T. F. Furquim*[1], *A. M. Martins*[1], *M. E. Eberlin*[2], *K. M. Magalhães*[1];
[1]*University of Brasília, Brasília, Brazil,* [2]*University of Campinas, São Paulo, Brazil.*

Fat tissues can regulate cancer development by modulating inflammatory response. However, the role of NLRP3 inflammasome in white and brown adipose tissues in this context is poorly understood. Here, we aimed to characterize the role of caspase 1/11 and NLRP3 inflammasome components in the lipidomic profile of brown and white adipocytes and their function in breast cancer cells activation. Brown and white adipose tissue were isolated from wild type, caspase-1/11 and NLRP3 knockout mice. White and brown adipocytes tissues from these mice were analyzed by Electrospray Ionization Mass Spectrometry (ESI-MS). Conditioned medium from these adipocytes were used to stimulate breast cancer cells 4T1. Breast cancer cells lipid droplet biogenesis was analyzed by Bodipy or Oil Red staining followed by flow cytometry or Microscopy analysis, respectively. Breast cancer cells viability was assessed by MTT assay. Our data showed that white adipocytes conditioned medium triggered significant higher levels of lipid droplet biogenesis in breast cancer cells compared to brown adipocytes stimulation or unstimulated cells. The secretion product of brown adipose tissue decreased the viability of tumor cells. ESI-MS data showed that both fat tissues have distinct lipidic metabolites and the absence of inflammasome components changed significantly the profile of these fat cells. Taken together, our data showed white and brown adipocytes presented distinct lipidomic profile and the absence of NLRP3 inflammasome components may influence directly their lipidomic composition and their ability to activate breast cancer cells, suggesting an important mechanism that may be involved in their differential function in carcinogenesis. **Support**: CNPq

Pro-tumoral role of complement activation in murine sarcoma models

S. Di Marco[1], *E. Magrini*[1], *C. Perucchini*[1], *K. Berthenet*[1], *M. Barbagallo*[1], *A. Ponzetta*[1,2], *C. Garlanda*[1,2], *A. Mantovani*[1,2];
[1]*Humanitas Clinical and Research Centre, Rozzano, Italy,* [2]*Humanitas university, Rozzano, Italy.*

Cancer related inflammation (CRI) plays a fundamental role in fuelling tumor appearance and development. Although the important contribution of complement activation to inflammation, its role in CRI still remains understudied. Recently our group demonstrated the pro-malignant role of complement activation in models of mesenchymal (3-MCA-induced) and epithelial (DMBA/TPA-induced) inflammation-driven skin carcinogenesis, showing that mice deficient for the key molecule C3 were protected from tumor development. First we observed the deposition of C3-cleavage products on vessels and tumor cells of sarcomas, while it was absent in normal tissues. C3 deposition on tumor cells was also observed *in vitro*, both on 3-MCA-derived sarcoma and on different murine cancer cell lines. Interestingly, both *in vitro* and *in vivo* experiments suggested that the activation of the classical and lectin pathways was involved in this process. Then, we investigated C3-downstream mechanism(s) of protection in two sarcoma murine models. We observed that $C3^{-/-}$ but not the $C5aR^{-/-}$ mice were protected from tumor growth in a transplantable model of sarcoma (MN-MCA), as well as in the 3-MCA-induced carcinogenesis model. $C3^{-/-}$ mice showed a protective phenotype which was associated with reduced macrophage and enhanced $CD8^{+}$ frequencies in tumor, suggesting that these cells could play a role in the protection. Similar results were obtained with $C3aR^{-/-}$ mice, suggesting that the C3a/C3aR axis was most likely responsible for the protection from tumor development observed in C3-deficient mice. All together our results indicate that complement activation occurs in tumor and contributes to sarcoma development.

P.B2.04.05

Leptin decreases susceptibility of breast cancer cells to NK-Lysis via PGC-1a pathway: Linking tumor progression with obesity

A. GATI[1,2]*, Hichem Bouguerra, Amal Gorrab, Stephan Clavel, Jean-François Louet, Guissouma Hager;*
[1]Faculté des Sciences de Tunis, EL manar, Tunisia, [2]Univeristy of Tunis El Manar, Faculty of science of Tunis, Tunisia.

Several studies established a link between obesity and breast cancer (BC) development. Yet, the mechanisms underlying this association are not understood. Among the diverse adipocytokine secreted by hypertrophic adipose tissue, leptin is emerging as a key candidate molecule linking obesity and cancer, since it promotes proliferation, migration and invasiveness of tumors. However, the potential implication of leptin on tumor escape mechanisms remains unknown. This study aims to explore the effect of leptin on tumor resistance to NK lysis and the underlying mechanism. We found that leptin promotes both BC resistance to NK92-mediated lysis and β oxidation on MCF-7, by the up-regulation of a master regulator of mitochondrial biogenesis, the Peroxisome proliferator activated receptor coactivator-1 α (PGC-1α). Using adenoviral approaches, we show that acute elevation of PGC-1α enhances the fatty acid oxidation pathway and decreases the susceptibly of BC cells to NK92-mediated lysis. Importantly, we identified new regulatory functions of PGC-1α and leptin in regulating the expression of the hypoxia inducible factor-1 alpha (HIF-1α) by tumor cells, a transcriptional factor with pleiotropic role in cancer. We further demonstrate that basal BC cells MDA-MB-231 and BT-20 exhibit an increased PGC-1α mRNA level, an enhanced activity of oxidative phosphorylation and are more resistance to NK92 lysis in comparison with luminal BC cells (MCF7 and MDA-361). Altogether, our results demonstrate for the first time how leptin could promote tumor resistance to immune attacks. Reagents blocking leptin or PGC-1α activity might aid in developing new therapeutic strategies to limit tumor development in obese BC patients.

P.B2.04.07

EZH1 was involved in inhibitory effect of miR-20a on the growth and metastasis of HCC

J. HUANG*, Q. Zhang, X. Deng, Y. Cai, X. Tang, X. He;*
Guangdong Provincial Key Laboratory of Organ Donation and Transplant Immunology, The First Affiliated Hospital, Sun Yat-sen University, GUANGZHOU, China.

Backgroud: Many miRNAs are associated with hepatocellular carcinoma (HCC). We found that miR-20a was down-regulated in HCC and could inhibit the proliferation and metastasis of HCC cells. It is worth to study deeply. **Objective:** To investigate the effect and mechanism of miR-20a on the growth and metastasis of HCC. **Methods:** transfection efficiency of miR-20a was detected by immunofluorescence and qRT-PCR; HCC cell proliferation was evaluated by CCK8 and plate clone formation; transwell experiments and cell scratch experiments were used to detect the invasion and migration of HCC cells; bioinformatics analysis and luciferase assay were used to search and verify miR-20a targets; tumorigenic ability and metastasis ability of SMMC7721 were observed by xenograft tumor growth assay in nude mice; the expressions of miR-20a and EZH1 were detected by qRT-PCR, in situ hybridization and immunohistochemistry; the levels of H3K27me, H3K27me2, H3K27me3 and PRC2-associated proteins were evaluated by immunohistochemistry. **Results:** miR-20a was down-regulated in HCC cell lines and inhibited HCC cell proliferation, invasion and migration. miR-20a could directly target EZH1, rather than EZH2. Overexpression of miR-20a could inhibit the growth and metastasis of SMMC7721 cells in vivo. Compared with adjacent tissues, miR-20a was decreased while EZH1 was increased in HCC tissues. H3K27me, H3K27me2 and H3K27me3 were up-regulated in HCC tissues. EZH2 and EZH1 were increased in HCC while SUZ12, EED and AEBP2 did not change significantly. **Conclusions:** EZH1 is the direct target of miR-20a and miR-20a/EZH1 axis is associated with growth and metastasis of HCC by modulating H3K27 methylation.

P.B2.04.08

Fratricide tumor-associated macrophages contribute to tumor destruction following chemotherapy

M. Laviron*, P. Loyher, P. Hamon, C. Combadière, A. Boissonnas;*
Centre d'Immunologie et des Maladies Infectieuses, Paris, France.

Tumor-associated macrophages (TAMs) are the most abundant cells within the tumor microenvironment and are thought to be implicated in tumor growth, metastasis formation and chemotherapy resistance. We recently highlighted the dual origin of TAMs in lung cancer in mice, being composed of both resident interstitial (Res-TAMs) and monocyte-derived (MoD-TAMs) macrophages. These subsets exhibited different sensitivity to the alkylating agent cyclophosphamide, as both were reduced in the early days following chemotherapy but MoD-TAMs transiently recovered after treatment while Res-TAMs did not. This MoD-TAMs wave was associated with tumor clearance but their level eventually dropped and tumor progression rebounded concomitantly. This observation unveils that TAMs' usefulness in chemotherapy efficacy is unclear. We thus attempted to decipher the relative contribution of these subsets in the first days following treatment. Using two-photon microscopy and histological analysis on mice expressing fluorescent reporters allowing for the discrimination between Res-TAMs and MoD-TAMs, we seek to characterize the distribution and dynamics of both populations during the first 3 days after treatment. Chemotherapy induced a rapid dissociation of the tight interactions between tumor cells, associated with an increased density of MoD TAMs, displaying higher protrusive activity between the tumor cells. In contrast, Res-TAMs in tumor nodules were rapidly eliminated following chemotherapy. Surprisingly, in mice deficient for the chemokine receptor CCR2, lacking MoD-TAMs, tumor destruction was not observed and Res-TAMs seemed to be less eliminated by cyclophosphamide. Our observations suggest an unexpected fratricide role for MoD-TAMs in the early phase following chemotherapy.

CCL17 in intestinal inflammation and cancer

R. Metzger*, A. B. Krug;*
LMU Institut für Immunologie, Planegg-Martinsried, Germany.

Colorectal cancer (CRC) is one of the most common cancers and a major cause of mortality. Pro-inflammatory and anti-tumor immune responses play a critical role in colitis associated and sporadic CRC. CCL17, a chemokine of the C-C family with its receptor CCR4, is mainly expressed by the $CD11b^+$ subset of dendritic cells, promotes intestinal inflammation in two mouse models of colitis and its expression correlates with disease activity in ulcerative colitis patients. CCL17 enhances toll-like-receptor (TLR) mediated cytokine induction, promotes pro-inflammatory Th cell differentiation and inhibits Treg expansion during colitis. TLR4, 7/8 or 9 ligation led to a lower IL12p40 secretion in CCL17 deficient DCs compared to heterozygous controls. CCL17 may play a dual role in the development of CRC as a driver of inflammation and cancerogenesis as well as a modulator of anti-tumor immune responses. The role of CCL17 for intestinal tumor development was investigated using the murine colitis associated cancer model induced by AOM/DSS and the APC1638N mutant mouse model for sporadic CRC. In both models increased CCL17 expression was observed in the tumor tissue, indicating a role for this chemokine. By comparing tumor numbers in $CCL17^{eGFP/wt}$ heterozygous and $CCL17^{eGFP/eGFP}$ knockout mice, we found that CCL17 promoted tumor development in the colitis-induced (AOM/DSS) model, but had only a minor effect on spontaneous intestinal cancerogenesis. Preliminary data obtained from syngeneic subcutaneous tumor models show that CCL17 expression is also induced in these tumors and drives tumor growth, indicating that CCL17 shapes the tumor microenvironment independently of intestinal inflammation.

P.B2.04.10

Tumor cells secretome impairs the plasmacytoid dendritic cells compartment in metastatic melanomas

M. Monti[1]*, R. Vescovi[1], D. Moratto[2], F. Consoli[3], M. Rossato[4], L. Paolini[1], L. Benerini Gatta[1], M. Bugatti[1], V. Salvi[1], D. Bosisio[1], M. Maio[5], E. Fonsatti[5], M. Simbolo[6], A. Scarpa[6], M. Delledonne[4], P. Bergese[1], S. Sozzani[1], F. Facchetti[1], W. Vermi[1,7];*
[1]University of Brescia, Brescia, Italy, [2]"Angelo Nocivelli" Institute, ASST Spedali Civili of Brescia, Brescia, Italy, [3]ASST Spedali Civili of Brescia, Brescia, Italy, [4]University of Verona, Verona, Italy, [5]University Hospital of Siena, Siena, Italy, [6]ARC-Net Research Centre, University of Verona, Verona, Italy, [7]Washington University School of Medicine, Saint Louis, United States.

Introduction: Among immune cells involved in cancer immunity, Plasmacytoid Dendritic Cells (PDC) exert an important role bridging the innate and adaptive immune responses. Properly activated PDC can eliminate cancer cells through the Toll-like receptor (TLR) 7 and TLR9-dependent type I Interferon (I-IFN) production and other effector functions. PDC infiltration has been documented in several types of cancer, however, their role within the melanoma immune-contexture is still largely unknown.
Methods: PDC frequency was evaluated in a cohort of 29 Metastatic Melanoma (MM) patients. Intracellular IFN-α and IP-10 were measured on Peripheral Blood Mononuclear Cells (PBMC) after TLR7/9 agonists administration. Purified PDC were exposed to melanoma cell line supernatants (SN-mel). *In vitro* viability and production of IFN-α and IP-10 were evaluated by flow cytometry. Finally, the mRNA-Sequencing (mRNA-Seq) analysis was performed.
Results: Circulating PDC are severely reduced and defective in IFN-α and IP-10 production in MM patients. Furthermore, *in vitro* exposure to SN-mel resulted in significant PDC death. Also, SN-mel induced a significant decrease of IFN-α and IP-10 production by PDC. Finally, mRNA-Seq has revealed deregulation of I-IFN pathway by different SN-mel exposure.
Conclusions: In this study we demonstrate that in MM the circulating PDC compartment is collapsed. In addition, the residual PDC component is not functional. Furthermore, our *in vitro* findings indicate that components released by melanoma cells have a relevant effect on the survival and anti-tumor activity of fully differentiated PDC. The underlying molecular mechanisms identification is underway through the mRNA-Seq data analysis.
This work was supported by AIRC (IG-15378).

P.B2.04.11

Survival and stemness of HT29 colon cancer cells is influenced by self-DNA via crosstalk of TLR9- and autophagy signaling

G. Müzes[1], *A. L. Kiss*[2], *F. Sipos*[1];
[1]*2nd Department of Medicine, Budapest, Hungary,* [2]*Semmelweis University, Budapest, Hungary.*

TLR9 and autophagy pathways seem to be bi-directionally involved in carcinogenesis. In cancer cells the biological consequences of the TLR9 and autophagy crosstalking induced by self-DNA is poorly documented. HT29 cells were incubated with genomic(g), artificially hypermethylated(m), fragmented(f), and hypermethylated/fragmented(m/f) self-DNA sequences. Cell viability, induction of apoptosis, cell proliferation, transcriptional alterations of TLR9-signaling and the autophagy process were assayed, respectively. Moreover, autophagy proteins, morphologic features of apoptosis and autophagy, and the presence of colonospheres were examined. Following incubation with g-, m-, and m/f-DNAs viability and proliferation of HT29 cells decreased and percentage of apoptotic cells increased, while f-DNA resulted in an appreciably increase of cell survival. Methylation of self-DNA resulted in decrease of TLR9 expression, but did not influence the positive effect of DNA fragmentation on overexpression of Myd88 and TRAF6, and downregulation of TNFα. Fragmentation of DNA abrogated the effect of methylation on IRAK2, NFκB and IL-8 mRNA upregulation. G- and f-DNAs significantly upregulated Beclin1, Atg16L1, and LC3 autophagy genes. On a protein level, the results were parallel with the gene expressions. According to TEM, presence of autophagy was observed in each groups. Incubation with m-DNA activated mitophagy, and suppressed tumor cell survival by inducing features of apoptosis. F-DNA treatment enhanced cell survival, activated macroautophagy and lipophagy. As a marker of stemness, CD133+ colonospheres were present only after m-DNA incubation. Our data provide evidence for an interplay between TLR9- and autophagy signaling using HT29 cells subjected to modified self-DNA with remarkable influences on survival and stemness of cancer cells.

P.B2.04.12

IL17a, IL21 and IL22 serum levels in colorectal cancer

N. İbrahimli[1], ***F. Ozmen***[1], *C. E. Guldogan*[2], *M. M. Ozmen*[2];
[1]*Department of Basic Oncology, Cancer Institute, Hacettepe University, Ankara, Turkey,* [2]*Department of Surgery, Medical School, Istinye University, Istanbul, Turkey.*

Background and Aim:T-helper 17 (Th17) pathway plays an important role in promoting colorectal cancer. The aim of this study was to evaluate serum levels of pivotal cytokines (IL-17a, IL-21 and IL-22) and their correlation with clinicopathologic parameters of colorectal cancer. **Patients and Methods:**40(19F) patients with colorectal cancer with a median(range) age of 61(30-83)years and 40(18F) healthy controls with no history of any cancer with a median(range) age of 44(25-58) years were included in the study. Preoperative blood samples were collected from the patients.Correlation between serum interleukin levels and stage, differentiation, presence of metastasis, lymph node invasion, perineural and vascular invasions were also evaluated.**Results:**IL-17, Il-21 and IL-22 levels as pcg/ml were 3.11(2.99-3.73), 108.3(11.9-1394), 38.8(38.4-42.9) respectively in patients with colonic cancer. Whereas, they were 1.3(0.7-6.2); 123.12(61.8-1157.6); 21.3(0.15-143.9) pg/ml respectively in healthy controls. IL-17 and Il-22 were found to be increased significantly in patients with colonic cancer (p<0.001). Cut-off value for the significance of IL-17 was found to be 2.755 pg/ml and cut-off value for IL-22 was found to be 35.63 pg/ml. Any values over those were found to be correlated with colonic cancer(*p<0.001*). On the other hand, presence of metastatic lymph nodes, vascular invasion and perineural invasion were all found to be correlated with increased IL-17 and IL-22 levels(*p<0.001*). Patients with distant metastasis(n=5) also had significantly increased levels of IL-17 and IL-22. **Conclusions:**There was a strong correlation between increased levels of IL-17 and IL-22 not only with the presence of cancer but also with the presence of invasion and metastasis.

P.B2.04.13

The sweet side of pancreatic cancer: the tumor glyco-code contribute to the tolerogenic microenvironment.

E. Rodrguez[1], *S. Schetters*[1], *G. Kazemier*[2], *E. Giovannetti*[3], *J. Garcia-Vallejo*[1], *Y. van Kooyk*[1];
[1]*Department of Molecular Cell Biology and Immunology, VUmc., Amsterdam, Netherlands,* [2]*Department of Surgery, VUmc., Amsterdam, Netherlands,* [3]*Department of Medical Oncology, CCA, VUmc., Amsterdam, Netherlands.*

Pancreatic cancer, one of the most aggressive malignancies, is characterized by an immune-suppressive tumor microenvironment. It has been postulated that changes in the glycosylation of tumor cells, which we call tumor glyco-code, have an impact in the induction of a tolerogenic microenvironment. Immune cells express different glycan-binding receptors (GBR) that can sense and respond to changes in the glyco-code; which often leads to inhibitory immune processes. In this work, we characterize changes in glycosylation during pancreatic cancer progression and analyze how they interact with the immune system.
An extensive glycoprofiling analysis in 10 different pancreatic cancer cell lines, which revealed that fucosylated antigens (eg. Lewis x, Lewis y, VIM-2) are expressed in cells that markers an epithelial phenotype, while they are absent in mesenchymal-like cells. The presence of those structures is associated with the expression the enzyme GALNT3, which expression is regulated by ZEB1 during epithelial to mesenchymal transition.
The presence of fucose-containing glycans in epithelial cells was correlated with a high DC-SIGN binding, a lectin receptor with well described immuno-modulatory properties. Interestingly, tumor cell lines are capable to induce the differentiation of monocytes towards DC-SIGN+ tumor associated macrophages (TAMs), characterized by the expression of CD163, CD14 and the mannose receptor. This data suggests that tumor-induced DC-SIGN+ TAMs cells could be differentially modulated by epithelial or mesenchymal cells. DC-SIGN signalling in TAMs may be a characteristic in their interaction with epithelial cells and therefore contribute to early local tolerance in the primary tumor.

P.B2.04.14

Refractory activation state of CD29 in multiple myeloma plasma cells from extramedullary sites as a possible new mechanism to explain their disseminated behaviour.

A. Roncancio-Clavijo, *E. Martínez-Viñambres, L. Villar, E. Roldán;*
Hospital Universitario Ramón y Cajal, Madrid, Spain.

Multiple myeloma (MM) is a disease characterized by malignant proliferation of clonal plasma cells (PC), usually restricted to the bone marrow (BM). However, in a subset of cases clonal PC expansion can occur outside of the BM and can present as plasma cell leukemia (PCL) or extramedullary MM (EMM). The mechanisms that explain PC egress out of the BM are poorly understood. Here we report that, in contrast to MM cases without disseminated disease, malignant PC in blood or extramedullary sites did not express the high-affinity form of CD29 and were refractory to cation-induced CD29 activation. Patients and methods Six MM patients with EMM or PCL and 15 with disease confined to the BM were studied. BM aspirates, peripheral blood or pleural effusions were stained with conjugated mAb against CD38, CD138, CD29 (clone MAR4 or HUTS21, detecting constitutive or active epitopes, respectively). For HUTS21 regulation experiments, tumoral cells were incubated with different Mn^{2+} concentrations (0.01-10mM). Antigen expression was monitored by flow cytometry. Results PC from EMM or PCL patients displayed very low levels of HUTS21 active epitope (median: 1.8%±1.6%), in contrast to PC from MM patients with disease confined to the BM (median: 58%±17%; p<0.001). Moreover, clonal PC in pleural fluids or blood showed a very poor response to exogenously added Mn^{2+}, even at 10mM concentration (median: 2.6%±2.2%) in comparison to PC from patients without disseminated disease (median: 93%±5%; p<0.001). Conclusion Malignant PC from EMM or PCL patients do not express active CD29 since were unresponsive to regulatory factors.

P.B2.04.15

The p38 MAPK pathway influence of dendritic cells treated with tumor-derived soluble factors

A. S. A. Santos, *E. M. Araujo, A. M. Vale;*
Federal University of Maranhão, São Luis, Brazil.

Introduction: Dendritic cells are antigen-presenting cells responsible for initiating adaptive immune response or induce peripheral tolerance. The microenvironment can induced change in DCs functional status. Thus, in tumor microenvironment, the suppressor factors cause tolerogenic phenotype in DCs that contribute to the development and progression of cancer. The aim was evaluated the DCs differentiation from human monocytes (Mo-DCs) in presence tumor-derived soluble factors, as well as a possible signaling pathway involved in this process. Materials and Methods: Mo-DCs were obtained from monocyte culture with GM-CSF and IL-4 and TNF as maturation stimulus. During the differentiation process, DCs were treated with p38 MAPK pathway inhibitor and 30% (v/v) supernatant of tumor cells MCF-7 and analyzed morphologically and phenotypically. Results: The results showed that the protocol used was efficient for the generation of DCs in vitro. Supernatant did not alter tumor HLA-DR expression, however, reduced the expression of costimulatory molecule CD86. The combined treatment with tumor supernatant and p38 pathway inhibitor promoted an increase in HLA-DR expression, indicating that p38 pathway may be involved in DC differentiation process. However, DCs treated tumor supernatant had less CD86 expression continued with this profile even with the use of a p38 inhibitor, indicating that the p38 pathway may not be the only one involved in this process. Conclusions: Thus, the results suggest that the supernatant of tumor cells alters the functional characteristics of DCs, acting in the maturation process, and that this influence of the supernatant can be dependent upon, but not exclusively, the p38 pathway.

P.B2.04.16
'Bystander' effects of senescent tumour cells induced by docetaxel or IFNγ+TNFα

***O. Sapega**, M. Romana, M. Blanka, H. Zdeněk, R. Milan;*
Institute of Molecular Genetics of the ASCR, v. v. i., Prague, Czech Republic.

Cellular senescence is a process of a cell-cycle arrest in response to various inducers. Senescence is characterized by a series of morphological changes and is typically connected with secretion of bioactive molecules (senescence-associated secretory phenotype, SASP). Thus, senescent cells can affect their local environment and through their SASP induce 'bystander' senescence. To investigate a relationship between the phenotype of senescent cells and "bystander" senescence induction, we induced senescence by treatment of tumor cells (TC-1 and B16) with two different inducers - cytotoxic agent docetaxel (DTX), and by the combination of cytokines IFNγ+TNFα. We have demonstrated that DTX induced senescence both in the TC-1 and B16 tumor cell lines, which was proved by *in vitro* and *in vivo* growth arrest, detection of increased p21 expression, positive beta-galactosidase staining, and the typical SASP capable to induce 'bystander' senescence. On the other hand, treatment with the combination of IFNγ+TNFα induced a proliferation arrest only in B16 cells. Despite the presence of some characteristic features resembling senescent cells (proliferation arrest, morphological changes), B16 senescent cells were able to form tumors *in vivo* and started to proliferate upon the cytokine withdrawal. In addition, B16 cells were not able to induce 'bystander' senescence. Collectively, our work presented here has established a murine model that is beneficial for research of direct and 'bystander' biological effects of senescent cells. This work was supported by the research grant No. 15-24769S provided by the Czech Science Foundation.

Platelet-activating factor (PAF) receptor promotes tumor cell repopulation after radiotherapy

***I. A. Silva-Junior**[1], A. P. Lepique[2], S. Jancar[2];*
[1]Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil, [2]University of São Paulo, São Paulo, Brazil.

Radiotherapy generates oxidized phospholipids that activate platelet-activating factor receptor (PAFR) associated with pro-tumorigenic effects. Here, we investigated the involvement of PAFR in tumor cell survival after irradiation. Cervical cancer samples presented higher levels of PAF-receptor gene (PTAFR) when compared with normal cervical tissue. In cervical cancer patients submitted to radiotherapy (RT), the expression of PTAFR was significantly increased. Cervical cancer-derived cell lines (C33, SiHa, HeLa, TC-1) and squamous carcinoma cell lines (SCC90 and SCC78) express higher levels of PAFR mRNA and protein than keratinocytes. Gamma radiation increased PAFR expression and induced PAFR ligands and prostaglandin E2 in these tumor cells. Irradiated, dying TC-1 feeder cells increased the proliferation of living TC-1 reporter cells in a PAFR-dependent way. The blocking of PAFR with the antagonist CV3938 before irradiation increased tumor cells death. Similarly, human carcinoma cells that do not express PAFR (KBM) were irradiated and co-injected with cells transfected with PAFR gene (KBP) into RAG mice. These tumors grew significantly bigger than the ones formed by co-injection of live KBM with irradiated KBM. Tumor repopulation correlated with increased M2 (CD206+) macrophages in KBP tumors. Taken together, these results suggest that PAFR ligands generated during tumor irradiation activates PAFR in tumor cells and enhance their survival and proliferation while the activating of PAFR in tumor macrophages reprogramming them to a pro-tumor profile. This may be relevant in tumor repopulation phenomenon after radiotherapy. We propose that PAF receptor represents a possible target for improving the efficacy of radiotherapy through inhibition of tumor repopulation.

P.B2.04.18
Oncostatin M promotes tumor progression in skin squamous cell carcinoma

***M. Simonneau**[1], E. Frouin[1,2], C. Jermidi[1,2], J. F. Jegou[1], A. Barra[1,2], I. Paris[1], V. Huguier[1,2], P. Levillain[2], S. Cordier-Dirikoc[3], N. Pedretti[3], F. X. Bernard[1,3], J. C. Lecron[1,2], F. Morel[1], L. Favot[1];*

Cutaneous squamous cell carcinoma (cSCC) is one of the most frequent keratinocyte malignancies worldwide and is chemotherapy resistant. Surgery is the curative treatment but there isn't any alternative in advanced cSCC. Reprogramming tumor microenvironment and tumor immunosuppressive mechanisms is a new therapeutic approach. Indeed, depending on cytokine expressed in tumor microenvironment, immune cells can inhibit (Th1/M1 cells) or enhance (Th2/M2 cells) tumor development. It was previously showed that Onconstatin M (OSM) had pleiotropic effects on cancer cells. OSM can promote cancer by inducing tumor cells motility, invasiveness or by reprogramming immune cells toward a more permissive phenotype (M2 polarization). Our previous data showed that OSM has proinflammatory effects on skin and modulate normal keratinocyte phenotype both *in vitro* and *in vivo*.
In this study, we hypothesized that OSM could be involved in cSCC development.
We showed that OSM was overexpressed in human cSCC as well as other cytokines such as IL-6, IL-1β, IFNγ whereas IL-4 was decreased, suggesting a Th1/M1 polarization of cSCC microenvironment. *In vitro*, OSM induced STAT-3 and ERK signalization, modified gene expression, promoted proliferation and migration of malignant keratinocyte PDVC57 cells. PDVC57 cells grafted in skin mice led to cSCC development associated to OSM overexpression by immune infiltrated cells. Finally, we showed that the absence of OSM led to a 30% reduction of tumor size and reduced M2 polarization in tumor microenvironment. Collectively, these results support a pro-tumoral role of OSM in cSCC development and suggest a new therapeutic approach targeting this cytokine.

P.B2.04.19
Immune cell composition in non-small cell lung cancer

***B. Stankovic**, H. Korsmo Bjørhovde, R. Skarshaug, H. Aamodt, E. Müller, C. Hammarström, K. Beraki, E. Bækkevold, P. Woldbæk, Å. Helland, O. Brustugun, I. Øynebråten, A. Corthay;*
Oslo University Hospital, Oslo, Norway.

Non-small cell lung cancer (NSCLC) has highest mortality rates in the world. Development of immunotherapy, in particular immune checkpoint inhibitors, has improved survival, but only for a fraction of patients. This could be due to variation in the immune response to cancer between individual patients, and analysis of tumor-associated immune cells could prove valuable in the selection of clinical treatment. However, the exact immune cell composition in NSCLC remains unclear. Here, we used flow cytometry to analyze immune cell composition in NSCLC of 69 patients. T cells dominated the lung cancer landscape (on average 46.1% of all CD45+ cells). Among these CD4+ T cells were the most abundant (25.8%), closely followed by CD8+ T cells (20.6%). CD19+ B cells were the second most common population (on average 15.9%) including naive, germinal center, memory and plasma cell subsets. Macrophages and natural killer (NK) were less abundant, composing 5.4% and 4.3% respectively. Dendritic cell (DC) populations, including plasmacytoid DCs, CD1c+ DCs and CD141+ DCs, together represented 1.9% of all immune cells. Among granulocytes, the neutrophils were variably present (0-35%), basophils (0.5%) and eosinophils (0.6%) were rare, while mast cells constituted 1.5%. Analysis of immune cell composition in 69 tumors revealed individual differences between the patients. Interestingly, across the cohort of patients, only B cells showed a significantly higher representation in the tumors compared to the distal lung, while macrophages and NK cells had a relatively lower representation. This shows that the immune cell repertoire is significantly influenced by the tumor presence.

P.B2.04.20
Characterization of tumor-induced immune suppression by monocytic myeloid-derived suppressor cells

***G. F. van Wigcheren**, G. Flórez-Grau, M. Tazzari, J. M. de Vries, C. G. Figdor;*
Radboud Institute for Molecular Life Sciences, Radboudumc, Nijmegen, Netherlands.

Monocytic myeloid-derived suppressor cells (M-MDSCs) are major regulators of immune responses in cancer as greatly evidenced in melanoma patients. Clinical studies have shown that circulating MDSC levels are closely related to tumor stage and prognosis. This tumor-induced conversion of monocytes into M-MDSCs promotes cancer progression by dampening spontaneous and therapeutic immune responses. A better understanding of M-MDSCs conversion and suppressive function is needed to identify potential targets for drugs that can inhibit cancer immune evasion and contribute to successful application of cancer immunotherapy.
M-MDSCs were generated out healthy donor monocytes and compared to monocyte-derived dendritic cells (MoDCs) and tolerogenic MoDCs (TolDCs) from the same donor. Phenotypic characterization of myeloid maturation and activation markers was performed using multicolor flow cytometry. Suppressive activities of generated monocytic subsets were compared in co-culture assays measuring the activation of T cells.
The culture protocol induced M-MDSCs with an immature monocytic morphology. These cells express myeloid lineage markers CD11b, CD33 and CD14 while downregulating HLA-DR expression. The expression of co-stimulatory markers CD86, CD83 and CD80 remained low. M-MDSCs were more potent in inhibiting T cell activation in co-culture assays than TolDCs. The conversion of healthy monocytes into pathologically activated M-MDSCs as seen in melanoma patients can be recapitulated using an ex vivo culture protocol. Ex vivo generated M-MDSCs are characterized by a $CD11b^{+}CD33^{+}CD14^{+}HLA\text{-}DR^{low}$ phenotype and an immature morphology. These cells were potently able to suppress activated T cells as demonstrated in co-culture assays. Molecular studies are warranted into the MDSC conversion and their suppressive activity.

Hospital Universitari Son Espases, Palma De Mallorca, Islas Baleares, Spain, Palma, Spain.*

Introduction: Chronic obstructive pulmonary disease (COPD) and lung cancer (LC) are prevalent diseases causing morbidity and mortality worldwide. Tobacco smoking is the main risk factor for both diseases. However, not all smokers develop COPD or LC. Several inflammatory cells have been involved in both diseases and can favor the chronic inflammatory process and/or promote carcinogenesis. Myeloid derived suppressor cells (MDSC) contribute to maintain the anti-cancer and the homeostasis of the inflammatory process.
Objective: We aimed to evaluate MDSC subpopulation in COPD and LC patients.
Materials and methods: Percentages of MDSC ($Lin2^-DR^-CD11b^+CD33^+$) were evaluated by flow cytometry in peripheral blood samples from COPD and smokers. In both groups, patients with and without LC were also separately evaluated.
Results: Although we did not find differences between COPD patients and smokers without COPD, we observed a trend toward higher percentages in the latter group (3,83±0,83 and 5,03±2,00% respectively; p=0,52). Percentages were higher in COPD patients with LC compared to COPD patients without LC (4.26±0.92 and 1,02±0,58% respectively; p=0,19) however the differences did not reach statistically significance again. Similarly, there was a trend toward higher percentages of MDSC in smokers with LC compared to smokers without LC (6,72±3,31 and 2,6±1,06% respectively; p=0,34).
Conclusion: We have found a trend toward higher percentages of MDSC in smokers without COPD when compare to COPD patients. When we evaluated LC patients in COPD and in smokers without COPD there was a trend toward higher percentages of MDSC in LC patients from both groups.

Introduction: Considering that inflammation is a major component of papillary thyroid carcinoma (PTC) pathogenesis, we investigated the role of the immune checkpoint soluble HLA-G (sHLA-G) molecule and a panel of plasma cytokines in PTC patients. Materials and Methods: We studied 85 PTC patients before thyroidectomy and 80 healthy controls. Plasma levels of sHLA-G and 13 different cytokines (IL-1α, IL-1β, IL-4, IL-5, IL-6, IL-10, IL-12p70, IL-13, IL-17A, IFN-α, IFN-γ, TGF-β1 and TNF) were determined by ELISA and cytometry, respectively. Data were evaluated using univariate and multiple logistic regression analyses, and ROC curves. Results: Compared to controls, IL-6 levels were increased, while IL-1β, IFN-α and TGF-β1 levels were decreased in PTC patients. IFN-α and TGF-β1 efficiently discriminated patients from controls after multiple logistic regression analysis, in which IFN-α presented the best diagnostic performance. Increased IL-1β and decreased IL-12p70 levels were independently associated with larger tumors (>2.0 cm), while decreased sHLA-G levels were associated with local invasion of the tumor. PTC patients exhibiting poor therapy response presented higher levels of IL-5 and IFN-α. Conclusions: The decreased sHLA-G plasma levels observed in patients do not reflect the increased expression of HLA-G reported for PTC samples. The IFN-α and TGF-β1 levels were able to discriminate patients from controls. Additionally, pro-inflammatory and anti-inflammatory cytokines were associated with poor prognosis factors of PTC and poor response to therapy. P.B2.05.03

Investigation of the role of IL-36 cytokines in colon cancer

E. Brint, *A. Houston, C. O'Donnell;*
University College Cork, Cork, Ireland.

The IL-36 cytokines (IL-36α, IL-36β and IL-36γ) are a recently described subset of the interleukin-1 (IL-1) family of cytokines. Given the involvement of other IL-1 family members in the tumorigenic process, it is highly likely that these novel IL-36 cytokines also play a role in cancer. Here we show that IL-36α and IL-36γ is increased in human colorectal cancer tissue compared to adjacent non-tumour tissue, at both the mRNA and protein, whilst IL-36β is altered at the mRNA level only. Expression did not, however, correlate with stage, grade or patient prognosis. Transcription of the IL-36 receptor (IL-36R) was unchanged, with both tumour cells and immune cells in the tumour microenvironment expressing the receptor. Whilst no IL-36 cytokine altered colon cancer cell migration or invasion, IL-36γ strongly increased cellular proliferation in two colon cancer cell lines. IL-36α and IL-36γ also induced high levels of expression of CXCL-1, CCL-2, CCL-20 and IL-8 in colon cancer cells. Finally, expression of all IL-36 cytokines is strongly induced in these cells in response to the colonic tumour-promoting stimulus PGE_2. Taken together, these data show that certain IL-36 cytokines are increased in colon cancer and that tumour cells may respond to IL-36R stimulation in terms of a positive increase in proliferation and an induction of pro-tumorigenic chemokines.

P.B2.05.04

Cross-presentation of tumor-associated antigens by lung DC1 is lost in tumors by downregulation of TIM4 mediated efferocytosis

N. Caronni[1], *F. Simoncello*[1], *G. M. Piperno*[1], *K. E. Cervantes Luevano*[1], *S. Vodret*[1], *S. Bicciato*[2], *F. Benvenuti*[1];
[1]*Icgeb, Trieste, Italy,* [2]*Center for Genome Research Dept. of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy.*

Batf3-dependent DC1 are critical for the initiation of anti-tumor immunity and their abundance in tumors correlates with good prognosis and responses to immunotherapies. Yet, original DC1 functions are hit in the tumor microenvironment facilitating tumor escape. We addressed the mechanism underlying DC1 suppression in an orthotopic model of non-small-cell-lung-cancer (NSCLC). DC1 effectively cross-presented tumor antigens at early stages whereas this activity was lost in established tumors. DC1 isolated from tumor bearing lungs and fed with antigen ex-vivo confirmed a selective loss in formation of MHC class-I immune complexes from ingested antigens. Gene expression profiling showed modulation of transcripts involved in antigen processing/intracellular trafficking and exhaustion of inflammatory pathways. Notably, tumor associated DC1 strongly down-regulated Tim4 a receptor for phosphatidylserine implicated in apoptotic cell uptake (efferocytosis) in macrophages. We found that TIM-4 expression is restricted to DC1 among lung phagocytes and we confirmed loss of receptor expression by flow cytometry in tumor associated DC1. Notably, the uptake of dying cells and the cross-presentation of cell-associated antigens was significantly diminished in tumors. In addition, TIM-4 blockade inhibited efferocytosis by DC1 and cross-priming of tumor specific T cells. These data identify TIM4-mediated engulfment of dying cancer cells by DC1 as a lung specific mechanism of immune surveillance that is lost upon tumor progression.

P.B2.05.05

Modulation of Glucocorticoid Induced Tumor Necrosis Factor Receptor (GITR)-GITR Ligand (GITRL) interaction in Breast Cancer Cells under the control of Ataxia Telangiectasia Mutated (ATM) Promoter

B. Dayanc[1], *D. Yoyen Ermis*[2], *E. Dayanc*[3], *G. Esendagli*[2];
[1]*Izmir Biomedicine and Genome Center, Izmir, Turkey,* [2]*Hacettepe University Cancer Institute, Ankara, Turkey,* [3]*Izmir University of Economics, Faculty of Medicine, Izmir, Turkey.*

Despite treatment, basal-like breast cancers (BLBC) has poor prognosis and high mortality. We investigated ATM activity in BLBC cell lines with radiation and examined the viability of BLBC cells during the GITR-GITRL interaction. ATM expression levels in basal-like (MDA-MB-231, HCC38, MDA-MB-468) and luminal (MCF-7, BT-474, SK-BR-3) breast cancer cell lines were a found similar. We observed an increase in ATM (S1981) phosphorylation in these cells. HCC38 cells transfected with "pATM-GL3" Luciferase reporter plasmid showed high basal and post-radiation ATM activity with experiments suggesting a post-transcriptional control mechanism. When we investigated GITR and GITRL expressions in BLBC cells, we observed no change in expression levels with radiation. While MDA-MB-231 and MDA-MB-468 cell lines show high GITRL expression, HCC38 cell line was GITR positive. GITR+ HCC38 cells were incubated with recombinant GITRL protein at different serum concentrations (1% and 10%) and the change of cancer cells' viability, proliferation and amount of metabolically active viable cells were investigated with DRAQ7 staining, CFSE assay and MTT assay, respectively. Even though GITR stimulation only has not changed viability and proliferation of HCC38 cells, both ionizing radiation and GITR stimulation had a cumulative effect on cell viability. When cell death was assayed, a significant decrease in viability of the cells was observed, with simultaneously exposure to 80 ng/ml rGITRL and 5 Gy ionizing radiation. This study demonstrated that cumulative effect of GITR stimulation and ionizing radiation may affect the viability of breast cancer cells.

P.B2.05.06

Glioblastoma exploits glycosylation-mediated immune regulatory circuits for immune escape

S. A. Dusoswa[1], *J. Verhoeff*[1], *E. R. Abels*[2], *E. C. Rodriguez*[1], *S. J. Van Vliet*[1], *D. P. Noske*[1], *T. Würdinger*[1], *X. O. Breakefield*[2], *M. L. Broekman*[2,3], *Y. Van Kooyk*[1], *J. J. Garcia-Vallejo*[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Massachusetts General Hospital, Harvard Medical School, Boston, United States,* [3]*University Medical Center Utrecht, Utrecht, Netherlands.*

Glioblastoma (GBM) is the most aggressive brain malignancy. Its histopathology is characterized by a significant infiltration with tumor associated macrophages and microglia (TAM), often comprising more than 30% of the tumor mass. TAMs express the macrophage galactose lectin (MGL) receptor in several tumor types, where it is thought to contribute to immune suppression upon binding to truncated O-linked glycans. Here we aim to elucidate the role of truncated O-glycans in GBM immune escape. To this end, GBM and control surgical samples were collected, and expression of MGL and its ligands was measured by flow cytometry, immunofluorescence, and ELISA. We detected significantly higher levels of the MGL receptor, and MGL-ligands in patient-derived GBM samples as compared to control samples. We then investigated the *in vivo* effects of varying levels of MGL ligands on immune composition in the tumor as well as systemically using an orthotopic immunocompetent GBM mouse model. Our data shows increased expression of MGL within several subpopulations of intratumoral myeloid cells as compared to mock injected mice. Our high dimensional mass cytometry analysis of tumors overexpressing truncated O-linked glycans revealed significantly increased subpopulations of immune suppressive TAMs. Our results suggest that GBM overexpress truncated O-linked glycans, and exploits glycosylation-mediated immune regulatory circuits for immune escape via immune suppressive TAMs. We hypothesize that manipulation of the MGL-MGL-ligand axis may provide new therapeutic avenues in preventing GBM immune escape.

P.B2.05.07

IDO dependent attenuation of NK cells contributes to enhanced mammary tumor growth in diabetic mice

N. M. Gajovic[1], *M. Jurisevic*[2], *N. Arsenijevic*[1], *M. Lukic*[1], *I. Jovanovic*[1];
[1]*Center for Molecular Medicine and Stem Cell Research, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia,* [2]*Department of Pharmacy, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia.*

Diabetic patients have higher incidence and mortality of cancer. Recent study revealed that hyperglycemia-induced oxidative stress is involved in the acceleration of tumor metastasis. We used model of high dose streptozotocin-induced diabetes to investigate its effect on tumor growth and modulation of antitumor immune response of 4T1 murine breast cancer in BALB/c mice. Diabetes accelerated tumor appearance, growth and weight, which was associated with decreased NK cells cytotoxicity against 4T1 tumor cells *in vitro*. Diabetes reduced frequencies of systemic NKG2D$^+$, perforin$^+$, granzyme$^+$, IFN-γ$^+$ and IL-17$^+$ NK cells, while increased level of PD-1 expression and production of IL-10 in NK cells. Diabetes decreased percentage of NKG2D$^+$NK cells and increased percentage of PD-1$^+$ NK cells also in primary tumor. Diabetes increased accumulation of IL-10$^+$ Tregs and TGF-β$^+$ myeloid derived suppressor cells (MDSCs) in spleen and tumor. Diabetic sera *in vitro* significantly increased percentage of KLRG-1$^+$ and PD-1$^+$ NK cells, decreased percentage of IFN-γ$^+$NK cells, expression of NKp46 and production of perforin, granzyme, CD107a and IL-17 per NK cell in comparison to glucose added mouse sera and control sera. Significantly increased percentages of inducible nitric oxide synthase (iNOS) and indoleamine 2,3-dioxygenase (IDO) producing MDSCs and dendritic cells (DC) were found in the spleens of diabetic mice prior to tumor induction. 1-*methyl*-DL-*tryptophan*, specific IDO inhibitor, almost completely restored phenotype of NK cells cultivated in diabetic sera. These findings indicate that diabetes promotes breast cancer growth at least in part through increased accumulation of immunosuppressive cells and IDO mediated attenuation of NK cells.

P.B2.05.08

IL-20 promoted tumor growth in hepatocellular carcinoma

Y. H. Hsu[1,2], *M. S. Chang*[3];
[1]*Institute of Clinical Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan,* [2]*Research Center of Clinical Medicine, National Cheng Kung University Hospital, Tainan, Taiwan,* [3]*Department of Biochemistry and Molecular Biology, College of Medicine, National Cheng Kung University, Tainan, Taiwan.*

Introduction: IL-20 is a proinflammatory cytokine involved in rheumatoid arthritis, atherosclerosis, and osteoporosis. However, the role of IL-20 in hepatocellular carcinoma (HCC) is unclear. We explored the function of IL-20 in HCC.Materials and Methods: Tumor tissue samples were analyzed the expression of IL-20 and cyclin D1 by using immunohistochemistry staining and quantitative real-time polymerase chain reaction analysis. To examine the role of anti-IL-20 monoclonal antibody in tumor growth, BALB/c mice was injected with ML-1 cells and treated with anti-IL-20 monoclonal antibody. Results: HCC tumor tissue expressed higher levels of IL-20 than did non-tumor tissue. High IL-20 expression in HCC was correlated with poor overall survival. IL-20 and cyclin D1 expression were also highly correlated in HCC patient specimens and 3 human HCC cell lines. IL-20 also increased cell proliferation and migration, and it regulated matrix metalloproteinase (MMP)-13, tumor necrosis factor (TNF)-α, cyclin D1, and p21WAF1 expression in ML-1 cells. Anti-IL-20 monoclonal antibody attenuated tumor growth in mice inoculated with ML-1 cells. The expression of cyclin D1, TNF-α, MMP-9, and vascular endothelial growth factor was significantly inhibited after anti-IL-20 monoclonal antibody treatment. Conclusions: IL-20 plays a role in the tumor progression of HCC. IL-20 might be a useful predictive marker for HCC progression.

P.B2.05.09

ACKR2 in hematopoietic precursors as a checkpoint of neutrophil release and anti-metastatic activity

M. Massara[1,2], *O. Bonavita*[1,2], *B. Savino*[1,2], *N. Caronni*[1,2], *V. Mollica Poeta*[1,3], *M. Sironi*[1], *E. Setten*[1,2], *C. Recordati*[4], *L. Crisafulli*[1], *F. Ficara*[1], *A. Mantovani*[1,3], *M. Locati*[1,2], *R. Bonecchi*[1,3];

96 Normal 0 14 false false false IT X-NONE X-NONE /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Tabella normale"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0cm 5.4pt 0cm 5.4pt; mso-para-margin:0cm; mso-para-margin-bottom:.0001pt; mso-pagination:widow-orphan; font-size:12.0pt; font-family:"Calibri",sans-serif; mso-ascii-font-family:Calibri; mso-ascii-theme-font:minor-latin; mso-hansi-font-family:Calibri; mso-hansi-theme-font:minor-latin; mso-fareast-language:EN-US;} Atypical chemokine receptors (ACKRs) are regulators of leukocyte traffic, inflammation, and immunity. ACKR2 is a scavenger for most inflammatory CC chemokines and is a negative regulator of inflammation. We reported that ACKR2 is expressed in hematopoietic precursors and downregulated during myeloid differentiation. Genetic inactivation of ACKR2 results in increased levels of inflammatory chemokine receptors and release from the bone marrow of neutrophils with increased anti-metastatic activity. In a model of NeuT-driven primary mammary carcinogenesis ACKR2 deficiency is associated with increased primary tumor growth and protection against metastasis. ACKR2 deficiency results in neutrophil-mediated protection against metastasis in mice orthotopically transplanted with 4T1 mammary carcinoma and intravenously injected with B16F10 melanoma cell lines. Thus, ACKR2 is a key regulator (checkpoint) of mouse myeloid differentiation and function and its targeting unleashes the anti-metastatic activity of neutrophils in mice. <!--EndFragment-->

P.B2.05.10

Factor H (FH) binding and elevated expression levels of membrane complement regulators (mCRP) are key players of enhanced complement resistance of breast cancer cells upon treatment with Paclitaxel and Doxorubicin

M. H. Nasrh[1], *M. Kirschfink*[1,2];
[1]*Institute of Immunology, 69120-Heidelberg, Germany,* [2]*National Research Centr (NRC), Cairo, Egypt.*

Tumor resistance to chemotherapy is a major problem in cancer treatment. Resistance exists against every effective anticancer drug and can develop by numerous mechanisms including decreased drug uptake, increased drug efflux, activation of detoxifying systems, activation of DNA repair mechanisms, evasion of drug-induced apoptosis, etc. There are contrasting data on a possible correlation between the level of expression of multidrug resistance (MDR)-associated drug transporter P-glycoprotein (P-gp) and the susceptibility to complement-dependent cytotoxicity (CDC). Our previous studies revealed that enhanced resistance of chemo-selected MDR ovarian carcinoma cells to CDC is not conferred by P-gp, but due at least partly to overexpression of mCRP. We here investigated the sensitivity of the human breast carcinoma cell lines SKBR3 and BT474 to complement-dependent cytotoxicity in response to short-term treatment with Paclitaxel and Doxorubicin. Drug treated carcinoma cells showed increased resistance to CDC associated with an overexpression of membrane-bound complement regulatory proteins, CD46, CD55 and CD59. Drug treatment of carcinoma cells also induced the release of the soluble regulator Factor H with secondary binding to the drug-treated cell as well as the production of C1 inhibitor and factor I.
We conclude that the release of multiple soluble complement regulators into the microenvironment of breast carcinoma cells together with enhanced levels of mCRPs induced by chemotherapeutic agents even upon short-term treatment are significant to increased tumor cell resistance to complement-mediated killing.
This work is financially supported by German Academic exchange service (DAAD), through German Egyptian Research Long-Term Scholarship Program (GERLS).

MicroRNA expression profiling in acute myeloid leukaemia patients and healthy donors according to age

*B. Sabchez-Correa[1], **A. Pera**[2], F. Hassouneh[2], C. Campos[2], N. Lopez-Sejas[2], J. M. Bergua[3], M. Arcos[3], H. Bañas[3], E. Durán[4], R. Solana[2], R. Tarazona[1];*
[1]Immunology Unit, University of Extremadura, Cáceres, Spain, [2]IMIBIC - Reina Sofia University Hospital - University of Cordoba, Cordoba, Spain, [3]Department of Haematology, Hospital San Pedro de Alcantara, Cáceres, Spain, [4]Histology and Pathology Unit, Faculty of Veterinary, University of Extremadura, Cáceres, Spain.

Introduction: MicroRNAs (miRNAs) are important regulators of biological processes such as cell proliferation/apoptosis, immune responses and tumorigenesis. miRNAs dysregulation have been identified in haematological malignancies including acute myeloid leukaemia (AML), which is a disease of older adults. Ageing has been associated with a progressive deterioration of the immune system that limits the capacity to mount an appropriate immune response to pathogens and may affect tumour immunosurveillance. Recently, age-associated changes in miRNA profiles have been described some of them related to immune system function.
Methods: we analysed miRNA expression profiles in AML patients and the effect of aging on miRNA expression.
Results: we identified six miRNAs significantly lower and seven miRNAs that were significantly upregulated in AML patients. Some of them have been implicated in cancer pathogenesis.
Conclusions: we demonstrate that AML induces changes in miRNA profile that have the potential to be diagnostic or prognostic biomarkers of disease. In addition, in healthy donors we have found three miRNAs (miR-15b, miR-181a, miR-494) that were significantly decreased with age. However, no age-associated differences were observed in AML patients suggesting that AML-induced changes in miRNA profile surpass the effect of age itself. In conclusion, circulating miRNAs in AML had a distinctive profile that distinguishes patients from healthy donors. Further characterization of circulating miRNAs in AML and the effect of age in their expression are required to use miRNAs as biomarkers of disease and ageing.

Comprehensive immune landscape of a lung cancer model

***X. L. Raffo Iraolagoitia**[1], D. Reijmer[1,2], A. J. McFarlane[1], B. Kruspig[3], J. Secklehner[1,4], J. B. MacKey[1,4], S. B. Coffelt[1,3], D. J. Murphy[3,1], L. M. Carlin[1,4];*
[1]Cancer Research UK Beatson Institute, Glasgow, United Kingdom, [2]Universiteit Utrecht, Utrecht, Netherlands, [3]Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom, [4]Imperial College London, London, United Kingdom.

Lung homeostasis relies on resident (immune and non-immune) cells and recruited leukocytes to cope with potentially harmful agents entering the airways without causing excessive damage and chronic inflammation. Both sides of this tightly regulated balance between tolerogenic circuits and inflammatory pathways could be potentially rewired by transformed cells to create a tumour permissive microenvironment. Although immunotherapies have proven to be very successful for a number of cancers, just a small fraction of lung cancer patients benefits from them and lung cancer remains the leading cause of cancer death. Therefore, gaining further insight into how lung leukocytes support and/or antagonise tumour growth is crucial to improve therapeutic strategies. To address this, we used a conditional transgenic mouse model (lsl-KRas^{G12D}; Rosa26-lsl-MYC) that develop lung cancer upon Adeno-Cre intranasal administration. By flow cytometry, we characterized the immune cell composition and phenotype in lung, blood, spleen, bone marrow and liver, 6 weeks after induction (when all mice have developed adenocarcinoma but have not yet shown any sign of sickness) and at end point. Additionally, we studied leukocyte localisation and distribution patterns by confocal imaging of large 3D volumes within agarose inflated precision cut lung slices. Overall, we found major tumour-induced changes in the immune-landscape of the lung which may play an important role promoting tumour escape. We next aim to interrogate potential connections between these alterations to gain mechanistic information to further dissect and exploit.

P.B2.05.13

Elucidating the pathophysiological role of dendritic cells in multiple myeloma

***J. R. Richardson**[1], M. Günter[1], K. Weisel[1], H. Bühring[1], H. R. Salih[2], S. E. Autenrieth[1];*

Introduction: Multiple Myeloma (MM) is a B cell malignancy, characterized by clonal expansion of malignant plasma cells in the bone marrow (BM). DCs are key players of the immune response by linking the innate and adaptive immune system. The role of DCs in MM pathogenesis is poorly understood. *Methods:* We analyzed different DC subsets and progenitors *ex vivo* (n=35 MM, n=20 HD) from the BM of MM patients upon initial diagnosis and correlated the data to the clinical status. Patients subjected to hip replacement served as healthy donors (HD). Furthermore, sorted CD34$^+$ progenitor cells from MM patients and HD were analyzed for their capacity to differentiate into DC subsets *in vitro*. *Results:* The frequencies of plasmacytoid DCs (0,476% ±0,277 vs. 0,202% ±0,174) and CD141$^+$ DCs (0,121% ±0,094 vs. 0,023% ±0,028) as well as that of their immediate progenitors, "common DC progenitors" (CDPs) (0,058% ±0,0085 vs. 0,0011 ±0,0014) and pre-DCs (0,0359% ±0,0826 vs. 0,0076% ±0,0096), were significantly reduced in the BM of MM patients compared to HD, whereas the frequency of monocytes was increased. Moreover, the reduction of CD141$^+$ DCs, pre-DCs and CDPs correlated with the disease stage. Besides, CD34$^+$ progenitors from MM patients showed a reduced *in vitro* differentiation potential as well as proliferation capacity compared to that of HD. *Conclusion:* Our data indicate that DC differentiation in MM patients is intrinsically impaired most likely leading to less differentiated DCs.

P.B2.05.14

Crosstalk between pericytes and colorectal cancer cell promotes tumorigenicity through release of soluble factors

*R. Navarro[1], A. Tapia[1], M. Compte[1], A. Erce[1], M. Zonca[1], L. Alvarez-Vallina[2], **L. Sanz**[1];*
[1]Molecular Immunology Unit, Hospital Puerta de Hierro, Majadahonda, Spain, [2]Immunotherapy and Cell Engineering Laboratory, Department of Engineering, Aarhus University, Aarhus, Denmark.

Introduction: Pericytes are mural cells that surround endothelial cells in small blood vessels and constitute a source of tumor-associated stromal cells. Crosstalk between cancer cells and stroma promotes tumor progression, but the potential role of pericytes (PC) in the tumor microenvironment had not been addressed.
Materials and Methods: To analyse the potential role of PC in the tumor microenvironment, *in vitro* proliferation, migration and invasion of the human colorectal cancer cell (CRC) line HCT 116 were assayed in co-culture with primary PC. The effect of coimplantation in tumor growth was studied *in vivo* establishing a xenograft model. Transcriptomic profiling of PC after mono- or co-culture with HCT 116 was performed. Antibody arrays were used to analyse the secretome of PC in mono- or co-culture.
Results: We demonstrated that co-culture with PC enhanced HCT 116 tumorigenicity increasing tumor cell proliferation, migration and invasion. Moreover, co-implantation of HCT 116 tumor cells with PC accelerated tumor growth *in vivo*. PC cultured with HCT 116 cells expressed a distinct gene signature which correlated with clinical outcome in CRC patients. Conditioned media of co-cultured PC contained different mediators that could explain the functional effects observed in HCT 116, including IL6, IL11 and LIF.
Conclusion: We have found the crosstalk between PC and CRC cells to be bidirectional, i.e. tumor cells modulate PC gene expression that, in turn, promote pro-tumorigenic behaviour by inducing the secretion of mediators that facilitate tumor progression. This study suggests that PC deserve further investigation as potential therapeutic targets in cancer.

P.B2.05.15

Effect of Nasopharyngeal Carcinoma-derived exosomes on the emergence of tolerogenic dendritic cells

***R. Sarah**[1], C. Havet[1], Z. Fitzpatrick[2], B. Hennart[3], D. Allorge[3], O. Moralès[1], N. Delhem[1];*
[1]CNRS UMR8161, Lille, France, [2]Harvard Medical School, Boston, United States, [3]Centre de Biologie-Pathologie, CHRU de Lille, Lille, France.

Background: A characteristic of the nasopharyngeal carcinoma (NPC) micro-environment is the presence of immunosuppressive exosomes released by tumor cells. Our team has recently shown that NPC-derived exosomes favor the recruitment and suppressive activity of human regulatory T cells (Treg), thus contributing to NPC immune escape (Mrizak et al., JNCI, 2015).
Question: In this study, our objective is now to evaluate whether these NPC-derived exosomes could promote the emergence of tolerogenic dendritic cells (tolDC) able to induce regulatory T cells contributing to the tolerance of tumor cells.
Methods: We performed a complete phenotypical and functional study comparing the effect of NPC and healthy donor-derived exosomes on DC maturation. This study includes (**i**) a transcriptomic study by RTqPCR, (**iii**) flow cytometric analysis of the expression of DC phenotype and Treg markers, (**iv**) a preliminary DC functional study by western blotting of the enzyme IDO1 and HPLC dosage of tryptophan metabolites, (**v**) a secretome analysis by ELISA (**vi**) and finally a functional assay where the DC-exposed to NPC-exosomes are co-cultivated with PBMCs or naïve T cells in order to determine the type of T cells generated.
Conclusions: Taken together our results strongly suggest that the presence of NPC-derived exosomes favors the emergence of semi-mature tolDCs. Despite the importance of tolDCs in immune escape, no other study has yet shown the impact of tumor exosomes on the maturation of human DCs. Thus, these promising results should open new prospects for antitumor immunotherapies based on the inhibition of factors involved in the emergence of Tregs.

P.B2.05.16

Overexpression of the chemokine receptor CXCR3 on CD5^{high} and CD5^{low} leukemic cells correlates with favorable prognosis in chronic lymphocytic leukemia

V. Smotkova Kraiczova[1], *G. Manukyan*[2,1], *R. Fillerova*[1], *Z. Mikulkova*[1], *G. Gabcova*[1], *R. Urbanova*[3], *P. Turcsanyi*[3], *A. Petrackova*[1], *T. Papajik*[3], *E. Kriegova*[1];

Despite the shared pattern of surface antigens, population of neoplastic cells in chronic lymphocytic leukemia (CLL) demonstrate a heterogeneity in their molecular and functional characteristics. Given the dynamic variations of CD5 expression and its link to the proliferating pool of neoplastic cells, we aimed to further characterize chemokine and adhesion molecule profile on CD5^{high} and CD5^{low} neoplastic clones in peripheral blood of CLL patients as well as their relevance to the disease progression and patient characteristics. CD5^{high} cell subpopulation expressed higher levels of CXCR3 (P<0.001), CXCR5 (P=0.007), CCR10 (P=0.001), CD62L (P=0.029) compared with those expressed on CD5^{low} cells, whereas CD5^{low} cells expressed higher levels of CXCR4 receptor (P<0.001). Accordingly, CXCR3/CXCR4 ratio was higher on CD5^{high} comparing to CD5^{low} B-cells (P<0.001). Mutated *IGHV* status was strongly associated with higher percentage of CXCR3 cells on both CD5^{high} (P=0.001) and CD5^{low} (P<0.001) cells, as well as higher MFI of CXCR3 on both CD5^{high} (P=0.006) and CD5^{low} (P=0.005) cells. Combination of CXCR4 (MFI) - CXCR3/CXCR4 ratio or CXCR3 (MFI) - CXCR4 (MFI) was the most significant able to discriminate CD5^{high} and CD5^{low} subpopulations. Our results suggest CXCR3 as a marker which greater expression portend a favourable prognosis. Further investigation of CLL cell heterogeneity will advance our understanding of neoplastic cell biology and its links to the prognosis.

Introduction: Immunotherapy aimed at blocking PD1/PDL1 pathway restores anti-tumor immunity but may result in a number of Immune-Related Adverse Events (iRAE).
Patients and Methods: Three patients, receiving PD1/PDL1 blockers (Cases 1 to 3) were referred to internal medicine because of symptoms suggestive of myopathy. Case 4 was already diagnosed as dermatomyositis. Clinical, immunological and histopathological evaluation confirmed immune-mediated myositis.
Results: Case 1 was a breast carcinoma who 24 hours after the first cycle of anti-PD1 (Pembrolizumab) presented with asthenia and a macular rash in both ankles followed 3 months later by neutropenia, hypothyroidism and amyopathic dermatomyositis. Case 2 was a malignant thymoma treated with anti-PDL1 (Atezolizumab) who developed immune-mediated necrotizing myopathy negative for myositis auto-antibodies (16 antigens). Case 3 was a non-Hodgkin lymphoma receiving anti-PD1 (Nivolumab) who developed sporadic inclusion body myositis with anti-CN1A. In cases 1 and 2 the suspension of immune-checkpoint therapy after 11 and 4 cycles respectively plus steroids induced remission of myositis. In Case 3 treatment interruption did not result in improvement. Case 4 was already diagnosed of paraneoplastic dermatomyositis associated to a primary small-cell lung carcinoma positive for anti-NXP2 prior to anti-PD1 (Nivolumab). Interestingly anti-PD1 was well tolerated with a partial response of the tumour without exacerbation of the dermatomyositis.
Conclusion: Immune mediated myositis has been reported in very few patients on checkpoint inhibitor therapy. Skin lesions and muscle weakness should alert and prompt for effective management. On the other hand, the presence of paraneoplastic dermatomyositis is not a contraindication of checkpoint inhibitors treatment.

P.B2.05.18

Identification of a stromal stem cell in pancreatic cancer that drives tumor growth and metastasis

Z. Wu[1,2,3], *X. Zhang*[1,2,3], *Y. Zhao*[1,2,3], *I. Mikaelian*[1,2,3], *P. Bertolino*[1,2,3], *A. Hennino*[1,2,3];
[1]*Cancer Research Center of Lyon, UMR INSERM 1052, CNRS 5286, F-69373, Lyon, France,* [2]*Université Lyon 1, F-69000, Lyon, France,* [3]*Centre Léon Bérard, F-69008, Lyon, France.*

Introduction: Cancer stem cells (CSCs) have been characterized as the properties of stem-like features, tumorigenicity and treatment-resistant. Investigations of CICs have been manipulated in pancreatic ductal adenocarcinoma (PDAC), in which tumor microenvironment plays an important role in tumor regulation. However, the identification of pancreatic CICs within native pancreatic tumor microenvironment still remains unclear.Materials and Methods:KC (p48-Cre;K-Ras$^{+/LSLG12D}$) and KIC(Ptf1/p48-Cre; K-RAS$^{+/LSLG12D}$; Ink4a/Arf$^{flox/lox}$) mice model, cell culture, immunohistochemistry and immunofluorescence, FACS, RT-qPCR, subcutaneous injection into Rag KO mice.Results: A subpopulation of cells in pancreas of the KC mice defined as CD45-EpCAM-PDGFRα-CD24+CD44+ have a stromal localization and stromal signature (Fsp1↑, Vim↑, Actα2↑), but no epithelial gene expression (CK19↓, CK7↓, Sox9↓). Moreover, this subpopulation shares some features of embryonic stem cells (Oct3/4) and adult stem cells (Nestin). Furthermore, Alk4 (Activin A cognate receptor) and Alk5 (TGF-βR1 receptor) expression is significantly higher in CD24+CD44+subpopulation compared to CD24-CD44-counterpart suggested the involvement of TGFβ/ActivinA signaling pathway in regulation of CD24+CD44+subpopulation. The in vivo co-injection of this stromal population along with transformed epithelial Kras primary cell line leads to increase tumor progression and metastasis. Surprisingly, we also discover that the cell and spatial density is highly related with their degree of differentiation and outcome both in vitroand in vivo.Conclusion: We have identified a population of stromal stem cells generated from KC mice that might be at least in part at the origin of the desmoplastic reaction in PDAC. Further in vivo and in vitro investigation will provide new hints into the mechanism of generation of the stromal reaction.

P.B2.05.19

Role of carbohydrate metabolism abnormality in non-small cell lung cancer-related immunoparalysis

Z. I. Komlósi[1,2,3], *G. Szücs*[2], *É. Imre*[3], *M. Szentkereszty*[4], *G. Barna*[4], *G. Losonczy*[2];
[1]*Department of Genetics, Cell- and Immunobiology, Semmelweis University, Budapest, Hungary,* [2]*Department of Pulmonology, Semmelweis University, Budapest, Hungary,* [3]*Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary,* [4]*1st Dept. of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary.*

Human Leukocyte Antigen-DR (HLA-DR), a major histocompatibility complex class II cell surface receptor, is involved in antigen presentation to T helper cells, and its reduced expression on monocytes is associated with poor prognosis in non-small cell lung cancer (NSCLC; Lancet Oncol 2013. 14:e218). Both elevated fasting serum glucose level (> 7 mmol/L) and diagnosed diabetes mellitus are independent negative prognostic markers in NSCLC (Lung Cancer 2012. 76:242), however the mechanisms by which the abnormality of carbohydrate metabolism aggravate lung cancer have not been fully clarified. Hyperglycemia and insulin resistance are known to induce a reduction in HLA-DR expression (immunoparalysis) in sepsis. We aimed to investigate the role of carbohydrate metabolism abnormality in NSCLC-related immunoparalysis. 33 NSCLC patients (stage IIIb-IV) were included in the study. Monocyte HLA-DR expression was measured by using flow cytometry. Serum glucose and insulin concentration was measured and Homeostasis Model Assessment - Insulin Resistance 2 (HOMA-IR2) score was calculated. 18 patients had hyperglycemia, and 16 out of them were insulin resistant (HOMA-IR2 > 2). A significant indirect correlation was revealed both between insulin concentration and HLA-DR expression, and between HOMA-IR2 and HLA-DR expression. Our results suggest that insulin resistance may contribute to the unfavorable alteration of antigen presentation capacity, and consequently, an insufficient anti-tumor immune response in NSCLC. This underline the previously unappreciated importance of the management of carbohydrate homeostasis in lung cancer patients. Funded by NKFIH K 108009.

P.B2.05.20

Monitoring antibody responses against tumour associated protein mutations might clinically be of prognostic relevance

H. Thiesen[1], *F. Steinbeck*[1], *E. Schade*[2], *M. Maruschke*[3], *O. Hakenberg*[4];
[1]*Institute of Immunology, Rostock, Germany,* [2]*Gesellschaft für Individualisierte Medizin, Rostock, Germany,* [3]*Helios Hanseklinikum Stralsund, Stralsund, Germany,* [4]*Department of Urology University Medicine Rostock, Rostock, Germany.*

Introduction: Whole somatic genome sequences of three patients suffering from clear cell renal cell carcinoma (ccRCC) have been computationally analysed to categorize protein structures mutated in these tumors. The working hypothesis addressed is focussed on the prognostic relevance (harmful or beneficial) of elicited tumor-associated antibody reactivities. Method: Peptides representing putative neoepitopes such as point as well as frame shift mutations were synthesized. Initially, peptide microarrays were used to select mutated peptides that show epitope-antibody-reactivities (EAR) in sera of ccRCC patients. The ten most informative peptides were finally subjected to MSD multi-arrays by addressing 10 different peptides per well. Results: Of 94 ccRCC sera tested, 20 sera showed at least one positive signal, of which 8 sera reacted with more than one peptide selected from our initial screen. Interestingly, the patient that show EAR with all 10 preselected peptides turned out to suffer from metastatic ccRCC. He died shortly after his tumour had been removed. Conclusion: Our multi-array analysis of tumour associated antibodies directed against mutated peptide sequences present in patients suffering from clear cell renal carcinoma indicate that the presence of antibodies directed against tumor related protein structures might have a negative prognostic effect.

In turn, peptide vaccination strategies should be carefully handled as long as they lead to enhanced humoral antibody responses. At the moment, we cannot exclude that these antibody specificities elicited might counterbalance current cellular immune therapies that stop ongoing checkpoint inhibitions. Multicentric studies await to be conducted to validate the clinical and prognostic value of EAR against mutated protein structures.

P.B2.05.21
Therapeutic induction of tertiary lymphoid structures in tumors

G. Vella[1], *O. Burton*[2], *Y. Hua*[1], *E. Allen*[1], *M. Duhamel*[1], *S. Schlenner*[2], *G. Bergers*[1,3];
[1]*Laboratory of Tumor Microenvironment and Therapeautic Resistance, VIB-KU Leuven Center for Cancer, Leuven, Belgium,* [2]*Laboratory of Genetics of Autoimmunity, VIB-KU Leuven Center for Brain & Disease Research, Leuven, Belgium,* [3]*3. Department of Neurological Surgery, Brain Tumor Research, Helen Diller Family, Comprehensive Cancer Center, University of California, San Francisco, United States.*

Tertiary lymphoid structures (TLSs) are induced postnatally in non-lymphoid tissues such as those affected by chronic infections or autoimmune diseases, but also spontaneously form in cancer tissues. They are composed of surrounding stromal and lymphoid cell constituents without the necessity of a capsule and contain high endothelial venules (HEV) that are adapted for lymphocyte trafficking and normally found in lymph nodes. While TLS formation in inflamed tissues is associated with a worse outcome, spontaneous TLS formation in several human cancer types correlated with improved patient survival. We have recently shown that intratumoral HEV formation can be therapeutically induced by antiangiogenic immunotherapy in mouse models of pancreatic and breast cancer, and is dependent on lymphotoxin-beta receptor activation. Intratumoral HEV formation enhanced T-and B-cell influx forming TLS-like structures, which subsequently inhibited tumor growth and enhanced survival. Using powerful analytical tools we are currently evaluating the immune composition and immune functionality in HEV+ tumors (by FACSymphony™) and specifically around HEV (by spatial transcriptomics and immunofluorescence staining) in a murine breast cancer model. Our data provide evidence that therapeutically induced TLS/HEVs in tumors generate an immunostimulatory microenvironment by specifically increasing the levels of intratumoral activated CD8+, CD4 Th1+ and NK cells.

P.B2.06.01
The regulatory effect of Type I IFNs on neutrophil angiogenic capability in tumor microenvironment

S. Bordbari[1], *E. Pylaeva*[1], *I. Spyra*[1], *I. Helfrich*[2], *S. Lang*[1], *J. Jablonska*[1];
[1]*Research division of Otorhinolaryngology department of University Hospital Essen, Essen, Germany,* [2]*Skin Cancer Unit of the Dermatology Department of University Hospital Essen, Essen, Germany.*

Introduction: Tumor-associated neutrophils (TANs) influence tumor growth and angiogenesis, depending on IFNs availability in milieu. Since angiogenesis plays a crucial role in tumor progression, the aim of this study is to determine the mechanism responsible for neutrophil-dependent tumor vascularization, and how IFNs impact this process. **Methods:** First, we analyzed TAN infiltration, vasculature development and maturation stages of endothelial cells in the tumors. We assessed also hypoxic areas and the vessel leakiness in tumors. Pro-angiogenic regulatory gene expression was analyzed in endothelial cells after stimulation with TANs. Additionally, we assessed the capacity of TANs to stimulate proliferation, migration, tube formation assay and sprout-forming capacity of endothelial cells. To delineate the role IFNs play in the regulation of tumor angiogenesis, we compared TANs from IFN-deficient mice with WT. **Results:** We could observe elevated tumor growth and higher TAN numbers in IFN-deficient mice which were associated with more mature, functional phenotype tumor vasculature and show significant upregulation of pro-angiogenic factors, such as Neuropilin1 (NRP1) and Endoglin (ENG). Interestingly, these tumors show also increased hypoxia. Co-culture of endothelial cells with such proangiogenic IFN-deficient TANs led to profound increase of their proliferation, migration, tube formation and sprouting capacity. In agreement, aortic ring assay showed more microvessel outgrowths after addition of IFN-deficient TANs. **Conclusion:** Taken together, our results suggest that IFN-deficient TANs of pro-angiogenic phenotype can efficiently stimulate tumor vascularization and tumor growth. The lack of type I IFNs stimulates their proangiogenic capacity due to upregulation of Pro-angiogenic regulatory genes.

P.B2.06.02
Cytotoxic effects of tamoxifen on MCF-7 cells may be improved by propolis without affecting the viability of human monocytes

E. O. Cardoso[1], *K. B. Santiago*[1,2], *B. J. Conti*[1], *F. L. Conte*[1], *L. P. Oliveira*[1], *K. I. Tasca*[1], *J. M. Sforcin*[1];
[1]*Department of Microbiology and Immunology, Biosciences Institute, Sao Paulo State University, Botucatu, Brazil,* [2]*Integrated Regional Faculties of Avaré, Avaré, Brazil.*

Cancer is a disease that affects millions of people in different continents, resulting in millions of deaths annually. Tamoxifen has been used to treat breast cancer and considering the side effects caused by anticancer agents, such as toxicity, induction of resistance in tumor cells and immunosuppression, the administration of natural products simultaneously with anticancer drugs has been investigated. Propolis is a bee product displaying a cytotoxic activity against tumor cells and modulatory effects on immune cells. This study investigated the cytotoxic effects of propolis in combination with tamoxifen (P + TAM) on MCF-7 cells and on human monocytes. MCF-7 cells were used as a tumoral model and were treated with tamoxifen (0.25, 0.5, 1 and 2.5 μM), propolis (25, 50, 75 and 100 μg/mL), and their combinations for 24, 48 and 72 h. Human monocytes were obtained from 5 healthy donors and treated with the same concentrations for 18 h. After these periods of time, cell viability was assessed by the colorimetric MTT assay. Significant differences between treatments were determined by analysis of variance (ANOVA), followed by Dunnett's test ($P < 0.05$). Among all treatments and concentrations, propolis (50 and 75 μg/mL) increased the cytotoxic action of tamoxifen (0.25 and 0.5 μM) against MCF-7 cells after 48 h without affecting monocyte viability. This finding indicated that these combinations may be efficient against tumor cells *in vitro* but not normal ones, preserving monocytes functions. Finnancial support: FAPESP 2016/09986-4.

P.B2.06.03
IFN-gamma signaling involved in PD-L1 expression in tumor associated macrophages of mouse orthotopic liver cancers treated with sorafenib

C. Chang[1], *S. Yang*[1], *C. Hsu*[1,2];
[1]*Graduate Institute of Oncology, College of Medicine, National Taiwan University, Taipei, Taiwan,* [2]*Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan.*

Introduction: We previously demonstrated that PD-L1 expression increased in tumor-associated macrophages (TAMs) of hepatocellular carcinoma (HCC) tumors progressing from sorafenib treatment. The current study explored the potential mechanisms underlying the increased PD-L1 expression in TAMs of HCC.
Materials and Methods: BNL cells, a mouse liver cancer cell line, were implanted on liver of BALB/c mice, and were fed with sorafenib (5 mg/kg/day) for 1 week. Specific antibodies were used to detect the expression of PD-L1, CD11b, F4/80, CD86, or MHC II in TAMs. RAW 264.7 and PMA-treated THP-1 cells were primed with IL-4, IL-10, IL-13 and TGF-β, followed by treating IFN-γ plus TNF-α or LPS. The expression of genes of interest was quantitated by Syber Green Real-Time PCR method.
Results: Sorafenib treatment suppressed the growth of BNL mouse liver tumors. $CD11b^+F4/80^+$ TAMs (50-73%) from sorafenib- treated liver tumors exhibited increased expression of PD-L1 (MFI 316.8), CD86 (MFI 136.3), and MHC II (MFI 341.7). Transcripts analysis not only confirmed the increased expression of PD-L1, CD86 and MHC II, but also revealed the upregulation of IFN-γ signaling including iNOS, IL-12, Stat1, IRF1, and JAK1/2 in TAMs from sorafenib-treated liver tumors. In cultured RAW 264.7 or THP-1 cells with M2 polarization, we found that IFN-γ/ TNFα or IFN-γ/ LPS upregulated the expression of PD-L1, CD86, and MHC II.
Conclusions: Our data suggest that activation of IFN-γ signaling contributes to PD-L1 upregulation in TAMs of mouse liver cancer treated with sorafenib.

P.B2.06.04
Food-derived β-glucans: polarization towards M1-like macrophages

P. de Graaff[1,2], *A. van Laar*[2], *M. M. Tomassen*[2], *C. Berrevoets*[1], *R. Debets*[1], *C. Govers*[2];
[1]*Erasmus MC-Cancer Institute, Rotterdam, Netherlands,* [2]*Food & Biobased Research, Wageningen, Netherlands.*

Introduction: Immune therapies have shown clear clinical effects in the treatment of solid tumors. Despite significant initial responses, these therapies are currently challenged by incomplete and non-durable responses in the majority of patients, which are in part related to T cell evasive mechanisms. In the current study, we assess non-digestible polysaccharides (ß-glucans) for their 'adjuvant effect' towards innate immune cells to support anti-tumor effects of T cells.
Materials and methods: Nine β-glucans (Maitake D-fraction, Oat, Zymosan, Lentinan, Curdlan, Schizophyllan, Whole Glucan Particles and two types of yeast-derived ß-glucans) were tested for their effects on the plasticity of human monocyte-derived macrophages (M0) or macrophages that were first polarized to M2 macrophages. The phenotype and function of resulting macrophages was assessed by qPCR, whole genome expression analysis, flow cytometry and ELISAs, as well as tumor cell:T cell:macrophage co-culture experiments.
Results: Zymosan, Yeast Immitec and Curdlan up-regulated gene expression of CCR7, ICAM-1 and CD80, and significantly increased the secretion of both TNFα and IL-6 in M0 macrophages. Notably, when starting from immune suppressive M2-like macrophages, often prevalent in solid tumors, these three β-glucans again pushed macrophages towards an M1-like phenotype. Moreover, these β-glucans induce expression of T cell selective chemoattractants, and were able to reverse macrophage-mediated inhibition of anti-tumor T cell responses.
Conclusion: These *in vitro* analyses demonstrate that selected β-glucans have the unique ability to preferentially skew macrophages towards an M1-like, T cell supportive, phenotype.

P.B2.06.05

Characterisation of novel CD73 antibodies as a therapeutic method of adenosine regulation

G. Gernon[1], *S. Grooby*[1], *L. Tonkin*[1], *A. Bitterwolf*[2], *L. Stewart*[2], *P. Shah*[1], *Z. Johnson*[1], *K. Ewings*[1];
[1]*Cancer Research UK Therapeutic Discovery Laboratories, Cambridge, United Kingdom,* [2]*Cancer Research UK Therapeutic Discovery Laboratories, London, United Kingdom.*

CD73 is a membrane-bound nucleotidase receptor which is frequently overexpressed in the tumour microenvironment and can be found on both tumour and infiltrating immune cell. Its function is to catalyse the conversion of adenosine monophosphate (AMP) to adenosine and phosphate and it has been proposed as a therapeutic target in cancer due to the role of adenosine in tumour immune suppression.
A series of novel CD73 antibodies have been characterised *in vitro* using multiple approaches. Inhibition of CD73 activity was evaluated using an Amplex Red-based coupled adenosine assay against both human and mouse CD73, and kinetics of antibody binding were determined using BioLayer Interferometry. Cellular assays were then utilised to further evaluate the antibodies *in vitro*. The ability of the CD73 antibodies to internalise was evaluated using two different methods, a Fab-ZAP killing assay and the IncuCyte™ FabFluor internalisation assay. The antibodies have also undergone functional studies that investigate the ability of the CD73 antibodies to disrupt the production of adenosine in tumour cells.
We demonstrate that amongst our panel of antibodies inhibit CD73 function by two different mechanisms, direct inhibition of enzyme activity and modulation of cell surface expression; both of which have therapeutic potential to disrupt CD73-mediated adenosine production and therefore reduce anti-tumor immune responses. Several antibodies from this panel will be advanced into late-stage preclinical development to identify a clinical development candidate.

Expression of the P2X7(k) splice variant by 4T1 breast cancer cells inhibits tumor growth *in vivo*

S. Javed, *F. Koch-Nolte, F. Haag;*
University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Immunogenic cell death caused by chemotherapy can favor T cell activation by the release of damage-associated molecular patterns, including ATP. Various tumor and immune cells express the ATP-gated P2X7 ion channel. Tonic activation of P2X7 on tumor cells benefits tumor growth by stimulating cell metabolism, but strong stimulation of P2X7 can kill tumor cells. Expression of P2X7 by host immune cells is detrimental to the tumor because it enhances the anti-tumor immune response. Little is known about the role of P2X7 in the context of chemotherapy. We therefore studied the effects of P2X7 stimulation on Doxorubicin (DOX) toxicity in lymphoma and breast cancer cell lines.
Low doses of extracellular ATP (eATP) synergistically enhanced the sensitivity to DOX. This effect was linked to a specific splice variant (P2X7k) of P2X7, and was further enhanced by an agonistic nanobody to P2X7. Mechanistically, gating of P2X7 augmented the initial uptake of DOX into cells. However, enhanced cell death was also observed when DOX was washed away before exposure to eATP, suggesting that the synergism resulted from an interaction of downstream signaling pathways. In the 4T1 breast cancer model expression of P2X7 inhibited tumor growth *in vivo* by increasing apoptosis and enhancing immune cell infiltration. Our results suggest that expression of P2X7 by tumor cells may contribute to their sensitivity to chemotherapeutic drugs.

P.B2.06.07

Hypoxia regulates the fate of γδ T cells in tumour microenvironment

S. Kashipathi Sureshbabu[1,2], *A. D'Cruz*[3,2], *D. Chaukar*[3,2], *S. V. Chiplunkar*[1,2];
[1]*Advanced Centre for Treatment, Research and Education in Cancer, Navi- Mumbai, India,* [2]*Homi Bhabha National Institute, Mumbai, India,* [3]*Tata Memorial Hospital, Mumbai, India.*

Oral cancer is the most common cancer in India with relatively poor prognosis. Hypoxia is one of the factors important in predicting survival,contributing to tumour progression, therapy resistance and poor clinical outcome. Understanding the complexity of tumour microenvironment(TME) is important for the development of immunotherapy. γδ Tcells infiltrate tumours and exhibit potent antitumor activity, hence are becoming the attractive candidates for cancer immunotherapy. In the current prospective study, we aimed at investigating the effect of hypoxia on the effector functions of γδ Tcells. γδ Tcells showed increased oral tumour infiltration, exhibited marked differences in the expression of activation markers CD69 and CD25, effector molecules-perforin and IFNγ. Enhanced expression of hypoxia inducible factor1-α was observed in γδ Tcells in oral tumours. Freshly isolated γδ Tcells from healthy individuals were stimulated with αCD3mAb and 1-Hydroxy-2-methyl-2-buten-4-yl4-diphosphate(HDMAPP) and cultured in the presence or absence of hypoxia. Under hypoxia, antigen specific proliferation and activation status of γδ Tcells was unaltered. A marked decrease was observed in the anti-tumour cytotoxic ability of γδ Tcells owing to the decreased expression of IFNγ, CD107a and transcription factors Eomes and Tbet which are responsible for regulating the cytotoxic effector functions. Under hypoxia, γδ Tcells express increased RORγt and secreted cytokines favouring γδT17 differentiation. Gene expression studies of hypoxia exposed γδ Tcells confirmed γδT17 differentiation to a pro-tumor phenotype promoting angiogenesis. In conclusion, we demonstrate that hypoxic TME gives survival advantage to γδT17,thus promoting immune evasion. Funding - Terry Fox International Research Grant, The Terry Fox Foundation

Targeting Myeloid-Derived Suppressor Cells (MDSC) in Myelodysplastic Syndromes (MDS).

J. Liu, *X. Chen, E. Eksioglu, S. Wei;*
Moffitt Cancer Center, Tampa, United States.

The acquisition of genetic abnormalities that lead to ineffective hematopoiesis is a characteristic of MDS. This event is associated with inflammatory bone marrow (BM) microenvironment; however, the underlying mechanisms are unclear. We have identified that myeloid derived suppressor cells (MDSC) are key driver of MDS progression. We found that MDSCs accumulated in excess in the BM of patients with MDS compared to controls and non-MDS cancer patients. FISH was performed to determine whether MDSCs represent a distinct cell population from the abnormal MDS clone. MDSCs chromosomal abnormality were separated by FACS sorting based on MDSC phenotype and the presence of chromosomal abnormalities was determined in this population and compared to non-MDSCs. Chromosomal abnormalities resided within the non-MDSC hematopoietic compartment indicating that MDSCs in MDS patients may represent a unique cell population from the HPCs with clonal potential. Furthermore, the key cytokines involved in MDSC suppressive function were higher in MDS patients compared to controls.
It was observed that the accumulation of MDSC in the BM from MDS patients has an impact on hematopoietic differentiation. Based on these findings, a novel form of adaptive immunotherapy based on the induction of MDSC maturation can be envisioned. DAP12, an adaptor protein, mediates signaling of myeloid cell maturation, were genetically modified to be a constitutively activated form. Infection of BM-MNC from MDS patients with constitutively active DAP12 increased expression of maturation surface markers and increased BFU-E colony formation after 14 days. These results suggest that activation of DAP12 has potential therapeutic implications in MDS.

P.B2.06.09

Epigenetic alteration of the PD-1/PD-L1 axis, a novel target for pharmacotherapy?

D. McKernan, *C. Hennessy, F. Quirke, G. O'Malley, A. Ryan;*
National University Ireland Galway, Galway, Ireland.

Introduction: Programmed death ligand 1 (PD-L1) is the primary ligand of the receptor programmed death-1 (PD-1), a coinhibitory cell surface immunoglobulin important in development of self tolerance. PD-L1 expression can be exploited by various cancers as a means of immune evasion with high PD-L1 expression associated with a poorer prognosis. Checkpoint inhibitors which target the PD-1/PD-L1 axis have shown some promise in the clinic but there is a lack of knowledge on the precise mechanisms by which PDL1 expression is regulated. Epigenetic modifications are known to alter gene expression, we therefore hypothesized that the DNA methylation and/or histone acetylation may alter PD-L1 expression. **Methods**: We used the colorectal cancer HCT116 cell line with genetically deleted DNA methyltransferase (DNMT) enzymes to determine the effect of DNA methylation on basal mRNA by QPCR and protein expression by flow cytometry. Using a number of microsatellite instable human colonic carcinoma cell lines to induce PD-L1 expression with the TLR3 ligand Poly I:C (10 μg/ml, 24 hrs) we determined the effect of both DNMT (decitabine 500 nM, 72 hrs) and histone deacetylase (SAHA, 10 μM) inhibitors on induction. **Results**: Genetic knockout of DNMT enzymes significantly reduced the basal expression of PDL1. Decitabine but not SAHA prevented Poly I:C-induced upregulation of PD-L1 mRNA and protein. Using a NF-κB superrepressed (SR) cell line, we determined that PD-L1 induction was NF-κB dependent and decitabine treatment prevented this induction. **Conclusion**: These data suggest that epigenetic modifying drugs may act as immunodulators and potentially form part of future PD-1/PD-L1 therapies.

P.B2.06.10

Development of a syngeneic mouse model of leukemia minimal residual disease: a new tool to study the involvement of the immune response in cancer cell persistence and test new immunotherapeutic strategies

A. MOPIN[1], *B. QUESNEL*[1], *C. BRINSTER*[2];
[1]*INSERM UMR-S-1172, CHU LILLE, UNIVERSITE LILLE, LILLE, France,* [2]*INSERM UMR-S-1172, UNIVERSITE LILLE, LILLE, France.*

Acute myeloid leukemia (AML) is a clonal disorder characterized by blocked differentiation and extensive proliferation of hematopoietic progenitors/precursors. Relapse is often observed after chemotherapy due to the presence of residual leukemic cells, also called minimal residual disease (MRD). Several studies have demonstrated that sub-clonal heterogeneity at diagnosis could be responsible for MRD, with major or minor sub-clones resisting chemotherapy or emerging after treatment. However, these studies do not provide information about the contribution of the immune system (elimination, control or escape) in these leukemic cell persistence or sub-clones hierarchy.

To generate this mouse model, we used well-characterized sub-clones of the murine C1498 cell line and selected them according to their *in vitro* aracytidine (Ara-c) sensitivity. These cells were stably transfected with a *ZsGreen* reporter gene to facilitate *in vivo* tracking. We tested different conditions of Ara-c administrations (concentrations, number and timing of injections). One protocol led to approximately 50% survival over an average of 90 days after non-treated control mice succumbed to AML (mean survival, 29-31 days). The assessment of residual leukemic cells in the blood of surviving mice at different time points (between 49 to 75 days after control mice died from AML) revealed the presence of 0.1 to 4.3% circulating ZsGreen$^+$ cells by flow cytometry without any signs of AML relapse. Thus, we have developed a mouse model of leukemia MRD that should offer valuable insights into the biology of residual leukemic cells and the immune mechanisms leading to their persistence, thereby enabling the development of new therapies.

P.B2.06.11

The gastrointestinal tract tumour microenvironment differentially influences maturation of and cytokine secretion from dendritic cells

M. Morrissey[1], *M. Dunne*[1], *R. Byrne*[1], *N. Lynam-Lennon*[1], *S. Kennedy*[1], *C. Nulty*[1], *N. McCabe*[1], *C. Butler*[2], *D. O'Toole*[3], *E. Ryan*[2], *J. V. Reynolds*[3], *J. O'Sullivan*[1];
[1]*Trinity College Dublin, Dublin, Ireland,* [2]*University College Dublin, Dublin, Ireland,* [3]*St James's Hospital, Dublin, Ireland.*

Oesophageal adenocarcinoma (OAC) and rectal adenocarcinoma are treated with neoadjuvant chemoradiotherapy in order to reduce tumour size prior to surgery however only 10-30% of patients have a complete pathological response. Inflammatory and angiogenic mediators in the tumour microenvironment (TME) have many functions, such as enabling evasion of anti-tumour immune responses by disabling infiltrating dendritic cells (DCs) and have been linked with radioresistance. Tumour Conditioned Media (TCM) from colonic cancer has been shown to strongly inhibit DC maturation. Our aim was to understand if this DC inhibition extends to other cancers of the gastrointestinal tract, to investigate if radiotherapy influences this and to profile constituents of TCM that may influence DC maturation.
Here we found that monocyte-derived DCs remained responsive to LPS following pre-treatment with OAC cell line TCM, whereas inhibition was induced by CRC cell line TCM. *ex vivo* TCM from different gastrointestinal adenocarinoma types induced different effects on DC maturation with oesophageal inducing DC activation, rectal inducing minor activation and colonic inducing inhibition of DC maturation markers. Interestingly, all cancer types induced DC inhibition of secreted TNF alpha. It was also found that 2Gy-irradiated TME induced significant inhibition of DC maturation for irradiated rectal adenocarcinoma and no effect with irradiated oesophageal cancer. Differential levels of inflammatory (IL2) and angiogenic mediators (Ang2 and bFGF) in TCM of GI tumours correlated with DC maturation.
Overall we found that there are differences in the human TME from different gastrointestinal cancers which can directly induce varying levels of inhibition of LPS-induced DC maturation.

P.B2.06.12

Investigation of the roles of anti-VEGFR1 natural antibodies in human plasma in hepatocellular carcinoma

C. Rodgers, *A. Pritchard, J. Wei;*
University of the Highlands & Islands, Inverness, United Kingdom.

Natural antibodies have been found to serve as an important anti-tumorigenic system in the body and their anti-tumor cytotoxicity has been confirmed with in vitro study. Natural antibodies are defined as the immunoglobulins produced by B1 lymphocytes in the absence of exogenous antigen stimulation. They are physiologically involved in maintaining tissue homeostasis such as clearance of apoptotic cell debris, elimination of invading pathogens as well as destruction of cancer cells formed in the body. In recent studies, it was found that natural IgG antibodies against vascular endothelial growth factor receptor 1 (VEGFR1) present in human plasma could be used to treat patients with hepatocellular carcinoma (HCC).
This study was thus designed to look at whether different epitopes derived from the VEGFR1 extracellular domain render HCC cells to have different responses to natural anti-VEGFR1 IgG in human plasma. An enzyme-linked immunosorbent assay was developed in-house with synthetic VEGFR1-derived peptides to screen human plasma rich in anti-VEGFR1 IgG that was applied to test the inhibitory effects of natural anti-VEGFR1 IgG on proliferation of HCC cell lines. Anticancer mechanism by which natural anti-VEGFR1 IgG kills HCC cells will be also investigated through analysis of cell viability, apoptosis, autophagy, gene expression, luciferase reporter assay, wound-healing and transwell migration.

P.B2.06.13

Alterations of the immune environment of Sezary cells

M. Roelens[1], *C. Ram Wolff*[2], *M. Delord*[3], *G. Maki*[4], *A. Marie-Cardine*[5], *A. Bensussan*[6], *M. Bagot*[6], *A. Toubert*[1], *H. Moins-Teisserenc*[1];
[1]*INSERM1160, IUH, AP-HP, Paris, France,* [2]*AP-HP, Hopital Saint Louis, Service de Dermatologie, Paris, France,* [3]*Biostatistics and Clinical Epidemiology, INSERM UMR-1153, Paris, France,* [4]*AP-HP, Hopital Saint Louis, Laboratoire d'Immunologie-Histocompatibilité, Paris, France,* [5]*INSERM UMR-976, UFR de Medecine, Paris, France,* [6]*INSERM UMR-976, UFR de Médecine, Paris, France.*

Introduction Sézary syndrome (SS) is a leukemic and aggressive form of Cutaneous T-cell Lymphomas. A challenge in SS is the preservation of antitumor and anti-infectious immunities, as infections are the most frequent cause of lethality. We previously defined the CD158k/KIR3DL2 molecule as a positive "generic" cell-surface marker for Sézary cells (SCs), and found an unexpected heterogeneity of naive/memory subsets. Such marker allows the characterization of non-SCs. Our aim was to analyze the phenotypes and functions of the "benign CD4+ T-cell counterpart" as well as other components of the innate and the adaptive immunity in the context of SS. **Methods**: Blood samples from patients and skin biopsies collected the same day, were analyzed using flow-cytometry for T-cell differentiation markers, resident-memory markers, as well as skin-homing, interleukins receptors and immune-checkpoint molecules. TCR repertoire was analyzed for 3 patients. Patients' derived monocyte subsets were analyzed both phenotypically and after maturation and differentiation into dendritic cells in proliferation assays.**Results**: We show that the "benign CD4+ T-cell counterpart" of SCs shares phenotypic similarity with malignant cells. These cells display skewed phenotypes and repertoire with enhanced expression of exhaustion molecules and defects in proliferative capacities. These abnormalities are not confined to the CD4+ T-cell-subset, as monocytes show a significant downregulation of HLA-DR molecules.**Conclusion**: Our results are in favor of profound alterations of the immune environment of SCs at phenotypic and functional levels. We are currently examining the relationships between SCs and the non-malignant immune compartment in both blood and skin compartments.

P.B2.06.14

Hypoxia effect on macrophages activation and fibroblasts cross-talk in chronic inflammation and tumor microenvironment

E. Setten[1,2], *M. Locati*[1,2];
[1]*Humanitas Clinical and Research Center, Rozzano (MI), Italy,* [2]*Department of Medical Biotechnologies and Translational Medicine, Università degli Studi di Milano, Segrate (MI), Italy.*

Macrophages (Mϕ) are highly plastic cells, able to assume different functional phenotypes depending on the microenvironment. To investigate the relevance of different microenvironmental cues on Mϕ activation, we generated in vitro Mϕ with an inflammatory phenotype using LPS+IFNγ (M1) or with an anti-inflammatory and pro-tumoral functional profile using IL4 (M2). In inflamed tissues and tumor lesions macrophages accumulate in areas of hypoxia, which is known to impact on macrophages activation. Similarly, in these contexts the interplay of macrophages with non-immune cells, such as fibroblasts, likely affects their biology. This project was planned in order to define the relative relevance of these cues and the underlying molecular mechanisms for the cross-talk between Mϕ and fibroblasts. Hypoxia-responsive genes (VEGF-A, GLUT1, MMP7, CXCR4) have been investigated by qRT-PCR in resting and activated Mϕ at short and extended time-points under normoxic or hypoxic conditions. We observed that Mϕ respond to hypoxia inducing specific transcripts and that their polarization has no significant impact on the induction of genes strictly related to hypoxia. On the contrary, hypoxia interferes with the expression of M1 transcripts, while having no impact on regulation of M2 genes. Model parameters will be extracted from molecular profiling approaches investigating Mϕ polarized to M1 and M2 settings under normal and hypoxic conditions in single cell cultures and direct-contact co-cultures with fibroblasts to better clarify the role of Mϕ in chronic inflammation and in tumor biology and to translate candidate genes into predictive biomarkers to support clinical decisions in therapy.

P.B2.06.15

Targeting PD-1/PD-L1 Pathway in tumor Microenvironment of Sebaceous Gland Carcinoma as a New Paradigm of Immunotherapy

L. SIngh[1], *M. K. Singh*[2], *S. Kashyap*[2], *S. Sen*[2], *M. A. Rizvi*[1];
[1]*Jamia Millia Islamia, New Delhi, India,* [2]*All India Institute of Medical Sciences, New Delhi, India.*

Introduction: Sebaceous gland carcinoma (SGC) is a malignant eyelid cancer and exhibit aggressive behaviour as it metastasizes to lymph nodes and distant organs. Understanding tumor-stromal interaction in tumor microenvironment has led to the development of immunotherapy in SGC. Programmed cell death-1/ligand (PD-1/PD-L1) interaction negatively regulates T cell activity and helps in the tumor escape mechanism. The aim of this study was to analyze PD-1/PD-L1 expression in tumor microenvironment as a prognostic marker and as a possible therapeutic target for SGC. Methods: Expression of immune markers (PD-1 and PD-L1 protein) was evaluated in 52 prospective cases of sebaceous gland carcinoma by immunohistochemistry and qRT-PCR. Results were correlated with clinicopathological parameters and patient outcome by statistical analysis. Results: Histopathological analysis revealed that 19 (36.5%) tumours were poorly differentiated and pagetoid spread was present in 22 cases. Immunoreactivity of PD-1 and PD-L1 expression was found in tumor and stroma cells. tPD-L1 showed immunoexpression in 51.92% cases whereas tPD-1 showed positive expression in 34.61%. sPD-1+ was more common than sPD-L1+ expression.

On univariate analysis, pagetoid spread, lymph node metastasis and tumor expressing PD-L1 expression was associated with a reduced disease-free survival (P<0.005). However, on multivariate analysis, only the tPD-L1 was associated with poor prognosis (P = 0.01). Conclusion: This is the first of its kind study, which states the role of tumor microenvironment in mediating the immune response in the pathogenesis of SGC. This paves the way for development of immunotherapy as a new strategy for treatment of metastatic sebaceous gland carcinoma patients.

P.B2.06.16

Interaction of NFκB-1 protein Expression with Inflammatory Microenvironment of Uveal Melanoma and its Prognostic Significance

M. K. Singh[1], *S. Kashyap*[2], *N. Pushker*[1], *S. Sen*[1], *R. Meel*[1], *K. Chodsol*[1], *S. Bakhshi*[1], *J. Kaur*[1];
[1]*AIIMS, New delhi, India,* [2]*AIIMS, New Delhi, India.*

Introduction: Uveal melanomas as malignant phenotype having a high density of macrophages, blood vessels and T-lymphocytes along with the presence of epithelioid cells and high melanin pigmentation which might be related to worse prognosis. High densities of inflammatory cells in uveal melanoma are associated with poor prognostic factors. NFκB-1 plays an important role in inflammation which promote cancer initiation and progression. The aim of the study is to detect NFκB-1 expression in the inflammatory microenvironment of uveal melanoma and its prognostic significance. **Method:** Evaluation of NFκB-1 expression was assessed by using immunohistochemistry and western blotting in 75 formalin fixed uveal melanoma tissues and transcriptional analysis was done on 58 fresh frozen tissues by real time pcr. Results were then correlated with clinicopathological parameters. **Results:** Out of 75 cases, 40 cases showed both nuclear and cytoplasmic expression and 15 showed cytoplasmic only. qRT-PCR showed upregulation of NFκB-1gene in 72.41% cases at transcriptional level. Expression of both cytoplasmic and nuclear c-REL protein showed significant correlation with cases having high tumour infiltrated lymphocytes, macrophages (CD68+) and presence of blood vessels (CD34+). There was a statistically significant difference in the overall survival of patients with nuclear/cytoplasmic NFκB-1 immunopositivity (p<0.05). **Conclusion:** This preliminary data suggests that NFκB-1 protein might play a role in the inflammatory microenvironment of uveal melanoma which is responsible for the pathogenesis of this disease. Further translational studies are required to explore the nature of NFκB-1 interactions in tumour microenvironment of uveal melanoma.

P.B2.06.17

Regulation of the expression of IL-1R8, a regulatory member of the Interleukin-1 receptor family

D. Supino[1], *C. Perucchini*[1], *M. Molgora*[1], *A. Ponzetta*[1], *S. Di Marco*[1], *E. Magrini*[1], *S. Carnevale*[1], *F. Gianni*[1], *S. Jaillon*[1,2], *A. Mantovani*[1,2], *C. Garlanda*[1,2];
[1]*Humanitas Clinical and Research Center, Rozzano, Italy,* [2]*Humanitas University, Rozzano, Italy.*

IL-1R8 is an Interleukin-1 receptor (ILR) family member which activates an anti-inflammatory program by inhibiting ILR and Toll like receptor (TLR) signaling. In NK cells IL-1R8 acts as checkpoint molecule in cancer and viral infections. The purpose of this study was to dissect the regulation of IL-1R8 expression in leukocytes. ChIP-seq analysis suggested that Colony Stimulating Factors (CSF)-inducible Transcription Factors and epigenetic modifications affect IL-*1R8* in NK cells and macrophages along maturation and activation. *IL-1R8* expression was down-regulated during macrophage differentiation. Pro-inflammatory molecules involved in macrophage and NK cell activation down-regulated *IL-1R8* expression in human and mice. Prostaglandin E2 and Interleukin-10 (IL-10), which are involved in cancer-associated immunosuppression, counteracted this effect in NK cells and up-regulated IL-1R8 in human monocytes and macrophages. *RNA*-seq analysis, q-PCR and Western Blot also revealed the existence of IL-1R8 truncated forms in human immune cells constituted by the exons coding for the intracellular part of IL-1R8, after M1 polarization. Thus pro-inflammatory stimuli are implicated in conventional isoform IL-1R8 down-regulation, overexpression of truncated forms of the protein, whose biological role is presently unknown. In addition, the up-regulation of IL-1R8 in NK cells by PGE2/IL-10 axis suggests that IL-1R8 could be part of the immunosuppressive activity of these molecules. IL-1R8 acts as a checkpoint molecule tuning antitumor and antiviral NK cell activity. Understanding how IL-1R8 expression in NK cells is affected by the tumor microenvironment is essential in the development of this checkpoint as a potential immunotherapy target.

P.B2.06.18

Patterns of immune checkpoint expression by primary tumor cells and tumor infiltrating lymphocytes across different tumor entities

M. Thelen[1], *A. Lechner*[1,2], *K. Wennhold*[1], *D. Pfister*[3], *F. Dörr*[4], *M. Heldwein*[4], *K. Hekmat*[4], *D. Beutner*[5], *M. Mallmann*[6], *F. Thangarajah*[6], *C. Bruns*[7], *M. von Bergwelt-Baildon*[1,8,9], *H. A. Schlößer*[1,7];
[1]*Cologne Center for Molecular Medicine, Cologne, Germany,* [2]*Department of Head and Neck Surgery, LMU, Munich, Germany,* [3]*Department of Urology, University of Cologne, Cologne, Germany,* [4]*Department of Cardiac and Thoracic Surgery, University of Cologne, Cologne, Germany,* [5]*Department of Head and Neck Surgery, University of Göttingen, Göttingen, Germany,* [6]*Department of Gynecology Surgery, University of Cologne, Cologne, Germany,* [7]*Department of General, Visceral and Cancer Surgery, University of Cologne, Cologne, Germany,* [8]*German Cancer Consortium (DKTK), Heidelberg, Germany,* [9]*Department of Internal Medicine III, LMU, Munich, Germany.*

Immune-checkpoint inhibition (CKI) demonstrated breakthrough therapeutic efficacy in several kinds of cancer. These therapies are unique, as the primary target is not the tumor cell itself, but the crosstalk between immune cells and cancer cells in the tumor microenvironment. Efficacy of CKI is not limited to patients with expression of the respective protein on tumor cells and recent publications demonstrated that expression of PD-L1 on tumor-infiltrating lymphocytes (TIL) can be of similar importance.
Expression patterns of 30 described immune checkpoint and regulatory molecules were analyzed on T, B and NK cells in peripheral blood and single cell suspensions of primary tumor samples of nine different tumor entities using flow cytometry. Expression of the respective ligands on primary tumor cells was assessed in tissue microarrays.
The majority of analyzed immune checkpoint pathways could be detected. Despite the variety of primary tumor sites, our analyses revealed similar expression patterns for most molecules included in this study. For example, PD-1 as well as PD-L1 were detectable on tumor cells and tumor-infiltrating lymphocytes in all analyzed tumor entities and expression patterns on TIL were largely overlapping. In addition, we correlated immune checkpoint expression to the infiltration by lymphocytic subsets including regulatory T cells.
Immune escape is a common feature of cancer and the specific expression patterns described in this study are of translational relevance for ongoing and future immunotherapeutic trials.

P.B2.06.19

Potential γδ T cell transdifferentiation into αβ T cells in transplanted children

A. Zorzoli[1], *G. Barbarito*[2], *P. Merli*[3], *F. Antonini*[4], *A. Bertaina*[2], *E. Ferretti*[1], *F. Frassoni*[1], *F. Locatelli*[3], *I. Airoldi*[1];
[1]*Laboratorio Cellule Staminali post natali e Terapie Cellulari, Istituto Giannina Gaslini, Genova, Italy,* [2]*Pediatrics Stem Cell Transplantation, Stanford University, Palo Alto, United States,* [3]*Dipartimento di Onco-Ematologia e Terapia Cellulare e Genica, Ospedale Pediatrico Bambino Gesù, Roma, Italy,* [4]*Core Facilities, Istituto Giannina Gaslini, Genova, Italy.*

We recently demonstrated that pediatric patients with acute leukemia receiving a graft depleted of αβ T and CD19+ B lymphocytes and treated with zoledronic acid (ZOL) showed: i) increased cytotoxicity of γδ T cells against leukemic blasts, ii) rapid reconstitution of αβ T cells and iii) a decrease of GvHD incidence. These data suggested that γδ T cells, reconstituted or infused with the graft, could induce αβ T cell reconstitution.
In this contest, it has been reported that the specific population of Vδ1+CD4+ γδ T cells can trans-differentiate into αβ T cells, through specific steps of TCR rearrangement.
Thus, we hypothesized that ZOL could be an appropriate stimulus for the process of trans-differentiation of γδ T into αβ T cells in transplanted patients.
In order to validate this hypotesis we started a set of experiments in order to characterized T cells from transplanted patients infused and not with ZOL.
Furthermore, we tested whether human γδ T cells may transdifferentiate in αβ T cell using highly immunodeficient mice NOD/SCID/IL2rg-/- (NSG).
Preliminary results showed that in transplanted patients treated with ZOL the population of Vδ1+CD4+ γδ T cells appears, and that NSG mice may represent a suitable model to recapitulate trans-differentiation of γδ T into αβ cells.
Further investigations are needed to confirm that the trans-differentiation of γδ T into αβ cells may be an innovative immunotherapy against pediatric acute leukemia.

P.B2.06.20

CD117 is expressed following CD8⁺ T cell priming and stratifies sensitivity to apoptosis according to strength of initial engagement

G. Frumento, ***J. Zuo****, K. Verma, P. Moss;*
Insititute of Immunology and Immunotherapy, Birmingham, United Kingdom.

CD117 (cKit) is the receptor for stem cell factor (SCF) and plays an important role in the development of early thymocytes, but it was not known to be expressed downstream the triple negative stage. Since we found CD117 transcripts in activated mature T cells, we studied the characteristics of the phenomenon. We found that CD117 is expressed following priming of mature CD8⁺ naive T cells *in vitro* and is detectable *in vivo* in CD8⁺ T cells following primary Epstein-Barr virus infection. CD117 expression is mediated through an intrinsic pathway and is suppressed by IL-12. Importantly, the extent of CD117 expression is inversely related to the strength of the activating stimulus and subsequent engagement with cell-bound SCF markedly increases susceptibility to apoptosis. CD117 is therefore likely to shape the pattern of CD8⁺ T cell immunodominance during a primary immune response by rendering cells with low avidity for antigen more prone to apoptosis. Furthermore, CD117⁺ T cells are highly sensitive to apoptosis mediated by galectin-1, a molecule commonly expressed within the tumour microenvironment, and expression may therefore represent a novel, and potentially targetable, mechanism of tumour immune evasion.

P.B2.07 Environmental regulation anti-tumor responses - Part 7

P.B2.07.01

Promoting NK cells anti-viral and anti-tumor function by *in vitro* manipulation

E. Badami[1], *F. Barbera*[2], *A. Gallo*[2], *C. Coronnello*[1], *D. Paini*[1], *P. Conaldi*[2];
[1]*Fondazione RiMED, Palermo, Italy,* [2]*ISMETT, Palermo, Italy.*

Background/Aims. Natural Killer (NK) cells respond to infection and tumor by releasing pro-inflammatory cytokines (IFNγ, TNFα) or by cell-to-cell contact using TRAIL-mediated apoptosis. Aim of this study was to discover if response to viral infection or cancer cells can be improved by manipulating NK cells *in vitro* with selected cytokines.
Methods. Healthy donors NK cells were differentiated with a selected mix of cytokines into cytotoxic TRAIL$^+$ or cytokine-releasing IFNγ$^+$TNFα$^+$ NK cells and phenotype assessed by Flow Cytometry. Cytotoxicity was determined by CRA. NK immune function was studied in transwell co-cultures with target cells +/- HCV; miRNome signature was investigated by NGS and cytokine profiling by Multiplex.
Results. NK cell differentiation with any of the cytokine cocktails tested induced upregulation of NKG2D, NKp30, NKp44 and NKp46. By cell-cell contact, cytotoxic TRAIL$^+$NK cells killed with the highest efficiency target cells, while cytokine-releasing IFNγ$^+$TNFα$^+$ NK were less functional. By transwell co-culture, we observed that TRAIL$^+$NK cells fully eradicated HCV infection and reduced the tumor phenotype by releasing soluble factors, while IFNγ$^+$TNFα$^+$NK were less efficient. By comparative miRNome analysis we underpinned a number of novel miRNA. Notably, hierarchical clustering showed systematic variations in the miRNA expression among the different groups. Protein analysis produced pattern of soluble factors and will be here discussed.
Conclusions. The pathways identified in activated TRAIL$^+$ NK cells that specifically characterize their enhanced anti-viral and anti-tumor function compared to IFNγ$^+$TNFα$^+$NK described herein might represent a tool to license fully functional NK cells with translational potential for clinical applications.

P.B2.07.02

Underlying mechanisms of tumor recurrence after incomplete cancer immunotherapy

E. Beyranvand Nejad*, C. Labrie, S. van Duikeren, T. van Hall, R. Arens, S. H. van der Burg;*
Leiden University Medical Center, Leiden, Netherlands.

Cancer vaccines aim to induce specific T cell responses directed against tumor cells. Previously, we have shown therapeutic efficacy of vaccination with synthetic long peptide (SLP) vaccines in mouse tumor models and in patients with human papilloma virus-induced neoplastic lesions. However, under less optimal vaccine conditions the SLP-vaccinated mice display tumor recurrences despite the initially T-cell mediated regression induced by the vaccine. Here, we investigated the underlying mechanisms focusing on the tumor microenvironment. Our data showed that recurrent tumors displayed a significantly reduced leukocyte infiltration in particular CD8 T cells compared to primary tumors. This was accompanied by lower levels of chemokine receptors including CXCR3 on the T cells, and a reduced chemokines production by intratumoral immune cells. Moreover, although these T cells are capable of producing inflammatory cytokines, the cytotoxic capacity to kill tumor cells was inferior compared to the T cells at the time of regression. Notably, we did not observe any difference in the expression of T cell inhibitory molecules such as PD-1, Tim3 and LAG3 at the time of relapse, confirming our results that blocking PD-1 did not prevent the tumor recurrence. Interestingly, vaccination of mice that were injected with recurrent tumor cells did not result in tumor regression. Together, that the observed defective T cell infiltration and increasing intrinsic tumor resistance to killing occurs suggests that incomplete cancer immunotherapy leads to immune selection and tumor escape. On-going work exploring immune selection and tumor heterogeneity by using RNA seq analysis and cell barcoding will be discussed.

Background: Tumour is associated with the M2 microenvironment as well as M2a-like macrophage accumulation. During allergen-specific immunotherapy (AIT) that M2 microenvironment is modulated by T-reg and B-reg cells via secreting IL10 resulting in class switch from IgE to IgG4. Moreover, IgG4 has also been found in tumour tissues correlated with poor clinical outcome. We hypothesized that tumour tissue IgG4 may interact with M2a macrophages and drive them into an immunoregulatory phenotype.
Methods: We analysed plasma levels of total IgE, IgG1 and IgG4 from healthy controls and non-metastatic or metastatic colon cancer patients. Moreover, we checked if monocyte derived macrophages from different donors would respond differently in presence of IgG1 or IgG4. **Results:** A significantly higher IgG4/IgE plasma level ratio was revealed in metastatic tumour patients compared to the other groups (p=0.025 and p=0.014 vs Healthy and non-metastatic tumour donors). This was associated with a lower surface marker expression of CD206, CD163 and CD86 and higher cytokine production of CCL1, IL10 and IL6 in IgG4-stimulated M2a macrophages in all groups, compared to IgG1 or no IgG stimulation. **Conclusions:** Our data indicate that macrophages from tumour patients do not differ in their capacity of polarization in comparison with healthy donors. However, stimulation with IgG4 may drive M2a macrophages to an immunoregulatory M2b-like phenotype. Therefore, the presence of IgG4 in tumour tissue repolarizes tumour-associated macrophages and both synergize in shaping a strong immunosuppressive microenvironment decisive for a poor prognostic outcome. **Supported by FWF-project SFB F4606-B28 to EJJ.**

Murine acute myeloid leukemia alters NK cells maturation and functions by affecting IL-15 signaling

B. Bou Tayeh[1], *V. Laletin*[1], *J. Fares*[1], *R. Leblanc*[1], *D. Payet-Bornet*[2], *B. Nadel*[1], *S. JC Mancini*[1], *O. Herault*[3], *D. Olive*[1], *M. Aurrand-Lions*[1], *C. Fauriat*[1];

The immune system is ineffective against tumor progression in acute myeloid leukemia (AML). Among immune effectors with anti-leukemic activity, Natural Killer (NK) cells display altered phenotype, functions, as well as molecular alterations at the diagnosis of leukemic patients. Although it has become clear that leukemic cells are responsible for these alterations, the molecular mechanisms by which they subvert NK cell functions remain elusive. Here, we have used syngeneic mouse model for AML to decipher these mechanisms. Hence, as AML progressed in mice, we observed a selective enrichment of CD27$^+$CD11b$^-$ immature NK cells. Additionally, AML progression resulted in the decrease of NK cell degranulation and cytokine production, irrespective of development stages.
Moreover, it has been shown that IL-15 signaling controls both maturation and activation of NK cells, two checkpoints that are altered in our model. Hence, we studied the effect of *in vitro* and *in vivo* activation of IL-15 signaling in leukemic mice NK cells. We noted lower phosphorylation of essential components of IL-15 signaling, which was associated with lower expression of IL-15 receptors leading to a decreased nutrient uptake and NK cell growth. Additionally, molecular analysis of murine AML cells showed expression of TGF-β, an immunosuppressive cytokine capable of inhibiting IL-15 signaling.
We propose that AML cells may alter NK cell functions and maturation by secreting TGF-β. Our preliminary results are in line with observations made in human patients and will be determinant to better understand the mechanisms of NK cells dependent immune evasion in AML.

Chronic myeloid leukemia (CML) is a malignant myeloproliferative disorder characterized by the constitutively active tyrosine kinase BCR/ABL1. Disease progression and relapse is caused by therapy resistant leukemia stem cells (LSCs), and cure relies on their eradication. The microenvironment in the bone marrow (BM) has been extensively studied and is known to contribute to LSC maintenance and resistance. Leukemic infiltration of the spleen is a hallmark of CML. However, the detailed composition of the splenic niche in CML and how it affects and maintains LSCs is unknown. In a mouse model of CML, we demonstrated that primitive leukemic stem and progenitor cells (LSPCs) preferentially accumulated in the spleen and contributed to disease progression by increasing LSC numbers in the BM. RNA sequencing of spleen and BM LSPCs revealed enriched stemness and decreased myeloid lineage priming in LSPCs of the spleen. Moreover, LSCs in the spleen were more quiescent than in the BM and showed increased resistance to tyrosine kinase inhibitor (TKI) therapy. Furthermore, spleen LSCs were exclusively located in the red pulp. Depletion of macrophages by clodronate treatment reduced LSC numbers in the spleen, whereas LSCs in the BM were not affected. In spleens of human CML patients, LSCs co-localized with red pulp macrophages (RPMs). These results reveal the spleen as an independent, disease-promoting niche for primitive LSPCs. Thus, targeting the splenic niche may be necessary to eradicate LSCs and cure CML.

Introduction: The iron concentration in the environment is crucial element for both pathogens and innate immunity. We investigate whether extracellular iron concentrations and intracellular ferritin heavy chain (FHC) may modulate MHC expression and NK cells cytotoxicity. This new and interesting link between iron metabolism and immunity can be exploited in the treatment of infections and cancer.
Materials and Methods: Primary melanoma tumor cells were treated with DFO and IFN gamma and established tumor cell lines were silenced with shFHC vector. PBMC derived from hemocromathosis patients' blood were isolated. All cell system were analysed for the expression of MHC molecules and NK cytotoxicity assays. To analyze ex vivo and in vivo the relationship between FHC annd MHC class I experresion the NCO4 -/- mice was used.
Results: FHC downregulation, either by environmental iron chelation or shRNA transfection, led to MHC-class I surface reduction. Moreover, low concentrations of iron in microenvironment interfere with IFN gamma receptor signaling preventing the related increase of MHC-class I molecules expression. Furthermore, ex vivo evidences confirm the in vitro observations: a) mouse bearing a NCO4-/- gene deletion leads to FHC accumulation and MHC class I cell surface overexpression b) Hemochromatosis patients with high iron blood concentrations expresses higher levels of MHC-I on their cell surface. Tumor cells growth in low iron environment are highly sucsceptible to NK cytotoxicity.
Conclusions: We propose a role for H-ferritin and iron metabolism in regulating the MHC class I expression in humans and mice and the related NK susceptibility.

P.B2.07.07

Blocking of beta adrenergic signalling improves the efficacy of anti-tumor responses

C. Daher*, L. Vimeux, E. Peranzoni, R. Stoeva, E. Donnadieu, A. Trautmann, N. Bercovici, V. Feuillet;*
Institut Cochin, Inserm U1016 CNRS UMR 8104, Université Paris Descartes, Paris, France.

Background: Adrenergic signals are known to exert a major influence in cancer. In addition to a direct action on tumor growth, numerous arguments support potential effects on anti-tumor immune responses. Our goal was to characterize the effects of adrenergic signals on anti-tumor responses, and to estimate the therapeutic interest of β–blockers for improving them.
Material and methods: To address this question, we used two murine tumor models: 1) a model of vaccine-induced regression of transplanted tumors (TC1) and 2) a model of progressing spontaneous mammary tumors (MMTV-PyMT) in which the "natural" anti-tumor response is in check. In both models, we evaluated the effects of a chronic treatment with propranolol (a β–blocker) by using multicolour flow cytometry, gene expression and imaging.
Results: In TC1 model, propranolol strongly improved the vaccine efficiency by increasing the number of $CD8^+$ T cells infiltrating the tumor. Moreover, we demonstrate that this effect mainly occurred during the priming of T cells in the draining lymph node (Dr-LN). In MMTV-PyMT tumors, tumor growth was markedly slowed down by propranolol, which also increased tumor infiltration by $CD8^+$ T cells. Finally, in vitro, adrenergic signalling had a major inhibitory effect on T cell activation, a phenomenon likely to alter T cell reactivity in both Dr-LN and the tumor.
Conclusions: Our results allow a better understanding of the influence of adrenergic signalling on anti-tumor responses. They provide a basis for the strategic use of β-blockers to improve them.

Multiparameter flow cytometry immunophenotypic identification and characterization of tumor infiltrating immune cells in glioblastoma multiforme

M. González-Tablas[1,2], *Á. Otero*[2,3], *D. Pascual*[2,3], *L. Ruiz*[2,3], *D. Miranda*[2,3], *P. Sousa*[2,3], *D. Arandia*[2,3], *M. Jaramillo*[2,3], *J. Gonçalves*[2,3], *A. Orfao*[1,2], *M. Tabernero*[1,2,4];
[1]*Centro de Investigación del Cáncer (CIC-IBMCC; CSIC/USAL; IBSAL) y Departamento de Medicina Universidad de Salamanca, Salamanca, Spain,* [2]*Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain,* [3]*Servicio de Neurocirugía, Hospital Universitario de Salamanca, Salamanca, Spain,* [4]*Instituto de Estudios de Ciencias de la Salud de Castilla y León (IECSCYL), Soria, Spain.*

Glioblastoma multiforme (GBM) is the most common and aggressive adult primary tumor of the brain. The specific distribution and role of tumor immune cells in favoring vs blocking malignant transformation, tumor progression and growth, remains unknown. Here we characterize the cellular composition of tumor immune infiltrates from primary GBM by multiparametric flow cytometry.
Resected primary tumors from 39 adults diagnosed with GBM were analyzed. Single tumor cell suspensions were obtained by mechanical disaggregation and stained with 8-color monoclonal antibody combinations for the enumeration of tumor infiltrating myeloid (CD45, HLADR, CD14, CD11B, CD16, CD15, CD33, CD192 and CD206) and lymphoid cells (CD3, CD4, CD8, CD19, CD20, CD25 and CD127). Stained samples were measured in a Fortessa X20 flow cytometer and analyzed with the Infinicyt software.
Overall, tumor infiltrating immune cells (TIICs) represented (median) 27% of the whole cellularity, with highly-variable numbers among distinct tumors (range: 3%-73%). Myeloid cells with a monocytic/dendritic cell phenotype predominated (23%; range: 2%-65%) with a minor proportion of neutrophils (2%; range: 0.2%-45%) and lymphoid cells (1.4%; range: 0.04%-8%). Among lymphocytes, CD8+ (0.5%; range: 0.02%-3%) and CD4+ T-cells (0.4%; range: 0.01%-3%) were represented at similarly low values, and extremely low numbers of regulatory T-cells (median: 0.05%) and B-lymphocytes (0.02%) were also found.
We demonstrate the feasibility of evaluating TIIC by flow cytometry and their systematic presence in GBM tumor samples at highly-variable levels, with clear predominance of antigen-presenting myeloid cells, over neutrophil and lymphoid infiltrates, their role in modulating the tumor microenvironment, deserves further investigations. (ISCIII ref PI16/0476)

P.B2.07.09

MHC II-dependent activation of regulatory T cells in the bone marrow of leukemia mice leads to immune evasion and disease progression

M. Hinterbrandner*, A. Ochsenbein, C. Riether;*
Bern University Hospital and Department for BioMedical Reasearch, University of Bern, Bern, Switzerland.

Leukemia stem cells (LSCs) in the bone marrow (BM) are the origin of leukemia and resistant against conventional therapies and immune control. This resistance is partially mediated by protective mechanisms of the hematopoietic stem cell niche in the BM. In leukemia, the BM microenvironment changes dramatically with regulatory T cells (Tregs) accumulating. However, little is known how Tregs affect LSCs.
We induced chronic myeloid leukemia (CML) in a murine model with BL/6 BCR-ABL-1 transduced LSKs (lineage$^-$Sca-1$^+$c-kit$^+$) in FoxP3$^{DTR\text{-}GFP}$ mice. We investigated the frequency, origin, activation and proliferation capacity of BM Tregs in CML compared to naïve mice and analyzed the Treg-accumulation during disease progression.
BM Tregs in CML mice were mostly thymic-derived, activated and showed higher proliferation capacity compared to controls. Treg-depletion resulted in long-term survival in the majority of the mice. Importantly, Treg-depleted CML mice showed decreased LSC numbers compared to controls phenotypically (FACS-analysis) and functionally by colony forming assays and secondary transplantation experiments. To show a direct Treg-LSC interaction or an indirect via CD8 T cells, we depleted Tregs and CD8 T cells simultaneously. Parallel depletion restored LSC numbers, suggesting that Tregs protect LSCs from CD8-mediated elimination. To investigate the activation of Tregs, we induced CML derived from MHC-II-deficient LSCs since we observed high MHC II expression on LSCs. MHC II$^{-/-}$ CML developed significantly slower than control CML and showed the same phenotype as the Treg-depleted CML mice.
Our data indicate that thymic-derived, MHC-activated Tregs protect LSCs from elimination by cytotoxic CD8 T cells and promote leukemia development.

P.B2.07.10

Cytomegalovirus-related cytokines improve natural killer cell activity against cancer cells

K. A. Holder[1], *J. Lajoie*[2], *M. D. Grant*[1];
[1]*Memorial University, St. John's, Canada,* [2]*University of Manitoba, Winnipeg, Canada.*

Through an unknown mechanism, cytomegalovirus (CMV) focuses the initially diverse natural killer (NK) cell repertoire into functionally and phenotypically distinct subsets. Given the global prevalence of CMV infection, at least 2 billion people have an adapted pool from within which NK cells can be selectively recruited against virus-infected or aberrant cells. We investigated whether cytokines produced in CMV infection alter NK cell activity against transformed cell lines.
Supernatants from CMV-infected (CMVsn) fibroblasts caused a 40% and 32% rise in NK cytotoxicity (K562) and antibody-dependent cellular cytotoxicity (ADCC; anti-MHC I-coated C1R-B27), respectively, enhancing NK activity through NKG2C, NKG2D, NKp30, and NKp46. While CMVsn had elevated levels of IL-6, IL-8, IL-15, IFN-α2 and IFN-β, disrupting stimulation through IFN-α/β receptors alone fully prevented increased NK cell activity. The CMV-encoded hIL-10 homolog (cmvIL-10) also enhanced NK cytotoxicity and we probed NK activity against a variety of malignant cell lines to study the breadth of cytokine-induced NK cell activation. CMVsn or cmvIL-10 treatment robustly increased NK cytotoxicity against breast (SKBR-3), ovarian (SKOV-3), prostate (22Rv1) and colon (HT-29) cancers, and myeloid (U937) leukemia. Exogenous cmvIL-10 also induced potent TNF-α and IFN-γ responses by NK cells from CMV^{pos} donors against antibody-coated SKOV-3 cells.
Adapted NK cells potentially offer a rich substrate for enabling broad immune activity against malignancy and could contribute to new iterations of cancer immunotherapy.

P.B2.07.11

Studying TGF-ß1 activation via GARP in megakaryocytes and its potential involvement in myeloproliferative neoplasms.

S. Lecomte*;*
de Duve Institute, Brussels, Belgium.

Myeloproliferative neoplasms (MPN) represent clonal proliferation of pathological hematopoietic stem cells. MPN encompass chronic myeloid leukaemia (CML), polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). MPN subtypes differ in their potential to develop bone marrow fibrosis, with PMF exhibiting the highest and ET having the lowest risk of progression to bone marrow fibrosis. The precise mechanisms leading to increased deposition of bone marrow stromal fibers remain unclear. A growing body of evidences suggest that it is mediated by Transforming Growth Factor-beta 1 (TGF-ß1) released by proliferating megakaryocytes. TGF-ß1 is a well-known pro-fibrotic cytokine. It is secreted by many cell types as an inactive form, called latent TGF-ß1. However, very few cell types have been shown to produce the active form of the cytokine, via mechanisms that are cell-type specific. Regulatory T lymphocytes (Tregs) can activate TGF-ß1 via GARP, a transmembrane protein that is induced on the surface after T cell receptor stimulation. GARP is also expressed on megakaryocytes. We want to address the question whether megakaryocytes can also activate TGF-ß1 via GARP, in physiological conditions, but more importantly in the context of myeloproliferative neoplasms where this mechanism could contribute to bone marrow fibrosis.

P.B2.07.12

Receptor expression and cytotoxicity of primary human NK cells is impaired in obesity

W. Naujoks[1], *A. Hauffe*[1], *J. Spielmann*[1], *I. Bähr*[1], *D. Quandt*[1], *J. Harth*[2], *H. Kielstein*[1];
[1]*Department of Anatomy and Cell Biology, Faculty of Medicine, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany,* [2]*Transfusion Medicine Unit, University Hospital, Halle (Saale), Germany.*

Introduction: Overweight and obesity are growing epidemic health problems. Obesity, as a major risk factor for developing severe cancers, e.g. colorectal and postmenopausal breast cancer, is associated with alterations in NK cell functionality. In the early phase of cancer development, NK cells are the central active component of a host's immune system. To date the pathophysiological mechanisms between obesity and cancer remain unclear. Therefore, the present study aimed to investigate the relation between bodyweight and NK cell receptor expression as well as NK cell cytotoxicity against tumor cells in humans.
Methods: PBMCs were collected from buffy coats of healthy blood donors with different body mass indexes (normal-weight, overweight, obese) and NK cell specific parameters were analyzed by flow cytometry. The cytolytic activity of isolated NK cells against human colon and breast cancer cell lines was analyzed by using an impedance-based cytotoxicity assay.
Results: Primary human NK cells isolated from obese donors compared to normal-weight donors showed a significantly decreased cytolytic activity against colon cancer cells. Flow cytometric analysis revealed an altered expression pattern of activating and inhibitory NK cell receptors and adhesion molecules on NK cell subsets of overweight and obese individuals compared to the normal weight control group.
Conclusions: The decreased cytotoxic activity against colon tumor cells and the altered receptor expression pattern of NK cells from overweight and obese individuals indicate that the linkage of obesity and the known increased risk for colorectal cancer can be related to an impaired NK cell functionality.

P.B2.07.13

Conformational epitope PAINS-13 on the CD9 tetraspanin is expressed on clonal plasma cells in a subset of patients with monoclonal gammopathies.

A. Roncancio-Clavijo*, C. Martín-Martín, E. Rodríguez-Martín, P. Walo, J. Fernández-Velasco, M. Espiño, M. Blanchard, L. Villar, E. Roldán;*
Hospital Universitario Ramón y Cajal, Madrid, Spain.

Monoclonal gammopathies (MG) are characterized by clonal proliferation of plasma cells (PC). Several molecules have been implicated in the adhesive interactions between PC and the bone marrow (BM) microenvironment, particularly beta 1 integrin (CD29), which is sometimes associated with tetraspanins. We described that clonal PC from the majority of MG patients express a functionally conformational epitope (PAINS-13) of the tetraspanin CD9. The study included diagnosed MG patients (41 MM, 14 MGUS). BM aspirates were stained using an indirect immunofluorescence technique with unconjugated PAINS-13 mAb (Dr. Cabañas; CBM, Madrid) and rat anti-mouse IgG3-FITC. BM aspirates were also stained with conjugated CD38, CD56, CD19 (to detect normal and clonal PC) and CD29, CD49d, CD49f or CD9 mAb to study the expression of adhesion molecules and tetraspanins. Flow cytometric studies showed the presence of PAINS-13 epitope in 29 out of 55 (52.7%) MG patients. There was not significant differences between MM or MGUS patients. PAINS-13 expression did not correlate neither with the active form of CD29 (HUTS21+ cells) nor with the level of CD49f expression. *In vitro* experiments also demonstrate that PAINS-13 expression was not associated with induction of activation of CD29 by divalent cation Mn^{2+}: whereas the addition of 0.5 mM Mn^{2+} clearly increased binding of mAb HUTS21 to MG cells, binding of PAINS-13 mAb was not influenced by CD29 activation state. Our results demonstrate that clonal PC usually express the CD9 conformational epitope PAINS-13 which did not depend on the previous activation of CD29.

P.B2.07.14

Destabilized liposomes as carriers for doxorubicin and siRNA to target tumor associated macrophages in a humanized mouse melanoma model

J. Schupp[1], *M. Voigt*[2], *M. Helm*[2], *A. Tuettenberg*[1];
[1]*Dept. of Dermatology, Mainz, Germany,* [2]*Johannes Gutenberg University, Mainz, Germany.*

An established tumor did overcome the patient's immune system and is exploiting its immune suppression mediating mechanisms to sustain tumor growth and avoid rejection. Repolarizing tumor associated macrophages into immunostimulatory M1 macrophages is a promising strategy to flip the switch in the tumor microenvironment from immune suppression towards an immune reaction against the tumor. In order to achieve repolarization of macrophages it is necessary to have (i) efficient nano carriers to transport small molecules or siRNA into macrophages and (ii) to subsequently release the functional cargo in an adequate amount. We developed destabilized liposomes being sensitive to low pH levels and physiological temperatures. The chemotherapeutic Doxorubicin and siRNA are used as cargo. We perform release studies *in vitro* and *in vivo*.
To analyze cargo release we perform *in vitro* cultures of human monocyte-derived macrophages and human melanoma cells. Doxorubicin release inside the cell is quantified by using flow cytometry and confocal microscopy. siRNA mediated transfection is detected via qPCR. *In vivo* studies are carried out in a subcutaneous melanoma model of human melanoma cell lines in humanized NOD/SCID mice transgenic for HLA-A2. Spleen and tumor showed a distinct composition of immune cell infiltration in immunohistochemistry staining proving the model to be valid for our purpose. Our data indicate, that destabilized liposomes show faster release of doxorubicin compared to stable liposomes. Control liposomes loaded without cargo are non-toxic. Therefore, we use them as nano carrier in our model. This work is supported by the DFG (CRC1066).

P.B2.07.15

Dissecting the role of MS4A4A in the context of macrophages

R. Silva-Gomes[1,2,3], *M. Sironi*[3], *R. Porte*[4], *I. Mattiola*[5], *A. Fontanini*[3,6], *M. Stravalaci*[4], *M. Oliveira*[2], *M. Locati*[6], *B. Bottazzi*[3], *A. Mantovani*[4,3];
[1]*Graduate Program in Areas of Basic and Applied Biology (GABBA), ICBAS, University of Porto, Porto, Portugal,* [2]*INEB-Institute of Biomedical Engineering/Instituto de Investigação e Inovação em Saúde (i3S), University of Porto, Porto, Portugal,* [3]*Department of Inflammation and Immunology, Humanitas Clinical and Research Center, Rozzano, Italy,* [4]*Humanitas University, Rozzano, Italy,* [5]*Department of Microbiology and Infection Immunology, Charité - University Medical Centre Berlin, Berlin, Germany,* [6]*Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy.*

Monocytes and macrophages (MØs) are key components of several pathological conditions, undergoing profound functional reprogramming influenced by the microenvironment. Several markers have been reported to identify specific MØs subsets and activation profiles. Recently, we described the tetraspanin MS4A4A as part of the transcription signature of M2-MØs and tumor-associated MØs (TAMs). It was shown that MS4A4A is selectively expressed in tissue resident MØs, is upregulated during polarization towards an M2/M2-like phenotype, being also highly expressed in TAMs. The pattern recognition receptor Dectin-1 was identified as a molecular partner of MS4A4A. MS4A4A-deficient MØs present an impaired Dectin-1-dependent crosstalk with NK cells, leading to uncontrolled metastatic spreading. Yet, several aspects of MS4A4A immunobiology remain unclear.
Our goal is to better understand the functional consequences of MS4A4A interaction with Dectin-1 and other partners. We are taking advantage of genetic models to characterize MS4A4A expression in the mouse. A second line of work concerns the characterization of MS4A4A role in carcinogenesis and metastatic spreading, with several models being currently under investigation.
Dectin-1 recognizes β-glucans in *Aspergillus fumigatus* cell wall, having a key role in the infection context. Thus, we are characterizing the susceptibility of *ms4a4a-ko* mice to *A. fumigatus* infection, a major risk factor in immunocompromised patients.
A better understanding of MS4A4A expression and function in the context of macrophages will pave the way to the use of this molecule as a therapeutic target or prognosis marker in both tumor and infection context.

P.B2.07.16

Tumor-associated macrophages in rectal cancer polarize to the proinflammatory M1 phenotype after irradiation in patients and 3D co-culture model

V. Stary, *D. Unterleuthner, B. Wolf, J. Strobl, A. Beer, H. Dolznig, M. Bergmann;
Medical University of Vienna, Vienna, Austria, Vienna, Austria.*

Tumor-associated macrophages initiate anti-tumoral (M1) or immunosuppressive (M2) responses depending on their polarization status. To test the effects of radiotherapy, we *ex vivo* irradiated tissue samples of human rectal cancer and assessed the phenotype of macrophages, T cells and NK cells by flow cytometry. We evaluated their distribution after short course radiotherapy (n=45) and compared findings to non-pretreated rectal cancer (n=25) using an immunostaining approach. We further investigated the influence of cancer-associated fibroblasts and cancer cells on the polarization of macrophages after *ex vivo* irradiation using 3D co-culture models. Irradiated rectal cancer samples contained less $CD68^+$ macrophages (18.2.±2 vs 12.6±3%$CD68^+$/total leukocytes) with a viability of >92% in both groups. Stainings of markers associated with the M1- (CD64, CCR7, iNos, TNFα, HLA-DR, CD86) or M2-like (CD206, CD163, IL-10, IL-4) phenotype revealed an increase of M1/M2-ratio arguing for a shift from M2- to M1-like macrophages due to irradiation. Irradiated tissue sections demonstrated diminished T cell counts (109.7±8.68 vs 45.7±17.26 $CD3^+$cells No./mm^2) but elevated infiltration of NK cells (50.3±15.51 vs 75.9±9.43 $CD56^+CD3^-$cells No./mm^2). Irradiation of 3D co-culture models led to a dose dependent increase of M1/M2. Untreated macrophages in co-cultures without fibroblasts tended to be less M2 but more M1-like. Neutralizing IL-10 antibody induced M1-like macrophages. Treatment with recombinant IL-10 partly rescued the effects of irradiation. Our findings highlight macrophages as effector cells upon irradiation by enhancing their anti-tumoral activities and diminishing their immunosuppressive behavior. This study provides a rationale for future investigation aiming for immune-modulation of macrophages to ensure optimal anti-cancer immune-activation.

P.B2.07.17

Macrophage subpopulations acquire distinct education programming along radiation treatment response in gliomas

J. Tessier, *J. Gadiot, S. Handgraaf, L. Akkari;
Netherlands cancer institute (NKI), Amsterdam, Netherlands.*

Glioblastoma (GBM) is the most malignant form of adult brain tumors. Due to resistance and tumor regrowth, overall survival only reaches 12-15 months. Interestingly, up to 30% of the tumor bulk consists of tumor-associated macrophages (TAMs). Their increase in number correlates with poor prognosis, and may therefore participate in establishing a favorable environment supporting treatment resistance and recurrence emergence. Our data support a progressive effect of radiation, a standard of care treatment for GBM, on the two subpopulations of TAMs found in GBM: microglia, the brain resident macrophages and the tumor infiltrating bone marrow-derived macrophages (BMDM). We aim to decipher how BMDM and MG are altered when in contact with GBM cell, and their respective phenotype modification after radiation. We made use of a spontaneous mouse model of GBM, faithfully recapitulating the human pathology, and performed RNA sequencing on TAMs isolated post radiation. While these two populations share similar pro-tumorigenic functions, they also differ in their response to treatment Our preliminary data show similar activation of both macrophage subpopulations, with a shift toward an M2-like phenotype in the early onsets after treatment, and acquisition of a common phenotype at recurrence. However, these phenotypes differ in intensity, indicating that despite a common education, MG and BMDM react differently to irradiation. We now aim to further understand the molecular mechanisms underlying BMDM and MG influence on GBM recurrence. These research questions will shed light on the heterotypic communication between glioma cells and their local and systemic environment.

Conventional (CV) and germ-free (GF) animals offer a potent model for understanding the cross-talk between immunity and tissue structure modeling, e.g. in the colon. The constant immune activation sustained by colon microbiota can be put in comparison with immune activation of the GF animal naïf mucosal system variously induced (bacteria, dextran sodium sulfate, azoxymethane). After induction, the bowel was harvested at established time points. Samples were taken for histology and second-harmonic generation (SHG) analysis by multi-photon confocal microscopy. Mucosa samples were analyzed for cytokine expression (ELISA, PCR). The healthy CV rat revealed higher pro-inflammatory cytokine (IFNγ, IL1, TNFα) and TGFβ expression in the mucosa than the GF rat, and also different collagen stroma texture. Highly dynamic scaffold remodeling resulted in the animals induced to inflammation or bacterial colonization. The induced inflammation thickened and quickly expanded the scaffold in GF animals, without significant alterations in its general architecture. The contrary was in CV animals. The importance of different threshold of immune activation can explain the differences between the two conditions. This is an evidence of the microbiota role on colonic structure maturation through promotion of immune activation. Depending on the basal "inflammatory threshold" the scaffold cannot adapt, as seen in CV animals. Similarly, transformed cells can alter the scaffold by continuous pro-inflammatory stimulations, generating the tumor microenvironment.

Modern immunotherapies are less effective in B cell chronic lymphocytic leukemia (CLL) than in other malignancies. This may be partially caused by highly immunosuppressive microenvironment observed in CLL. Several immune dysfunctions occur in CLL including impairments in T cell and myeloid cell populations. In a subset of CLL patients, elevated oxidative stress is accompanied by dysfunctions of cytotoxic T cells and may be one of the triggers of immunosuppression. However, the causes of dysregulated redox homeostasis in CLL are not well understood. We employed Eμ-TCL1 mice model of CLL to investigate the role of selected populations of immune cells in the generation of oxidative stress and immune evasion in CLL. To measure the levels of reactive oxygen species (ROS) in defined subpopulations of immune cells we used CM-H_2-DCFDA fluorescent probe and flow cytometry analysis. To assess the amounts of secreted H_2O_2 we used Amplex Red assay.
In spleens and lymph nodes of TCL1 leukemic mice we observed increased percentages of immunosuppressive populations of cells such as regulatory T cells, CD11b+/MHC-II^{low}/PD-$L1^{high}$ and, CD11c+/MHC-II^{low}/PD-$L1^{high}$. In addition, we detected elevated ROS levels in malignant B cells as well as in CD11b+ and CD11c+ cells isolated from the spleens of Eμ-TCL1 mice. Accordingly, our preliminary data suggest that Eμ-TCL1 mice-derived splenocytes produced more H_2O_2 as compared to their equivalents from non-leukemic mice. Further studies are underway to better define pathways responsible for increased ROS levels in the selected populations of immune cells.

Regulatory T-cells (Tregs) are a subset of CD4+ T-cells that maintain immunological tolerance and regulate immune homeostasis. Tregs have been classified as regulatory T helper (Th)-like cells according to the expression of specific transcription factors, cytokines and chemokine receptors that mirror effector Th lineages. We have recently characterised peripheral blood and tissue resident Th-like Tregs in healthy donors and patients with cancer. Our results revealed that CCR4-expressing Th2-like Tregs were enriched in tumorigenic areas compared to healthy tissues. However, it is not clear whether Tregs migrate in response to specific chemokines or whether the environment supports the differentiation of Th2-type Tregs. Chemotactic assays demonstrated that Th2-like Tregs migrate preferentially to chemokines CCL17 and CCL22. However, CCR8, a chemokine receptor associated with tumour-infiltrating Tregs, was also preferentially expressed in Th2-like Tregs, therefore it is also possible that Th2-like Tregs migrate in response to CCL1 and CCL18. In this study, we evaluated the expression of CCL1, CCL17, CCL18 and CCL22 in cancer tissues from patients with oral squamous cell carcinoma compared to healthy oral mucosa. Our results demonstrated that patients with oral cancer expressed higher levels of CCL18 and CCL17. These results suggest that both, CCR4 and CCR8, can support the migration of Th2-like Tregs to malignant areas in oral cancer.

P.B3.01 T-cell regulation - Part 1

P.B3.01.01

Abundance of Tregs and effects of their inhibition in oral cancer

***S. Aggarwal**, S. Sharma, S. Das;*
All India Institute of Medical Sciences, Delhi, India.

Oral squamous cell carcinoma (OSCC) is one of the major cancers affecting in Asian countries. The main causative factor has been tobacco habit. It has been reported that immune dysfunction in these patients is one of the major factors for tumor growth and dissemination that affects disease-free survival of the patients. We assessed the phenotypic and functional characteristics of Regulatory T (T_{reg}) $CD4^+CD25^+FoxP3^+$subsets in patients with OSCC by multicoloured flow cytometry. The effects of garcinol mediated, MACS-purified Tregs inhibition on growth of cell lines was also studied. An increased frequency of $CD4^+CD25^+$, $CD4^+FoxP3^+$, $CD8^+FoxP3^+$ and $CD4^+CD25^+FoxP3^+$ was observed in the peripheral circulation of OSCC patients that positively correlated with clinicopathological features. The increased frequency of $CD4^+CD8^+CD25^+FoxP3^+$, CTLA-4^+, $GITR^+$, $NrP1^+$, HLA-DR^+, $CD127^+$, $Tbet^+$ and granzyme B^+ (GzmB) T_{regs} alsoshowed a significantly higher prevalence in OSCC patients. Functionally $CD4^+FoxP3^+T_{regs}$ showed skewed expression of IL-2, IL-10 and IL-35 in patients as compared with the normal controls. Further, enhanced expression of CCR5 and CCR7 on T_{regs} with up regulation of their ligands (CCL5, CCL19 and CCL21) in tumor cells indicates efficient recruitment and trafficking of T_{regs} to the tumor site. Additionally, garcinol treatment significantly ($P < 0.001$) inhibited the growth of OSCC cells with a concomitant induction of apoptosis, cell cycle arrest and anti-angiogenesis. It appears that garcinol concurrently prevents many tumour-promoting effects Treg. Hence, modulation of functional dynamics of selective T_{reg} subsets may be useful in enhancing anti tumor immunity and developing immunotherapeutic strategies for patients with oral squamous cell carcinoma.

CD39+ regulatory T cells accumulate in colon adenocarcinomas and display markers of increased suppressive function

***F. Ahlmanner**[1], P. Sundström[1], P. Akeus[1], J. Eklöf[1], L. Börjesson[2], B. Gustavsson[2], E. Bexe Lindskog[2], S. Raghavan[1], M. Quiding-Järbrink[1];*
[1]Dept of Microbiology and Immunology, Gothenburg, Sweden, [2]Dept of Surgery, Gothenburg, Sweden.

Increasing knowledge of the function and regulation of tumor-infiltrating lymphocytes has led to new insights in cancer immunotherapy. Regulatory T cells (Treg) accumulate in colon tumors, and we recently showed that $CD39^+$ Treg from cancer patients inhibit transendothelial migration of conventional T cells. CD39 mediates the hydrolysis of ATP to immunosuppressive adenosine and adds to the immunosuppressive effects of Treg. Here, we further investigated the regulatory features of intratumoral $CD39^+$ Treg in colon cancer. Using flow cytometry analyses of cells from 46 colon cancer patients, we confirmed the accumulation of $CD39^+$ Treg in the tumor tissue compared to unaffected colon tissue, and also observed a positive correlation between CD39 expression among intratumoral Treg and CD39 expression among circulating Treg ($p < 0.01$). Furthermore, tumor-infiltrating Treg express significantly more CD39 and Foxp3 on a per cell basis, as well as markers indicating increased turnover and suppressive function, such as Ki67, ICOS, PD-L1 and CTLA-4. Functional suppression assays suggest potent suppressive capacity of $CD39^+$ Treg on proliferation and IFN-γ secretion by conventional T cells. Preliminary studies also indicate that high levels of CD39 expression among intratumoral Treg may correlate to a worse patient outcome. In conclusion, our results show a large infiltration of $CD39^+$ Treg in colon tumors, and this subset appear more immunosuppressive than their $CD39^-$ counterparts. We suggest that immunotherapy aimed at reducing tumor-infiltrating $CD39^+$ Treg activity may be particularly useful in the setting of colon cancer.

Lymphopenia induces homeostatic T-cell proliferation after autologous stem cell transplantation

***M. Baliu-Piqué**[1], V. van Hoeven[2], J. Drylewicz[1], L. E. van der Wagen[1], A. Janssen[1], L. J. Ackermans[1], S. A. Otto[1], J. H. Kuball[1], J. A. Borghans[1], K. N. Tesselaar[1];*
[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands.

Hematopoietic stem cell transplantation (SCT), an increasingly common treatment for many types of cancer and immune disorders, comes at a cost of lymphopenia and the concomitant need for immune reconstitution. A successful reconstitution depends on the early recovery of T-lymphocytes. However, T-cell recovery after SCT generally occurs extremely slowly. There is evidence in mice that lymphocyte production and/or survival rates increase when cell numbers are low. Studies in humans have suggested that increased T-cell proliferation after SCT is associated with clinical events (GVHD) rather than with low lymphocyte numbers. Here, we investigated whether T-cell production is also increased under lymphopenic conditions in humans. Using *in vivo* deuterium labelling and mathematical modelling we quantified the dynamics of T-cells in patients who underwent autologous SCT, and had no signs of infectious complications. After a reconstitution period of up to 1.5 years, absolute numbers of $CD4^+$ T-cells, particularly of the naive subset, were still very low in these patients. Deuterium labelling demonstrated that the production rates of naive and memory $CD4^+$ and $CD8^+$ T-cells in SCT patients were significantly increased compared to healthy individuals. TREC content analysis and CD31 expression of naive $CD4^+$ T-cells suggested that these increases in T-cell production were due to increased peripheral proliferation, and not thymic output. Taken together, this work shows that despite the slow reconstitution of lymphocyte numbers after SCT in humans, lymphocyte proliferation rates are in fact homeostatically increased in response to lymphopenia, bringing new insights in the cellular dynamics behind a timely T-cell reconstitution.

Tyrosine kinase inhibitor Dasatinib effects on iNKT cells and innate CD8 T-cells in chronic myeloid leukemia patients

***A. Barbarin**[1], L. Lefevre[1], M. Abdallah[1], N. Piccirilli[1,2], E. Cayssials[1,2], L. Roy[3], A. Herbelin[1], J. M. Gombert[1,2,4];*
[1]INSERM U1082, Poitiers, France, [2]CHU de Poitiers, Poitiers, France, [3]Hopital Henri Mondor, Créteil, France, [4]Université de Poitiers, Poitiers, France.

Introduction: Chronic myeloid leukemia (CML) is a clonal hematopoietic stem cell malignancy caused by the presence of the chimerical BCR-ABL oncoprotein, with deregulated tyrosine kinase (TK) activity. Dasatinib is a highly potent second-generation BCR-ABL tyrosine kinase inhibitor (TKI) with off-target immunological effects. We recently identified in healthy individuals a distinct new innate CD8 T-cell subset characterized by the expression of NK receptors (KIR/NKG2A), high Eomesodermin expression and prompt IFN-γ production in response to innate-like stimulation by IL-12+IL-18. Like iNKT cells, innate CD8 T-cells are severely reduced and functionally deficient in CML patients at diagnosis and partially restored after therapy with Imatinib, a first-generation TKI. Here, we tested the hypothesis of a direct effect of Dasatinib on iNKT cells and innate CD8 T-cells.
Methods: Using flow cytometry, we analyzed iNKT cells and innate CD8 T-cells in the peripheral blood from patients treated 12 months with Dasatinib. In a mouse model, we tested Dasatinib effects both *in vivo* (oral gavage) and *in vitro* using thymocyte and splenocyte culture systems.
Results: In CML patients treated 12 months with Dasatinib, we observed an increased percentage of both iNKT cells and innate CD8 T-cells. In the mouse model, *in vivo* and *in vitro* analysis showed an increase of iNKT cells with a Th1 profile. Despite the decrease of the memory CD8 T-cell compartment, the innate-memory CD8 T-cell pool was increased.
Conclusion: Taken together, our data are in favor of a direct effect of Dasatinib on both iNKT cells and innate CD8 T-cell numbers and functions.

P.B3.01.05

Unconventional T-αβ cells (iNKT and innate CD8 T cells) in solid tumors and their tumor environment

A. Barbarin[1], *B. Morin*[1], *N. Piccirilli*[1,2], *N. Gonzalo Nunez*[3], *E. Piaggio*[3], *V. Lavoue*[4], *V. Catros*[4], *A. Herbelin*[1], *J. M. Gombert*[1,2,5];
[1]*INSERM U1082, Poitiers, France,* [2]*CHU de Poitiers, Poitiers, France,* [3]*CICBT 1428 SiRIC, institut Curie, Paris, France,* [4]*CHU de Rennes, INSERM U991, CRN de Rennes, Rennes, France,* [5]*Université de Poitiers, Poitiers, France.*

Introduction: Cancer immuno-surveillance involves innate and adaptive cells as well as non-conventional T cells like iNKT cells. Recently, we have identified in humans a new CD8 T-cell subset, named innate CD8 T-cells, expressing a classical TCR-αβ and NK markers and responding to innate-like stimulation by the pro-inflammatory cytokines IL-12, IL-18 and IL-33. Our recent data support a possible link between iNKT cells and innate CD8 T-cells *via* the secretion of IL-4 by iNKT cells. Here, our aim was to study the iNKT/innate CD8 T-cell axis in solid tumors.
Methods: We analyzed by flow cytometry blood samples, ascites, pleural fluid, carcinosis and tumor samples from patients with ovarian, breast, pancreas or colon cancer for the presence and activation state of iNKT cells and innate CD8 T-cells. IL-12, IL-18 and IL-33 levels were measured in plasma and ascite supernatants by ELISA.
Results: iNKT cells and Innate CD8 T-cells were present in the tumor, carcinosis and ascites. iNKT cells from the tumor and tumor environment were enriched in CD69 positive cells, reflecting their higher activation state than their peripheral counterparts. Furthermore, we observed a positive correlation between the expression of the two transcriptional factors characterizing iNKT and innate CD8 T-cells, PLZF and Eomes, respectively. Finally, we showed that the tumor environment was enriched in IL-12 and IL-33 whereas IL-18 was detected at the periphery.
Conclusion: Taken together, our results support the hypothesis of anti-tumoral cooperation between iNKT cells and innate CD8 T-cells in response to the cytokines IL-12 and IL-33 in solid tumors.

P.B3.01.06

Regulatory T-cell compartment in HIV-1+ pregnancies loses gestation adaptations and function

A. Cocker[1], *S. Sivarajasingam*[1], *A. Sassine*[1], *I. Raj*[2], *S. Dermont*[2], *A. Khan*[2], *N. Imami*[1], *M. Johnson*[1];
[1]*Imperial College London, London, United Kingdom,* [2]*Chelsea and Westminster Hospital, London, United Kingdom.*

Regulatory T cells (Treg) are thought to maintain tolerance towards the fetus during pregnancy, and mediate responses to viruses such as Cytomegalovirus (CMV) that risk disrupting immunological balance. HIV-1+ women have higher incidences of preterm labour, potentially caused by increased immune activation. Here the longitudinal development of the Treg compartment and its relation to viral responses in HIV-1- and HIV-1+ pregnancies is compared.
Peripheral blood mononuclear cells were isolated from pregnant HIV-1+ (n=19) and HIV-1- (n=15) women, and flow cytometric analysis performed to determine the frequency of Treg cells (CD3+CD4+CD25+CD127^{low}) and their expression of CD45RA, and HLA-DR. IFNγ and IL-2 ELISpot assays were completed to quantify CMV specific responses. Statistical analysis was carried out using Prism version 7.0. Spearman's rank correlation and linear regression were applied, and statistical significance defined as p≤0.05. Point estimates for gestational changes were derived using MIXED procedure in SAS version 9.4.
Treg frequency of CD4+ T cells and CD45RA expressing cells increased with gestation in HIV-1- women. Treg expressing HLA-DR decreased with gestation. None of these changes were seen in the HIV-1+ group. IFNγ and IL-2 responses to CMV were negatively correlated with Treg frequency and CD45RA, and positively with HLA-DR expression in HIV-1- participants. Only HLA-DR and IFNγ demonstrated a positive relationship in the HIV-1+ women.
The Treg compartment demonstrates gestational developments and correlates to anti-viral responses, supporting their suppressive function. Loss of these relationships in HIV-1+ participants highlights this compartment as clinically relevant to their increased preterm labour rate.

P.B3.01.07

Role of the interleukin-33/ ST2L-axis for the CD8-dependent anti-cancer cytotoxicity

C. Dreis[1], *F. Ottenlinger*[1], *M. Herrero San Juan*[1], *M. Putyrski*[2], *A. Ernst*[2], *M. U. Martin*[3], *J. M. Pfeilschifter*[1], *H. H. Radeke*[1];
[1]*pharmazentrum frankfurt, Frankfurt am Main, Germany,* [2]*Institute of Biochemistry II, Frankfurt am Main, Germany,* [3]*Immunology FB08 Justus-Liebig-University, Giessen, Germany.*

Novel cancer therapies target the activation of tumor-antigen specific cytotoxic T cells to improve treatment efficacy. For the alarmin Interleukin-(IL-)33, ligand of Th2 marker ST2L and IL-1 family member, increasing evidence suggests an involvement in Th1 immunity. We previously demonstrated IL-33/ IL-12-dependent co-activation of murine cytotoxic T cells and hypothesize induction of anti-tumoral Th1 activity by IL-33. We re-evaluated the regulation of IL-33 bioactivity within optimized *in vitro* bioactivity assays and analyzed regulation of ST2L/ sST2 expression of human immune cells.
IL-33 aa (amino acid) 111-270 and recombinantly generated hyperactive aa95-270 potently activated ST2L-expressing HEK293 reporter cells. In a competitive assay with ST2L, significant downregulation of IL-33 bioactivity required 100-fold excess of soluble decoy receptor sST2. However, in the absence of ST2L, aa111-270 and aa95-270 exhibited high binding affinities to sST2 (2.21 nM ± 1.1; 13.47 ± 2.9 nM). IL-33 and IL-1β detected by ELISA in serum of healthy donors (n=30) failed to induce a corresponding bioactivity. Still, bioactivity of exogenous recombinant IL-33, but not IL-1β, was significantly reduced in human plasma. Proteases and oxidation have been excluded as elicitors of this effect.
Peripheral blood mononuclear cells and isolated CD8+ T cells revealed expression of cell surface ST2L as well as sST2 mRNA. These results support our hypothesis of a crucial role of IL-33 in the activation of Th1 immunity, followed by a systemic, strongly regulated inactivation. Understanding the regulation of IL-33 bioactivity will lead to optimized activation of tumor-antigen specific activation of cytotoxic T cells. Funded by Else-Kröner-Fresenius Stiftung.

P.B3.01.08

The role of the PD-1 inducible ARF-like GTPase 4d in immune inhibition of anti-tumor CD8 T cell immunity

B. Geers*, P. Sprezyna, J. Endig, L. Diehl;*
University Medical Center Hamburg-Eppendorf, Institute of Experimental Immunology and Hepatology, Hamburg, Germany.

Blockade of the inhibitory PD-L1/PD-1 pathway holds promise for cancer immunotherapy. Priming of CD8 T cells by liver sinusoidal endothelial cells (LSEC) leads to development of T cells with memory function but lacking immediate effector function, which depended on PD-L1 signaling and restriction of IL-2 availability. We previously found that the small GTPase Arl4d was PD-L1 dependently highly induced in naïve CD8 T cells and that Arl4d functions to repress their production of IL-2. As PD-L1/PD-1 signaling may inhibit effector function of anti-tumor CD8 T cells, we aimed to investigate whether Arl4d is involved in PD-1 mediated inhibition of anti-tumor CD8 T cell responses *in vivo*. Therefore, we analyzed B16-OVA melanoma tumor growth after s.c. injection into male *Arl4d*$^{+/+}$ or *Arl4d*$^{-/-}$ mice. All mice developed solid tumors within ~14d, but Arl4d-deficiency led to a significant decrease in tumor size and weight. We, furthermore, found high percentages of tumor infiltrating CD44^{+}CD62L^{-}CD8^{+} T cells expressing PD-1 in both *Arl4d*$^{+/+}$ or *Arl4d*$^{-/-}$ mice. We did not, however, observe differences in CD8 T cell numbers or activation state in the tumor nor in the draining lymph nodes. We demonstrate that Arl4d-deficiency leads to a better control of B16-OVA tumor growth in mice but did not find any overt changes in the intra-tumoral and tumor-draining T cell compartment. To identify the mechanism responsible for the decreased tumor growth in *Arl4d*$^{-/-}$ mice, a more detailed functional and phenotypical analysis of tumor infiltrating CD8 T cells but also other immune cells in the tumor may be needed.

P.B3.01.09

Evaluating *in vivo*anti-tumor T cell responses to melanoma using newly developed tumor cell lines

J. L. Hope*, M. L. Barraza, R. Tinoco, L. M. Bradley;*
Sanford Burnham Prebys Medical Discovery Institute, La Jolla, United States.

Mouse models of cancer remain the preferred means to assess the efficacy of anti-cancer therapies, and several models have been used to address the effect of cancer drugs or in the discovery of biomarkers. The YUMM1.5 and YUMMER1.7 murine tumor models were developed from the *Braf/Pten* engineered mouse model to more closely reflect melanomas that are driven by human disease-relevant mutations; however, the dominant T cell-recognized epitopes specific for these tumors remains unknown. We therefore sought to engineer OVA-expressing versions of the YUMM1.5 and YUMMER1.7 tumor lines, hereafter referred to as YUMM1.5-OVA and YUMMER1.7-OVA. Using stable transfection to insert a plasmid expressing full-length secretory ovalbumin, we have generated polyclonal and monoclonal cell lines that generate an *in vivo* OVA-specific response as validated by MHC class I tetramer staining and cytokine production following OVA peptide stimulation. Together, these two new models for melanoma will allow us to assess intrinsic and extrinsic mechanisms regulating the generation of effective and recovery of exhausted T cell responses to melanoma *in vivo*.

P.B3.01.10

Immunogenicity and immunophenotypes in young-onset colorectal cancers

M. E. Ijsselsteijn*, T. Brouwer, D. Ruano, R. van der Breggen, H. Morreau, K. Jordanova, N. De Miranda;*
Leiden university medical centre, Leiden, Netherlands.

Immunotherapy has emerged as one of the most promising options for cancer treatment. Tumour-infiltrating immune cells have great prognostic value in solid tumours, including colorectal cancer. In recent years, a tendency has been observed towards an increased incidence of colorectal cancer in young (<50) patients. These patients are not included in screening programs and thus often diagnosed at advanced stages of tumour progression. To our knowledge, no study has yet characterized immunophenotypes and immune evasive mechanisms in young-onset colorectal cancers. To that end, we investigated the expression of HLA class I and PD-L1 by Immunohistochemistry in over 200 young-onset colorectal cancers. Furthermore, we applied a novel multispectral immunofluorescence technique to simultaneously assess 7 T-cell related markers.

We describe that HLA class I is maintained in 62% of mismatch-repair proficient tumours, which allows the development of neo-antigen targeted therapies, but lost in 78% of mismatch-repair deficient tumours. Interestingly, reduced, but not lost, HLA class I expression was specifically observed in liver metastasis, which suggests a specific pressure that could be utilised for immunotherapeutic exploitation. As previously demonstrated, PD-L1 expression is limited and often restricted to immune cell compartments. Multispectral immunofluorescence imaging allows for a comprehensive overview of T-cell immunophenotypes and their relation to HLA class I expression in young-onset colorectal cancer. Retained HLA class I expression in the majority of colorectal cancers associated with low infiltration by effector immune cells suggests the possibility for therapeutic induction of anti-tumour immune responses in young-onset colorectal cancers, for instance, by means of neo-antigen-targeted therapies.

P.B3.01.11

GITR targeting enhances functionality of tumor-infiltrating T cells in hepatocellular carcinoma

*A. A. van Beek[1], G. Zhou[1], M. Doukas[1], P. P. Boor[1], L. Noordam[1], S. Mancham[1], L. Campos Carrascosa[1], M. van der Heiden-Mulder[1], W. G. Polak[1], J. N. IJzermans[1], Q. Pan[1], C. Heirman[2], A. Mahne[3], S. L. Bucktrout[3], M. J. Bruno[1], D. Sprengers[1], **J. Kwekkeboom**[1];*
[1]Erasmus MC - University Medical Centre, Rotterdam, Netherlands, [2]Vrije Universiteit, Brussels, Belgium, [3]Rinat Laboratories, Pfizer Inc., South San Francisco, United States.

No curative treatment options are available for advanced hepatocellular carcinoma (HCC). A recent study demonstrated that anti-PD1 antibody therapy can induce tumor regression in 20% of advanced HCC patients, thereby revealing that co-inhibitory immune checkpoint blockade may have therapeutic potential for this type of cancer. However, whether agonistic targeting of costimulatory receptors can stimulate anti-tumor immunity in HCC is as yet unknown. We studied expression of the co-stimulatory receptor GITR on tumor-infiltrating lymphocytes (TIL) isolated from freshly resected tumors, and on lymphocytes isolated from paired tumor-free liver tissues and blood of HCC patients. We determined whether agonistic targeting of GITR could enhance ex vivo functional responses of HCC TIL. In all three tissues, GITR was predominantly expressed on $CD4^+FoxP3^+$ regulatory T cells (Treg). The highest expression levels were found on $CD4^+FoxP3^{hi}CD45RA^-$ activated Treg in tumors. Addition of recombinant GITR-ligand or a humanized agonistic antibody against GITR (10H2#13, Pfizer) to *ex vivo* cultures of HCC TIL enhanced $CD8^+$ T cell proliferation, granzyme B and IFN-γ production, in response to CD3/CD28 stimulation. GITR ligation also enhanced proliferative responses of tumor-derived $CD4^+$ and $CD8^+$ TIL to tumor antigens presented by mRNA-transfected autologous B cell blasts. Interestingly, GITR-expressing Treg, CD4+Foxp3- T helper cells, and CD8+ T cells in tumors co-expressed PD-1. Combining GITR ligation with anti-PD1 antibody further enhanced proliferative responses of $CD4^+$ and $CD8^+$ TIL to tumor antigens compared to either single treatment. Conclusion: Agonistic targeting of GITR may be a promising strategy for single or combinatorial immunotherapy in HCC.

Thymus derived Treg cell development is regulated by C type lectin mediated BIC miRNA155 expression

*R. Sánchez Díaz[1], R. Blanco Dominguez[1], S. Lasarte[1], K. Tsilingiri[1], E. Martín Gayo[2], **B. Linillos Pradillo**[1], H. de la Fuente[3], F. Sánchez Madrid[3], R. Nakagawa[4], M. Toribio[5], P. Martin[1];*
[1]CNIC, Madrid, Spain, [2]Centro de Biología Molecular Severo Ochoa, Consejo Superior de Investigaciones Científicas, Universidad Autónoma de Madrid, Madrid, Spain, [3]Hospital de la Princesa, Madrid, Spain, [4]The Francis Crick Institute,, London, United Kingdom, [5]CIBER de Enfermedades Cardiovasculares, Instituto de Salud Carlos III, Madrid, Spain.

BACKGROUND AND OBJECTIVE: Thymus-derived regulatory T (tTreg) cells are key to preventing autoimmune diseases, but the mechanisms involved in their development remain unsolved. Here, we show that the C-type lectin receptor CD69 controls tTreg cell development and peripheral Treg cell homeostasis through the regulation of BIC/microRNA 155 (miR-155) and its target, suppressor of cytokine signaling 1 (SOCS-1).
METHODS: Using Foxp3-mRFP/*cd69*$^{+/-}$ or Foxp3-mRFP/*cd69*$^{-/-}$ reporter mice and short hairpin RNA (shRNA)-mediated silencing and miR-155 transfection approaches, we found that CD69 deficiency impaired the signal transducer and activator of transcription 5 (STAT5) pathway in $Foxp3^+$ cells
RESULTS: This results in BIC/miR-155 inhibition, increased SOCS-1 expression, and severely impaired tTreg cell development in embryos, adults, and Rag2$^{-/-}$ γc$^{-/-}$ hematopoietic chimeras reconstituted with *cd69*$^{-/-}$ stem cells. Accordingly, *mirn155*$^{-/-}$ mice have an impaired development of $CD69^+$ tTreg cells and overexpression of the miR-155-induced CD69 pathway, suggesting that both molecules might be concomitantly activated in a positive-feedback loop. Moreover, *in vitro*-inducible $CD25^+$ Treg (iTreg) cell development is inhibited in *Il2rγ*$^{-/-}$/*cd69*$^{-/-}$ mice.
CONCLUSIONS: Our data highlight the contribution of CD69 as a nonredundant key regulator of BIC/miR-155-dependent Treg cell development and homeostasis.

GMP-compliant generation of human granzyme B^+ regulatory B cells for the therapy of graft-versus-host disease

***C. Mangold**[1], A. Felsen[1], L. Kurz[1], T. Trzaska[1], P. Reinhardt[1,2], H. Schrezenmeier[1,2], D. Fabricius[3], K. Schilbach[4], B. Jahrsdörfer[1,2];*
[1]Department of Transfusion Medicine, Ulm, Germany, [2]Institute for Clinical Transfusion Medicine and Immunogenetics, German Red Cross Blood Transfusion Service Baden-Württemberg – Hessen and University Hospital Ulm, Ulm, Germany, [3]Department of Pediatrics, Ulm, Germany, [4]Department of General Pediatrics, Oncology/Hematology, Eberhard-Karls University Tübingen, Tübingen, Germany.

Granzyme B (GrB)-secreting regulatory B cells (B_{reg}) suppress T cell proliferation by GrB-mediated degradation of the T cell receptor and are involved in various pathologies. Their exploitation as novel cell-therapeutic agents may therefore represent a promising approach for the treatment of *graft-versus-host disease* (GvHD*)*. Recently, we developed a cocktail consisting of IL-21 and antibodies against the human B cell receptor, allowing for easy *ex-vivo* induction of GrB^+ B_{reg} from peripheral B cells isolated from whole blood. In our current study, we now used a GMP-compliant positive selection kit to directly isolate $CD19^+$ B cells from leukapheresis products collected from eight unstimulated healthy donors. Subsequently, we tested the isolated B cells in terms of their potential to differentiate into B_{reg}. On average, we were able to isolate $56.5x10^6$ B cells from ~$6.6x10^8$ total PBMC. Purity was 99.4%, viability was 98.1%. Extrapolated to the size of a full leukapheresis product, the generation of >$600x10^6$ B_{reg} is possible. After 48 hours of stimulation, an average of 64.7% of B cells showed the typical GrB^+ phenotype. Of note, these B cells maintained their B_{reg} phenotype for up to another 72 hours after the end of stimulation. In conclusion, our findings demonstrate that GMP-compliant generation of induced B_{reg} is feasible. Our results pave the way for further development of B_{reg} as novel cell-therapeutic agent. A first pilot study on the effect of GrB^+ B_{reg} on GvHD in a humanized mouse model will be starting in June 2018. Initial results will be discussed on the conference.

MicroRNA-31 is induced in repeatedly activated T Helper 1 Lymphocytes and regulates their motility

*M. Bardua[1], C. Haftmann[1], P. Durek[1], M. Mcgrath[1], C. Tran[1], G. Heinz[1], P. Maschmeyer[1], M. Lohoff[2], H. Chang[1], A. Radbruch[1], **M. Mashreghi**[1];*
[1]Deutsches Rheuma-Forschungszentrum, Berlin, Germany, [2]Institute for Medical Microbiology and Hospital Hygiene, University of Marburg,, Marburg, Germany.

T helper (Th) lymphocytes can be readily found in inflamed tissues of patients with rheumatic diseases despite immunosuppressive therapies and express the transcription factor Twist1, which is a functional biomarker for Th1 cells with a history of repeated (auto-)antigenic stimulation. Little is known about the molecular adaptations which allow these cells to persist in the inflamed tissues. To mimic Th cells from either protective immune reactions or chronic inflammation, we have generated acutely (once) and repeatedly (four times) activated Th cells *in vitro*. By performing high throughput sequencing of small RNAs, we have identified the microRNA-31 (miR-31) being selectively upregulated in repeatedly activated murine Th1 (Th1 rep.) and in memory Th lymphocytes isolated from the synovial fluid of patients suffering from rheumatic joint diseases as compared to once activated Th1 cells or memory Th cells isolated from the blood, respectively.
In order to identify direct targets and the molecular function of miR-31, we determined the transcriptomes of Th1 rep. cells after antagomir mediated miR-31 knockdown. We observed a significant enrichment of miR-31 target genes and identified the gene set “Regulation of actin cytoskeleton” to be enriched in Th1 rep cells lacking miR-31 expression. In an *in vitro* transwell migration assay Th1 rep. cells showed 50% less migration as compared to once activated Th1 cells. This reduction in the migratory capacity is partly repealed by miR31 knockdown in Th1 rep. cells. MiR-31 might represent a molecular switch important for the persistence of proinflammatory Th cells in inflamed tissues.

P.B3.01.15

Characterising immune dysregulation in the inflammatory skin disease Hidradenitis suppurativa

***B. Moran**[1], J. Musilova[2], R. Hughes[2], A. Malara[2], K. H. Mills[1], D. C. Winter[2], A. Tobin[3], B. Kirby[2], J. M. Fletcher[1];*
[1]Trinity College Dublin, Dublin, Ireland, [2]St Vincent’s University Hospital, Dublin, Ireland, [3]Tallaght Hospital, Dublin, Ireland.

Introduction: Hidradenitis suppurativa (HS) is a chronic, debilitating skin disease with 1-4% prevalence and high morbidity. Symptoms include painful lesions, which leak a bloody, suppurative, foul-smelling discharge. These lesions can merge to form dermal tunnels, leading to restricted and painful movement, and a significant reduction in quality of life. Risk factors include obesity and smoking, with a 3:1 female:male ratio. HS pathogenesis is poorly understood, with immune dysregulation strongly implicated. Materials and Methods: Cells isolated from skin biopsies and blood from HS patients and healthy volunteers were dissociated and analysed by flow cytometry to characterise infiltrating cells, and reveal their function. A fraction of biopsy was reserved for immunohistochemistry analysis. Results: We observed substantial immune cell infiltration in HS lesions, including significantly increased numbers of neutrophils, macrophages, B cells and T cells, particularly $CD4^+$ T cells. Whilst phenotypic and molecular characterisation is ongoing, we have observed a striking T_h17-skewed profile in HS skin, even in non-lesional biopsies. Regulatory T (T_{reg}) cells were also enriched; however the T_h17:T_{reg} cell ratio was highly dysregulated in favour of T_h17 cells. In contrast, lesions from anti-TNF treated HS patients exhibited a significant reduction in T_h17 cell frequency, and normalisation of the T_h17:T_{reg} cell ratio. Further, these infiltrating cells appear to have a much less inflammatory phenotype, similar to that of healthy individuals. Conclusion: These data suggest that IL-17 inhibition via TNF blockade is associated with correction of immune dysregulation in HS, and provides a rationale for targeting the IL-17 pathway in the disease.

P.B3.01.16

Regulation of Foxp3 level and suppressive activity of thymic regulatory T cells by CML-derived extracellular vesicles

J. Swatler[1], *W. Dudka-Ruszkowska*[1], *L. Bugajski*[1], *E. Kozlowska*[1,2], *K. Piwocka*[1];
[1]*Laboratory of Cytometry, Nencki Institute of Experimental Biology, Polish Academy of Sciences, Warsaw, Poland,* [2]*Department of Immunology, Faculty of Biology, University of Warsaw, Warsaw, Poland.*

Regulatory T cells constitute a significant immunosuppressive factor in BCR-ABL-positive chronic myeloid leukemia (CML), as they participate in inhibition of effector immune response against leukemic cells. As CML cells are autologous and upregulate various self-antigens, thymic Treg (tTreg), as auto-tolerant cells, are of significant interest. Immune cells can be regulated by extracellular vesicles (EVs) secreted by cancer cells, as demonstrated in solid tumors. Leukemic EVs have been shown to influence stromal and endothelial cells in bone marrow niche, but their immunomodulatory role has not been explored.
We have investigated role of leukemic EVs in differentiation and function of tTreg, using different mouse models, including *ex vivo* model of tTreg differentiation and *in vitro* suppression assay, followed by multicolor flow cytometry. EVs from 32D BCR-ABL+ cells were isolated by differential ultracentrifugation and characterized by TEM, nanoparticle tracking and western blotting.
Mature, sorted tTreg exposed to CML-derived EVs exhibit higher suppressive activity. They also express significantly higher level of Foxp3 transcription factor, which suggests global regulation of tTreg function. This effect is attenuated by BCR-ABL inhibitor (imatinib) treatment. We also show that even though CML-derived EVs do not increase tTreg differentiation *ex vivo*, naïve thymocytes exposed to these EVs during *ex vivo* culture and eventually differentiated into Tregs demonstrate higher level of Foxp3 and higher suppressive activity.
Collectively, our results demonstrate that leukemic extracellular vesicles upregulate suppressive activity of both differentiating and mature tTreg, thus suggesting a novel immunosuppressive mechanism in chronic myeloid leukemia.

P.B3.01.17

Regulatory T cells in ovarian cancer are characterized by a highly activated phenotype that is distinct from melanoma

A. Toker[1], *L. T. Nguyen*[1], *S. C. Stone*[1], *C. S. Yang*[2], *S. R. Katz*[1], *P. A. Shaw*[1], *B. A. Clarke*[1], *D. Ghazarian*[1], *A. Al-Habeeb*[1], *A. Easson*[1], *W. L. Leong*[1], *D. R. McCready*[1], *M. Reedijk*[1], *C. J. Guidos*[3], *T. J. Pugh*[2], *M. Q. Bernardini*[1], *P. S. Ohashi*[1];
[1]*University Health Network, Toronto, Canada,* [2]*University of Toronto, Toronto, Canada,* [3]*Hospital for Sick Children Research Institute, Toronto, Canada.*

Regulatory T (Treg) cells expressing the transcription factor FOXP3 are essential for the maintenance of immunological self-tolerance but play a detrimental role in most cancers due to their ability to suppress antitumor immunity. The phenotype of human circulating Treg cells has been extensively studied, but less is known about tumor-infiltrating Treg cells. We studied the phenotype and function of tumor-infiltrating Treg cells in ovarian cancer and melanoma to reveal potential Treg cell-associated molecules that can be targeted by tumor immunotherapies. Treg cells isolated from ovarian tumors displayed a distinct cell surface phenotype with increased expression of a number of receptors associated with TCR engagement, including PD1, 4-1BB and ICOS. Higher PD-1 and 4-1BB expression was associated with increased responsiveness to further TCR stimulation and increased suppressive capacity, respectively. Transcriptomic and mass cytometry analyses revealed the presence of Treg cell subpopulations and further supported a highly activated state specifically in ovarian tumors. In comparison, Treg cells infiltrating melanomas displayed lower FOXP3, PD-1, 4-1BB and ICOS expression and were not as potent suppressors of CD8 T cell proliferation. The highly activated phenotype of ovarian tumor-infiltrating Treg cells may be a key factor in the establishment of an immunosuppressive tumor microenvironment and constitute a roadblock to successful immunotherapy. Receptors that are specifically expressed by tumor-infiltrating regulatory T cells could be exploited for the design of novel combination tumor immunotherapies.

MDSC specifically suppress IFN-γ production and antitumor cytotoxic activity of Vδ2 T-cells

A. Sacchi, N. Tumino, A. Sabatini, E. Cimini, R. Casetti, V. Bordoni, G. Grassi, ***C. Agrati****;*
National Institute for Infectious Diseases Lazzaro Spallanzani, Rome, Italy.

γδ T cells represent less than 5% of circulating T cells, they exert a potent cytotoxic function against tumor or infected cells, and secrete cytokines like conventional αβ T cells. As αβ T-cells γδ T cells reside in the typical T cell compartments (the lymph nodes, and spleen), but are more widely distributed in tissues throughout the body. For these reasons, some investigators are exploring the possibility of immunotherapies aimed to expand and activate Vδ2 T cells, or using them as CAR carriers. However, the role of immunosuppressive microenvironment on Vδ2 T cells during infections and cancers has not been completely elucidated. In particular, the effects of myeloid derived suppressor cells (MDSC), largely expanded in such pathologies, was not explored. In the present work we demonstrated that MDSC may inhibit IFN-γ production and degranulation of phosphoantigen-activated Vδ2 T cells. Moreover, the Vδ2 T cells cytotoxic activity against the burkitt lymphoma cell line Daudi and Jurkat cell line were impaired by MDSC. This impairment was not mediated by the classical MDSC inhibition pathways iNOS, IDO and ArgI. However, ArgI specific inhibition in the absence of MDSC augment Vδ2 T cell cytotoxicity, suggesting that tumor cell itself is able to partially impair Vδ2 T cell functions. These data open a key issue in the context of Vδ2-targeted immunoteraphy, suggesting the need of combined strategies aimed to boost Vδ2 T cells circumventing tumor- and MDSC-induced Vδ2 T cells suppression.

P.B3.02.02

Autosomal dominant immune dysregulation syndrome in a patient with CTLA4 deficiency

G. Aksu*, A. Aykut, E. Severcan, N. Edeer Karaca, S. Eren Akarcan, E. Parıltay, A. Durmaz, O. Cogulu, N. Kutukculer;*
Ege University School of Medicine, Izmir, Turkey.

Cytotoxic T lymphocyte antigen-4 (CTLA4) protein, is an essential negative regulator of immune responses, and its loss causes autoimmunity and immune dysregulation. The patient presented to a local hospital with weakness and fatty stool at the age of 10. He had autoimmune hemolytic anemia (AIHA) with splenomegaly and was treated with corticosteroids. Laboratory tests showed panhypogammaglobulinemia. He was referred to a pediatric immunology clinic for further evaluation. He had splenomegaly, failure to thrive, multiple lymphadenopathies, pancytopenia, panhypogammaglobulinemia and *Cryptosporidum* diarrhea. Lymphocyte subsets were normal with poor responses to vaccines, bone marrow aspiration and viral serology were also normal. Lymphadenopathies regressed with antibiotics. Regular intravenous immunoglobulin replacement and prophylactic antibiotics were initiated with the diagnosis of common variable immunodeficiency (CVID). As AIHA was refractory to medical therapy, he underwent splenectomy. During follow-up, he was also treated for short stature and osteoporosis. He was hospitalized several times for fungal or bacterial bronchopneumonia and diarrhea due to *Giardia lamblia* or *Cryptosporidium*. He had lymphoproliferation during infectious episodes. Genetic analysis for X-linked lymphoproliferative syndrome (*SH2D1A* gene) was normal. Computerized tomography of the thorax showed chronic fibrotic lung changes and bronchiectasis. He also had EBV and CMV viremia. We identified a heterozygous mutation in *CTLA4* gene (c.518G>A, p.Gly173Glu) by targeted next-generation sequencing, he was 18 at the time of diagnosis. Many CTLA-4-deficient patients are clinically diagnosed with CVID. As the phenotype of CTLA-4 deficiency includes autoimmunity, recurrent infections and lymphoproliferation, a high level of suspicion in CVID patients is required for earlier diagnosis.

P.B3.02.03

Profiling calcium signals of *in vitro* polarized human effector CD4⁺ T cells

S. Kircher, M. Merino-Wong, B. Niemeyer, ***D. Alansary****;*
Molecular Biophysics, Homburg, Germany.

Differentiation of naïve CD4⁺ T cells into effector subtypes with distinct cytokine profiles and physiological roles is a tightly regulated process, the imbalance of which can lead to an inadequate immune response or autoimmune disease. The crucial role of Ca^{2+} signals, mainly mediated by the store operated Ca^{2+} entry (SOCE) in shaping the immune response is well described. However, it is unclear if human effector CD4⁺ T cell subsets show differential Ca^{2+} signatures in response to different stimulation methods. Herein, we provide optimized *in vitro* culture conditions for polarization of human CD4⁺ effector T cells and characterize their SOCE following both pharmacological store depletion and direct T-cell receptor (TCR) activation. Moreover, we measured whole cell Ca^{2+} release activated Ca^{2+} currents (I_{CRAC}) and investigated whether the observed differences correlate to the expression of CRAC genes. Our results show that Ca^{2+} profiles of helper CD4⁺ Th1, Th2 and Th17 are distinct and in part shaped by the intensity of stimulation. Regulatory T cells (Treg) are unique being the subtype with the most prominent SOCE response. Analysis of *in vivo* differentiated Treg unraveled the role of differential expression of ORAI2 in fine-tuning signals in Treg vs. conventional CD4⁺ T cells.

P.B3.02.04

Identification of a key epigenetic barrier towards terminal cytotoxic T lymphocyte differentiation

M. A. ASLAM[1], *M. F. Alemdehy*[1], *E. M. Maliepaard*[1], *T. v. Welsem*[1], *D. v. Dinther*[2], *J. d. Hann*[2], *F. v. Leeuwen*[1], *H. Jacobs*[1];
[1]*The Netherlands Cancer Institute, Amsterdam, Netherlands,* [2]*VU University Medical Center, Amsterdam, Netherlands.*

T cell development and differentiation requires highly specific and tight epigenetic regulation, involving specific alterations to the chromatin structure by covalent modifications of histones. Here we study the role of histone modification, specifically H3K79 methylation in T cell biology. H3K79 methylation is a unique histone mark that requires the activity of the evolutionary conserved methyltransferase DOT1L. H3K79me is associated with transcription and in some cases with the inhibition of repression of the genes it methylates. To accomplish this goal, *DOT1L*was selectively ablated in the T cell lineage at an early developmental stage. DOT1L ablation did not grossly affect intrathymic T cell development. However, transcriptome analysis of single positive (SP) mature CD8$^+$ thymocytes revealed an upregulation of memory associated genes that normally require antigen exposure in the periphery. This effect of *Dot1L* ablation was most striking in the peripheral CD8$^+$ T cells. Here, without any deliberate immunogenic exposure, the virtual absence of naïve CD8$^+$T cells was accompanied with a dramatic increase in memory-like CD8$^+$ T cells. Our results indicate that DOT1L is key element in establishing a barrier towards terminal T cell differentiation. Future studies will address the functional potential of T cells lacking DOT1L as well as the mechanism by which the methylation mark at H3K79 maintains naivety.

P.B3.02.05

Immunomodulatory effects of a soluble form of human CD6 in experimental cancer

S. Casadó-Llombart[1], *I. T. Simões*[1], *M. Velasco-de Andrés*[1], *M. Consuegra-Fernández*[1], *F. Aranda*[1], *E. Carreras*[1], *F. Lozano*[1,2,3];
[1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain,* [2]*Servei d'Immunologia, Centre de Diagnòstic Biomèdic, Hospital Clínic de Barcelona, Barcelona, Spain,* [3]*Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain.*

CD6 is a surface receptor expressed by all T cells and a subset of B and NK cells. In T cells, it is physically associated to the TCR/CD3 complex and it mediates cell adhesion and modulation of TCR signaling during T cell activation and differentiation, likely through interactions with its reported ligands (CD166/ALCAM, CD318 and Galectin-1/3). To elucidate the *in vivo* relevance of CD6-mediated interactions, the decoy receptor effects of recombinant soluble human CD6 (rshCD6) were analyzed. Thus, C57BL/6 mice treated with rshCD6 (1.25mg/kg; *i.p.*) every other day for two weeks showed significantly reduced total cell numbers in spleen, increased total cell numbers in peritoneum and decreased percentage of Treg in lymph nodes, compared with vehicle-treated control mice. The functional significance of such changes was evidenced by observation of an enhanced anti-tumoral response when rshCD6-treated mice were simultaneously challenged with melanoma B16-F0 cells (7x10^4 cells, *s.c.*) compared with human seroalbumin-treated controls. This was concomitant with significantly increased NK and decreased Treg percentages in tumor-draining and contralateral lymph nodes. *In vitro* studies showed that rshCD6 decreased Treg but not Th1, Th2 and Th17 polarization of naïve CD4$^+$ T cells in a dose-dependent manner. Taken together, these results support decoying CD6 ligand-receptor interactions by rshCD6 as a feasible strategy for immunomodulation in cancer. Supported by WCR (14-1275), Fundació La Marató TV3 (201319-30), Portuguese FCT (SFRH/BD/75738/2011), and Spanish MINECO (SAF2016-80535-R, BES-2014-069237), ISCIII (SB Program; CD15/00016), and MECD (FPU15/02897), -co-financed by European Development Regional Fund "A way to achieve Europe".

Improved survival in HPV$^+$oropharyngeal cancer patients is associated with tumour-resident CD8$^+$ T cells

R. V. Hewavisenti[1], *A. L. Ferguson*[1], *D. Jones*[2], *A. Hong*[2], *U. Palendira*[1];
[1]*Centenary Institute for Cancer Medicine and Cell Biology, Sydney, Australia,* [2]*Central Clinical School, Royal Prince Alfred Hospital, Sydney, Australia.*

Introduction: Human papilloma virus-positive (HPV$^+$) oropharyngeal squamous cell carcinoma (OSCC) is a clinically and immunologically distinct subset of head and neck cancer, which is increasing in prevalence. HPV$^+$ tumours have shown improved patient prognoses compared to HPV-negative (HPV$^-$) tumours. Tumour-resident CD8$^+$ T cells (TR8s) have been associated with better patient survival in various cancers, but have not been extensively studied in virally-induced cancers. Differing patient outcomes, between HPV$^+$ and HPV$^-$ tumours, illustrate the importance of tailoring treatments to specific subsets of OSCC, which may be altered in intensity based on immunological mechanisms. To understand the role TR8s play in HPV$^+$OSCCs, we investigated whether TR8 numbers correlate with patient survival, in the context of HPV status, tumour microenvironment, and clinical outcomes.
Materials and Methods: Infiltrating TR8s were analysed using quantitative multiplex immunofluorescence staining and multi-parameter flow cytometry, using tumours from a prospective cohort of HPV$^+$OSCC and HPV$^-$OSCC patients.
Results: HPV$^+$OSCC patients had higher TR8 numbers compared to HPV$^-$OSCC patients, with higher infiltration of total CD8$^+$ T cells within HPV$^+$ tumours. Increased TR8 numbers were associated with better patient prognosis and improved survival in HPV$^+$OSCC patients, compared to those with lower TR8 numbers.
Conclusions: The higher TR8 numbers found in HPV$^+$OSCC, compared to HPV$^-$OSCC, suggests that TR8s may be critical in controlling OSCC tumour progression, resulting in better patient prognosis. Further investigation of TR8s may provide a better understanding of how we approach vaccine strategies, with the aim of boosting TR8 numbers and improving the immune response.

P.B3.02.07

TCR/ITK signaling tunes CD8+ T cell metabolism, homeostatic proliferation and anti-tumor effector function

W. Huang[1,2], *J. Luo*[3], *A. August*[2,4];
[1]*Department of Pathobiological Sciences, Louisiana State University, Baton Rouge, LA, United States,* [2]*Department of Microbiology and Immunology, Cornell University, Ithaca, NY, United States,* [3]*Department of Biological Chemistry and Neuroscience, Center for Sensory Biology, The Johns Hopkins University School of Medicine, Baltimore, MD, United States,* [4]*Howard Hughes Medical Institute, Cornell University, Ithaca, NY, United States.*

T cell homeostatic proliferation (HP) is regulated by T cell receptor (TCR) signals and homeostatic cytokines, and suggested to be proportional to TCR signal strength. However, we show that ITK, a positive regulator of TCR signaling, negatively tunes CD8$^+$ T cell metabolism, HP and effector function. Under lymphopenic environments, *Itk*$^{-/-}$ CD8$^+$ T cells exhibit T cell-intrinsic, immediate and massive HP, which requires mTOR activity and can be driven by T cell-T cell interaction. TCR signals through ITK to tune IL-7-mediated CD8$^+$ T cell metabolism and HP in an mTOR-dependent manner. The lack of ITK also resulted in enhanced effector cell programming, antigen sensitivity and anti-tumor immunity of the HP cells. Thus TCR signaling via ITK, is a negative tuner of CD8$^+$ T cell homeostasis, metabolism and effector function, and may be a target for clinical benefit in cancer therapy.

BTLA and PD-1 signaling pathways regulate proliferation and cytotoxicity of human V delta 2 gamma/delta T cells independently

H. Hwang[1], *K. Koh*[2], *J. Lee*[1], *S. Kang*[3], *H. Im*[2], *N. Kim*[1];
[1]*Asan Institute for Life Sciences and Department of Convergence Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,* [2]*Department of Pediatrics, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,* [3]*Department of Pediatrics, Korea University Anam Hospital, Seoul, Korea, Republic of.*

B- and T-lymphocyte attenuator (BTLA) and programmed cell death-1 (PD-1) inhibit T cell activation and function through recruitment of SHP2. Although there are studies on the individual roles of BTLA and PD-1 in human gd T cells, it is not well known how these immune checkpoints interact in response to cancer cells. This study was set up to examine whether BTLA and PD-1 signaling pathways were convergent or independent in human peripheral blood gd T cells, where Vg9Vd2 T cells recognizing phospho-antigens are majority. Herein we show that BTLA/HVEM and PD-1/PD-L1 interactions suppressed proliferation and cytotoxicity of human gd T cells, respectively. As expected, IL-2 and zoledronate-mediated proliferation of gd T cells was increased when PBMCs were co-cultured with inactivated HVEM^{low} Jurkat cells, compared with that of wild-type Jurkat cells. CD107a expression and cancer cell death were not affected in expanded gd T cells by co-culture with inactivated HVEM^{low} Jurkat cells and further increased in the presence of anti-PD-L1 mAb. The results suggest that inactivation of BTLA/HVEM signaling pathway during expansion could help produce more gd T cells without compromising cytotoxicity. In addition, reduction of HVEM expression in Jurkat cells repressed phosphorylation of SHP2 and increased activation of ERK1/2 in gd T cells. However, blockade of PD-L1 signaling did not have a synergistic or additive effect on it. Taken together, our study demonstrates that BTLA and PD-1 signaling may independently act on the proliferation, cytotoxicity and phosphorylation of SHP2 and ERK1/2 in human Vd2 gd T cells.

P.B3.02.09

Costimulatory molecule B7-H3 in Myelodysplastic syndrome

A. Kindermann, *P. Mandasari, D. Quandt;*
University of Halle, Halle, Germany.

Costimulation is an important way of regulating T cell immunity. B7-H3 belongs to the B7 family of costimulatory molecules and has been shown to modulate T cell outcomes in health and disease. Many solid tumor cells in situ show a differential expression of B7-H3 that is associated to patient's outcome. The role of B7-H3 for hematological disease is not well established. Myelodysplastic syndrome (MDS) is a hematological stem cell disease leading to diverse phenotypes of altered red and white blood cell hematopoiesis. Analyzes of human bone marrow samples from patients with MDS, other hematological disorders and healthy donors using flow cytometry were performed. B7-H3 expression was found on blast cells, HSC as well as on myeloid cells. In leukemia (THP-1, HL-60, K562) as well as MDS cell lines, B7-H3 protein is expressed constitutively with a great heterogeneity. This is in contrasts to solid tumor cell lines that show a homogenous high level of B7-H3 expression.

Cytokine treatment with important adaptive as well as innate mediators did not alter B7-H3 protein expression, whereas other molecules of the B7 family as well as of the antigen presentation are highly regulated. Co-culture assays of B7-H3 modulated THP-1 cells with human primary T cells are currently performed in order to reveal the functional consequences of this costimulatory pathway. T cells are an important part of the stem cell niche. Therefore we believe on a contribution of costimulatory molecules on the regulation of the complex hematopoietic stem cell network.

P.B3.02.10

Strong sustained IL-2 signal selectively targeted to CD25$^+$ cells dramatically increases sensitivity to LPS

*J. Tomala, P. Weberova, B. Tomalova, **M. Kovar**;*
Institute of Microbiology, Prague, Czech Republic.

IL-2 exerts its pleiotropic activities through binding either to dimeric receptor composed from IL-2Rβ (CD122) and common cytokine receptor gamma chain (γ_c, CD132) or to trimeric receptor composed from IL-2Rα (CD25), IL-2Rβ and γ_c. CD25 has been termed "low-affinity" IL-2R (Kd~10 nM) and it is not involved in signal transduction. A dimer of CD122 and CD132 binds IL-2 with intermediate affinity (Kd~1 nM) and is present on CD122^{high} populations, namely memory CD8$^+$ T cells and NK cells. A complex of CD25, CD122 and CD132 binds IL-2 with high affinity (Kd~10 pM) and it is present on CD25^{high} populations, namely activated T and Treg cells. It was reported that *in vivo* biological activity of IL-2 can be dramatically increased by association of IL-2 with anti-IL-2 mAbs. These IL-2 complexes possess selective stimulatory activity determined by the clone of anti-IL-2 mAb used. IL-2/S4B6 mAb complexes are highly stimulatory for NK and memory CD8$^+$ T cells and intermediately also for Treg cells. IL-2/JES6-1 mAb complexes are stimulatory solely for CD25^{high} cells. We have found that mice treated with IL-2/JES6-1 mAb complexes show dramatically increased sensitivity to LPS-mediated shock and mortality (~10-30 times). Mice treated with IL-2/JES6-1 mAb complexes and challenged with 10 μg LPS possess 5-10 times higher plasma concentration of TNF-α (90 min. after LPS challenge) in comparison to control mice challenged with 200 μg LPS. Interestingly, IL-2/S4B6 complexes almost do not sensitize mice to LPS. **Acknowledgement:** This work was supported by grant 13-12885S from GACR and Institutional Research Concept RVO 61388971.

P.B3.02.11

IFN-g and TNF-a production by T cells in HNSCC stroma promotes a distinct transcriptional signature with immunosuppressive properties by tumor-enriched mesenchymal stem cells

***A. Mazzoni**[1], G. Montaini[1], M. Ramazzotti[1], G. Barra[2], L. Maggi[1], M. Capone[1], M. Rossi[1], B. Rossettini[1], R. De Palma[2], L. Cosmi[1], F. Liotta[1], F. Annunziato[1];*
[1]University of Florence, florence, Italy, [2]University of Campania, Naples, Italy.

Introduction: Mesenchymal stem cells (MSC) are enriched in Head-Neck squamous cell carcinoma (HNSCC) and display immunosuppressive properties, thus favoring tumor immune escape. The identification of the molecular programs involved may suggest novel therapeutical targets. Methods: HNSCC specimens were enzyme-digested. Tumor infiltrating lymphocytes (TIL) were analyzed by flow cytometry to investigate their phenotypic and functional properties. MSC were derived from HNSCC and bone marrow (BM) and expanded *in vitro*. Transcriptome data were generated via microarray technology. Quantitative PCR and flow cytometry were used to validate transcriptome data. T cell proliferation was evaluated via 3H-TdR incorporation assay. Results: We observed an accumulation of IFN-γ and TNF-α producing T cells in HNSCC specimens. T regulatory (Treg) cells were also enriched if compared to peripheral blood (PB). To investigate how IFN-γ and TNF-α affect the immunosuppressive potential of MSC, we obtained transcriptome data from resting or IFNg+TNFa stimulated BM- and HNSCC-MSC. Principal component analysis showed that BM- and HNSCC-derived MSC have a distinct transcriptional signature either resting or after cytokine stimulation, thus suggesting that are distinct cell subsets. Looking for genes selectively induced by cytokine treatment that may confer immunosuppressive potential to MSC we found IDO1, PD-L1 (CD274) and IL4I1. We confirmed microarray data by qPCR or flow cytometry. Selective inhibition of these three pathways during In vitro MSC-T cell cocultures highlighted their immunosuppressive capacities. Conclusions: HNSCC-TIL are enriched in Treg cells, while T effector cells-derived IFN-γ and TNF-α potentiate MSC immunosuppression via activating several non-redundant pathways. Altogether, these mechanisms favor HNSCC immune-evasion.

P.B3.02.12

Tim-3$^+$ CD4$^+$ T cells in the breast tumor draining lymph nodes

***F. Mehdipour**[1], S. Shariati[1], A. Ghods[1], A. Talei[2], A. Ghaderi[1];*
[1]Shiraz Institute for Cancer Reaserch, Shiraz Medical School, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [2]Breast Diseases Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of.

Introduction: It has been suggested that T cell immunoglobulin and mucin domain-3 (Tim-3) is an important immune checkpoint receptor which can be involved in the immune suppression in the tumor microenvironment. It has been shown that exhausted or regulatory T cells express Tim-3. In this study, the frequency of Tim-3$^+$CD4$^+$T cells in the tumor draining lymph nodes (TDLNs) of breast cancer patients and its relation with disease parameters were investigated.
Materials and methods: Using Ficoll-Hypaque gradient centrifugation, mononuclear cells were isolated from axillary lymph node specimens of 35 breast cancer patients. After surface staining for CD4 and Tim-3, cells were subjected to flow cytometry.
Results: Our results revealed that 6.4± 5.8% of CD4$^+$ T cells expressed Tim-3 without significant difference in the metastatic (MLNs) and non-metastatic lymph nodes (nMLNs). The mean fluorescent intensity (MFI) of Tim-3 expression showed a non-significant increasing trend in the MLNs (P=0.091), however when considering patients with invasive ductal carcinoma and excluding patients whose tumor had medullary features, the MFI of Tim-3 was significantly higher in the MLNs (P=0.023). In addition, the MFI of Tim-3 expression had significant direct correlation with the number of involved lymph nodes (R=0.3, P=0.041). The frequency of Tim-3 expressing T cells or Tim-3 MFI did not show significant associations with stage, grade or tumor size.
Conclusion: This study revealed that a fraction of CD4$^+$ T cells expressed Tim-3 in the TDLNs of breast cancer patients. Lymph node involvement was associated with higher intensities of tim-3 expression on T cells.

P.B3.02.13

Conserved human effector regulatory T cell signature is reflected in super-enhancer landscape

***G. Mijnheer**[1], M. Mokry[1], V. Fleskens[2], M. van der Wal[1], R. Scholman[1], S. Vervoort[1], C. Roberts[2], A. Petrelli[1], J. Peeters[1], M. Knijff[1], S. de Roock[1], S. Vastert[1], L. Taams[2], J. van Loosdregt[1], F. van Wijk[1];*
[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]King's College London, London, United Kingdom.

Regulatory T cells (Treg) are critical regulators of immune homeostasis. Increasing evidence demonstrates that environment-driven Treg differentiation into effector Treg is crucial for optimal functioning. However, programming of human Treg under inflammatory conditions remains poorly understood. Here, we combine transcriptional and epigenetic profiling to identify the human effector Treg core signature. Autoimmune inflammation-derived Treg demonstrated normal suppressive function and enhanced IL-2 signaling. Transcriptome analysis revealed a unique transcriptional profile characterized by upregulation of both a core Treg (FOXP3, CTLA-4, TIGIT) and effector program (ICOS, GITR, BLIMP-1, BATF, T-bet), indicating effector Treg differentiation and adaptation to the inflammatory environment. Moreover, we identified specific human effector Treg markers including VDR and IL12Rβ2. H3K27ac occupancy revealed large changes in the (super-)enhancer landscape, including enrichment of the binding motif for VDR and BATF. The observed Treg profile showed striking overlap with tumor-infiltrating Treg. Our data demonstrate that human inflammation-derived Treg acquire a specific effector Treg profile guided by epigenetic changes. The core effector Treg profile is strongly conserved, and fine-tuned by environment specific adaptations.

P.B3.02.14

Type 1 regulatory cells (Tr1) express c-MAF in response to CD55 but not CD28 costimulation

***T. Musarrat**;*
University of Nottingham, Nottingham, United Kingdom.

A healthy immune system is maintained in a state of balance between pro-and anti-inflammatory cells. The paradigm for T-cell activation requires CD80/86:CD28 engagement resulting in differentiation of proinflammatory response. However, alternative costimulatory molecules may favour the induction of alternate T-cell phenotypes such as Type 1 Regulatory T-cells (Tr1). One such receptor-ligand pair is CD55-CD97. These are widely expressed on leukocytes, including T cells, dendritic cells (DC) and macrophages. We have previously demonstrated that costimulation of T cells via CD3/CD55 results in the differentiation of naive T-cells into Tr1 phenotype which is defined as IL-10$^+$, IFN-γ$^-$ IL-4$^-$ as opposed to Th1 phenotype (IFN-γ$^+$, IL-10$^-$, IL-4$^-$) by CD3/CD28 costimulation. IL-10 is the predominant inhibitory cytokine produced by adaptive immune system and it is required for immune resolution, promoting tolerance and controlling autoimmunity. Considering the important role of IL-10$^+$ Tr1 in immune-balance, there still remains little in the way of a defined phenotype for these cells. We aimed to study CD3/CD55 induced Tr1 cells in order to determine the transcription factors associated with the regulation of these cells. CD3/CD55 induced IL-10$^+$ Tr1 cells were positive for T-bet and c-MAF whereas they were negative for FoxP3, GATA-3 and HELIOS. Interestingly, c-MAF was only expressed by IL-10$^+$ cells in response to CD3/CD55 but not to CD3/CD28 stimulation. c-MAF expression was persistent upon secondary restimulation with CD3/CD55 and was not induced by non-specific stimulation with PMA/Ionomycin indicating that c-MAF expression could be an integral part of signalling for CD3/CD55 mediated IL-10 production by Tr1 cells.

P.B3.02.15

Comparison of glucocorticoid-induced apoptosis in thymocytes and mature T cells

***L. Prenek**, R. Kugyelka, F. Boldizsár, P. Németh, T. Berki;*
Department of Immunology and Biotechnology, Pécs, Hungary.

Non-genomic effects of the glucocorticoids (GC) play an important role in the GC-induced apoptosis of thymocytes. We have found that in the most GC sensitive, DP thymocytes the activated GC receptor (GR) translocated to the mitochondria, which was followed by the decrease of the mitochondrial membrane potential, an early sign of apoptosis. The activated GR associated with members of the Bcl-2 protein family, especially with Bim, and influenced their balance leading to the activation of mitochondrial apoptotic pathway. The effect of *in vivo* dexamethasone (DX) treatment on regulatory T cells (Tregs) was different; they seemed to be resistant to DX-induced apoptosis. Which suggests that the GC-induced apoptotic process is different in other cell populations. But the exact mechanism requires further investigation. In our work we analysed the differences and similarities between the DX-induced apoptosis of thymocytes and mature T cells, especially that of Tregs. Splenocytes and thymocytes were isolated from 4-6-week-old BALB/c mice. The cells were treated with 10^{-6} M DX *in vitro* for different intervals. After DX treatments Annexin V labelling, kinetics of caspases' activation, mitochondrial membrane potential and Ca-signalling were analysed with flow cytometry. DX-induced apoptotic process was different in mature T cells, particularly in Tregs, than in thymocytes. DX inhibited Ca-signalling of cell populations suggesting its potential role in apoptotic signalling. These results can be the consequences of the different non-genomic effects in T cell subpopulations. Funding: OTKA K105962, K101493, EFOP-3.6.1.-16-2016-00004; GINOP 2.3.2-15-2016-00050.

P.B3.02.16

The role of Ca^{2+} dependent proteins for the killing capacity of human cytotoxic T cells

***S. Zöphel**[1], G. Schwär[1], P. Leidinger[2], K. S. Friedmann[1], A. Knörck[1], C. Hoxha[1], E. Meese[2], V. Helms[3], M. Hoth[1], M. Hamed[4], E. C. Schwarz[1];*
[1]Biophysics, Homburg, Germany, [2]Human Genetics, Homburg, Germany, [3]Center for Bioinformatics, Saarbrücken, Germany, [4]Institute for Biostatistics and Informatics in Medicine and Ageing Research, Rostock, Germany.

Introduction: Cytotoxic T lymphocytes (CTLs) eliminate infected or transformed cells by releasing perforin-containing cytotoxic granules at the immunological synapse. Cytotoxic granule release is highly dependent on the influx of extracellular Ca^{2+}, mediated by STIM-activated Orai channels. Previous work has shown that members of the SNARE-family are primarily responsible for exocytosis of lytic granules. However, considerably less is known about other molecules modulating the Ca^{2+} influx and exocytosis of cytotoxic granules, and thereby elimination of target cells. **Material and Methods**: Human PBMC were isolated from LRS chambers provided by the local blood bank. Subtype isolation was performed by antibody-coated magnetic beads. Total RNA from non-stimulated $CD8^+$ T cells or from *Staphylococcus aureus* enterotoxin A (SEA) stimulated $CD8^+$ T cells was isolated and investigated by microarray technology. Expression data were further analyzed by a bioinformatical approach. **Results:** Based on the results of the bioinformatics analysis, we selected 42 siRNAs against highly expressed proteins with a potential function in calcium signaling pathways and screened for a putative role in target cell killing. By using a real-time killing assay under reduced extracellular Ca^{2+} concentrations, we identified several candidates which altered the killing capacity of $CD8^+$ T cells. One candidate is the Ca^{2+}-induced potassium channel KCa3.1. Its downregulation decreased the elimination of target cells under limited extracellular Ca^{2+} concentration. **Conclusion:** Bioinformatical analysis is a powerful tool to narrow-down possible candidates relevant for target elimination by CTL. Screening of the selected siRNAs by a real-time killing assay led to positive hits under limited extracellular Ca^{2+} concentration.

P.B3.02.17

Engineering chimeric antigen receptor T cells to specifically target *Aspergillus fumigatus*

***M. Seif**[1], T. Nerreter[1], M. Machwirth[1], M. Hudecek[1], F. Ebel[2], H. Einsele[1], J. Löffler[1];*
[1]University Hospital Wuerzburg, Wuerzburg, Germany, [2]Ludwig-Maximilians-University, Munich, Germany.

Immunocompromised patients are susceptible to invasive fungal infections mainly caused by *Aspergillus fumigatus* (Af). Adoptive transfer of *Aspergillus*-specific T cells reduces the burden of invasive aspergillosis. Such specific T cells are hard to isolate and expand. Alternatively, T cells modified to express a chimeric antigen receptor (CAR) can be used. CARs are recombinant receptor constructs composed of an extracellular single-chain antibody fragment (scFv) linked to an intracellular signaling module.
To redirect specificity towards Af, a scFv derived from an antibody directed against Hyphal cell wall was designed. CARs containing the scFv fused to extracellular IgG4-Fc spacer domains of different lengths were constructed. T cells were engineered to express the CARs on their surface using the Sleeping Beauty gene transfer system. CAR T cells were co-cultured with Af germ tubes and specific T cell activation was evaluated.
Upon binding to the target, CAR T cells signaled via chimeric CD28 and CD3-ζ signaling domain. The cytolytic machinery of CAR T cells was activated leading to the release of perforin and granzyme B. Activated CAR T cells secreted cytokines like IFN-γ and IL-2. Furthermore, activated CAR T cells underwent proliferation. Finally, CARs containing long "Hinge-CH2-CH3" extracellular spacer conferred superior T cell activation when compared with CARs having short "Hinge-only" spacer.
Our results show that CAR T cells are specially activated upon recognition of Af and customizing spacer design enhances their effector function.
This project is funded by the BMBF (Infect Control 2020—consortium ART4Fun; subproject 2 to HE).

P.B3.03.01

Human memory CD8 T cell effector function is epigenetically preserved during in vivo homeostasis

***H. Abdelsamed**[1], A. Moustaki[1], Y. Fan[1], P. Dogra[1], H. Ghoneim[1], C. Zebley[1], B. Triplett[1], R. Sekaly[2], B. Youngblood[1];*
[1]St Jude Children's Research Hospital, Memphis, United States, [2]Case western Reserve University, Cleveland, United States.

Maintenance of memory CD8 T cell quantity and quality through antigen-independent homeostatic proliferation is vital for sustaining long-lived T cell-mediated immunity, yet the underlying mechanisms that preserve memory T cell functions during homeostasis remain largely unexplored. Here we show that preservation of effector-potential among human memory CD8 T cells during *in vitro* and *in vivo* homeostasis is coupled to maintenance of memory-associated DNA methylation programs. Whole-genome bisulfite sequencing of primary human naïve, short-lived effector memory (T_{em}), and longer-lived central memory (T_{cm}) and stem cell memory (T_{scm}) CD8 T cells identified demethylated promoters of effector molecules that are poised for rapid expression among all memory cell subsets. Effector-loci demethylation was heritably preserved during IL-7 and IL-15 mediated *in vitro* cell proliferation. In contrast to the effector-potential, antigen-independent proliferation induced a phenotypic conversion of T_{cm} and T_{scm} memory cells into T_{em} cells that was coupled to increased methylation of the CCR7 locus. Furthermore, *in vivo* proliferation of haploidentical donor memory CD8 T cells in lymhodepleted recipients resulted in a similar preservation of effector-associated methylation programs while enriching for Tem-associated programs. These data demonstrate that long-lived human memory CD8 T cells retain the ability to undergo antigen-independent epigenetic reprogramming during their developmental conversion into other memory subsets while at the same time preserving the poised effector state utilized by all memory T cells. Further investigation into upstream signaling events that promote changes in T cell epigenetic states is needed to uncover the role of epigenetics in T cell function during homeostasis.

P.B3.03.02

Tissue-resident memory T-lymphocytes (T_{RM}) display proliferative capacity *in vitro* under hypoxic conditions

***A. Chuwonpad**[1], F. M. Behr[1,2], T. H. Wesselink[1], N. A. Kragten[1], R. Stark[1,2], K. P. van Gisbergen[1,2];*
[1]Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands.

Tissue-resident memory (T_{RM}) have been recently established as an important subset of memory cells that provide early and essential protection against reinfection in the absence of circulating memory cells. In addition, $CD8^+$ T cells with a T_{RM}-like phenotype have been found to infiltrate tumor tissue. The presence of these T_{RM}-like cells are associated with patient survival, suggesting that T_{RM} also have a protective role in cancer. Immunotherapy using adoptive transfer of *in vitro* reactivated T cells from the tumor site has provided a breakthrough in the treatment of cancer patients. Despite promising results, further improvement of therapy is required for the majority of patients. Because T_{RM} are beneficial in both cancer and infection settings, we aim to study whether these memory T cells can be expanded in culture for immunotherapy-related purposes.
We have found that T_{RM} from the small intestine proliferate *in vitro* after anti-CD3/28 stimulation and subsequent resting in cytokines. The expanded T_{RM} retained their phenotype, including expression of key T_{RM} markers CD69 and CD103. Optimal culture of T_{RM} required low O_2 tension, indicating that these cells can resist hypoxic conditions in the tumor microenvironment. T_{RM} also exerted increased metabolic activity and efficiently acquired glucose, a requirement to compete with highly glycolytic tumor cells.
These findings suggest that *in vitro* re-stimulation of existing T_{RM} is possible under conditions reflecting the tumor microenvironment, which is promising for future usage of these memory T cells in tumor treatment using adoptive cell therapy.

P.B3.03.03

Dissecting the role of MAZR isoforms in T cell development and function

***N. Dhele**, L. Anderson, A. Gülich, S. Sakaguchi, W. Ellmeier;*
Medical University of Vienna, Vienna, Austria.

T cells are key players of adaptive immunity and their differentiation and function has been tightly controlled. We previously identified that the transcription factor MAZR, also known as Patz1, is an important regulator of *Cd8* gene expression during the double-negative (DN) to double-positive (DP) transition of T cell development. Further, by generating MAZR-deficient mice we showed that MAZR is part of the transcription factor network regulated CD4/CD8 cell fate decision of DP thymocytes. MAZR is a member of the BTB domain and zinc finger (ZF) motifs containing transcription factor family and is encoded by the *Patz1* gene. There are 4 potential alternative splice forms known that can give rise to MAZR isoforms containing 4-7 ZF domains, however whether all splice forms are expressed in T cells has not been described. Moreover, the role of the various MAZR isoforms in the regulation of T cell development and function is not known. The aim of the study is to dissect isoform- specific functions of MAZR by using gain-of-function and loss-of-function approaches in combination with RNA-seq and ChIP-seq experiment. Results from ongoing studies will be presented. The project is funded by the EU ITN Grant “ENLIGHT-TEN” (675395) and the Austrian Science Fund (P29790)

P.B3.03.04

Regulation of integrin activation on antigen-specific T cells by Galpha$_s$-coupled receptor signaling and sleep in humans

***S. Dimitrov**[1], T. Lange[2], C. Gouttefangeas[1], A. T. Jensen[3], M. Szczepanski[1], J. Lehnnolz[1], S. Soekadar[1], H. Rammensee[1], J. Born[1], L. Besedovsky[1];*
[1]University of Tübingen, Tübingen, Germany, [2]University of Lübeck, Lübeck, Germany, [3]University of Copenhagen, Copenhagen, Denmark.

An efficient T-cell effector immune response requires a strong adhesion of T cells to their targets, e.g., to virus-infected cells. This adhesion is dependent on the immediate activation of β_2-integrins upon T-cell receptor (TCR) engagement by cognate peptides presented by major histocompatibility complex molecules (pMHC). Gα_s-coupled receptor agonists are known to have immunosuppressive effects, but their impact on TCR-mediated integrin activation is unknown so far. We used soluble multimers of pMHC and ICAM-1 - the ligand of β_2-integrins - to assess the effect of different Gα_s-coupled receptor agonists (including catecholamines, prostaglandins (PGs), adenosine, histamine and serotonin) on TCR-induced integrin activation of human cytomegalovirus (CMV)- and Epstein-Barr (EBV) virus-specific CD8$^+$ T cells. We show that isoproterenol, epinephrine, norepinephrine, PGE_2, PGD_2 and adenosine strongly inhibit TCR-mediated integrin activation of antigen-specific CD8$^+$ T cells in a dose-dependent manner, already at physiological concentrations. Using sleep as a natural condition of low levels of Gα_s-coupled receptor agonists, we found that nocturnal sleep upregulates TCR-induced integrin activation compared to nocturnal wakefulness. The effect was slightly more pronounced for CMV-specific T cells with an early-differentiated phenotype (CD27$^+$CD28$^+$) than for intermediate- or late-differentiated subsets. Our findings indicate that conditions characterized by low levels of Gα_s-coupled receptors agonists, such as sleep, support the formation of immunological synapses and thereby enhance T-cell responses. The results might be also relevant to a variety of pathologies associated with increased levels of catecholamines (during chronic stress or sleep disturbances), PGs (tumor growth or malaria) and adenosine (hypoxia, sleep apnea, or tumor growth).

P.B3.03.05

LAT transmembrane domain in the plasma membrane of T cells

***D. Glatzová**[1,2], T. Chum[1], J. Králová[2], L. Cwiklik[1], T. Brdička[2], M. Cebecauer[1];*
[1]J. Heyrovsky Institute of Physical Chemistry, Czech Academy of Sciences, Prague, Czech Republic, [2]Institute of Molecular Genetics, Czech Academy of Sciences, Prague, Czech Republic.

LAT is transmembrane adaptor protein essential for T cell development and function. It is phosphorylated by ZAP70 protein tyrosine kinase upon T cell receptor activation and recruits multiple adaptor proteins to form a multisubunit signalling complex. It contains a very short extracellular region, transmembrane domain (TMD) and tyrosine-rich cytoplasmic tail. LAT is palmitoylated on two conserved cysteines (amino acids 26 and 29). Furthermore, TMD of LAT contains two proline amino acids (position 8 and 17) function of which is still unknown. In agreement with the literature about other proteins, our MD simulations of LAT TMD demonstrate that the presence of prolines disrupts α-helical structure and causes so-called proline-kinks in its structure. Expression of mutants with prolines changed to alanines or in combination with mutants lacking the palmitoylation sites suggest their importance for sorting of LAT to the plasma membrane and their impact on T cell signalling.

Human double-negative regulatory T cells induce a metabolic switch in effector T cells by suppressing mTOR activity

***T. Haug**, M. Aigner, H. Bruns, A. Mackensen, S. Völkl;*
Dept. of Internal Medicine 5 – Hematology/Oncology, Erlangen, Germany.

The recently discovered subpopulation of TCRαβ+ CD4-/CD8- (double-negative, DN) T cells are highly potent suppressor cells in mice and human. In murine transplantation models, adoptive transfer of DN T cells specifically inhibits alloreactive T cells and prevents development of transplant rejection or Graft-versus-Host-disease (GvHD). Interestingly, clinical studies in patients who underwent stem cell transplantation reveal an inverse correlation between the frequency of circulating DN T cells and the severity of GvHD, suggesting a therapeutic potential of human DN T cells. Investigating the impact of DN T cells on effector T cells, we show that DN T cells diminish upregulation of glycolytic machinery, expression of glucose transporters and glucose uptake. In contrast, the uptake of fatty acids stays unchanged, indicating that DN T cells induce a metabolic switch in effector T cells. Consistent with this finding, DN T cells selectively inhibit the metabolic key regulator mTOR and enforced activation of mTOR in effector T cells with a chemical activator reversed the suppressive effect of DN T cells. Given that both, mTOR activity and cell metabolism are crucial in determining T cell fate, suppressed effector T cell produce less inflammatory cytokines. Taken together DN T cells impair metabolic reprogramming of effector T cells by abrogating mTOR signaling, thereby inducing a quiescent phenotype. These results uncover a new manner of DN T cell mediated-suppression and deeper understanding of DN T-cells may have important implications for using them as a cellular-based therapy to limit alloreactive immune responses.

P.B3.03.07

Rolling circle translation of a circular RNA in T helper lymphocytes

***G. A. Heinz**[1], C. L. Tran[1], P. Durek[1], F. Heinrich[1], Z. Fang[1], C. Haftmann[1], V. Treffner[1], W. Chen[2], H. D. Chang[1], A. Ostareck-Lederer[3], D. H. Ostareck[3], A. Radbruch[1], M. F. Mashreghi[1];*
[1]Deutsches Rheuma-Forschungszentrum, Berlin, Germany, [2]Max Delbrück Center for Molecular Medicine, Berlin, Germany, [3]Medical Faculty, RWTH Aachen University, Aachen, Germany.

Circular RNAs (circRNAs) have gained considerable interest in the course of their re-characterization as endogenous RNA species which is present in various cell types including T cells. However, the function and biological impact of circRNAs on cellular mechanisms still remain poorly understood. Analyzing total RNA sequencing data from naive and activated murine T helper lymphocytes under Th1, Th2 and Th17 polarizing condition, we discovered a highly abundant circRNA (circ11607907). This circRNA candidate showed high expression in naive T helper cells, which strongly decreases with T cell activation and is further reduced upon repeated activation of Th1 cells. The corresponding mRNA expression follows a similar pattern, yet with a stable intermediate expression in Th1 cells. Interestingly, we identified one transcript variant in Th1 cells that harbors an alternative exon 1 and resembles the drastically reduced expression upon T cell activation. This suggests that the circ11607907 might be generated from the alternative transcript rather than from the protein coding mRNA. Dissecting the circ11607907 sequence, we found that it contains an infinite open reading frame with a potential for rolling circle translation. Indeed, ectopic overexpression of the circRNA in murine embryonic fibroblasts resulted in the expression of cryptic proteins which could be abolished by mutating the start codon or introducing a stop codon. Using polysome profiling revealed that the endogenous circ11607907 can be detected in the polysomal fractions indicating that it is also subjected to rolling circle translation.Currently, we aim at deciphering the role of these cryptic proteins in T helper cells.

P.B3.03.08

Development of gene knock-down method in primary T cells

***J. Hillis**, S. Kidger;*
CRUK-TDL, Cambridge, United Kingdom.

Genetic manipulation is an important tool in target validation. Through knock-down and overexpression of genes we can determine effects on biomarkers, determine synthetic lethalities and investigate phenotypic effects. In addition, use of mutated constructs can illuminate the function of protein domains.
Genetic manipulation of primary immune cells is known to be challenging. These cells often have very specific culture conditions required for survival and proliferation, and can be quite sensitive to additional reagents. In addition to this, primary immune cells do not easily take up lipid particles or extracellular DNA. These characteristics make them particularly difficult to genetically manipulate by common methods such as transfection with lipid particles.
We have employed electroporation as a method of delivery of siRNA into primary T cells. Using this method, we can achieve consistent knock-down of at least 70% at both mRNA and protein levels, whilst maintaining good viability. So far, this method has been optimised for use in activated CD3+, CD8+ and expanded Treg populations.
Ongoing work will expand this knock-down method to further T cell subtypes, including unstimulated cells, to allow for wider target validation work. We also intend to develop a robust method of overexpression in primary T cells, which would allow us to investigate protein domain function.

P.B3.03.09

Elevated activation of CD83-deficientT cells

***K. Liedtke**, J. Buer, W. Hansen;*
Institute of Medical Microbiology, Essen, Germany.

The glycoprotein CD83 is upregulated on T cells upon activation. By using a T cell specific CD83 conditional knockout mouse ($CD83^{flx/flx}$/CD4cre, CD83cKO) we aim to define the role of CD83 on T cells. Among the murine T cell subsets CD83 is more frequently expressed on $CD4^+CD25^+$ regulatory T cells (Tregs) in contrast to $CD4^+CD25^-$ conventional T cells (Tcons). Despite the expression on Tregs the inhibitory activity of sorted Tregs and the differentiation of Tcons into induced Tregs was similar between cells from WT and CD83cKO mice in vitro. However, Tcons from CD83cKO mice exhibited a more activated phenotype and showed increased differentiation into T helper 1 cells upon stimulation in vitro. In vivo, CD83cKO mice showed an elevated inflammatory immune response in a contact hypersensitivity reaction compared to WT littermates, which was accompanied with stronger $CD4^+$ T cell activation and secretion of inflammatory cytokines within the spleen and draining lymph nodes. Overall our data indicates that CD83 expression on T cells somehow regulates their activation resulting in an altered disease outcome. Whether the increased activation of CD83-deficient T cells might have a beneficial effect on anti-tumor immune responses will be analyzed in a subcutaneous murine tumor model in vivo.

P.B3.03.10

α-ketoglutarate regulates the balance between Th1 and induced regulatory T cell differentiation

***M. I. Matias**[1], C. S. Yong[1], A. Foroushani[2], M. Wong[2], A. Talebi[3], J. Dehairs[3], C. Mongellaz[1], J. V. Swinnen[3], S. A. Muljo[2], V. Dardalhon[1], T. Naomi[1];*
[1]Institut de Génétique Moléculaire de Montpellier, CNRS, Montpellier, France, [2]Laboratory of Immunology, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD 20892, United States, [3]Department of Oncology, KU Leuven, Leuven 3000, Belgium.

The proliferation and differentiation of T lymphocytes is regulated by antigen and cytokine signals but the induction of metabolic pathways is also required, resulting in an integration of environmental cues in cell fate decisions. Indeed, T lymphocyte activation is regulated by the metabolism of glucose, fatty acids and amino acids, allowing the cell to meet increased energetic and biosynthetic demands. Notably, we recently found that glutamine availability is a key determinant of T cell differentiation; CD4 lymphocytes undergo differentiation to IFNγ-secreting Th1 effectors under conditions of optimal glutaminolysis but are converted to $Foxp3^+$ regulatory T cells when glutamine catabolism is abrogated. We now show that the glutamine-derived metabolite, α-ketoglutarate (αKG), significantly augments IFNγ-secretion while attenuating Treg generation. Interestingly, adding αKG increases extracellular nutrients transport and alters human Treg differentiation potential. Mechanistically, αKG inhibited Foxp3 expression via an IFNγ-regulated mechanism and an altered lipid metabolism. Furthermore, αKG promoted the effector activity of chimeric antigen receptor (CAR)-engineered T cells against the HER2 tumor antigen, increasing IFNγ secretion by >10-fold. Thus, our study identifies the potential of a single metabolite to translate metabolic signals into an enhanced anti-tumor CAR-T cell response.

Fatty acid metabolic reprogramming via mTOR-mediated induction of PPARγ directs anabolic requirements in early activation of T cells

***A. Mulki**, Y. Endo, H. K. Asou, T. Yamamoto, D. J. Tumes, H. Tokuyama, K. Yokote, T. Nakayama;*
Department of Immunology, Chiba University Japan, Chiba city, Japan.

To fulfill the bioenergetic and biosynthetic requirements for increased cell size and massive clonal expansion, activated CD4+ T cells need to reprogram their metabolic signatures from energetically quiescent to activated. However, the molecular mechanisms and essential components controlling metabolic reprogramming in T cells remain poorly understood. We herein show that the mTORC1-PPARγ pathway is crucial for the fatty acid uptake program in activated CD4+ T cells. The mTORC1- SREBP1 pathway was also important for the induction of fatty acid biosynthesis program. Both pathways were required for full activation and rapid proliferation of naive and memory CD4+ T cells. PPARγ directly binds and induces genes associated with fatty acid uptake in naïve and memory CD4+ T cells in both mice and humans. The PPARγ-dependent fatty acid uptake program is critical for metabolic reprogramming. Thus, the results of this study provide important mechanistic insight into the metabolic reprogramming mechanisms that govern the expression of key enzymes, fatty acid metabolism and the acquisition of an activated phenotype via the metabolic reprogramming during CD4+ T cell activation.

T cell receptor signal responsive Pellino 1 ubiquitin ligase in monitoring the pathogenesis

***J. Park**, C. Lee;*
Sungkyunkwan University, Suwon, Korea, Republic of.

Ubiquitination has been implicated in many dynamic cellular processes, including transcriptional regulation, regulation of protein-protein interactions and association with ubiquitin-binding scaffolds, and thus the defects within these pathways cause a wide range of diseases. Pellino 1 (Peli1) is initially characterized as a family of ubiquitin E3 ligases that can catalyse the ubiquitination of several proteins involved in the regulation of innate and adaptive immune responses. Importantly, Peli1 is a receptor-mediated signal responsive ubiquitin ligase that promotes the lysine 48- or 63-linked ubiquitination of target substrates.
Ligand-independent activation of receptor-mediated signaling is one of critical mediators for triggering pathogenic processes. Interestingly, the expression of Peli1 protein is highly suppressed under normal and non-pathogenic conditions, and is distinctly activated in response to the various receptor-mediated signalings. We have recently found that the constitutive expression of Peli1 resulted in ligand-independent hyperactivation of B cells and facilitated the development of lymphoid tumors, with prominent B cell infiltration observed across multiple organs. Aberrant regulation of Peli1 expression is also associated with autoimmunity. To examine the gain- or loss-of-functional role of Peli1 in autoimmunity and tumor immunity, we employed both inducible transgenic and T cell specific knockout mouse models. Thus, this study will include the immunologic basis of Peli1-mediated T cell regulation and the related pathogenesis.

P.B3.03.13

Analysis of mitochondrial content and mitochondrial membrane potential in CD8+ T cells from lung cancer patients

***H. Prado-Garcia**, S. Romero-Garcia, R. Sandoval-Martinez, J. S. Lopez-Gonzalez, U. Rumbo-Nava;*
National Institute of Respiratory Diseases, Mexico City, Mexico.

Background: Nutrient supply and energy production are key requirements so that T-cells can proliferate and mediate effector functions. Mitochondrial metabolism has an essential role in activation of CD8+ T-cells. Patients with advanced stages of lung cancer frequently show malignant pleural effusions, which are infiltrated by lymphocytes and tumor cells. Pleural effusion CD8+ T-cells from lung cancer patients show reduced effector functions. We evaluated whether CD8+ T-cells from lung cancer patients have alterations in their mitochondria. Material and Methods: Mitochondrial mass and mitochondrial membrane potential (MMP) were analyzed using specific fluorescent probes in CD8+ T-cells from pleural effusions and peripheral blood of lung cancer patients by multiparametric flow cytometry. For comparison pleural effusions from chronic diseases (tuberculosis) and peripheral blood from healthy donors were included. Results: Mitochondrial mass, measured as mean fluorescence intensity (MFI) of MitoTracker Green, was reduced in pleural effusion CD8+ T-cells respect to CD8+ T-cells from the comparison groups, this phenomenon was accentuated in the memory subset. MMP was decreased (MFI values of $DiOC_6(3)$) in memory CD8+ T-cells from malignant effusions, compared to the same subset from peripheral blood. After polyclonal stimulation, MMP was reduced in memory CD8+ T-cells from lung cancer patients, which correlated with a reduced production of reactive oxygen species. These phenomena were not observed in the other groups. Conclusions: Pleural effusion CD8+ T-cells from lung cancer patients showed increased mitochondrial mass associated to depolarization of mitochondrial membrane potential, which might compromise the antitumor function of CD8+ T-cells.

P.B3.03.14

Innate-likeactivation of memory $CD4^+$ T cells during heterologous challenge with*Legionella pneumophila*

***N. Rakebrandt**, K. Littringer, N. Joller;*
Institute of Experimental Immunology, University of Zürich, Zürich, Switzerland.

Introduction: Several studies have shown that T cells can function as innate sensors and produce cytokines in response to an inflammatory environment in an antigen-independent manner. This bystander activation has mainly been described for memory $CD8^+$ T cells and is often associated with cytotoxicity and tissue damage. Since antigen-independent activation of $CD4^+$ T cells has been described by some studies but is less well understood we aim to shed more light on this phenomenon in the context of a heterologous challenge. Materials and Methods: B6 mice were infected with an acute dose of the Lymphocytic choriomeningitis virus (LCMV) WE and subsequently challenged with *Legionella pneumophila*. The bacterial titer was determined and T cell populations were analyzed by flow cytometry or sorted for further experiments. Results: We show that previous experience of an acute LCMV infection in mice enables antigen-independent protection against a secondary challenge with *L. pneumophila* by allowing faster bacterial clearance. In this setting not only $CD8^+$ T cells but interestingly also $CD4^+$ T cells in the lungs of LCMV-primed mice rapidly produce IFNγ upon heterologous challenge. Similarly to earlier reports for $CD8^+$ T cells, a subset of LCMV-experienced $CD4^+$ T cells can produce IFNγ in response to proinflammatory cytokines in the absence of TCR signaling. Conclusions: Our results indicate that infection-experienced $CD8^+$ as well as $CD4^+$ T cells might help to convey protection against a heterologous pathogen challenge. These long-lived cells harbor the potential for directed and transient activation by cytokine signaling or receptor engagement. Funding: SNF

Circular RNAs are abundantly expressed in a subset-specific manner in T helper lymphocytes

C. L. Tran[1], *G. A. Heinz*[1], *P. Durek*[1], *F. Heinrich*[1], *Z. Fang*[1], *K. Lehmann*[1], *D. Schulz*[1], *C. Haftmann*[1], *W. Chen*[2], *H. D. Chang*[1], *A. Radbruch*[1], *M. F. Mashreghi*[1];
[1]Deutsches Rheuma-Forschungszentrum, Berlin, Germany, [2]Max-Delbrück-Centrum for Molecular Medicine, Berlin, Germany.

Circular RNAs represent a class of covalently closed RNA molecules, which are spliced from primary transcripts in a head-to-tail fashion and generally considered to be non-coding. Due to their ring-structure, they lack both 5' cap and poly-A tail and display exonuclease resistance. Next-Generation Sequencing (NGS) data revealed that circRNAs are abundant and display development- and stage-specific expression patterns, although little is known about the function of most identified circRNAs.
Here, we hypothesize that circRNAs play a role in the function of proinflammatory T helper (Th) cells, which are involved in the initiation and maintenance of chronic inflammatory diseases.
Using NGS, we assessed the global expression profile of circRNAs in naive, once and repeatedly activated Th cells, mimicking protective and proinflammatory Th cells, respectively. As a result, 41,169 potential circRNAs were detected in Th cells. Of the highly expressed circRNAs (>50 reads), the majority consists of one to three exons with an overall enrichment for translation start sites and is largely expressed in all Th subsets with the highest number in naive Th cells. However, their expression is subset- and activation-dependent with overall higher expression in naive Th cells. We selected several circRNAs which were highly expressed and differentially regulated in Th cells. Using Northern Blot, RT-PCR and RNA FISH we validated these candidates, verified their RNase R resistance and confirmed their location in the cytoplasm. Our data suggest that circRNAs are abundantly expressed and might have a regulatory function in proinflammatory Th lymphocytes.

P.B3.03.16

Ig-like transcript 2 (ILT2) suppresses T cell function in Chronic Lymphocytic Leukemia

M. Villa-Álvarez[1,2,3], *S. Lorenzo-Herrero*[1,2,3], *A. Gonzalez-Rodriguez*[4,2,3], *A. Lopez Soto*[1,2,3], *A. Payer*[4,3], *E. Gonzalez-Garcia*[5,3], *L. Huergo-Zapico*[1,2], *S. Gonzalez*[1,2,3];
[1]University of Oviedo, Oviedo, Spain, [2]Instituto Universitario de Oncología del Principado de Asturias (IUOPA), Oviedo, Spain, [3]Instituto de Investigación Biosanitaria del Principado de Asturias (IISPA), Oviedo, Spain, [4]Hospital Universitario Central de Asturias, Oviedo, Spain, [5]Hospital de Cabueñes, Gijón, Spain.

Introduction Chronic lymphocytic leukemia (CLL) is associated with a profound dysregulation of the immune system. Loss of T cell function is frequently caused in cancer by sustained signaling of inhibitory receptors. In this work, we analyzed the role of the inhibitory receptor Ig-like transcript 2 (ILT2) in the pathogenesis of CLL. **Methods** The expression and function of ILT2 and its ligands in different lymphocyte subsets from 52 CLL patients and 20 healthy donors were evaluated in this study. **Results** ILT2 expression was markedly reduced on leukemic cells, whereas it was increased on T cells from CLL patients, particularly in patients harboring chromosome 11q deletion, which includes the ATM gene. The expression of ILT2 ligands in leukemia cells was also deeply dysregulated. ILT2 impaired the activation and proliferation of CD4 and CD8 T cells in CLL patients, but it had no effect in leukemic cells. ILT2 downregulated the production of IL-2 by CD4 T cells of CLL patients and induced the expression of cytokines that promote the survival of leukemic cells, such as IFN-, by T cells. Importantly, ILT2 blockade restored the activation, proliferation and cytokine production of T cells. **Conclusion** Our experiments indicate that ILT2 impairs T cell function in CLL. Here, we describe a novel immune inhibitory pathway that is up-regulated in CLL and delineate a new potential target to be explored in this disease. Funding: This work was supported by the Spanish grants of Fondo de Investigaciones Sanitarias (Instituto de Salud Carlos III) PI12/01280 and PI16/01485.

P.B3.03.17

The effects of redox regulated cofilin-1 on T-cell mediated immunity

Y. Xiong[1], *I. Seeland*[1], *B. Jahraus*[1], *G. Küblbeck*[2], *G. Wabniz*[1], *J. Küblbeck*[1], *Y. Samstag*[1];
[1]Institute of Immunology, Heidelberg, Germany, [2]German Cancer Research Center, Heidelberg, Germany.

Cofilin-1 is an actin-remodeling protein, which is essential for T cell development, activation and migration. Oxidation of cofilin-1 causes it to lose its affinity for actin and to translocate to the mitochondria, which leads to T cell hypo-responsiveness or even programmed cell death. This includes both oxidation of cofilin-1 at Cys residues and dephosphorylation at Ser 3.
In terms of this, we hypothesized that cofilin-1 Cys to Ala mutants may make T cells more resistant to oxidative stress. Therefore, we investigated the functionality and regulatability of different non-oxidizable Cys to Ala mutants expressed in human peripheral blood T-cells under oxidative stress conditions. We identified a double Cys to Ala mutant that showed notable resistance towards cytotoxic H_2O_2 effects. Still, this mutant differentially rescued T cells under oxidative stress conditions with regard to sustained adhesion of T cells to APCs and formation of the immunological synapse, the phosphorylation and actin-remodeling functions of cofilin-1, T cell activation and migration.
Furthermore, we have generated T cell specific knock-in mice which express these cysteine-to-alanine mutants instead of the wildtype cofilin-1. These mice will serve as tools to clarify the role of cofilin-1 redox-regulation during T cell responses *in vivo* and its potential role in different immune-related diseases (e.g. infections, tumor immunology, or chronic inflammation).

Superior contact avidity of Treg membrane orchestrates antigen specific suppression via stripping cognate peptide-MHCII from DC surface

B. Akkaya, *M. Akkaya, Y. Oya, J. Al Souz, A. H. Holstein, O. Kamenyeva, J. Kabat, D. W. Dorward, D. D. Glass, E. M. Shevach;
NIH, Bethesda, United States.*

Tregs are professional suppressors of the immune response, yet their mechanism of action in vivo remains unclear. We compared stoichiometry of the interactions of activated 5CC7 T cells and 5CC7 iTregs with $MCC_{88\text{-}103}$ pulsed splenic DCs by electron and confocal microscopy. Image analyses revealed that Tregs displayed a distinct morphology with finger like membrane projections at the DC binding site and uropods at the rear end within three hours of co-culture. In contrast, activated T cells maintained their round morphology. Tregs occupied a greater extent of the DC surface than activated T cells consistent with a higher binding avidity. Intravital two-photon microscopy of adoptively transferred OTII iTregs and activated OTII cells demonstrated that Tregs displayed greater volume and duration of contact with $OVA_{323\text{-}339}$ pulsed DC compared to that of activated cells. Subsequent to their high avidity interactions, 5CC7 iTregs captured $MCC_{88\text{-}103}$-I-E^k complexes from DC surface reducing the amount of MCC presented on DC. Reduced antigen presentation was not due to global suppression of the DC's ability to present antigen as 5CC7 and 3A9 iTregs only captured their cognate peptide-MHCII from MCC/HEL double pulsed DC, reducing the DC presentation in an antigen specific manner. When double pulsed DCs were cultured with iTregs specific for one peptide, separated from the iTregs, the DC failed to prime T cells specific for the antigen seen by the iTreg, but primed T cells specific for the second antigen. Altogether, we propose antigen specific depletion of peptide-MHCII complexes as a new mechanism for Treg-mediated suppression.

P.B3.04.02

Immunophenotyping of suppressor and cytotoxic lymphocyte subsetsand cytotoxic mechanisms innon-small cell lung cancer

E. Cetin Aktas[1], *A. Turna*[2], *A. Engin*[3], *D. I. Cikman*[4], *G. Ayan*[5], *G. Deniz*[1];
[1]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology, İstanbul, Turkey, [2]Istanbul University, Cerrahpasa Medical School, Department of Thoracic Surgery, İstanbul, Turkey, [3]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey, [4]Istanbul University, Cerrahpasa Medical School, Department of Medical Oncology, İstanbul, Turkey, [5]Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, İstanbul, Turkey.

Lung cancer is the leading cause of cancer-related death worldwide and non-small cell lung cancer (NSCLC) is the most common form of it. The aim of this study was to assess immunological properties of circulating T lymphocyte subsets and natural killer (NK) cells.Thirty newly diagnosed patients with T1-3N0M0 NSCLC, without a history of preoperative chemotherapy and/or radiotherapy, and 46 healthy subjects were included. Lymphocyte subsets were analyzed by flow cytometry. Cytotoxic capacity of NK and $CD8^+$ T cells were evaluated by CD107a degranulation assay. Compared to healthy subjects, NK, NKT, $CD3^+HLADR^+$ and $CD8^+CD28^-$ suppressor T cells were significantly increased, while percentage of $CD8^+CD28^+$, $CD4^+$and $CD3^+$T lymphocytes were significantly decreased in patients with NSCLC (p=0.002, p=0.005, p=0.000, p=0.001, p=0.001, p=0.02 and p=0.02, respectively). Although the cytotoxic capacity of NK cells were similar between the groups, increased CD107a expression was observed in $CD8^+$T cells in stimulated and unstimulated groups (p=0.001). The rates of lymphocyte and NK subsets were not significantly different between earliest stage (T1) patients and patients with T2-3 (p>0.05).Increased $CD8^+CD28^-$ T cells might suppress antitumor immunity. Although the numbers of NK cells were increased in NSCLC group, their cytotoxic capacity was impaired. An immunological scoring system might contribute to better understanding of the prognosis of NSCLC. The role of immune cells in different stages of cancer needs to be further studied.

P.B3.04.03

AMPK pathway in regulatory T cell is critical to maintain oxidative metabolism and keep energy balance within the tumor micro environment

***J. Divoux**, R. Valion, M. Laviron, E. Ronin, S. Gregoire, B. Salomon;*
CIMI Paris, Paris, France.

Cellular metabolism is a critical factor in immune cell activity. It has been well studied in conventional T cells (T_{conv}), where mTORC1 promotes anabolism during antigenic stimulation while AMPK favors catabolism to support memory function. Regulatory T cells (T_{reg}) are essential to maintain immune tolerance. Although they have been extensively studied, little is known about their metabolic profile. We therefore developed a model where AMPK was selectively deleted in T_{reg} (Foxp3^{CRE} Prkaa1^{Lox} mice). These mice were healthy and homeostasis of T_{reg} and T_{conv} seemed unchanged. However, AMPK deficient T_{reg} showed decreased mitochondria activity and palmitate harnessing as well as increased mTORC1 activity. In a tumor context, the proportion of tumor-infiltrating T_{reg} was decreased in Foxp3^{CRE} Prkaa1^{Lox} mice which correlated with a better activation of T_{conv} and slowed tumor growth. Analysis are underway to further evaluate these metabolic changes and their impact on the stability, migration and survival of tumor-infiltrating T_{reg}.

P.B3.04.04

Chloroquine promotes up-regulation of CD39 expression and suppressive function during TGF-beta mediated Treg induction

***M. C. Gerner**, L. Ziegler, R. L. Schmidt, K. G. Schmetterer;*
Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria.

Regulatory T-cells (Treg) are a subpopulation of CD4$^+$ T-cells, associated with immunosuppression and preservation of self-tolerance. Treg can suppress activation of effector T-cells through various mechanisms including the degradation of ATP into the suppressive molecule adenosine through the ectoencymes CD39 and CD73. The mechanisms regulating CD39 on CD4$^+$ T-cells are yet unknown and is independent of FOXP3. Previous studies in tumor cells have described that inhibition of autophagy leads to the up-regulation of CD39 expression. Thus, we hypothesized a similar correlation in T-cells. Consequently, we investigated signals leading to the *de novo* induction of CD39 on iTreg and assessed the influence of chloroquine, an autophagy inhibitor, on this process. Naïve CD4$^+$CD25$^-$CD39$^-$ T-cells were activated *in vitro* with anti-CD3/CD28 coated microbeads in the presence of IL-2 and TGF-β/*all trans* retinoic acid (atRA) with or without chloroquine. First experiments revealed that TGF-β/atRA led to a stronger induction of CD39 on the CD25^{high}CD127^{low} iTreg population than culture in IL-2 alone. The combination of TGF-β/atRA + chloroquine boosted CD39- and FOXP3 expression, and led to a stronger suppressive function *in vitro* compared to TGF-b/atRA Treg-induction without chloroquine. Intriguingly, T-cells cultured in chloroquine without TGF-b/atRA did not induce iTreg. Thus, chloroquine synergizes with TGF-b/atRA signaling to enhance tolerogenic functions during iTreg induction. The exact molecular mechanisms underlying these observations will be the focus of further studies. In conclusion, our studies reveal that additional signals may influence induction of Treg by TGF-beta/atRA which may allow to develop strategies for the manipulation of T-cell tolerance.

P.B3.04.05

Role of the zinc-finger protein MAZR during iNKT cell lineage differentiation

*M. J. Orola[1,2], C. Tizian[1,3], **A. F. Gülich**[4], I. Taniuchi[5], W. Ellmeier[1], S. Sakaguchi[1];*
[1]Institute of Pathophysiology, Infectiology and Immunology, Medical University Vienna, Vienna, Austria, [2]Institute of Specific Prophylaxis and Tropical Medicine, Medical University Vienna, Vienna, Austria, [3]Charité, Universitätsmedizin Berlin, Institute of Microbiology Infection and Immunology, Germany, [4]Institute of Pathophysiology, Infectiology and Immunology; Medical University Vienna, Vienna, Austria, [5]Laboratory for Transcriptional Regulation, RIKEN Center for Integrative Medical Sciences, Vienna, Japan.

Myc-associated zinc finger-related factor (MAZR, also known as PATZ1) is an essential transcription factor for CD8$^+$ lineage differentiation of "conventional" T cells, However, its role in innate-like T cells such as invariant NKT (iNKT) cells is not known. Here we showed that T cell lineage-specific deletion of MAZR resulted in an enlargement of CD44$^+$NK1.1$^-$ stage 2 iNKT cells, accompanied with the elevated expression of CD4 and Th-inducing Pox virus and zinc finger/Krüppel-like factor (ThPOK). In the absence of MAZR there is an increase in iNKT2 cell number, concurrent with a reduced number of iNKT17 cells, and that this alteration occurred in a cell intrinsic manner. Consistent with the altered iNKT cell lineage differentiation, MAZR-deficient iNKT cells displayed an enhanced production of IL4, along with a reduction in IL17A production, both upon *in vitro* PMA/ionomycin and *in vivo* alpha-galactosylceramide (α-GalCer) stimulation. Ongoing studies address the impact of MAZR on liver injury in α-GalCer- and Concanavalin A (ConA)-induced hepatitis models. Together, our study identified MAZR as an essential factor regulating the lineage differentiation of iNKT2 and iNKT17 cell.

P.B3.04.06

Regulatory T cells promote metabolic reprogramming of CD8 T cells from cytotoxic effector to quiescent memory state

***V. Kalia**[1], A. Vegaraju[2], Y. Yuzefpolskiy[1], H. Xiao[2], S. Sarkar[1];*
[1]University of Washington School of Medicine, Seattle, United States, [2]Seattle Children's Research Institute, Seattle, United States.

Metabolism adapts to support distinct T cell functional states as naïve cells differentiate into effector and memory cells. TCR, costimulatory and cytokine signals rapidly switch the metabolic program of quiescent naïve cells from oxidation of fatty acids and glucose via OXPHOS to a program of anabolism via augmented aerobic glycolysis to support the proliferative burst and cytotoxic function. After antigen clearance, conversion from cytotoxic effector state to quiescent memory state is associated with a metabolic switch to catabolic processes such as fatty acid oxidation and autophagy. Availability of antigen, cytokine and nutrients is believed to largely orchestrate metabolic transitions of naïve, effector and memory CD8 T cells. Nonetheless, it remains unclear how anatomic micro niches and interactions with other immune cells (such as CD4 T cell help or regulation by Treg cells) impact CD8 T cell differentiation-associated metabolic remodeling. Here we show that anatomic location of memory-fated effector CD8 T cells within the splenic micro niches dictates their metabolic state and protective functional outcome. Our studies further reveal a critical requirement of Treg cells in promoting metabolic remodeling of memory-fated effector CD8 T cells as they enter quiescence after antigen clearance. Ablation of Treg cells led to specific metabolic dysregulation in the memory-fated CD8 T cell subset, resulting in compromised memory function. These studies define novel molecular targets that may be exploited to manipulate metabolism, migration and memory function during vaccination.

P.B3.04.07

The role of granzyme B in the function of regulatory T cells induced by B cells

***S. Kang**, S. Lin, B. Chiang;*
Graduate Institute of Immunology, Collage of Medicine, Taipei, Taiwan.

Introduction. The regulatory T cells have been found to be essential for immune modulation and maintenance of tolerance. Recent studies demonstrated a novel subset of regulatory T cells, the Treg-of-B cells, which are induced by B cells. Our group is studying the characteristics and functions of Treg-of-B cells, and their implications on autoimmune and allergic diseases.
Materials and Methods. In this study, we co-cultured naïve T and B cells and isolated the B-cell-induced Treg-of-B cells after activation. We examined and characterized the cells with qPCR, ELISA and flow cytometry, and also studied their immune suppression ability. In addition, we also like to investigate the role of granzyme in the function of Treg-of-B cells.
Results. The results showed that Treg-of-B cells were a subset of CD4$^+$CD25$^+$ regulatory cells with significant immune suppressive function. This subset of T cells did not express the key markers of naturally occurring regulatory T cells, Foxp3, and secreted higher level of granzyme B. We will like to further study the role of granzyme B in the function of Treg-of-B cells with granzyme B knockout mice.
Conclusion. Here we demonstrated a novel subpopulation of regulatory T cells induced by co-culture with B cells. This particular subpopulation of Treg-of-B cells express LAG-3, CTLA-4 and produced IL-10, however, they do not express Foxp-3 gene. We believe that granzyme B might also play a critical role in the function of Treg-of-B cells.

P.B3.04.08

Tracing of the NKT1 differentiation pathway using Hobit reporter mice

***N. A. M. Kragten**[1], L. Parga Vidal[1], F. M. Behr[1,2], R. L. Taggenbrock[1], T. H. Wesselink[1], R. Stark[1], K. P. van Gisbergen[1,2];*
[1]Dept. of Hematopoiesis, Sanquin Research and Landsteiner Laboratory AMC/UvA, Amsterdam, Netherlands, [2]Dept. of Experimental Immunology, AMC, Amsterdam, Netherlands.

Natural killer T (NKT cells) are unconventional T cells that play a regulatory role in a broad range of infectious diseases and autoimmune disorders. We have previously shown that the transcription factor Homologue of Blimp-1 in T cells (Hobit) is highly upregulated in NKT1 cells and plays an essential role in the development of the NKT1 lineage, but not in the NKT2 and NKT17 lineages.
To address the differentiation pathway of NKT1 cells, we have developed a reporter mouse that expresses the fluorescent protein tdTomato, Cre recombinase and the diphtheria toxin receptor (DT) under the control of the Hobit promoter. Using the tdTomato reporter as a read-out for Hobit expression, we found that mature NKT1 in contrast to immature NKT cells, NKT2 cells and NKT17 cells expressed Hobit. To examine the potential of thymic precursors to generate NKT1 cells, we depleted tdTomato+ NKT1 cells using DT and analyzed the re-appearance of these cells. We found that mature NKT1 cells did not re-develop after depletion, suggesting that the population is stably maintained in the periphery independent of thymic input. Using lineage tracer mice (Hobit CRE x Rosa26-(floxed STOP)-YFP mice), we addressed the potential of NKT1 to contribute to the development of the other NKT lineages. We did not find YFP expression in NKT2 and NKT17 cells, suggesting that Hobit+ NKT1 cells lack NKT2 and NKT17 potential. Thus, our data show that NKT1 form a thymus-independent population of terminally differentiated NKT cells in the peripheral organs.

P.B3.04.09

Human CD8+HLA-DR+ regulatory T cells share phenotypic and functional features with classical CD4+Foxp3+ regulatory T cells

***A. Machicote**, S. Belén, P. Baz, L. A. Billordo, L. Fainboim;*
Laboratorio de Inmunogenética, Instituto de Inmunología, Genética y Metabolismo, Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires-Consejo Nacional de Investigaciones Científicas y Técnicas, CABA, Argentina.

Introduction: We previously described a human $CD8^+$ regulatory T cell subset, constitutively expressing the HLA-DR molecule ($CD8^+HLA\text{-}DR^+$ Tregs), which suppresses the proliferation of autologous PBMCs through cellular contact and CTLA-4. We aimed to characterize the regulatory signature of these Tregs, to identify additional mediators involved in the regulatory mechanism, and to evaluate their exhaustion status.
Materials and Methods: Peripheral and cord blood samples were obtained from healthy donors. Phenotypic markers were analyzed by flow cytometry. Suppression assays were performed with CellTrace Violet-stained PBMCs as responders, co-cultured with sorted $CD8^+HLA\text{-}DR^+$ or $CD8^+HLA\text{-}DR^-$ cells, and activated with aCD3/aCD28. Cytokine secretion was analyzed after PMA/Ionomycin stimulation.
Results: In comparison with $CD8^+HLA\text{-}DR^-$ cells, $CD8^+HLA\text{-}DR^+$ Tregs showed an increased frequency of PD-1 ($p<0.0001$) and TIGIT ($p<0.0001$), and lower expression of CD127 ($p=0.0009$). Consistent with the high expression of PD-1, the addition of PD-1 and PD-L1 neutralizing antibodies abrogated the suppression effect of $CD8^+HLA\text{-}DR^+$ Tregs ($p=0.0015$), acting preferentially on $CD8^+$ responder cells. In comparison with $CD8^+HLA\text{-}DR^-$ cells, $CD8^+HLA\text{-}DR^+$ Tregs presented a higher frequency of IFNg ($p=0.0098$), TNFa ($p=0.0004$) and CD107a ($p=0.0006$) after PBMCs stimulation, and a higher proliferation rate ($p=0.0037$). Within adult PBMCs, 90±2% of $CD8^+HLA\text{-}DR^+$ have a differentiated- or memory-like phenotype, that contrasted with cord blood $CD8^+HLA\text{-}DR^+$ Tregs being mostly naïve (86±6%) ($p<0.0001$).
Conclusions: $CD8^+HLA\text{-}DR^+$ Tregs show high similarities with classical $CD4^+Foxp3^+$ Tregs, including expression of PD-1, TIGIT and CD127 molecules, and abrogation of suppressor capacity by anti-PD-1 antibody. Our results also confirmed that $CD8^+HLA\text{-}DR^+$ Tregs are not exhausted cells.

Heterogeneity of one-cell derived mesenchymal stem cells on immunomodulation of lymphocyte subsets

***P. Martinez-Peinado**[1], S. Pascual-García[1], A. López-Jaen[1], F. Navarro-Blasco[1], E. Roche[2], J. Sempere-Ortells[1];*
[1]University of Alicante, San Vicente del Raspeig, Spain, [2]University Miguel Hernández, Elche, Spain.

Mesenchymal stem cells (MSC) are widely used in cell therapy to treat autoimmune diseases because of their immunomodulatory properties. However, the results of such clinical trials are, in many cases, incongruent. The heterogeneous character of MSC may be responsible for these results. In this study, we analysed the differences of five MSC clones to exert their *ex vivo* immunomodulation.
We conducted proliferation assays of CD3, CD4 and CD8 purified lymphocytes co-cultured with the different MSC clones, as well as assays to analyse the effect of these clones on the Treg population in co-cultures with PBMC. We also analysed the effect of these clones on the viability of PBMC in the presence of a pro-apoptotic stimulus. Finally, Th1/Th2 cytokine environment of co-cultures with PBMC was characterised as well. We also checked the effect of conditioned media on the above parameters.
The clones inhibited the proliferation of $CD3^+$ and $CD4^+$ lymphocytes with different intensity. Surprisingly, all the clones promoted the proliferation of $CD8^+$ lymphocytes, with significant differences between them. MSC clones and their CM increased the number of Treg with varying intensities. Clones promoted both increases and decreases in the viability of UV-treated PBMCs. Finally, the clones also promoted heterogeneous cytokine environments.
Considering all these results, it seems that different clones can promote a wide range of responses, from anti-inflammatory to pro-inflammatory. This may be important in the standardization of the design of personalized cell therapy protocols, thus decreasing the undesirable outcomes that currently exist in this type of therapy.

The AMP analog AICAR modulates the Treg/Th17 axis through AMPK-mediated enhancement of fatty acid oxidation

***K. A. Mayer**[1], G. A. Gualdoni[1,2], L. Göschl[1,2], N. Boucheron[1], W. Ellmeier[1], G. J. Zlabinger[1];*
[1]Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, [2]Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria.

Introduction: T cells must tightly regulate their metabolic processes to cope with varying bioenergetic demands depending on their state of differentiation. The metabolic sensor AMPK is activated in states of low energy supply and modulates cellular metabolism toward a catabolic state. Although this enzyme is known to be particularly active in regulatory T (Treg) cells, its impact on T helper (Th) cell differentiation is poorly understood. Results: We investigated the impact of several AMPK activators on Treg differentiation and found that the direct activator AICAR (5-aminoimidazole-4-carboxamide ribonucleotide), but not the indirect activators metformin and 2-deoxyglucose, strongly enhanced Treg cell induction. Further investigation of the metabolic background of our observations revealed that AICAR enhanced both cellular mitochondrogenesis and fatty acid uptake. Consistently, increased Treg-induction was entirely reversible upon inhibition of fatty acid oxidation. Translating our findings to an in vivo model, we found that the substance enhanced Treg cell generation upon IL-2 complex-induced immune stimulation. Strikingly, AICAR had no effect in AMPK-deficient T cells, therefore highlighting the important role of AMPK in Treg expansion. Discussion: We provide a previously unrecognized insight into the delicate interplay between immune cell function and metabolism and delineate a potential novel strategy for metabolism-targeting immunotherapy.

P.B3.04.12

Cross talk between naïve CD4+ T cells and cancer and normal adipose derived mesenchymal stem cells (ASCs) and induction of distinct subsets of regulatory T cells

***M. Razmkhah**[1], M. Fakhimi[1], A. Talei[2], M. Habibagahi[3], A. Ghaderi[4];*
[1]Shiraz Institute for Cancer Research, School of Medicine, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [2]Breast Diseases Research Center (BDRC), Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [3]Department of Immunology, School of Medicine, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [4]Shiraz Institute for Cancer Research, Department of Immunology, School of Medicine, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of.

Tumors are complex tissues containing many different cell types, including stromal cells, cells of the immune system and mesenchymal stem cells (MSCs). MSCs play a significant role as immunomodulators in the tumor microenvironment through producing different cytokines. The present study aimed to clarify Treg subsets and their cytokines after exposing naïve T lymphocytes to adipose derived mesenchymal stem cells (ASCs). Human ASCs were obtained and characterized from breast adipose tissues of a breast cancer patient and a normal individual. Naïve CD4+T cells were purified from peripheral blood of healthy donors using magnetic cell sorting (MACS) and were cultured for 5 days with cancer and normal ASCs. The phenotype of harvested regulatory T cells and the production of IL-10, TGF-β and IL-17 by T cells were evaluated using flow cytometry and ELISPOT assay, respectively. As a result, CD4+CD25+Foxp3+CD45RA+ and CD4+CD25+Foxp3+Helios+ Treg cells increased significantly in the presence of normal-ASCs and breast cancer-ASCs compared to those cultured without ASCs (P values= 0.002 and 0.005). Coculturing of naïve T cells with cancer-ASCs resulted in significant expansion of CD4+CD25-Foxp3+Helios+ T cells. Also, the percentage of CD25+Foxp3+CD73+CD39+ T cells was significantly upregulated in the presence of cancer-ASCs (P value=0.005). The production of IL-10, TGF-β and IL-17 by T cells was increased with both normal- and cancer-ASCs but cancer-ASCs had more significant effects on IL-10 and TGF-β production (P value< 0.05). Results of the present study suggest more evidences for the immunosuppression of ASCs on T lymphocytes and deviation of these cells to distinct regulatory phenotypes providing conditions in favor of immune evasion and tumor growth.

P.B3.04.13

A role for RORα-expressing CD4 cells in the immune response to the helminth *Nippostrongylus brasiliensis*

***J. Roberts**, C. Schwartz, P. Fallon, E. Hams;*
School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland.

The transcription factor Retinoic acid-related Orphan Receptor (ROR)-α is a member of the ROR family, also including RORβ and RORγ. RORα has roles in cerebellar development, circadian rhythm and inflammatory responses and is required for the development of Th17 cells and group 2 innate lymphoid cells (ILC2). Infection of mice with the helminth *Nippostrongylus brasiliensis* induces a strong type 2 response, characterized by localised recruitment of eosinophils, alternatively activated macrophages and Th2 cells, which is required to clear the worms from the host. It has previously been shown that ILC2s are crucial for *N. brasiliensis* clearance, herein we sought to investigate the potential role of other RORα-expressing cells. Infecting staggerer mice ($Rora^{sg/sg}$), which have a natural mutation in the gene encoding Rora resulting in a premature stop codon, with *N. brasiliensis* we show a delay in worm rejection compared to wild type mice. Furthermore, we have observed an altered type 2 immune response in helminth infected $Rora^{sg/sg}$ mice, associated with decreased eosinophil and Th2 cell recruitment. Using the Cre-lox system we have generated mice with specific deletion of Rora in CD4+ T cells ($Rora^{fl/fl}$CD4Cre) and ILC2 ($Rora^{fl/sg}$IL-7RaCre/+). Infection of these mice has shown reduced worm burden in the absence of Rora-expressing CD4+ T Cells, compared to a delay in worm clearance in the absence of ILC2s. These data suggest a role for Rora-expressing CD4+ T cells in the progression of a functional type 2 response to infection with the helminth *N. brasiliensis*.

P.B3.04.14

The role of anergy-related molecules in development and function of regulatory T cells induced by B cells

***T. Yeh**, B. Chiang;*
Graduate Institute of Immunology, Taipei, Taiwan.

Introduction: Naïve B cell could act as antigen presenting cell to convert $CD4^+CD25^-$ T cell into $FOXP3^-$ regulatory T cell which called Treg-of-B cells. Treg-of-B cell suppressed effector T cell proliferation by cell-cell contact manner which is different from other Treg population, included tTreg, Tr1 and Th3. In seraval studies of autoimmune disease animal models, Treg-of-B cell could alleviated inflammation. Anergy is a mechanism of peripheral tolerance which caused by weak or non-costimulatory signal. Treg are considered to be naturally anergic because of its hypoproliferative characteristics and low IL-2 production with involvement of anergy associated factors. Treg-of-B cells have been found also with the anergic phenotype. Materials and Methods: In this study, we aim to identify the anergic phenotype of Treg-of-B cells, and analyze the anergy associated genes expression. We established several induction systems to discuss how antigen specificity and co-stimulatory signal affect Treg-of-B cell development and function. Then we will further analyze the IL-2 suppressor - Aiolos expression of Treg-of-B cell. Results: Treg-of-B cell exerted anergic phenotype but did not express NFAT associated anergic factors. Treg-of-B cell Induced with antigen specific B cell or higher co-stimulatory signal slightly restored the suppressive function and accompanied with decreased Aiolos expression. Conclusions: Antigen specificity and high costimulatory signal caused Treg-of-B cell to be more activated which affect their suppressive function. Different expression of Aiolos suggested that it might be associated to the anergic status of Tre-of-B cell. but whether Aiolos involved in development and function of Treg-of B cell still needs clarification.

P.B3.04.15

Characterization of the FOXP3-regulated anti-proliferative gene signature in thymus-derived regulatory T-cells

***L. Ziegler**, M. Gerner, R. Schmidt, K. Schmetterer;*
Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria.

Background: The transcription factor Forkhead-box protein 3 (FOXP3) is master regulatory factor for thymic-derived regulatory T-cells (tTreg) and controls the expression of several hundred genes. Still our knowledge about this FOXP3-regulated gene signature is far from complete. Using microarray screenings of FOXP3-transgenic human T-cells, we identified several genes, which are regulated by FOXP3 and have been described as cell-cycle regulators in various cell types: Juxtaposed with another zinc finger 1 (JAZF1), MAX-interacting protein 1 (MXI1), B-cell translocation gene 1 (BTG1) and Glucocorticoid-induced leucine zipper (GILZ). Methods: Expression of these genes was measured by RT-PCR in resting or anti-CD3/anti-CD28 activated FOXP3- or control-vector transduced T-cells or CD4+CD25+ Treg. cDNAs for the genes were cloned into a retroviral expression vector and the effects of overexpression in CD4+ T-cells on proliferation, marker expression and cytokine secretion were measured. Results: Expression of all four genes was induced in FOXP3-transgenic T-cells and tTreg following activation. In contrast, expression in control-vector transduced or CD4+ effector T-cells was significantly down-regulated. Overexpression of GILZ showed a marked up-regulation of the tTreg markers CD25 and GITR. Following activation, proliferation of all transgenic T-cells was significantly decreased. All four genes showed effects on the secretion of different cytokines, including IL-2, IL-17 and IFN-γ. Conclusion: JAZF1, MXI1, BTG1 and GILZ are involved in the maintenance of hypo-responsiveness in Treg and contribute to their reduced cytokine secretion. Thus, our data add to the understanding of the FOXP3-regulated gene signature in Treg and may open new strategies for the manipulation of these cells.

P.B3.04.16

Platelets induce a regulatory phenotype in T cells via the expression of GARP

***N. Zimmer**[1], S. A. Hahn[1], S. Wilden[1], E. Walter[2], K. Jurk[2], S. Grabbe[1], A. Tuettenberg[1];*
[1]Department of Dermatology, Mainz, Germany, [2]Center for Thrombosis and Hemostasis Mainz (CTH), Mainz, Germany.

Introduction: Beside their main function in hemostasis, platelets are important modulators of the innate and adaptive immunity through their interaction with immune cells. Glycoprotein A repetitions predominant (GARP), first described on platelets and as an activation marker on regulatory T cells (Treg), is known to modulate the bioavailability of TGF-beta and is therefore involved in the regulation of the peripheral immune responses. Recently, we were able to show that the soluble form of GARP (sGARP) has strong regulatory and anti-inflammatory properties in vitro and in vivo. sGARP leads to induction of peripheral Treg (pTreg) as well as to inhibition of tumor antigen-specific $CD8^+$ T cells.
Materials and Methods: In the present study, we investigated the effect of platelets on the differentiation and phenotype of $CD4^+$ T cells dependent on GARP.
Results: sGARP was detected in the supernatant of activated platelets. Consequenlty, platelets were able to inhibit dose dependently the proliferation and cytokine production, while inducing a strong Foxp3 expression and a suppressive capacity in coculture. Using a blocking anti-GARP mAb, we were able to reverse these effects.
Conclusion: Our data give evidence that platelets are capable to induce pTreg in a GARP-dependent manner. The expression and shedding of GARP by platelets could be of importance in diseases like cancer, where poor prognosis and metastasis are associated with elevated numbers of circulating platelets (thrombocytosis).

P.B3.04.17

Tr1-like ($IL\text{-}10^+$, $IFNg^-$, $IL4^-$) cells in peripheral blood are part of the T effector memory pool and are preferentially stimulated via CD55

***I. A. Charles**, J. M. Ramage, I. Spendlove, Cancer Immunotherapy group;*
The University of Nottingham, Nottingham, United Kingdom.

Effector T cells arise from naïve T cell stimulation and enter a long term memory pool. While they can adapt their function to specific environmental cues, sometimes called plasticity, their phenotype remains broadly fixed. Unlike natural T regulatory cells that emerge from the thymus with a defined phenotype ($CD4^+CD25^{hi}CD127^{lo}FoxP3^+$), there is uncertainty over the characterisation of inducible Tr1-like regulatory cells. In this study we stimulated human total $CD4^+$ T cells with PMA/ Ionomycin. A Small (<5%) population were $IL\text{-}10^+$ $IL\text{-}4^-$, IFN-γ^- and expressed other markers commonly associated with Tr1-like cells. These included; CD49b, LAG-3, CD226, PD-1, CTLA-4, and TIM-3. However they were negative for FoxP3 expression. Furthermore, we show that these Tr1-like cells form part of the immunological memory and reside predominantly within the effector memory ($CD62L^-$ $CD45RO^+$, TEM) pool. Unlike the majority of other studies where Tr1 is generated by chronic stimulation of PBMCs in the presence of IL-10 for several days, as far as we are aware, this is the first report characterising Tr1 directly ex vivo from human peripheral blood. We have also demonstrated that these cells respond specifically to costimulation via CD97-CD55 to drive proliferation and maintain the IL-10 single positive, Tr1-like phenotype outlined above. This supports the idea that once differentiated from naïve precursors, Tr1-like cells respond to CD55 costimulation to maintain a small (<5%) pool with a committed $IL\text{-}10^+$ $IL\text{-}4^-$IFN-γ^- phenotype.

P.B3.04.18

Co-stimulatory activity of TLR7/8 and STING ligands on interferon-γ induction in human γδ T cells

***R. D. Serrano**[1], B. Putschli[2], C. Coch[2], G. Hartmann[2], D. Wesch[1], D. Kabelitz[1];*
[1]Institute for Immubnology/University of Kiel, Kiel, Germany, [2]Institute of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany.

Human phosphoantigen-reactive Vγ9Vδ2 γδ T cells are potent producers of pro-inflammatory cytokines including TNF-α and IFN-γ. An expression of several Toll-like receptors (TLRs) on/in human γδ T cells inducing direct co-stimulatory effects after ligation with corresponding ligands has been reported, while strong co-stimulation can also provided by TLR activated monocytes. In our study, we have analyzed the IFN-γ induction in peripheral blood γδ T cells in response to phosphoantigen (E)-4-Hydroxy-3-methyl-but-2-enyl pyrophosphate (HMBPP) in the absence or presence of a variety of ligands for TLR7, TLR8 and stimulator of interferon genes (STING). Induction of IFN- γ expression in Vγ9-expressing γδ T cells was measured by intracellular flow cytometry after 6 to 48 hours either within PBMC or in cocultures of purified γδ T cells and purified monocytes. In the absence of HMBPP stimulation, some IFN-γ expression was induced by TLR8 (TLR8-506 and ss40 RNA) and TLR7/8 ligands (Resiquimod and 9.2s RNA). In the presence of low concentrations of HMBPP, the same ligands strongly co-stimulated IFN-γ expression in γδ T cells. In addition, adenosine- but not guanosine/inosine-containing cyclic dinucleotide STING ligands also exerted strong co-stimulatory activity only in company with HMBPP. The same ligands, however, inhibited the proliferative expansion of freshly isolated γδ T cells cocultured with monocytes in response to HMBPP and zoledronic acid. Microscopic inspection suggested that the adenosine-containing cyclic dinucleotides induced cell death in purified monocytes, in line with a recent reports. Our data indicate a dual role of some PRR ligands in human γδ T cell activation, a notion which requires further studies to uncover the underlying mechanisms.

Switching cytotoxicity to inflammation pattern in relation to cutaneous melanoma stages

*M. Surcel[1], **C. Constantin**[1,2], R. Huica[1], A. Munteanu[1], I. Pirvu[1], G. Isvoranu[1], O. Bratu[3], D. Ciotaru[1], C. Ursaciuc[1], M. Neagu[1,4,2];*
[1]"Victor Babes" National Institute of Pathology, Bucharest, Romania, [2]Colentina University Hospital, Bucharest, Romania, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [4]Faculty of Biology, University of Bucharest, Bucharest, Romania.

Cutaneous melanoma (CM) represents only 4% of all skin cancers, but it is responsible for 80% of skin cancer deaths, thus identifying new prognostic and evolution markers remains a constant endeavor. **Methods.** Using flow-cytometry peripheral blood form CM patients diagnosed in all the stages was quantified for total T cells ($CD3^+$), B cells ($CD3^-CD19^+$), NK cells ($CD3^-CD16^+$ and/or $CD56^+$), T helper cells ($CD3^+CD4^+$), T supressor/cytotoxic cells ($CD3^+CD8^+$) and regulatory T cells ($CD4^+/CD25^+/FOXP3^+$) (T-reg); % of lymphocytes secreting IL-2, IFN-γ and TNF-α. **Results.** The main changes found in 83% of patients were the decrease of both percentage and absolute number of T-CD8+ with an increase of $T\text{-}CD4^+/T\text{-}CD8^+$ ratio. T-reg values were found elevated in 53% of cases; 63% of patients with increased T-reg presented decreased percentage of T-CD8+ lymphocytes.
Significant changes in the % of lymphocytes synthetizing IFN-γ (17±7% patients compared to 9±3% in controls, $p<0.02$) and in TNF-α synthesis (33±9% patients, compared to controls 22±11%, $p<0.05$) were found. **Conclusions.** CM cellular profile suggests a trend of dissociation of antitumor immune response efficiency. Firstly, the decreasing of T-cytotoxic cells and the increasing of regulatory T cells diminish the cytotoxic activity. The increasing of secretory cells % for pro-inflammatory cytokines (IFN-γ and TNF-α) may be relative, being the consequence of increasing the percentage of T-helper cells, indicating the switch of antitumour activity from cytotoxicity to inflammation. **Acknowledgement:** This work was supported by Core Program, implemented with the support NASR, project no. 18.21.02.02 and PN-III-P1-1.2-PCCDI-2017-0341/2018.

Effective expansion and reprogramming of tumor infiltrating lymphocytes from non-small cell lung cancers

***R. De Groot**[1], M. M. van Loenen[1], A. Guislain[1], M. M. Van den Heuvel[2], J. De Jong[2], R. M. Spaapen[1], D. Amsen[1], J. B. Haanen[2], K. Monkhorst[2], K. J. Hartemink[2], M. C. Wolkers[1];*
[1]Sanquin Research, Amsterdam, Netherlands, [2]Netherlands Cancer Institute, Amsterdam, Netherlands.

Non-small cell lung cancer (NSCLC), the second most occurring type of cancer, is highly recurrent with limited 5-year survival. NSCLCs contain high numbers of T cells, and although suggestive of tumor reactivity, these tumor infiltrating lymphocytes (TILs) are unable to eradicate the cancer. Here we investigated whether TILs from NSCLC can be reprogrammed and used for autologous T cell therapy. TILs were isolated from tumor tissues and reprogrammed via in vitro activation using a standard TIL expansion protocol. Strikingly, the vast majority of expanded TILs from primary NSCLC tumor tissues (stage I-IIIA) were tumor reactive; TILs from 13/17 donors (76,5%) produced inflammatory cytokines in response to tumor digests, but not in response to distal non-tumorous lung tissues. Tumor responses ranged from 1%-35% of cytokine-producing TILs, which correlated with expression of activation markers CD137 on tumor-reactive T cells and CD40L on tumor-reactive $CD4^+$T cells. Importantly, TIL cultures with high cytokine responses contained polyfunctional T cells that produced IFN-γ together with TNF-α and/or IL-2. Strikingly, high expression of $CD103^+/CD69^+$on $CD8^+$T cell, and the presence of B cell as well as regulatory T cell infiltrates in the tumors were strong predictors of the intensity of tumor reactivity in expanded TILs. Our data show that reprogramming of TILs from NSCLC is effective, strongly suggesting that autologous T cell therapy should be considered to treat NSCLC patients.

The SPPL3-controlled tumor glycosphingolipid repertoire determines MHC class I functionality

***A. A. de Waard**[1], M. L. Jongsma[1,2], M. Raaben[3], T. Zhang[2], V. A. Blomen[3], R. Platzer[4], S. Bliss[1], S. Holst[2], P. Schatzlmaier[4], L. J. Janssen[2], A. Mulder[2], M. H. Heemskerk[2], F. H. Claas[2], M. Griffioen[2], H. S. Overkleeft[5], J. B. Huppa[4], M. Wuhrer[2], T. R. Brummelkamp[3], J. Neefjes[2], R. M. Spaapen[1];*
[1]Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Netherlands Cancer Institute, Amsterdam, Netherlands, [4]Institute for Hygiene and Applied Immunology, Vienna, Austria, [5]Leiden University, Leiden, Netherlands.

MHC class I (MHC-I) molecules are key regulators of T cell activation. Processes catalyzing functional MHC-I antigen presentation are therefore often dysregulated in cancer. To identify such processes, we performed a state-of-the-art genome-wide screen using haploid genetics. We identified the intramembrane protease SPPL3 as a novel positive regulator of antigen presentation as validated by a reduction of CD8+ T cell responses against CRISPR/Cas9 engineered SPPL3 knockout (KO) cells.
Additional genome-wide screens revealed that SPPL3 controls enzymes of the glycosphingolipid (GSL) synthesis. Indeed, mass spectrometry of the GSLs showed that the repertoire is completely altered in SPPL3 KO cells. Moreover, systematically knocking out enzymes in the GSL synthesis pathway enabled us to create a map of the GSL repertoire affecting MHC-I. In combination with the mass spectrometry data, we discovered that lacto- and neolactoseries GSLs generated by the enzyme B3GNT5, hinder antibody and receptor association with MHC-I. We determined that SPPL3 controls this process by proteolytically inactivating B3GNT5 and therefore (neo-)lactoseries GSLs are only present in the absence of SPPL3. Screening a panel of diverse tumor cell lines revealed that GSLs impair MHC-I in AML and several other types of tumors, suggesting that GSLs may be involved in escape from T cell surveillance.
In conclusion, GSL regulation by SPPL3 is a novel regulatory mechanism of functional MHC-I antigen presentation. Targeting GSL synthesis may therefore constitute a novel mode of immunotherapy for cancer.

Tumor infiltrating T cells: complete workflows allow faster and improved flow cytometric analysis of syngeneic mouse tumors

***C. Evaristo**, R. Siemer, D. Agorku, J. Brauner, O. Hardt, C. Dose, A. Richter;*
Miltenyi Biotec, Bergisch Gladbach, Germany.

Immunotherapies have proven clinical efficacy in multiple cancers. Syngeneic mouse models represent the gold standard to develop and analyze effects of immunotherapy. However, phenotypic and functional analysis of tumor-infiltrating leukocytes (TILs) is technically challenging and time/labor intensive. Importantly, T cells are embedded in a highly immunomodulatory microenvironment, hindering unbiased functional characterization. It is fundamental to use innovative tools to streamline workflows and generate reliable data.
We established complete workflows combining tissue-storage, dissociation, T cell-isolation and phenotyping. Tissues were processed immediately or stored in a solution that maintains cell viability and phenotype up to 48h (Tissue Storage Solution™). Tumor-dissociation was automated and optimized for epitope preservation using a tissue dissociator (gentleMACS™ Octo). Phenotypic analysis revealed that optimal enzymatic dissociation was essential for analysis of critical tumor-specific sub-populations, such as $PD1^{hi}Tim3^+Lag3^+CD39^+CD8^+$ T cells. We developed new reagents which enrich for rare tumor infiltrating T cells up to 500-fold, while maintaining activation status and phenotype. Importantly, use of recombinant REAfinity™ antibodies significantly diminished non-specific labeling of cells present in the tumor microenvironment. Finally, flow cytometric analysis was performed using an automated analyzer (MACSQuant X™). This instrument decreased total and hands-on acquisition time by facilitating fast and automated sample processing, including sample mixing and cell counting.
In conclusion, we optimized workflows including standardized processing of tumor samples, new tools for TIL isolation and automated flow cytometry. These workflows reduce experimental time and allow the performance of more complex experiments. Use of these tools can significantly increase the data quality in immuno-oncology and immunotherapy research.

P.B4.01.05
Immune profiling of the tumour microenvironment in cancer to determine patient responses to immunotherapy

***A. L. Ferguson**[1,2], J. Toh[3,2], K. Lo[4], A. Hong[2,5,6], G. Long[2,6,5], R. Scolyer[2,6,5], U. Palendira[1,2];*
[1]Centenary Institute, Sydney, NSW, Australia, [2]Sydney Medical School, The University of Sydney, Sydney, NSW, Australia, [3]Westmead Hospital, Sydney, NSW, Australia, [4]Department of Anatomical and Cellular Pathology at the Chinese University of Hong Kong, Hong Kong, Hong Kong, [5]Royal Prince Alfred Hospital, Sydney, NSW, Australia, [6]Melanoma Institute Australia, The University of Sydney, North Sydney, NSW, Australia.

Cancer immunotherapy targeting immune checkpoints and inhibitory molecules is a promising treatment option for many types of cancer. However, durable response are seen in less than 40% of patients and many experience immune-related adverse events such as the development auto-immune disease. Recent advances in tumour immunology research have found that certain immune cell subsets such as CD103+ tumour-resident CD8+ T cells are associated with improved survival in some cancers. It has become clear that the more we understand about the immune profile of the tumour micro-environment (TME) the more we will be able to predict a patients response and therefore direct the choice of immune-therapy in the clinic. In order to profile the resident immune cells and presence of immunotherapy targets in the human TME, we employed a technique that could evaluate this utilising both high-dimensional mass cytometry and spatial analysis, imaging mass cytometry (IMC). Using formalin fixed paraffin embedded human tumour tissues we designed an IMC panel to enable high-throughput immune profiling of prospectively collected tumours. This study provides novel information about the immune profile of the TME in multiple cancers. These findings may be crucial in determining better strategies for treatment of cancer by immunotherapies.

Intratumoral T cell exhaustion in a murine pancreatic cancer model: Influence of induced regulatory T cells

A. Hanlon[1], *V. Lutz*[1], *E. Landmann*[1], *M. Huber*[2], *M. Buchholz*[1], *T. Gress*[1], *C. Bauer*[1];
[1]*Division of Gastroenterology, Endocrinology, Infectiology and Metabolism, University Hospital Giessen and Marburg, Philipps University Marburg, Marburg, Germany,* [2]*Institute for Medical Microbiology and Hygiene, Philipps University Marburg, Marburg, Germany.*

Introduction: Pancreatic cancer is one of the most aggressive malignancies with poor prognosis where new therapeutic approaches are needed. T cell exhaustion plays a critical role in at least some subtypes of pancreatic carcinoma. This $CD8^+$ cytotoxic T cell (CTL) dysfunction has evolved as a paradigm to understand tumor escape from immune surveillance. We have set up a model system of adoptive T cell transfer in order to elucidate mechanisms of T cellular exhaustion and of ways to disinhibit intratumoral T cells.
Methods: We work with the OVA model antigen system. Antigen-specific CTL were generated from transgenic OT-I mice and transferred into tumor-bearing mice. To investigate the role of induced regulatory T cells (iTreg) on our CTL, antigen-specific iTreg were co-transferred. Beside therapeutic response, ex vivo parameters were characterized, such as expression of coinhibitory receptors (PD-1, TIM-3, LAG-3, CTLA-4), Lamp-1-associated degranulation and intracellular production of IFN-γ and TNF.
Results: We have established growth chracteristics of PancOVA and intratumoral infiltration kinetics of effector CTL. Additionally, in vitro and in vivo characterization of iTreg behavior was performed and also their effect on cytotoxic T cell responses investigated. The induction of T cellular dysfunction was exposed as an active, antigen- and contact-dependent process.
Conclusions: We intend to validate our results in an orthotopic tumor model to approximate to real cancer conditions. Furthermore, mechanisms of iTreg-induced T cell dysfunction will be investigated using FOXP3-IRES-mRFP (FIR) OT-II mice in an in vivo/in situ approach using a dorsal skinfold chamber model to visualize intratumoral T cells.

$CXCR5^+PD\text{-}1^+$ $CD8^+$ T-cells in human blood and lymph nodes

T. Hofland[1], *E. B. Remmerswaal*[1], *F. Bemelman*[1], *M. Levin*[2], *A. P. Kater*[1,3], *S. H. Tonino*[1,3];
[1]*AMC Amsterdam, Amsterdam, Netherlands,* [2]*Albert Schweitzer Hospital, Dordrecht, Netherlands,* [3]*LYMMCARE, Amsterdam, Netherlands.*

Re-invigorating exhausted T-cells with immune checkpoint blockade (ICB) has shown promising efficacy in the treatment of several malignancies. However, response rates vary between patients, and it's unclear which parameters predict clinical response to ICB. Recently, a subset of $CXCR5^+PD\text{-}1^+CD8^+$ T-cells has been identified in mice. This memory-like population appears to be crucial for the essential expansion of CD8+ T-cells during ICB, and is characterized by the expression of transcription factor Tcf1. Although $CXCR5^+$ $CD8^+$ T-cells have been identified in humans, it's unknown whether these cells have a similar phenotype and function as described in mice, and play a similar important role during ICB. To investigate $CXCR5^+$ $CD8^+$ T-cells, we analyzed human peripheral blood and lymph node samples from healthy donors with flow cytometry. We found $CXCR5^+PD\text{-}1^+$ $CD8^+$ T-cells to be more frequent in lymph nodes. $CXCR5^+PD\text{-}1^+$ $CD8^+$ T-cells resemble antigen-experienced memory-like cells, with high expression of KLRG1, CD127, granzyme K, and Eomes, and low expression of effector molecules like granzyme B and T-bet. They also express high levels of Tcf1, which is in accordance with the phenotype described in mice studies. We found $CXCR5^+PD\text{-}1^+$ $CD8^+$ T-cells within the EBV-specific T-cell population, but not within the FLU-specific T-cell compartment, showing that chronic antigens are required for this population to develop. To study their functionality, we are currently analyzing the transcriptome and functional capabilities of these cells in relation to ICB. These results can further elucidate the role for $CXCR5^+PD\text{-}1^+$ $CD8^+$ T-cells in clinical responses during ICB.

P.B4.01.08

TCR-activated T cells release cytokines that induce MDSC to express arginase-1, which does not suppress T cell proliferation

K. S. Kidder*;*
Georgia State University, Atlanta, United States.

Although previous reports suggest that tumor-induced myeloid-derived suppressor cells (MDSC) inhibit T cell proliferation by L-arginine depletion through arginase-1 activity, we herein show that arginase-1 is neither inherently expressed in MDSC nor required for MDSC-mediated inhibition of T cell proliferation. Employing Percoll density gradient centrifugation, large expansions of MDSC in the bone marrow of tumor-bearing mice were isolated and exhibit potent inhibition on T cell proliferation induced via TCR-ligation, Concanavalin A, PMA plus ionomycin, or IL-2. These MDSC, though suppressive toward T cell proliferation, do not hinder TCR-induced IFNγ secretion or granzyme B expression. Despite effectively inhibiting of T cell proliferation, both G- and M-MDSC exhibit no arginase-1 expression; however, arginase-1 can be induced by exposure to TCR-activated T cells or their culture medium, but not by T cells activated by other means or growing tumor cells. Western blot analysis revealed that TCR-activated T cells confer arginase-1 expression in MDSC by secreting cytokines that manifest as two distinct signaling-relay axes, IL-6-to-IL-4 or GM-CSF/IL-4-to-IL-10. Specifically, IL-6 signaling increases IL-4R on MDSC, enabling IL-4 to induce arginase-1 expression; similarly, GM-CSF in concert with IL-4 induces IL-10R, allowing IL-10-mediated induction. Surprisingly, our data demonstrate that the induction of arginase-1 is not conducive, per se, for MDSC-mediated inhibition of T cell proliferation, as neither supplementation of L-arginine nor arginase-1 inhibitor rescue T cell proliferation. Furthermore, this inhibition relies upon direct cell contact that is not dampened by PD-L1 blockade or SIRPα deficiency.

P.B4.01.09

CTLA-4 (CD152) impairs cytotoxic T-lymphocyte responses via PDCD4 induction

H. Lingel[1], *J. Wissing*[2], *A. Arra*[1], *F. Klawonn*[2], *M. Pierau*[1], *L. Jänsch*[2], *M. C. Brunner-Weinzierl*[1];
[1]*Otto-von-Guericke University, Magdeburg, Germany,* [2]*Helmholtz Centre for Infection Research, Braunschweig, Germany.*

Inhibitory T-cell surface receptors like Cytotoxic T-lymphocyte-associated Protein-4 (CTLA4) and Programmed cell death 1 (PD-1) play a crucial role in the termination of adaptive immune responses and promote the functionally impaired state of $CD8^+$ T cell exhaustion. Their blockade is being used in immune-checkpoint therapy as a promising approach to restore effective T-cell responses against tumors. However, the intracellular pathways triggered by these receptors still remain incompletely understood. To determine target molecules downstream of CTLA-4, an accurate mass spectrometry analysis was performed. The dataset revealed that the engagement of CTLA-4 led to altered phosphorylation of proteins involved in T-cell signaling, DNA replication, RNA processing and microtubule polymerization. Beside other targets, a CTLA-4-induced expression of the translational inhibitor Programmed cell death 4 (PDCD4) could be revealed and characterized. This mechanism was responsible for the restriction of cytotoxic T-lymphocyte effector functions. Accordingly, the deficiency of PDCD4 led to superior control of melanoma growth *in vivo*. Furthermore, identified upstream elements suggest this pathway as a part of a redundant mechanism that is activated by both CTLA-4 and PD-1. These findings point out that targeting of PDCD4 could provide a potent strategy to improve anti-tumor immunotherapy.

P.B4.01.10

Differentiation of CD8 T cells in the tumor microenvironment

A. Moustaki, *S. Alli, B. Youngblood;*
St Jude Children's Research Hospital, Memphis, United States.

Introduction: Differentiation of CD8 T cells to effector, memory, or exhausted state has been well characterized during viral infection, but it's poorly understood during tumorigenesis. Tumor infiltrating CD8 T cells reside in and are adapted to a unique, cellulary diverse and rapidly evolving environment, which delivers highly immunosuppressive signals. Here we investigate the role of tumor microenvironment in CD8 T cell activation in response to tumor antigens.
Methods: To monitor activation of tumor-specific CD8 T cells, we stably expressed the dominant MHCI-restricted LCMV-derived epitope GP33, in MC38 tumor cells. Co-expression of a reporter gene encoding for mCherry allows for detection of antigen presentation.
Results: Subcutaneous inoculation of MC38-GP33 cells into immunocompetent syngeneic hosts resulted in a massive expansion of highly functional CD8 effector cells in peripheral lymphoid tissues. However, GP33-reactive tumor infiltrating CD8 cells exhibit reduced polyfunctionality. Tumor cells genetically modified to express low levels of MHCI molecules were able to elicit a weakened immune response as manifested by the decreased frequency of tumor-reactive CD8 T cells. However, the reduced antigen presentation by tumor cells had no impact on the TME-induced dysfunction of CD8 T cells. Further characterization of MC38-GP33 tumors revealed the tumor infiltrating monocytes/macrophages as a source of tumor antigen cross-presentation, which coincidence with higher expression levels of PDL1 by the same cells.
Conclusions: Our findings highlight the importance of antigen and TME in the suppression of CD8 T cells function. We also identify tumor associated monocytes/macrophages as a potential driver of antigen-induced CD8 T cell exhaustion.

Intratumoral CD4+ T cells with tissue-resident features resist exhaustion in non-small cell lung cancer

A. E. Oja[1], *B. Piet*[2], *D. van der Zwan*[1], *H. Blaauwgeers*[2], *M. Mensink*[3], *R. Stark*[1], *J. Borst*[3], *M. Nolte*[1], *R. van Lier*[1], *P. Hombrink*[1];
[1]*Sanquin Research, Amsterdam, Netherlands,* [2]*OLVG, Amsterdam, Netherlands,* [3]*The Netherlands Cancer Institute, Amsterdam, Netherlands.*

Resident memory T cells (T_{RM}) inhabit peripheral tissues and are critical for protection against localized infections. Recently, it has become evident that CD103 expressing T_{RM} are not only important in combating secondary infections, but also for the elimination of tumor cells. In several solid cancers, intratumoral CD103+CD8+ tumor infiltrating lymphocytes (TILs), with T_{RM} properties, are a positive prognostic marker. To better understand the role of T_{RM} in tumors, we performed a detailed characterization of CD8+ and CD4+ TIL phenotype and functional properties in non-small cell lung cancer (NSCLC). We found comparable levels of CD8+ and CD4+ T cell infiltrates in tumors, but observed a sharp contrast in T_{RM} ratios compared to surrounding lung tissue. While CD103+CD8+ T cells were enriched in tumors, CD103+CD4+ T cell frequencies were decreased when compared to surrounding lung tissue. In line with the immunomodulatory role of the tumor microenvironment, CD8+ and CD4+ TILs expressed high levels of co-inhibitory receptors, such as 2B4, CTLA4, and PD1, with the highest levels found on CD103 expressing TILs. Yet, CD103+CD4+ TILs proved to be the most potent producers of TNF-α and IFN-γ, while other CD4+ subsets and the majority of CD8+ TILs lacked such cytokine production. Furthermore, we found TILs with resident-memory features to express more costimulatory receptors, CD27 and CD28, when compared to lung T_{RM} suggesting a less differentiated phenotype. Agonistic triggering of these receptors improved cytokine production of TILs. Our findings provide a rationale to target CD103+CD4+ TILs to improve the efficacy of immunotherapies and cancer vaccines.

P.B4.01.12

Identification of potential immunological markers associated with the PD1 checkpoint blockade Nivolumab in non small cell lung cancer patients

S. Ottonello[1], *P. Carrega*[2], *I. Cossu*[3], *C. Genova*[4], *V. Fontana*[5], *F. Grossi*[4], *L. Moretta*[6], *M. Mingari*[7], *G. Pietra*[8];
[1]*Center of Excellence for Biomedical Research, Department of Experimental Medicine University of Genoa, Genoa, Italy,* [2]*Laboratory of Immunology and Biotherapy, Department of Human Pathology, University of Messina, Messina, Italy,* [3]*Immunology Unit, San Martino Hospital, Genoa, Italy,* [4]*Lung Cancer Unit, San Martino Hospital, Genoa, Italy,* [5]*Clinical Epidemiology Unit, San Martino Hospital, Genoa, Italy,* [6]*Immunology Area, Pediatric Hospital Bambino Gesù, Rome, Italy,* [7]*Center of Excellence for Biomedical Research, Department of Experimental Medicine University of Genoa, Immunology Unit, San Martino Hospital, Genoa, Italy,* [8]*Department of Experimental Medicine University of Genoa, Immunology Unit, San Martino Hospital, Genoa, Italy.*

PD-1 blockade represents a breakthrough in NSCLC therapy. However, to date robust biomarkers associated with response have not been identified. In this study we assessed whether particular immunological signatures evaluated over the course of treatment might be predictive of response to Nivolumab. We performed a deep phenotypic analysis in longitudinal blood samples of 73 advanced NSCLC patients treated with Nivolumab, collected at baseline and every 2 weeks before each therapy cycle. We examined the frequencies of several peripheral blood lymphocyte subpopulations ($CD4^+$ T cells, $CD8^+$ T cells, exhausted CD8+ T cells, NK cells) and their PD-1 expression. Cytometry data were then correlated with overall survival (OS) and clinical response as assessed by following RECIST. The higher % of $CD3^+$ T cells at baseline correlated with longer OS (*P =0.048*). In contrast, a baseline higher % of $PD1^+CD3^+$ T cells (*P =0.048)*, as well as of $PD1^+CD8^+$ T cells correlated with shorter OS (P=0.034). We next evaluated the frequency and the kinetics of exhausted $CD8^+$ T cells on therapy. Interestingly, we observed a lower frequency of exhausted $CD8^+$ T cells in pretreatment samples of PR+SD patients compared with PD patients (P=0.0462). In addition, in PR+SD patients, the frequency of exhausted $CD8^+$ T cells was reduced during treatment (from cycle 1 to 4) (P=<0.0001, P=0.0032, and P=0.0239, respectively*)*. Our results suggest that a higher % of PD-1 in T cells at baseline could correlate with shorter OS. Furthermore, the different amount of exhausted $CD8^+$ T cells could predict response and clinical outcome.

P.B4.01.13

Evaluation of potential factors contributing to the exhaustion of T lymphocytes in the tumor microenvironment

M. Rouault*, A. Laermanns, N. Li, J. Kim, X. Ma, E. Park;*
Advanced Cell Diagnostics, Newark, United States.

Immunosuppressive molecules and cells in the tumor microenvironment can lead to T cell dysfunction. CD8-positive cytotoxic T cells are ineffective in killing tumor cells primarily due to upregulated expression of inhibitory checkpoint molecules and decreased production of cytokines. Moreover, immune suppressive cell types and tumor associated macrophages are recruited to the TME, further establishing a suppressive immune environment. We evaluated expression profiles of immunosuppressive molecules and cells by applying RNAscope® assay and dual ISH-IHC staining. We evaluated CD8-positive cell infiltration in TME of human tissues from NSCL and ovarian cancer. Selected tissues with either high or low CD8-positive cell number were evaluated for (1) the presence of Tregs and TAMs, (2) the expression of immune checkpoint molecules PD1, PD-L1, TIM3, and LAG3, (3) the expression of immune suppressors IDO1 and TGFβ, and (4) IFNγ expression in CD8-positive subsets. CD8-high tissues expressed higher level of immune checkpoint molecules, while expression of IDO1 and TGFβ was independent of CD8-positive cell inflammation. Tregs and TAMs co-existed with IFNγ-positive CTLs in the same TME. PD1, TIM3, and LAG3 were expressed in tumor cells at lower level than in immune cells. Expression of IDO1 and TGFβ was observed in tumor cells. This study highlights the potential of RNAscope® ISH to understand the mechanisms associated with T cell dysfunction and exhaustion in TME. The RNAscope® platform is well suited for evaluating secreted factors in a cell type-specific manner and may facilitate the identification and development of biomarkers to stratify patients based on their specific cell states.

P.B4.01.14

HLA-DR in cytotoxic and regulatory T cells dictates breast cancer aggressiveness and patient response to neoadjuvant chemotherapy

D. P. Saraiva[1], *S. Braga*[1,2], *A. Jacinto*[1], *M. G. Cabral*[1,3];
[1]*CEDOC, NOVA Medical School, Lisbon, Portugal,* [2]*Instituto CUF de Oncologia, Lisbon, Portugal,* [3]*Faculdade de Engenharia da Universidade Lusófona, Lisbon, Portugal.*

Neoadjuvant chemotherapy (NACT) is the treatment option for locally advanced breast cancer (BC). However, approximately half of the patients have no response. To promptly direct non-responders to personalized therapies, there is an urgency to find a predictive biomarker of response. Tumor infiltrating lymphocytes are being appointed as biomarkers; nonetheless, tumor cells can escape the immune system, dampening CD8+ T cells (CTLs) and increasing regulatory T cells (Tregs) activation. HLA-DR, a T cell activation marker, can reflect the tumor-immune environment and be a reliable biomarker of NACT-response.
Fresh BC biopsies, surgical specimens and blood were immunophenotyped by flow cytometry. Peripheral blood mononuclear cells (PBMCs) were isolated and cultured under canonical stimuli.
BC with no metastasis in the lymph nodes have $HLA\text{-}DR^{hi}$ CTLs (p=0.003) and $HLA\text{-}DR^{lo}$ Tregs (p=0.002), when compared to node positive, although the average percentage of lymphocytes and myelocytes are similar between groups. Biopsies from NACT-responders have $HLA\text{-}DR^{hi}$ CTLs (p=0.0006) and $HLA\text{-}DR^{lo}$ Tregs (p=0.0002). HLA-DR+ CTLs upregulate IFN-γ, Granzyme B, Perforin, TNF-α and Eomes, essential for the effector function. $HLA\text{-}DR^{hi}$ CTLs negatively correlate with pro-tumorigenesis molecules - TGF-β, PD-L1, IL-6, IL-1β and IL-8 (p<0.005); while $HLA\text{-}DR^{hi}$ Tregs positively correlate with them and also with IL-10 (p<0.005). HLA-DR in tumor T cells correlates with its level in systemic T cells (CTLs: r=0.58, p=0.001; Tregs: r=0.65, p=0.0002). PBMCs stimulated *in vitro* from NACT-responders reveal higher IFN-γ and lower IL-10 (p<0.05).
HLA-DR levels in T cells can be used as biomarker of BC aggressiveness and NACT-response with the advantage of peripheral detection.

P.B4.01.15

Tumor-infiltrating Mucosa-Associated Invariant T (MAIT) cells express cytotoxic effector molecules and kill target cells

P. Sundström[1], *L. Szeponik*[1], *F. Ahlmanner*[1], *M. Sundquist*[1], *J. S. Wong*[2,3], *E. Bexe Lindskog*[4], *B. Gustavsson*[4], *M. Quiding-Järbrink*[1];
[1]*Dept of Microbiology and Immunology, Sahlgrenska Academy at University of Gothenburg, Sweden,* [2]*Department of Pathology, National University Hospital, Singapore, Singapore,* [3]*Department of Microbiology, National University of Singapore, Singapore,* [4]*Dept of Surgery, Sahlgrenska Academy at University of Gothenburg, Sweden.*

Mucosa-associated invariant T (MAIT) cells all express a semi-invariable T cell receptor recognizing microbial metabolites presented on the MHC class I-like molecule MR1. Upon activation, they rapidly secrete cytokines and increase their cytotoxic potential. We showed recently that MAIT cells accumulate in human colon adenocarcinomas, but that their ability to produce IFN-γ upon polyclonal stimulation is compromised. Here, we investigated the cytotoxic potential of MAIT cells in colon adenocarcinoma patients, and to what extent it may be affected by the tumor microenvironment. MAIT cells were identified by flow cytometry and analyzed for their expression of cytotoxic effector molecules and degranulation. Polyclonal, T cell receptor-, and cytokine-mediated activation of MAIT cells from tumors induced increased Granzyme B, while degranulation was mainly seen in response to cognate antigen recognition. The cytotoxic potential of tumor-associated MAIT cells was similar to that of MAIT cells from unaffected colon. Furthermore, tumor infiltrating pre-activated MAIT cells killed antigen-presenting target cells. MAIT cells were also identified by immunofluorescence in direct contact with tumor cells in sections from colon cancer specimens. Taken together, our data demonstrate that tumor-associated MAIT cells from colon tumors have potent cytotoxic function and are not compromised in this regard compared to MAIT cells from the unaffected colon. We conclude that MAIT cells may contribute significantly to the protective immune response to tumors, both by secretion of Th1-associated cytokines and by direct killing of tumor cells.

A novel CD3/BCMA bispecific antibody for the treatment of multiple myeloma and plasma cell disorders selectively activates effector T cells with improved safety

*M. Farinacci[1,2,3], K. Juelke[1,2,3], B. Buelow[4], **W. vanSchooten**[4], R. Buelow[4], H. Volk[2,3];*
[1]Core Unit Immunocheck, Charite University of Medicine, Berlin, Germany, [2]Institute for Medical Immunology, Charite´ University of Medicine, Berlin, Germany, [3]Berlin-Brandenburg Center for Regenerative Therapies, Charite´ University of Medicine, Berlin, Germany, [4]Teneobio Inc., Menlo Park, United States.

Introduction: Multiple myeloma (MM) is a cancer of plasma cells, and the second most common hematological malignancy. A promising therapeutic in development for MM is TNB-383B, an antiCD3*BCMA bispecific antibody. This T cell engager combines high tumor specificity (anti-BCMA arm) with a selective novel T cell activating anti-CD3 arm. Efficacious T cell engagers with limited toxicity will allow combination therapies with other immune-modulators in MM and expansion into non-malign "plasma cell" disorders such as several autoimmune diseases.
Material and methods: TNB-383B was tested in standard in vivo and in vitro tumor models. To assess the potential risk of cytokine release syndrome (CRS) human peripheral blood mononuclear cells from healthy volunteers (n=3) were pre-incubated for 48 hours at high densities and, subsequently, incubated with increasing concentrations of TNB-383B overnight in the presence of recombinant BCMA protein coated to plastic. OKT3 and a T cell engaging bispecific with a high-affinity anti-CD3 arm were used throughout these experiments as positive controls.
Results: Both TNB-383B and the positive control T cell engager (PC) mediated tumor cell lysis in in vitro and animal tumor models. In vitro analysis of upregulation of CD69 and CD137 on T cells showed that TNB-383B, in contrast to PC, preferentially activated $CD4^+$ and $CD8^+$ T effector cells relative to $CD4^+$ T regulatory cells. Remarkably, T-cell activation by TNB-383B was associated with low cytokine production compared to PC.
Conclusions: TNB-383B represents a novel immunotherapeutic with potentially improved safety and efficacy for the treatment of MM and pathogenic long-lived plasma cells.

P.B4.01.17

Prognostic implications of tissue resident memory T cells in human melanoma development

***M. Willemsen**[1,2,3], G. Krebbers[1,2,3], F. R. Kasiem[1], T. R. Matos[1,3], R. Luiten[1,2,3];*
[1]Academic Medical Center, Amsterdam, Netherlands, [2]Cancer Center Amsterdam, Amsterdam, Netherlands, [3]Amsterdam Infection & Immunity Institute, Amsterdam, Netherlands.

Tissue-resident memory T (T_{RM}) cells permanently reside in epithelial barrier tissues and can respond rapidly upon reinfection. Recently, expression of the retention integrin very late antigen (VLA)-1, by vaccine-induced T cells was found to correlate with longer patient survival in melanoma. More interestingly, VLA-1 was frequently co-expressed with tissue residence markers, such as CD69 and CD103. Furthermore, CD103-dependent T_{RM} cells seem to play a key role in sustaining immunity to melanoma, indicating a crucial function for T_{RM} cells in antitumor immunity. Yet, its role in melanoma development remains unknown and might be relevant, for there are numerous neoplastic lesions in the skin that rarely become overt cancers. This research, therefore, aimed to identify the prognostic relevance of skin resident memory T cells in human melanomagenesis.
Healthy skin, naevocellulares nevi, dysplastic nevi, lentigo maligna, lentigo maligna melanoma, nodular primary melanoma, superficially spreading primary melanoma and cutaneous metastatic melanoma (all n=7) were analyzed by immunohistochemistry for the presence of T_{RM} cells. The prognostic significance of CD103 and VLA-1 expression on T_{RM} cells was also investigated.
The presence of T_{RM} cells may serve as prognostic marker for disease progression. Furthermore, intratumoral T_{RM} cells, especially in primary melanoma, may potentially be a good effector in cancer immunotherapies.

P.B4.01.18

General outlook of the immune surveillance status in oncourological patients

***P. Yakovlev**[1], D. Klyushyn[2];*
[1]O.Bogomolets National Medical University, Kyiv, Ukraine, [2]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

Cancer initiation, progression and immune surveillance recruit lymphocytes as common key cellular players. The progression of the cancer occurs against the immunocompromised status in the patient. Much attention is being paid to the cellular branch of immunity in cancer patients either as marker or therapeutic target. Aim. To analyze the status of the immune surveillance system in patients with urinary tract cancer. Materials and methods. The retrospective analysis of pretreatment immunogram of 90 patients staged I-IV cancer of urinary bladder, kidney and prostate scheduled for definitive surgical treatment at the department of urology in 2015-2018 was performed. Levels of lymphocytes CD3+, CD4+, CD8+, CD3+56+16+, CD3-56+16+, CD19+, CD14+, and immune-regulatory index were compared to normal range disregard of the cancer stage. Results. Majority of immune cell parameters fell below the normal range: CD14+ were lower in 80% of patients, CD19+ in 76%, CD4+ in 42%, CD3+ in 40%, CD3+56+16+ in 20%, CD8+ in 15%, CD3-56+16+ in 12%, and IRI - in 40%. Elevation in immune cells content was observed: with CD3+56+16+ in 15%, CD8+ in 12%, and CD3-56+16+ in 12% of patients, mostly in advanced cancer patients. Conclusion. Vast deficiency in B-cell immunity was observed in majority (76%) of urological cancer patients, and prevails such of the T-cell branch. The T-cells quantitative fluctuations present the diverse pattern, with elevation above normal range of cytotoxic, NK-cells, and T-suppressors mostly in patients with advanced urinary cancer.

P.B4.01.19

Evaluation of autologous tumor-antigen specific $CD8^+$ T-cell responses to $BRAF^{V600E}$ melanoma cells in the course of MAPKi treatment

*N. Pieper[1], F. N. Harbers[1], A. Zaremba[1], M. Schwamborn[1], S. Lübcke[2], B. Schrörs[2], A. Sucker[1], V. Lennerz[2], T. Wölfel[2], D. Schadendorf[1], A. Paschen[1], **F. Zhao**[1];*
[1]University Hospital Essen, Essen, Germany, [2]University Medical Center, Johannes Gutenberg University Mainz, Mainz, Germany.

Expressed in approximately 50% of melanomas, the V600 mutation in the *BRAF* gene promotes tumor proliferation via constitutive activation of BRAF-MEK-ERK in the MAPK signaling pathway. Significant clinical responses in patients with advanced metastatic melanoma can be achieved by targeting this axis using MAPK inhibitors (MAPKi), such as BRAFi and MEKi as single or combination therapy. But over time the majorities of treated patients acquire resistance and experience disease progression. Salvage therapies for resistant patients often involve immunotherapies, e.g. immune checkpoint blockade to reinvigorate tumor-reactive T cells and generate sustained clinical responses. However, the impact of MAPKi on melanoma immunogenicity over time remains largely unknown. For the development of an optimal treatment protocol, we evaluated the recognition of MAPKi-exposed melanoma cells by autologous tumor infiltrating $CD8^+$ T-cells *in vitro* and regularly observed the evolution of melanoma resistance to the pre-existing tumor-specific T-cell repertoire during prolonged BRAFi treatment in different patient models. While efficiently recognizing short-term BRAFi-treated melanoma cells, TILs were less responsive towards long-term exposed tumor cells. Similar results were obtained with four out of five $CD8^+$ T-cell clones against three shared antigens and one mutated neoantigen due to a time-dependent downregulation of their respective target antigens. Moreover, T-cell resistance evolved not only after mono-treatment of melanoma cells with BRAFi but also after combined BRAFi/MEKi exposure. Our observation that T cell-resistance coevolves with drug-resistance in melanoma cells suggests that BRAFi application preceding T cell-based immunotherapy might be disadvantageous.

P.B4.01.20

Multifactorial contribution to follicular helper bias in the CD4 T cell response to a retroviral antigen

***L. Danelli**, G. Kassiotis;*
The Francis Crick Institute, London, United Kingdom.

The extent of CD4 T cell differentiation during an immune response is influenced by multiple intrinsic and extrinsic factors resulting in the generation of a diverse array of T helper (Th) cell phenotypes. Here, we analysed the response of CD4 T cells reactive with a murine retroviral envelope glycoprotein model antigen and identified an uncommonly strong bias towards follicular helper (Tfh) commitment and impaired Th1 differentiation in its natural context during retroviral infection. Comprehensive quantitation of variables known to influence CD4 T cell fate decision suggested that Tfh differentiation closely correlates with persistent TCR signalling, irrespective of TCR clonotypic avidity. However, strong TCR signalling leading to TCR downregulation and induction of LAG3 expression further restrained CD4 T cell commitment and differentiation. The response to the same antigen in the context of altered lymphocyte alteration and in different immunisation regimens generated a variable balance of Tfh and Th1 cells, suggesting that the stunted Th1 differentiation could be due to limited IL-2 availability during retroviral infection. These results highlight the potent contribution of T cell extrinsic variables in determining the relative balance of Tfh and Th1 responses according to the nature of the antigenic stimulus.

P.B4.01.21

Control of cytotoxic lymphocyte anti-tumor functions through CD226 expression

*M. Weulersse, A. C. Pichler, M. Joubert, H. Avet-Loiseau, **L. Martinet**;*
Cancer Research Center of Toulouse, Toulouse, France.

Although $CD8^+$ T lymphocytes activation mainly relies on TCR recognition of antigenic peptides presented by MHC-I, numerous signals transmitted through activation and inhibitory receptors impact their functions. Promising results obtained by immune checkpoint blockers in cancer highlight the necessity of defining receptors that control cytotoxic lymphocyte anti-tumor reactivity. CD226 (DNAM-1) is an adhesion molecule stimulating $CD8^+$ T cell cytotoxicity against target cells expressing its ligands, CD112 and CD155. Despite the recent defects associated with the absence of this molecule in several malignancies, the molecular role of CD226 in cytotoxic T lymphocyte biology remains poorly understood to date. We recently identified two distinct CD8+ T cells populations based on CD226 expression. We found that unlike the $CD226^+$ counterparts, the $CD226^-$ $CD8^+$ T cells population have functional defects in response to TCR stimulation including lower proliferation, pro-inflammatory cytokine production and cytolytic activity. Global transcriptional analysis and gene transfer experiments revealed that $CD8^+$ T cells effector program initiated upon TCR stimulation requires CD226 expression.

Indeed, CD226 absence leads to reduced phosphorylation of key downstream TCR signaling proteins and lower calcium influx highlighting an unsuspected role for CD226 in TCR signaling. Finally, we found that CD226$^-$ T cells with reduced effector functions accumulate in Human cancer patients and that CD226 loss may be involved in immune exhaustion and cancer escape. P.B4.02 T-cell activation and exhaustion - Part 2

P.B4.02.01

Flow cytometry as a diagnostic tool to detect cellular and functional defects in patients with primary immunodeficiencies

***M. Bitar**, A. Boldt, U. Sack;*
Institute of Clinical Immunology, Leipzig, Germany.

Primary immunodeficiency diseases (PIDs) are genetic disorders, that mostly cause susceptibility to infections and are sometimes associated with autoimmune and malignant diseases. Mutations can affect cells and molecules of the innate as well as the adaptive immune system (T and/or B cells). Here, we present the use of flow cytometry in the diagnostic cascade to identify possible PID. First, simple immunophenotyping of B-, NK-, CD4+, CD8+, double negative T cells and analysis of HLA-DR/CD38 is recommended to identify severe abnormalities in lymphocyte subsets e.g. in Brutons Disease or SCID. Further differentiation (naïve, memory, recent thymic emigrants, activation markers etc.) of T-, B- and NK-cell subsets in a second step is necessary to differentiate PID with defects in the subsets such as CVID or DiGeorge syndrome and many others. Based on that well defined immunophenotyping, functional analysis of leukocytes can be performed in a third step.
For instance, flow cytometry is a useful tool for measurement of (1) T- and B-cell proliferation in case of different forms of lymphopenia or unclear deficiencies in lymphocyte subsets, (2) phagocytosis/oxidative burst in chronic granulomatous disease, (3) loss-of-function STAT1 mutation and chronic mucocutaneous candidiasis CMC (gain-of-function gene mutations in STAT1), (4) STAT3 phosphorylation to distinguish between different Hyper-IgE syndrome (HIES) traits (autosomal dominant with STAT3 mutation in contrast to autosomal-recessive without STAT3 mutation).
In conclusion, flow cytometry is well-standardized and a flexible method for investigation of most relevant leukocyte subsets and their immune function. Therefore, FCM should be considered as an important tool in PID-diagnostics.

P.B4.02.02

Function of T-bet and Eomes in CTLs - an evolutionary approach

***J. Fixemer**[1], J. F. Hummel[1], T. Kögl[2], K. Weißert[2], C. Klose[3], S. Arnold[4], P. Aichele[2], Y. Tanriver[1];*
[1]Institute of Medical Microbiology and Hygiene, University Medical Center Freiburg, Freiburg, Germany, [2]Institute of Medical Microbiology and Hygiene, Department of Immunology, Freiburg, Germany, [3]Jill Roberts Institute for Research in Inflammatory Bowel Disease, Cornell University, New York, United States, [4]Institute of Experimental and Clinical Pharmacology and Toxicology, Freiburg, Germany.

The two T-box transcription factors *Tbx21* (encoding for T-bet) and *Eomesodermin* (encoding for Eomes) have arisen from duplication of a single ancestral gene. In contrast to their ancestor both have various functions in adaptive immunity indicating a benefit for the host throughout evolution. Usage of knock-out mice for T-bet or Eomes revealed redundant and non-redundant functions in T cells. However, recent studies emphasized that transcription factors act in highly context and cell specific networks.
To dissect the individual contributions of T-bet and Eomes to the differentiation of T cells we developed a novel mouse model. We used TALEN technology to knock-in *Eomesodermin* into the first exon of *Tbx21* to ensure the expression of *Eomesodermin* under complete transcriptional control of *Tbx21*.
By infecting *Tbx21*$^{+/+}$, *Tbx21*$^{-/-}$ and *Tbx21*$^{Eomes/Eomes}$ mice with 200 pfu LCMV WE we use FACS technology to compare transcriptional activities of *Tbx21* and *Eomesodermin* on the protein level in T cells at day 8 and 30 post infection. We point out that T-bet is essential for expansion and cytotoxicity of CTLs and that Eomes compensates poorly for T-bet on an overall level in T cells. In conclusion our data shed light on the evolutionary pressure leading to the genesis of T-bet as a master regulator of type 1 immune responses.

P.B4.02.03

TLR2 and TLR7-mediated co-stimulation differently enhance cytokine production of cytotoxic T cells

***J. J. Freen-van Heeren**, F. Salerno, A. Guislain, M. Wolkers;*
Sanquin Research, Amsterdam, Netherlands.

Optimal T cell activation requires antigen recognition through the T cell receptor (TCR), engagement of costimulatory molecules, and cytokines. T cells can also directly recognize pathogen associated molecular patterns through the expression of toll-like receptors (TLRs). Whether TLR ligands can provide costimulatory signals and enhance antigen-driven T cell activation is not well understood. Here, we show that TLR2 and TLR7 ligands potently lower the antigen threshold for cytokine production in T cells. To investigate how TLR triggering supports cytokine production, we adapted the protocol for flow cytometry-based fluorescence *in situ* hybridization (Flow-FISH) to mouse T cells. The simultaneous detection of cytokine mRNA and protein with single-cell resolution revealed that TLR triggering primarily drives *de novo* mRNA transcription. *Ifng* mRNA stabilization only occurs when the TCR is engaged. TLR2- but not TLR7-mediated costimulation can potentiate mRNA stability at low antigen levels. Importantly, TLR2 costimulation also increases the percentage of polyfunctional T cells. In conclusion, TLR-mediated costimulation effectively supports and potentiates T cell effector function.

Effect of transition metal containing particulate matter (TMCPM) on the activity of human immune cells

***A. Gałuszka**, M. Stec, M. Siedlar, J. Baran;*
Department of Clinical Immunology, Institute of Pediatrics, Jagiellonian University Medical College, Cracow, Poland.

In recent years, significant increase in air pollutions seriously impacts the human health. Growing evidence supports the role of various environmental agents in the breakdown of tolerance leading to inflammatory reaction via numerous mechanisms. The aim of our study was to determine the effect of TMCPM on antigen presenting capacity of monocytes and production of pro-inflammatory cytokines, as well as on the activity of CD4+ T cell subsets.
Two different preparations of TMCPM were used in the study: NIST (SRM 1648a- standard urban particulate matter) and LAP (NIST 1648a treated with a low-temperature plasma). Antigen presenting capacity of monocytes, production of reactive oxygen species (ROS) and pro-inflammatory cytokines (IL-1β, IL-6, IL-8, TNF), mitochondrial membrane potential and viability of monocytes were examined after exposure to TMCPM. In case of CD4+ T lymphocyte subpopulations (Th1, Th2, Th17, Treg), their relative amount (percentage) was evaluated after culture with TMCPM.
Decreased capacity of monocytes to present antigen to T lymphocytes and increased production of pro-inflammatory cytokines and ROS induced by TMCPM has been observed. Production of ROS caused decrease of mitochondrial membrane potential and lowers viability of monocytes. In case of T lymphocytes, the level of Th1 and Th17 cells increased, while the percentage of Treg cells decreased after exposure to TMCPM.
TMCPM treatment alters antigen presenting capacity of human monocytes, induces production of proinflammatory cytokines and upsets the balance of Th1/Th2 and Treg/Th17 cells, promoting pro-inflammatory activity of Th subsets.
This study was supported by grant from the NCN in Poland no. 2015/16/WST5/00005.

P.B4.02.05

Regulation of innate-like T cell activation by IL-32

***J. P. Hagel**[1], K. Powell[1], H. Mehta[1], P. Phalora[1], T. Leng[1], F. M. Buffa[2], P. Klenerman[1,3], C. B. Willberg[1,3];*
[1]The Peter Medawar Building for Pathogen Research, University of Oxford, Oxford, United Kingdom, [2]Computational Biology and Integrative Genomics, Department of Oncology, University of Oxford, Oxford, United Kingdom, [3]NIHR Biomedical Research Centre, University of Oxford, Oxford, United Kingdom.

Natural Killer (NK) and innate-like T cells, including the mucosal-associated invariant T (MAIT) cell subset, share the ability to respond to cytokines such as IL-12 and IL-18. A novel pluripotent cytokine, IL-32, has been reported to modulate NK cell responses to cytokine-induced activation, but its effect on MAIT cells is currently unknown.
We show IL-32 can significantly increase cytokine-mediated IFNγ- and Granzyme B-expression in CD161++ T cells, which includes the MAIT cell subset, within PBMCs and isolated CD8+ T cells. However, it does not have any measurable effect on TNFα-expression. Moreover, IL-32 promotes cytokine-mediated upregulation of checkpoint markers, including LAG3, PD1 and TIM3. The observed IL-32-mediated effects are time- and dose-dependent. No significant effect of IL-32 on TCR-mediated responses was detected. Blocking IL-32 during cytokine- or *E.coli*-mediated MAIT cell activation, within PBMCs, decreased MAIT cell responses significantly, indicating a crucial role for IL-32 in MAIT cell activation. Furthermore, IL-12+IL-18 stimulation of PBMCs and CD3+ T cells resulted in the expression of IL-32 by CD161++ T cells. This identifies a previously undescribed function of MAIT cells. In summary, our data show that IL-32 can promote cytokine-mediated responses of CD161++ T cells, including the MAIT cell subset. These cells are also the predominant subset of T cells expressing IL-32 in response to IL-12 and IL-18, indicating a potential feedback loop. Our findings broaden the understanding of cytokine- and bacterial-mediated activation of MAIT cells and potentially provide another reference point for future clinical intervention in disease.

P.B4.02.07

Acid Sphingomyelinase deficiency reduces cytotoxic activity of CD8+ T cells during melanoma progression

M. Hose[1], *A. Westendorf*[1], *J. Buer*[1], *A. Haimovitz-Friedman*[2], *W. Hansen*[1];
[1]*Institute of medical microbiology, University Hospital Essen, Germany,* [2]*Memorial Sloan Kettering Cancer Center, New York City, United States.*

Acid sphingomyelinase (Asm) is a hydrolyzing enzyme and part of the sphingolipid metabolism. After activation Asm converts sphingomyelin to ceramide at the outer leaflet of the plasmamembrane. Self-accumulating properties of ceramide lead to the generation of ceramide-enriched platforms. These platforms are involved in receptor clustering and thereby in intracellular signal transduction. Tumor cells were shown to have a double growth rate when implanted into Asm-deficient mice as compared to wildtype mice. The role of T cells in this differential tumor progression is still elusive. Therefore we transplanted B16-F1 melanoma cell lines s.c. into Asm-deficient mice and analyzed the activation status of tumor infiltrating lymphocytes. Moreover, we depleted different T cell subsets to dissect their specific function in our experimental setting. Our results indicate that tumor infiltrating T cells in Asm-deficient mice are less activated. Moreover, we could show that Asm-deficiency in CD8+ T cells lead to an impaired cytotoxic activity and shifts them to a suppressive phenotype within the tumor tissue. In summary our study reflects the importance of Asm abundance in T cells during melanoma progression.

P.B4.02.08

Analysis of signaling pathways triggered by costimulatory receptor GITR

Š. Janušová*, H. Draberova, A. Drobek, O. Stepanek, P. Draber;*
Institute of molecular genetics, Praha, Czech Republic.

T cell immune responses are initiated upon the recognition of an antigen presented on MHC glycoproteins by specific T cell receptors. However, for proper immune response, additional costimulatory signals are required. Several members of the TNF-receptor superfamily, such as GITR, CD27, CD137 or OX40, can provide the required costimulatory signaling, which affects T cell survival, proliferation, and effector functions. These receptors are expressed on activated T cells and, after engagement with their ligands, they trigger downstream signaling events, such as activation of NF-κB, p38 or JNK signaling pathways. The precise understanding how the costimulatory signaling is propagated would provide a potential target(s) to modulate T cell responses in autoimmune diseases or cancer. In this study we analysed molecular mechanisms modulating signaling after GITR stimulation. We aimed to find novel molecules participating in these pathways and elucidate how they affect GITR-induced signaling responses.

P.B4.02.09

TCR and inflammatory signals tune human MAIT cells to exert specific tissue repair and effector functions

T. Leng*, T. King, C. Willberg, P. Klenerman;*
Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom.

Background: Human mucosal associated invariant T (MAIT) cells are present in circulation as well as immune privileged sites such as the liver and the gut. They are a homogenous innate T cell subset with regard to their phenotypic and functional properties. Studies have illustrated an array of MAIT cell effector functions, ranging from MR1-mediated antibacterial responses to TCR-independent, cytokine-mediated antiviral properties, also proinflammatory roles in autoimmune diseases.
Aim: We aim to examine the impact of combinations of TCR-dependent and -independent signals in blood and tissue-derived human MAIT cells, and to extend our knowledge on the functional properties of this tissue-resident T cell subset.
Conclusion: We show that while TCR triggering is insufficient to drive full activation, gene expression signatures of TCR-triggered MAIT cells showed specific enrichment of tissue-repair functions (e.g. TNF, FURIN, VEGFA, CSF1). Activation of certain effector and antimicrobial functions - measured by IFN-γ release and Granzyme B expression – may be triggered further with specific innate cytokine signals, such as the TNF superfamily member TL1A. These features were reproduced in gut-derived cells. By genome-wide comparison of functional responses to TCR-dependent and independent signals, we defined novel functions of MAIT cells relevant not only to host defence but also tissue homeostasis.
Discussion: Our study suggests that MAIT cells could serve a potential therapeutic target in IBD treatment, where reducing local inflammation and promoting tissue repair is essential. We hope to gain deeper insight into relevant functions of MAIT cells by investigating transcriptional signatures of gut-derived MAIT cells.

A segment of amino acids of LAT adaptor modifies its turnover and has a dual role in TCR intracellular signaling

M. Martinez de Arbulo-Echevarria[1], *I. Narbona-Sanchez*[1], *C. Fernandez-Ponce*[1], *I. Vico-Barranco*[1], *J. Muñoz-Miranda*[1], *M. Rueda-Ygueravide*[2], *M. L. Dustin*[3], *A. Miazek*[4], *M. Duran-Ruiz*[1], *F. Garcia-Cozar*[1], *E. Aguado-Vidal*[1];
[1]*University of Cádiz, Cadiz, Spain,* [2]*Neumology and Alergic diseases, Hospital Puerta del Mar, Cadiz, Spain,* [3]*The University of Oxford, Headington, United Kingdom,* [4]*Institute of Immunology and Experimental Therapy, Wroclaw, Poland.*

Normal T cell development and function requires TCR/CD3 signaling that proceeds through the activation of protein tyrosine kinases and phosphorylation of downstream molecules. The membrane-anchored adaptor Linker for Activation of T cells (LAT) has an essential role transducing intracellular signals coming from the TCR/CD3 complex. It has been shown that upon T-cell activation LAT interacts with the tyrosine kinase Lck, leading to the inhibition of its kinase activity. The segment comprising residues 112-126 of human LAT is required for its interaction with Lck, and this domain is rich in negatively charged amino acids and is conserved among different species. In order to deepen into the functional relevance of LAT-Lck interaction, we have substituted this segment of LAT with a non-charged segment of amino acids and expressed this mutant LAT (LAT-NIL, from Not Interacting with Lck) in LAT deficient J.CaM2 cells. Substitution of this segment in LAT does not alter its expression in the plasma membrane, but prevented the activation-induced interaction with Lck. LAT-NIL mutant shows a reduced stability with regard to WT-LAT after cycloheximide treatment. J.CaM2 cells expressing this mutant form of LAT showed a statistically significant increase of proximal intracellular signals, such as phosphorylation of LAT in tyrosine residues 171 and 191, and also enhanced ZAP70 phosphorylation approaching borderline statistical significance ($p = 0.051$). Nevertheless, downstream signals such as Ca^{2+} influx or MAPK pathways were partially inhibited. Overall, our data reveal that LAT-Lck interaction constitutes a key element regulating proximal intracellular signals coming from the TCR/CD3 complex.

P.B4.02.11

Cell type dependent activation of Mucosal associated invariant T cells in the Liver

H. K. Mehta[1,2], *C. B. Willberg*[1,2], *P. Klenerman*[1,2,3];
[1]*University of Oxford, Oxfordshire, United Kingdom,* [2]*Peter Medawar Building for Pathogen Research, University of Oxford, Oxfordshire, United Kingdom,* [3]*Oxford NIHR Biomedical Research Centre, The John Radcliffe Hospital, Oxfordshire, United Kingdom.*

Mucosal associated invariant T (MAIT) cells are enriched within the Liver representing a major hepatic T cell subset. However, the ability of diverse liver parenchymal cells to interact with MAIT cells has not been well explored. We investigated the capacity of different hepatic cell lines to activate MAIT cells in response to both bacteria and viruses. Immortalized primary hepatocyte (IPH) (HHL12), hepatocellular carcinoma (HCC) (HepG2 and Huh7), stellate (TW-NT) and liver sinusoidal endothelial cell (LSEC) lines were used to stimulate MAIT cells in the presence of E.coli or hepatotropic viruses. MAIT cell activation was analysed by flow cytometry. The HCC lines, HepG2, Huh7 and IPH line, HHL12 and stellate cell lines were not able to stimulate MAIT cells after exposure to E.coli or viruses. However, the LSEC cell line is able to readily activate MAIT cells for cytokine production (IFN-γ and TNF-α). In addition to this we observed an increase in GrB production from MAIT cells upon activation. LSECs activate MAIT cells primarily through the MR1 pathway but also utilise the alternative cytokine pathway (IL-12/IL-18). HBV-infected LSECs partially activated specific MAIT cell functions. In conclusion, through their anatomical location and interaction with pathogens, together with their functional activity as antigen presenting cells, LSECs may be critical activators of MAIT cells in the liver for bacterial and potentially for viral infections.

P.B4.02.12

Differences in ERAP1 allotype function correlate with HPV epitope processing, TIL status and prognosis in HPV-positive OPSCC

E. Reeves*, E. King, G. Thomas, T. Elliott, E. James;*
University of Southampton, Southampton, United Kingdom.

Human papillomavirus (HPV) infection accounts for 5% cancers worldwide, with cervical carcinoma and oropharyngeal squamous cell carcinoma (OPSCC) being most common. Levels of tumour infiltrating lymphocytes (TIL) in HPV+ cancers are an indicator of prognosis and survival, with fewer TIL having a worse clinical outcome. Polymorphisms in the endoplasmic reticulum aminopeptidase1 (ERAP1), a key component of antigen processing trimming N-terminally extended peptides for MHC I, are associated with prognosis and outcome in cervical carcinoma. We have previously demonstrated ERAP1 to be highly polymorphic, forming distinct allotypes with functional differences. Here we investigate the contribution of ERAP1 in OPSCC. We identified a number of ERAP1 allotype combinations (co-dominantly expressed chromosomal copies) from HPV+ OPSCC patients. Assessment of trimming function revealed a range of abilities to generate the model epitope SIINFEHL from individual amino acid precursors. Further analysis revealed that the activity of ERAP1 from TIL^{high} and TIL^{low} patients correlates with the property of the amino acid extension. Importantly, the ability of ERAP1 to generate the HPV-16 $E7_{82-90}$ epitope (LLMGTLGIV) from predicted precursors also correlated with TIL status. ERAP1 allotype pairs identified in TIL^{low} patients were poor at generating the final epitopes (SIINFEHL and LLMGTLGIV), whereas those identified in TIL^{high} patients generated the epitopes efficiently. These data reveal that ERAP1 gene sequence and function stratifies with TIL levels and prognosis, suggesting that the successful presentation of HPV-16 epitopes at the cell surface, and thus a strong anti-HPV T cell response, depends on the ERAP1 allotype pairs expressed within an individual.

P.B4.02.13

Assessment of CD320 expression and vitamin B12 function on human T-cells

***R. Schmidt**, A. Dopler, M. Gerner, L. Ziegler, K. Schmetterer;*
Department of Laboratory Medicine, Vienna, Austria.

Backgorund: Vitamin B12 is an essential co-factor for proliferating and metabolically active cells. After uptake into the organism, it is bound to transport proteins in the serum. Transcobalamine II is the transport protein that delivers Cobalamine to peripheral cells, where it binds to CD320, the Transcobalamin II receptor. Vitamin B12 deficiency presents with failure of highly proliferating and metabolically active tissue resulting in megaloblastic anemia or neurological dysfunctions. The effects of vitamin B12 on activation and function of lymphocytes have not been fully investigated so far.
Methods: T-Cells were negatively isolated from peripheral blood derived PBMC and polyclonally stimulated using antiCD3/antiCD28 coated beads. Following activation, mRNA levels and protein concentration of CD320 were measured by immunoblotting and flow cytometry. For functional assays, binding of TCII to CD320 was blocked using a monoclonal antibody.
Results: Upon activation, CD320 levels were up-regulated, with the highest expression after 72h. In the presence of anti-TCII antibody, the proliferation of T-Cells decreased while early activation markers, such as surface expression of CD69, CD25 and CD71 and production/secretion of IL-2 were not influenced. Similarly, TCR-proximal signaling events, such as phosphorylation of the CD3-zeta chain and the adapter molecules LAT and SLP-76 were also not influenced by the presence of anti-TCII.
Conclusion: These observations indicate that CD320 is an activation marker on T-cells. Furthermore, Vitamin B12 is essential for long-term T-cell activation/proliferation while activation steps preceding the induction of proliferation are independent of vitamin B12.

P.B4.02.14

PD-1/PD-L1 expression in malignant hematological diseases

*A. Dodopoulos, K. Psarra, **E. Grigoriou**, G. Papagiannopoulou, A. Tsirogianni, C. Tsigalou;*
Immunology-Histocompatibility Dept. "Evaggelismos" General Hospital, Athens, Greece.

Patients suffering from malignant hematological diseases, often fail to reach full remission. T lymphocyte dysfunction, as the result of inhibitory receptor expression, could be one of the causes.
The expression of PD-1 on normal lymphocytes as well as the expression of PD-L1 on patient's malignant cells was studied using flow cytometry. The group of patients consisted of 73 people (5 ALL, 18 AML, 10 MDS, 7 MM, 13 NHL and 20 CLL-MBL patients). 10 normal subjects consisted the PD-1 control group. PD-L1/PD-1 expression was assessed with a 5 and 7 color protocol respectively.
PD-1 expression was increased significantly on T lymphocytes concerning ALL, AML, MDS and NHL patients. MM had the strongest and CLL the weakest PD-1 expression. In NHLs, positive correlation was shown regarding PD-1 expression on CD4 and CD8 cells as well as NK and CD8 T cells in MM and ALL. MDS were the only group with a higher PD-1 expression in all lymphocytes subpopulations, compared to the control group. PD-L1 showed a unique expression pattern among groups. ALL showed the highest and MM the lowest expression. PD-L1 levels are significantly elevated on malignant cells compared to lymphocytes. But, no correlation was found between patient's PD-1 and PD-L1 levels. PD-1/PD-L1 expression using flow cytometry might be used for prognosis assessment for these diseases.

P.B4.02.15

Molecular transport at the immunological synapse controls T cell responses

***M. van Ham**[1], N. Amsberg[1], L. Philipsen[2], S. Kliche[2], J. Niemz[1], L. Simeoni[2], C. Falk[3], A. Müller[2], J. Hühn[1], B. Schraven[2], L. Jänsch[1];*
[1]Helmholtz Centre for Infection Research, Braunschweig, Germany, [2]Otto von Guericke University, Magdeburg, Germany, [3]Hannover Medical School, Hannover, Germany.

The assembly and activity of the TCR signalling network at the immunological synapse (IS) requires molecular transport of signalling microvesicles (MV). Following TCR activation, MVs are rapidly recruited along IS-projecting microtubules by the dynein motor complex. Interestingly, molecular transport at the IS discriminates Tconv- and Treg cells. We reported a subset-specific TCR network assembly and defined involved cytoskeleton regulators by phopshoproteomics. Among those we identified the dynein light intermediate chain 1 (LIC1), a dynein motor subunit that regulates cargo selection.
To analyse the role of LIC1 in T cell activation, component recruitment and IS formation we generated LIC1-deficient Jurkat T cells ($LIC1^{-/-}$ cells). General T cell functions including proliferation, adhesion, migration and TCR surface expression were not affected. Upon TCR engagement, however, $LIC1^{-/-}$ cells indicated aberrant phosphorylation dynamics at proximal components. Conjugation with Raji B cells revealed enhanced accumulation of an Lck phosphovariant at the IS. In addition, activated $LIC1^{-/-}$ cells exhibited reduced secretion of selected cytokines. Thus, the dynein motor subunit LIC1 seems to act as a TCR-dependent regulator for the selected adaptation of TCR signalling and cytokine releases. A better understanding of the regulatory network underlying MV molecular transport at the IS might pave the way for novel checkpoints to regulate TCR signalling of T cell subsets *in vitro* and *in vivo*.

P.B4.02.16

Role of diacylglycerol kinase alpha in X-linked lymphoproliferative disease 1 (XLP1) and autoimmunity

***S. Velnati**[1,2], E. Ruffo[3], A. Massarotti[4], M. Talmon[5], S. V. Konduru[1,2], A. Gesu[4], L. G. Fresu[5], A. L. Snow[6], G. C. Tron[4], A. Graziani[3], G. Baldanzi[1,2];*
[1]Department of Translational Medicine, university of piemonte orientale, Novara, Italy, [2]Institute for Research and Cure of Autoimmune Diseases, Novara, Italy, [3]School of Medicine, University Vita e Salute San Raffaele, Milan, Italy, [4]Department of Pharmaceutical Science, University of Piemonte Orientale, Novara, Italy, [5]Department of Health Sciences, School of Medicine, University of Piemonte Orientale, Novara, Italy, [6]Department of Pharmacology and Molecular Therapeutics, Uniformed Services University of the Health Sciences, Bethesda, United States.

X-linked lymphoproliferative disease 1 (XLP1), a primary immunodeficiency due to mutations in SLAM adaptor protein (SAP). SAP deficiency results in constitutive diacylglycerol kinase alpha (DGKα) activity, that decreases TCR signaling and impairs restimulation-induced cell death (RICD) of CD8+ T cells. Indeed, pharmacological inhibition of DGKα restores RICD in cellular model of XLP1 and limits CD8+ accumulation associated immunopathology in XLP1 animal models suggesting the development of DGKα inhibitors for XLP1 therapy. Alternatively, we promote RICD resistance by treating normal lymphocytes with osteopontin (OPN), a matrix protein that is known to promote lymphocyte proliferation and migration. Interestingly, DGKα inhibitors restore RICD also in OPN treated cells, indicating a major DGKα role in the OPN signaling and as a general regulator of RICD sensitivity. Finally, to find new DGKα inhibitors suitable for human use, we used a 2D/3D in silico approach based on chemical homology with the two commercially available DGKα inhibitors (R59922 and R59949). Out of the resulting 127 compounds, ritanserin (serotonin antagonist) and compound01 (uncharacterised molecule) were highly specific for DGKα and showed equal or superior potency compared to R59022 and R59949. In cellular models of XLP-1, both ritanserin and compound01 restored RICD of SAP-deficient CD8+ without significant toxicity. Furthermore, compound01 doesn't perturb serotonin signaling, thus represent a lead compound for further development. Indeed, we are executing compound optimization program to find compound01 derivatives.
Our findings may contribute to the development of innovative therapies for diseases characterized by RICD resistance such as XLP-1 but also in autoimmunity.

P.B4.02.17

Use of melanin from yeast-like fungies *Nadsoniella nigra* sp. X1 (i. Galindez, Antarctica) in surgically treated urological stage IV cancer patients

***P. Yakovlev**[1], T. Falalyeyeva[2], L. Garmanchuk[2], T. Beregova[2], L. Ostapchenko[2];*
[1]O.Bogomolets National Medical University, Kyiv, Ukraine, [2]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

Patients with stage IV cancer require combined treatment approach to achieve good outcomes. Surgery is always supplemented with adjuvant treatment. Supportive medicinal care plays crucial role in correcting immunosuppressed state due to cancer itself and further worsened by the surgical intervention, to enable patients the faster recovery to proceed with adjuvant treatment. Purpose: Assess the effect of melanin on immune surveillance parameters of stage IV urological cancer patients after definitive treatment. Materials and methods. During 2015-2018 forty patients with stage IV urological cancer (19 - bladder cancer, and 21 - kidney cancer) were subjected to extirpative surgery with postoperative systemic treatment. Postoperatively patients took "Melatal" pills (Melanin 10g) twice a day during 30 days. Blood analysis and immunogram were collected prior, after surgery, and after 30 days of Melatal intake. Controls were 20 patients with similar stage cancer subjected to same surgery but with no adjuvant "Melatal". Results. All study patients demonstrated significant decline below the norm on white blood cell count and immunogram, in particular: lower leucocytes (2.7-3.5*10*3/ml), lymphocytes (0.6-1.0*10*3/ml), CD4+ cells (0.1-0.22*10*3/ml, 13-20%), IRI (0.2-0.6), CD3+56+16+ (1.2%), CD3-56+16+(1.9-3.2%), CD19+ (1.7-6.3%), CD14+ (2-4%). One month after surgery, patients after "Melatal" had better total leucocytes (5.1 vs. 3.5*10*3/ml), CD4+ (35% vs. 28%), IRI (1.3 vs. 0.9), CD14+ (9% vs. 6%), CD19+ (12% vs. 9%) than control patients. Conclusion. Intake of polyphenol compound Melanin during one month in the adjuvant regimen in patients with stage IV urological cancer after extirpative treatment yields beneficial effect in strengthening the parameters of immune surveillance.

P.B4.02.18

Signal 3 cytokines promote effector-associated epigenetic programs during mouse and human memory CD8 T-cell differentiation

***C. C. Zebley**, H. Abdelsamed, H. E. Ghoneim, A. Moustaki, S. Alli, M. Wehenkel, M. McGargill, B. Youngblood;*
St. Jude Children's Research Hospital, Memphis, United States.

Recent evidence suggests that the CD8 T-cell subset of stem cell memory (T_{scm}) cells has an enhanced ability to eradicate tumor and is therefore considered an ideal subset for chimeric antigen receptor (CAR) T-cell therapy. Consequently, significant interest exists in determining how long-lived memory T-cells, such as T_{scm}, are generated. We recently reported that human memory T-cell differentiation is associated with the acquisition of DNA methylation programs that promote effector function. Using these epigenetic signatures, we assessed the differentiation status of currently established CAR T-cell protocols. Surprisingly, we found current protocols for *in vitro* differentiation of T_{scm} from naïve CD8 T-cells do not instill cells with effector-associated DNA methylation programs. Given the epigenetic profiles of *in vitro* generated T_{scm} do not reflect those of a bona fide T_{scm} we assessed the requirement of signal 3 cytokine co-stimulation for inducing effector-associated epigenetic programs during memory CD8 T-cell differentiation. Varying *in vitro* culture cytokines induces changes in the phenotype of naïve human CD8 T-cells which are reflected at the epigenetic level. For instance, *in vitro* culture conditions involving IL-12 result in demethylation at the IFNγ locus with corresponding increase in IFNγ expression. Furthermore, *in vivo* experiments with coinfection of C57BL/6 mice with Listeria monocytogenes and LCMV Armstrong induce an inflammatory environment that results in epigenetic poising of the downstream IFNγ locus. Demethylation of the IFNγ locus likely results from infection-induced cytokines. These data demonstrate that cytokines can be used to engineer an epigenetically defined memory T-cell population poised to recall effector functions.

P.B4.02.19

In vitro induction of CTL exhaustion

***M. Zhao**, C. J. Stairiker, M. van Meurs, Y. M. Mueller, P. D. Katsikis;*
Erasmus Medical Center, Rotterdam, Netherlands.

Exhaustion is a dysfunctional state of CTL during chronic infection and cancer. Establishing an in vitro system that induces CTL exhaustion could greatly facilitate the study of this phenotype and allow the testing of novel approaches to reverse exhaustion. Chronic antigen stimulation has been proposed as a critical contributor to CTL exhaustion. To simulate chronic antigen stimulation, purified splenic OT-1 CD8+ T cells from transgenic mice were cultured with cytokines and were repeatedly stimulated with SIINFEKL peptide. On day 5, cells were harvested and inhibitory receptors and cytokine production after restimulation with peptide were assayed by flow cytometry. Cells were also rested for 3 or 5 days and reassessed for functions. After 5 days of repeat peptide stimulation, there was significant upregulation of inhibitory PD-1 and Lag-3 expression on CTL. Furthermore, the production of IL-2 and TNF-α was reduced, while IFN-γ was unaffected. Additionally, these cells expanded less than controls. After resting without peptide, the high expression of inhibitory receptors was maintained, while cytokine deficiencies were partially recovered. Further validation of these cells in vivo is under investigation. In summary, we have established an in vitro system to induce CTL exhaustion. Such a system will facilitate the exploration of exhaustion reversing strategies.

P.B4.02.20

Deletion of Map4k4 enhances CD8 T cell function

***E. Esen**;*
Genentech, San Francisco, United States.

Map4k4 is a serine threonine kinase of the STE20 family that is expressed broadly. It is highly expressed in immune cells. We investigated the role of Map4k4 in CD8 T cell function. Deletion of Map4k4 induces CD8 T cell cytokine production, activation, proliferation and target killing *in vitro*. Map4k4 iKO (induced knock-out) animals showed reduced tumor growth when MC38 cells were injected subcutaneously. In the tumors, T cells expressed less exhaustion markers and produced more inflammatory cytokines when stimulated ex vivo. We showed that CD8 T cells were both necessary and sufficient for reduced tumor growth difference in the Map4k4 iKO animals. Using LCMV-Armstrong infection model, we showed that there is increased antigen specific CD8 T cell production in the iKO animals and these CD8 T cells showed enhanced cytokine production. We also showed elevated activation markers using OT1 transgenic model. To sum up, Map4k4 deletion leads to enhanced CD8 T cell proliferation and activation. Mechanistically, we found that Map4k4 kinase activity is necessary for its role in CD8 T cells and it signals through ERM family of proteins.

Visualizingthe immune response of the T helper cells to the osteopathic manipulativetreatment in normal subjects

***A. Abdelfattah**, N. Abdelraoof, S. Nasef;*
Faculty of physical therapy - Cairo University, Cairo, Egypt.

Purpose: This study was designed to investigate the Effect of selected osteopathic lymphatic techniques on immune system in healthy subjects. Method: Forty five subjects (33 males and 12 females), with age ranged from 20 to 30 years old participated in this study. They were assigned into three equal groups each one has 15 subjects: group A received sternal pump and sternal recoil techniques .Group B received thoracic lymphatic pump and splenic pump techniques for 12 sessions, three sessions per week. Group C (control group) did not receive any physical therapy modality. Absolute count of CD4 and WBCs count were used to evaluate participants before and after the study. Results: Statistical analysis revealed that there was a significant increase in CD4 P value was ≤ 0.045 and WBCs count P-value was ≤ 0.006 between before and after treatment with the second group in the two experimental groups. While there was no significant difference in the same measuring variables in the first and control groups. Comparison between groups revealed that there was a significant difference between the first and second groups in CD4 and WBCs, P: probability< 0.05. Conclusion: The second osteopathic manipulative treatment group was the effective method of enhancing the immune system in healthy subjects (thoracic lymphatic pump (TLPT) and splenic pump techniques (SPT). Key words: Osteopathy, CD4, Thoracic lymphatic pump, splenic pump technique, Sternal pump technique and Sternal recoil technique. Ethical committee approval: Cairo university:P.T.R.E/012/00945 ANZCTR NO: ACTRN12616000216415

Introduction: During chronic infections, virus-specific CD8 T cells acquire a differentiation program that is distinct from the one acquired in acute infections. In this case, the persisting antigen stimulation causes T cells to become dysfunctional which means that they show impaired effector functions and up-regulated inhibitory receptor expression. To understand the molecular foundation of CD8 T cells dysfunction, we compared the transcriptional profiles of normal and dysfunctional CD8 T cells. We found the transcription factor TOX as one of the mostly upregulated gene in chronically stimulated CD8 T cells.
Materials and methods: To study the function of TOX, we generated a conditional KO mouse which facilitates peripheral deletion of functional TOX protein in P14 T cells. Following adoptive transfer of KO or WT P14 in naïve mice, we monitored their behave in LCMV Armstrong or clone13 infections. Flow cytometry, NGS, immunofluorescence and immunohistochemistry analysis were performed.
Results: The absence of TOX impairs the survival of dysfunctional CD8 T cells, without affecting CD8 T cells baring an acute phenotype. This impaired survival goes along with a loss of the critical TCF-1 expressing population, decreased PD-1 but increased KLRG1 expression and augmented cytokine production. The resulting enhanced effector phenotype leads to a better viral clearance but also to an increase in immunopathology.
Conclusions: TOX promotes the dysfunctional phenotype in CD8 T cells, nonetheless ensures their fitness for long term maintenance during chronic infection.

Innocent Bystanders: Chronic Virus Infection Compromises Memory Bystander T cell Maintenance and Function

***I. Barnstorf**[1], N. Baumann[1], M. Borsa[1], K. Pallmer[1], A. Yermanos[1], N. Joller[2], S. P. Welten[1], N. J. Krautler[1], A. Oxenius[1];*
[1]ETH Zurich, Zurich, Switzerland, [2]University of Zurich, Zurich, Switzerland.

Chronic viral infections are widespread among humans, with approximately 8-12 chronic viral infections per individual and there is epidemiological proof that these impair heterologous immunity. We studied the impact of chronic virus infections on the phenotype and function of memory bystander CD8 T cells. Active chronic virus infection had a profound effect on total numbers, phenotype and function of memory bystander T cells in mice. The phenotypic changes included upregulation of markers commonly associated with effector and exhausted cells and were induced by IL-6 in a STAT1-dependent manner in the context of chronic virus infection. Furthermore, bystander CD8 T cell functions were reduced with respect to their ability to produce inflammatory cytokines and to undergo secondary expansion upon cognate antigen challenge with major cell-extrinsic contributions responsible for the diminished memory potential of bystander CD8 T cells. These findings open new perspectives for immunity and vaccination during chronic viral infections**.**

P.B4.03.04

Distinct function of the co-signaling partners BTLA and HVEM on the virus-specific CD8+ T cells response during LCMV infection

***P. Diethelm**, I. Schmitz, J. Kisielow, M. Kopf;*
Institute of Molecular Health Sciences, Zurich, Switzerland.

Activation of naïve T cells is controlled through engagement of co-stimulatory and co-inhibitory molecules. It has been reported that binding of HVEM (Herpes Virus entry mediator) to BTLA (B and T lymphocyte attenuator) inhibits T cell expansion however recent evidence suggests that BTLA can serve reciprocally as an activating ligand for HVEM. By infecting single and double KO animals with an acute or a chronic dose of LCMV we made the unexpected finding that neither effector anti-viral T cell responses nor memory formation were impaired. Accordingly, no difference in virus clearance was found between knockout and control wild-type animals. Interestingly, staining of BTLA and HVEM on gp33-specific CD8+ T cells at the peak of the immune response revealed that both molecules were down regulated implicating that this may promote T cell expansion. Indeed, retroviral overexpression of HVEM on virus-specific CD8+ T cells resulted in reduced numbers of effector cells 7dpi. In contrast, BTLA overexpression rather increased the cytokine production of gp33-specific CD8+ T cells. Whether sustained expression of HVEM affects proliferation or survival of anti-viral CD8+ T cells during the effector phase and whether the cytotoxic activity of BTLA overexpressing CD8+ T cells is increased is currently under investigation. Together these data imply that HVEM down regulation on gp33-specific CD8+ T cells ensures efficient accumulation 7dpi and thus control of an LCMV infection whereas down regulation of BTLA dampens the cytokine response of anti-viral CD8+ T cellsand thus limits inflammation.

Bacillus Calmette-Guérin (BCG) causes Vgamma9 Vdelta2 T-cell proliferation and potentiates cytotoxic responses towards tumour cells

***J. R. Fenn**[1], R. Reljic[1], S. Sharpe[2], M. D. Bodman-Smith[1];*
[1]St. George's, University of London, London, United Kingdom, [2]Public Health England, Salisbury, United Kingdom.

Vγ9Vδ2 T-cells can recognise malignantly transformed cells as well as those infected with mycobacteria. This cross-reactivity supports the idea of using mycobacteria to manipulate Vγ9Vδ2 T-cells in cancer immunotherapy. To date, therapeutic interventions using Vγ9Vδ2 T-cells in cancer have involved expanding these cells in or ex vivo using zoledronic acid (ZA). In this study we show that the mycobacterium-based vaccine, Bacillus Calmette-Guérin (BCG), also causes Vγ9Vδ2 T-cell expansion in vitro. We phenotypically and functionally compared Vγ9Vδ2 T-cells expanded using ZA to those expanded using BCG and compared the ability of these two populations of Vγ9Vδ2 T-cells to kill myeloid THP-1 target cells. We show that ZA expanded Vγ9Vδ2 T-cells kill ZA pre-treated THP-1 cells but are unable to target untreated THP-1 cells. Conversely, BCG expanded Vγ9Vδ2 T-cells are able to target both ZA treated and untreated THP-1 cells. Furthermore, BCG expanded Vγ9Vδ2 T-cells were able to effectively kill BCG infected THP-1 cells whereas ZA expanded Vγ9Vδ2 T-cells were not. These data suggest that BCG treatment could be a way of generating Vγ9Vδ2 T-cells with greater tumouricidal potential compared to ZA treatment and that either ZA or BCG could be used intratumourally as a means to potentiate stronger anti-tumour Vγ9Vδ2 T-cell responses.

Molecular imaging of the antigen recognition dynamics in CD8+ cytotoxic T-cells

***M. Kraller**, R. Platzer, P. Spechtl, J. Huppa, H. Stockinger;*
Medical University of Vienna, Vienna, Austria.

Cytolytic T-cells (CTLs) can detect with their low affinity T-cell antigen receptors (TCRs) the presence of even a single antigenic peptide-loaded MHC molecule I (pMHCI) among thousands of structurally related yet non-stimulatory pMHCs (Purbhoo et al. 2004). How they achieve this is not clear but appears to depend at least in part on the special binding conditions within the special constraints of the immunological synapse, the area of contact between a T-cell and an antigen presenting cell. Here receptors and their ligands are not only pre-oriented, but they are often enriched in specific membrane domains and also subjected to cellular forces. To relate these cell biological parameters to T-cell antigen sensitivity in a more comprehensive manner we are monitoring TCR-pMHC binding in nascent synapses with the use of molecular imaging modalities. We confront TCR transgenic CTLs with a glass-supported lipid bilayer (SLB) functionalized with pMHCI, adhesion and co-stimulatory molecules. This allows us to conduct (single molecule) measurements in noise-attenuated Total Internal Reflection (TIRF) mode, to control for ligand composition and density to quantitate their specific influence on TCR-pMHCI binding and TCR-proximal downstream signaling. We also plan to assess the role of CD8 co-receptor engagement with the use of pMHCI mutants, which are deficient in CD8 binding. In this fashion we expect to gain novel insights into cell biological and molecular processes underlying the phenomenal sensitivity of CTLs towards antigen.

Analyzing chimeric single chain antigen receptors by using a triple parameter T cell reporter line

*J. Brunner[1], **J. Leitner**[1], D. A. Boardman[2,3], G. Lombardi[2,3], J. Maher[4], M. H. Heemskerk[5], W. Paster[6], P. Steinberger[1];*
[1]Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria, [2]MRC Centre for Transplantation, King's College London, Guy's Hospital, NIHR Biomedical Research Centre, Guy's & St Thomas'NHS Foundation Trust & King's College London, Guy's Hospital, London, United Kingdom, [3]NIHR Biomedical Research Centre, Guy's & St Thomas'NHS Foundation Trust & King's College London, Guy's Hospital, London, United Kingdom, [4]CAR Mechanics Group, Division of Cancer Studies, King's College London, Guy's Hospital, London, United Kingdom, [5]Department of Hematology, Leiden University Medical Center, 2300 RC Leiden, Netherlands, [6]Department of Clinical Cell Biology and FACS Core Unit, Children's Cancer Research Institute (CCRI), Vienna, Austria.

Adoptive transfer of genetically modified T cells expressing single-chain antigen receptors like chimeric antigen receptors (CAR) or chimeric single-chain TCR (cTCR) are emerging and highly promising approaches for cancer treatment. Within this study different signaling domains for such receptors were assessed in a Jurkat triple parameter transcriptional cell line 76 (Jurkat 76 TPR). This T cell reporter line allows to simultaneously assess the activity of three transcription factors that play essential roles in T cell activation processes - NF-kappaB, NFAT and AP-1. A CAR recognizing HLA-A2 and the HLA-A2 restricted cTCR X15 specific for the human T cell lymphotrophic virus (HTLV) Tax peptide were used as model single-chain antigen receptors. Both were fused to signaling domains derived from 4-1BB, CD28 and CD3ζ to generate signaling modules that correspond to first, second and third generation CARs. The resulting reporter lines were stimulated with engineered antigen-presenting cells (APC). Assessment of reporter gene expression by flow cytometry showed that activation of Jurkat reporter cells critically depended on the signaling modules contained in the single-chain antigen receptors. Direct comparison of 4-1BB and CD28 as costimulatory modules in both types of receptors (CAR and cTCR) demonstrated a much higher capacity of the 4-1BB domain to induce reporter gene expression. Our results indicate that transcriptional T cell reporter cells are a powerful mean to assess signaling domains for single-chain antigen receptors.

P.B4.03.08

The role of Interleukin-18 on the phenotypical and functional plasticity of cytotoxic T cells in pancreatic cancer

***V. Lutz**, A. Hanlon, E. Landmann, M. Buchholz, T. Gress, C. Bauer;*
Clinic for Gastroenterology, Endocrinology, Metabolism and Infectiology, Philipps-University Marburg, Marburg, Germany.

Introduction: $CD8^+$ cytotoxic t cells (CTL) play a central role in tumor response mechanisms. In pancreatic cancer CTL show decreased activation. Mechanistically, proinflammatory cytokines, like IL-1 and IL-18, might play a crucial role in the induction of this dysfunctional state. This project investigates the role of IL-18 on cytotoxic T cell responses in a murine model of pancreatic cancer.
Methods: Antigen-specific CTL were generated from transgenic OT-I mice and from transgenic OT-I mice crossed with IL-18R-KO mice. CTL were co-cultured with antigen-loaded dendritic cells (DC), in the absence or presence of IL-18 and IL-1. As a parameter of effector function the intracellular production of IFN-γ and TNF was determined. OT-I or OT-IxIL-18R-KO CTL were adoptively transfected in PancOVA tumor bearing mice. CTL were analyzed for exhaustion markers, degranulation efficiency and intracellular production of IFN-γ and TNF.
Results: IL-1 enhances CTL effector function, whereas IL-18 does not influence IFN-γ production of CTL. Interestingly, IL-18R-deficient T cells demonstrate increased effector activation when stimulated with IL-1 in co-culture with antigen-loaded DC in comparison to WT-CTL. However, stimulation of DC with IL-18 prohibits increase of IFN-γ production in WT-CTL.
Conclusions: In the next steps we intend to characterize the potentially suppressive signaling pathway of IL-18. The role of IL-18 in the immune response against pancreatic cancer will be determined further by examining the effect on non-t cells, tumor cells and stroma cells on phenomena of T cell exhaustion in an *in vivo* model.
This project is funded by von Behring-Röntgen-Stiftung.

Utility of *STAT3* and *STAT5b* mutations as diagnostic and prognostic tool in T/NK large granular lymphocyte leukemia (LGLL)

N. Muñoz-García[1,2,3], *M. Jara-Acevedo*[1,2,3], *C. Caldas*[1,2,3], *P. Bárcena*[1,2,3], *A. López*[1,2,3], *N. Puig*[4,2,3], *M. Alcoceba*[4,2,3], *N. Villamor*[5,6,7], *P. Fernández*[8], *M. González*[9,2,3], *A. Orfao*[1,2,3], *J. Almeida*[1,2,3];

[1]*IBMCC (University of Salamanca), Salamanca, Spain,* [2]*IBSAL, Salamanca, Spain,* [3]*CIBERONC, Salamanca, Spain,* [4]*University Hospital of Salamanca, Salamanca, Spain,* [5]*Hospital Clínic, Barcelona, Spain,* [6]*IDIBAPS, Barcelona, Spain,* [7]*University of Barcelona, Barcelona, Spain,* [8]*Kantonsspital, Aarau, Switzerland,* [9]*University Hospital of Salamanca and USAL, Salamanca, Spain.*

Introduction: the clinical utility and significance of *STAT* mutations in T-cell LGLL (T-LGLL) and NK-cell chronic lymphoproliferative disorders (CLPD-NK) remains uncertain. Here, we analyzed the frequency of somatic mutations in *STAT3* and *STAT5b* genes in clonal LGLL expansions from diverse T/NK-cell lineages and its relationship with biological (phenotype) and clinical characteristics of the disease.
Materials and Methods: *STAT3* and *STAT5b* genes were sequenced in 157 populations of FACS-sorted cells (previously phenotyped by multiparametric flow-cytometry), from patients with 97 monoclonal and 7 oligoclonal LGL expansions, 17 non-cytotoxic T-CLPD and 36 polyclonal T-cell populations.
Results: *STAT3* or *STAT5b* somatic mutations were detected in 30/97 populations from patients with clonal LGL expansions (31%), all but one in the *STAT3* gene. According to the LGLL cell lineage, mutations were present in 31% of TαβCD8$^+$, 32% of CLPD-NK, 7% of TαβCD4$^+$CD8$^{-/+d}$, 100% of TαβCD4$^+$CD8$^+$, 50% of TαβCD4$^-$CD8$^-$ and 44% of Tγδ expansions. *STAT3* was also detected in 1/17 non-cytotoxic T-CLPD, but in none of polyclonal cytotoxic T-cell populations. Two patients who had ≥2 clonal LGL expansions from different cell-lineages showed *STAT3* mutations in at least two of them. Interestingly, patients carrying *STAT* mutated LGL expansions showed a significantly higher incidence of autoimmune disorders (vs. non-mutated monoclonal LGL expansions), supporting a prognostic value.
Conclusions: we support the utility of *STAT3*/*STAT5b* mutations for clonality assessment and prognostic evaluation in T-LGLL and CLPD-NK; additionally, these findings suggest that similar activation pathways would be involved in the pathogenesis of LGLL, regardless of the cytotoxic cell-lineage involved.

P.B4.03.10

Identification of two human CD8$^+$ T cell subsets with distinct cytokine profile

B. P. Nicolet*, A. Guislain, F. van Alphen, M. van den Biggelaar, M. C. Wolkers;*
Sanquin Research, Amsterdam, Netherlands.

CD8 T cells are critical to kill virally infected and tumor cells. Intriguingly, when activated, human CD8 T cells show a dichotomy in cytokine production. Whereas some T cells produce only IFNg, others are found to make specifically IL-2, or they produce both cytokines. Whether this cytokine profile is fixed or whether it is dependent on kinetics and oscillation is not to date known. Here we developed a method that allowed us to perform proteomics analysis on fixed, FACS-sorted T cells based on their cytokine expression profile. This analysis revealed that a distinct expression profile between the cell types. Whereas IL-2 single producing cells display a helper-like phenotype, the IFNg-single and double producing T cells show a cytotoxic profile with a high co-expression of TNFa, granzymes, perforin, granulysin and chemokines. Furthermore, we identified several surface markers that can be used to enrich for the different cytokine producers. Using this approach, we found that the cytokine profile was robust over a prolonged culture period of the cells. In conclusion, we identified two distinct T cell populations in human T cells that exert differential functions. This may be exploited for T cell-mediated therapies.

P.B4.03.11

A rapid, high throughput multiplex assay that measures T-cell activation, cytokine secretion, and identifies T-cell subsets from multiple donors

J. O'Rourke*, Z. Liu;*
Intellicyt Corporation, A Sartorius Company, Albuquerque, United States.

The identification of T-cell subsets and assessing their *ex vivo* activation is a key step in the adoptive cell therapy process. To facilitate this workflow, we developed a high throughput flow cytometry-based, multiplexed assay to measure T cell activation in different T-cell subsets. PBMCs from multiple donors were profiled prior to and after T cell enrichment with CD3/CD28 magnetic beads. Purified T cells were cultured in the presence of the beads and media containing IL-2 for 3 days and cell phenotypes and secreted cytokines were analyzed. For each sample well, 11 cytokines and 13 cellular endpoints were measured each day over the course of a three-day activation protocol including quantifying cells expressing the activation markers CD69, CD25 and HLA-DR. A 96-well sample plate contained T cells from 12 different donors, with each sample analyzed in quadruplicate using two different sample dilutions. The plates were read on the iQue Screener Plus and the high-content data was analyzed using the integrated ForeCyt software. The results indicate a time course dependent, donor to donor variation in T-cell activation. These high throughput, large-scale flow cytometry studies provide extensive T cell activation and subset profiles from multiple donors with assay times of ~15 minutes. The adoption of these assays can provide actionable data to optimize adoptive cell therapy culture conditions and improve manufacturing protocols.

P.B4.03.12

Evaluation of helper T cell proliferation in the co-cultures of lung adenocarcinoma cells, neutrophils and monocytes

F. G. OZBAY*, G. ESENDAGLI;*
Hacettepe University Cancer Institute Department of Basic Oncology, Ankara, Turkey.

T cell responses are modulated especially by antigen presenting cells; on the other hand, in the inflammatory microenvironment of lung adenocarcinoma, these cells have been shown to be located nearby neutrophils. Hence, this study aims to investigate helper T (Th) cell proliferation in a co-culture setting containing lung adenocarcinoma cells, neutrophils and monocytes.
Peripheral blood CD66b+ neutrophils, CD14+ monocytes, and CD4+ T cells were purified from the healthy volunteers with density gradient centrifugation, followed by MACS and/or FACS procedure. These cells were co-cultured at 1:1:1 ratio in the presence of anti-CD3 mAb. A549 and H1299 were used as lung adenocarcinoma cell lines. On a flow cytometry, T-cell proliferation was assessed by eFluor670 dilution assay, cell viability by propidium iodide exclusion, neutrophil and monocyte activation by CD62L, CD66b, CD11b, CD86, HLA-DR expression.
The presence lung cancer cells and monocytes supported the viability of neutrophils and inhibition of ROS production leaded to higher T cell proliferation in the co-cultures. Neutrophils were in an activated state with decreased CD62L and increased CD11b levels.
In a co-culture setup, which was established to partially model the tumor microenvironment, employing neutrophils, monocytes, Th-cells and lung cancer cells, our initial findings show the importance of neutrophils as a critical modulator for Th-cell responses.

Mapping of T-cell responses in dengue exposed individuals from India

E. Reddy[1], *S. Gunisetty*[2], *K. Nayak*[1], *M. Gupta*[1], *H. Panda*[1], *M. Singla*[3], *R. Lodha*[3], *S. Kabra*[3], *P. Coshic*[3], *M. Kaur*[1], *S. Yazdani*[i], *M. Kaja*[1], *A. Chandele*[1];
[1]*International Centre for Genetic Engineering and Biotechnology (ICGEB), New Delhi, India,* [2]*Emory Vaccine Centre, ATLANTA, Georgia,* [3]*All India Institute of Medical Sciences (AIIMS), New Delhi, India.*

Dengue is a global epidemic and T cells have been implicated in both protection and pathogenesis of dengue infections. Thus far, a handful of studies have *in silico* predicted and tested CD4 and CD8 T cell epitopes but none have comprehensively characterized dengue-specific CD4 and CD8 T cell epitopes *ex vivo*.
In this study, using overlapping peptides spanning the entire proteome of the dengue 2 virus, we performed a detailed analysis to identify immune epitopes recognized by dengue-specific memory CD4 and CD8 T cells. Because of low precursor frequency of memory T cells, we employed a methodology of approach of long-term peptide and IL-2 stimulation of PBMC's derived from dengue-seropositive and seronegative individuals, followed by restimulation and assessment of peptide-specific proliferation and IFNγ production by flow cytometry.
Corroborating with previous reports, we observe CD4 T cell specificities are distributed across all dengue proteins. In contrast the CD8 T cell specific responses are typically conserved to the non-structural and viral envelope. By combining knowledge of subject specific HLA and their IFNγ producing antigenic regions, we have identified 117 CD8 T-cell epitopes and 240 CD4 T-cell epitopes. A majority of these dengue 2 epitopes are conserved in dengue 1, 3 and 4. However, interestingly, up to 10% of epitopes are cross conserved in other Flavivirues, like Zika, JEV, YFV and WNV.
Taken together, our study shows breadth of both CD4 and CD8 T cell responses found *in vivo* to the entire dengue proteome and opens novel implications in dengue T-cell cell-based vaccine.

P.B4.03.14

***In vivo* TCR signaling during chronic viral infection**

***I. Sandu**, D. Cerletti, A. Oxenius, M. Claassen;*
ETH, Zürich, Switzerland.

A hallmark of chronic infections is exhausted CD8 T cells, characterized by a perturbed transcriptional program, upregulation of inhibitory receptors, impaired effector function, reduced numbers, and alteration of normal memory development, driven by prolonged T cell receptor (TCR) engagement.
This project focuses on characterizing the kinetics of TCR signaling in different tissues in mice chronically infected with Lymphocytic Choriomeningitis virus. TCR signaling was quantified *in vivo* using virus-specific transgenic CD8 T cells expressing a reporter under the control of the *Nur77* promoter.
Our data reveals that, despite available antigen *in vivo*, NUR77 expression is very low in exhausted cells. In addition, these cells express multiple co-inhibitory receptors known to inhibit TCR signaling. Indeed, both blockade of the major inhibitory PD-1-PDL1 pathway and transfer of target cells lacking ligands binding co-inhibitory receptors into chronically infected mice increased NUR77 reporter levels temporarily.
Preliminary results of single-cell RNAseq performed on exhausted cells isolated from various organs revealed distinct subpopulations, suggesting that tissue microenvironment has a major impact on shaping the structure, phenotype, and function of these cells.
Thus, persistent TCR triggering during chronic infection leads to a near complete shut-down of *in vivo* TCR signaling, largely due to the combined action of inhibitory receptors, explaining the poor ability of exhausted cells to kill endogenous virus-infected targets. However, cytotoxic potential is preserved because they can efficiently kill transferred target cells lacking ligands for inhibitory receptors. Moreover, single-cell transcriptomics reveals that exhausted cells are heterogeneous and adopt tissue-specific signatures.
Project funded by ETH grant 39_14-2

P.B4.03.15

Phenotypic and functional characteristics of HER2-specific cytotoxic T lymphocytes activated by DNA-transfected dendritic cells and enriched by magnet sorting and cytokine stimulation

*M. Kuznetsova, J. Lopatnikova, **S. Sennikov**;*
Research Institute of Fundamental and Clinical immunology (RIFCI), Novosibirsk, Russian Federation.

Introduction. Approaches based on antigen presentation to cytotoxic T lymphocytes (CTLs) by dendritic cells (DCs) are actively applied in modern cancer immunotherapy. The aim of the study was to obtain $CD8^+$ T cells specific for HER2/neu (HER2) antigen and evaluate their phenotype and effector functions.
Methods. A developed protocol for obtaining HER2-specific $CD8^+$ T-lymphocytes was used, consisted of magnet-assisted transfection of monocyte-derived DCs, co-culturing of antigen-loaded DCs with autologous lymphocytes, magnet sorting of CTLs specific to HER2 epitopes and stimulation of separated CTLs by IL-2, IL-7 and IL-15. HER2-specific CTL phenotyping and identification of T memory subsets was carried out using multicolor flow cytometry. Cytotoxity assay against HER2-expressing MCF-7 cell line was performed to evaluate effector function of obtained T cells.
Results. Here we show that HER2-specific CTL populations obtained with the protocol we developed contain large percent of T stem cell-like memory cells (T_{SCM}) (about 60% of $CD8^+$ HER2-specific T cell population). Cytotoxicity analysis of HER2-specific T-cells showed significantly higher level of cytotoxic effect against cell line MCF-7, as compared with that of the fraction of activated PBMCs and that of the fraction of $CD8^+$ T cells of different specificities.
Conclusion. HER2-specific T cells obtained by the protocol we developed characterized by a high level of cytotoxicity against HER2-expressing tumor cells and which are mostly represented by T memory cells, especially T_{SCM} subset. Obtained T cells could be used for eliminating tumor cells and prevent tumor relapse after the primary tumor burden deletion in HER2-overexpressed cancer patients.

The newly-arisen Devil Facial Tumour disease 2 (DFT2) reveals gradual loss of MHC class I as a mechanism for the emergence of a contagious cancer

*A. Caldwell[1], R. Coleby[1], M. R. Stammnitz[2], M. Tringides[1], E. P. Murchison[2], K. Skjødt[3], G. J. Thomas[1], J. Kaufman[2], T. Elliott[1], G. Woods[4], **H. Siddle**[1];*
[1]University of Southampton, Southampton, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom, [3]University of Southern Denmark, Odense, Denmark, [4]University of Tasmania, Hobart, Australia.

Devil Facial Tumour 2 (DFT2) is a recently discovered contagious cancer circulating in the Tasmanian devil (*Sarcophilus harrisii*), a species which already harbours a more widespread contagious cancer, Devil Facial Tumour 1 (DFT1). Here we show that in contrast to DFT1, DFT2 cells express major histocompatibility complex (MHC) class I molecules, demonstrating that loss of MHC is not necessary for the emergence of a contagious cancer. However, the most highly expressed MHC class I alleles in DFT2 cells are non-polymorphic or common among host devils, reducing immunogenicity in a population sharing these alleles. In parallel, MHC class I loss is emerging *in vivo*, thus DFT2 is mimicking the evolutionary trajectory of DFT1. Based on these results we propose that contagious cancers can exploit partial histocompatibility between the tumour and host, but selective pressure from the immune system will drive loss of allogeneic antigens, which could facilitate widespread transmission of DFT2. Funding: Leverhulme Trust project grant RPG-2015-103.

TACS - traceless affinity cell selection

*H. Stadler, M. Kiene, F. Leonhardt, K. Stanar, L. Breithaupt, **M. Tietzel**;*
IBA GmbH, Göttingen, Germany.

Traceless affinity cell selection is a novel approach for positive cell isolation, which completely avoids the use of high affinity antibodies that often lead to irreversible cell binding and cause undesired stimulation of target cells. In contrast to fluorescence-activated cell sorting (FACS) and magnetic-activated cell-sorting (MACS), traceless affinity cell selection utilizes a principle, which we have termed “tag-activated cell sorting” or TACS. TACS comprises an innovative immune-affinity chromatography, whereby target cells are captured by cognate Fab fragments that are reversibly immobilized on a column matrix via an epitope tag. Specifically, low affinity Fab-fragments harboring a C-terminal Strep-tag® (Fab-Streps) are attached to Strep-Tactin®-coated cell-grade agarose, and this multimerization of Fab-Streps promotes their binding to target cells with high avidity. Hence, when a single-cell suspension is passed through a Fab-Strep/Strep-Tactin® column, target cells adhere to the affinity matrix based on the exclusive binding of the Fab-Strep to the target cell. Non-target cells are washed away efficiently. Finally, the addition of biotin triggers the elution of the target cells, and the Fab-Streps spontaneously self-dissociate from the cell surface due to the reduced affinity. This novel “Fab-TACS®” procedure delivers label-free, non-activated target cells of highly reproducible quality and purity directly from a variety of single cell suspensions, e.g. whole blood, buffy coat or rodent spleen, allowing a multitude of downstream applications. Manual Fab-TACS® gravity columns as well as fully automated Fab-TACS® cell isolation using the FABian® bench top instrument provide convenient and cost efficient options for conducting standardized TACS experiments in the laboratory.

P.B4.03.18

Effect of long-term IFN exposure on CD8 T cell functionality

***J. Mikulec**[1], M. Hofmann[2], R. Thimme[2], R. Bartenschlager[1,3];*
[1]Division of Virus-associated Carcinogenesis, German Cancer Research Center, Heidelberg, Germany, [2]Department of Medicine II, University Hospital Freiburg, Freiburg, Germany, [3]Department of Infectious Diseases, Molecular Virology, University Hospital Heidelberg, Heidelberg, Germany.

Chronic infection with the hepatitis C virus (HCV) is a major risk factor for serious liver diseases and affects around 1% of the population. A hallmark of HCV is the high propensity to establish persistence, which occurs in around 80% of infected individuals. This is achieved by suppression of both innate and adaptive immune response. Innate immunity, most notably induction of interferons (IFNs), is the first line defense limiting viral replication and determining the outcome of an infection. However, it has been shown that sustained activation of the IFN system in case of persistent *lymphocytic choriomeningitis virus* infection has detrimental impact on T cell response. Elevated IFN signature is observed in chronically HCV-infected patients displaying impaired CD8 T cell responses arguing that persistent activation of the IFN system might dampen T cell response also in chronic hepatitis C. To address this hypothesis we aim to investigate effect of long-term IFN exposure on HCV-specific CD8 T cell function. For this purpose, we take advantage of a cell-culture model, which is based on a HCV replicon-containing cell line stably transduced with the HLA-A2 gene. These cells are used as target cells to measure biological activity of HCV-specific CD8 T cells that have been cultured in the absence or presence of IFNα for extended time spans. Furthermore, we will characterize the IFN-induced changes of CD8 T cells, including their differentiation status, the expression of inhibitory molecules as well as transcription factors. By using these approaches we want to determine to what degree long-term IFN-treated T cells alter their responsiveness to HCV-infected target cells.

P.B4.03.19

Analysis of genes involved in antigen presentation to MR1T cells

***A. Vacchini**, J. Spagnuolo, L. Mori, G. De Libero;*
University Hospital and University of Basel, Basel, Switzerland.

The MHC class I-related (MR1) protein is a non-polymorphic molecule presenting bacterial metabolites to MR1-restricted MAIT cells. We have identified a novel population of MR1-restricted T cells (MR1T cells) that recognize unidentified antigenic molecules belonging to diverse classes and with small-molecular-weight. MR1T cells have polyclonal TCRs and display heterogeneous antigen specificity, recognize and kill different tumor cells in MR1-restricted manner. Activated MR1T cells release various cytokines supporting different types of immune response. Molecular mechanisms underlying the generation of self-antigens presented by MR1, their loading onto MR1 and presentation to T cells remain unknown. To identify candidate genes involved in such functions, we transduced MR1-overexpressing A375 melanoma cells with a CRISPR knock-out library (containing 123'411 sgRNAs encompassing the whole human genome) and killed them with MR1T cells, enriching for surviving A375 cells. Guide RNAs amplified from the genomes of surviving A375 cells were deep sequenced and analysed using the edgeR package.
Hits were chosen based on the strictly standardized mean difference (SSMD) calculated for the two most enriched/depleted guides for each gene target, considering an SSMD ≥3 for enriched and ≤-5 for depleted guides, compared to unkilled cells. Gene ontology analysis of significantly enriched or depleted sgRNAs revealed genes involved in different cell functions, the most abundant being those with a role in primary metabolism. Other identified genes contribute to cell adhesion, protein trafficking, metabolite transport, and RNA stability. We are currently validating selected genes that might participate in the generation/degradation of MR1T-stimulating antigens and in MR1-restricted antigen presentation.

P.B4.03.20

Functional characterization of gd T cells in human colon tumours

***W. Rodin**[1], P. Sundström[1], F. Ahlmanner[1], E. B. Lindskog[2], M. Quiding-Järbrink[1];*
[1]Dept. of Microbiology and Immunology, Göteborg, Sweden, [2]Dept. of Surgery, Göteborg, Sweden.

In colorectal cancer, tumour progression and patient outcome is affected by cytokine balance in the tumours. IFNγ, TNFα and Granzyme B production are all associated with favorable patient outcome, while high IL-17 expression is associated with accelerated tumour progression. However, the knowledge of regulation and activation of intraepithelial T cells in colon cancer is still limited. The aim of this study was to characterize intestinal intraepithelial T cells in colon tumours and unaffected tissue as well as to determine their capacity to produce cytokines affecting tumour progression, using flow cytometry. We show that the frequencies of Vδ1$^+$ γδ T cells and CD8$^+$ T cells are reduced in the epithelium of colon tumors compared to unaffected tissue. Intraepithelial T cells in both tissues express markers associated with an activated memory phenotype and moderate levels of PD-1. On a per cell basis the tumour epithelium contains higher frequencies of γδ and αβ T cells producing IFN-γ and TNFα compared to the unaffected tissue. Likewise, frequencies of IL-17 producing cells are also higher in IELs from tumours, but much lower than the T_H1 - associated cytokines. Granzyme B production was observed in γδ and αβ T cells both before and after activation and is also expressed at higher levels in tumour IELs compared to IELs from unaffected tissue. Taken together, this study indicates that IELs actively contribute to the cytokine balance in colon tumours with a T_H1 – dominated profile, which may influence tumour progression and patient outcome.

P.B4.03.21

Depletion of intratumoural regulatory T cells by the anti-ICOS antibody KY1044 in combination with immune checkpoint blockade enhances the anti-tumour response in pre-clinical models

*R. C. Sainson, A. Thotakura, N. Praveen, **M. Kosmac**, G. Borhis, J. Carvalho, T. Okell, R. Rowlands, H. Ali, H. Craig, V. Wong, Q. Liang, V. Germaschewski, M. McCourt;*
Kymab, Cambridge, United Kingdom.

Inducible T-cell costimulator (ICOS/CD278) is a CD28 superfamily member that is induced when T cells are activated. Although ICOS expression levels vary in different T cell subtypes and in different tissues, in preclinical mouse tumour models, we have observed that nearly all T regulatory cells (TRegs; CD4+/FOXP3+) express ICOS on their surface and that the expression level of ICOS on TRegs is significantly higher than that on effector T cells (TEffs). In addition, ICOS expression on TRegs in the tumour microenvironment is higher than that of TRegs in the blood or spleen, which makes it a strong candidate for cancer immunotherapy via TReg depletion. By immunizing Kymice™, in which the endogenous *Icos* gene has been knocked out, we have identified a novel, cross-reactive, fully human antibody called KY1044 that selectively binds to dimeric ICOS (Fc fusion protein) with an affinity of less than 2nM. Using in vitro and in vivo approaches we demonstrate that KY1044 has dual mechanisms of action: (1) it promotes the preferential depletion of intratumoural ICOS^{high} TRegs resulting in an increase in the TEff:TReg ratio in the TME; and (2) it co-stimulates ICOS^{low} TEff cells. Notably, our pharmacodynamic studies demonstrated long-term durable depletion of TRegs and a significant increase in the TEff:TReg ratio in response to KY1044 treatment, an effect that is crucially dependent on CD8+ but not CD4+ T cells. In summary, our data demonstrate that targeting ICOS with KY1044 is a valid approach for modulating the immune system and for inducing a strong anti-tumour response in multiple indications.

Negative Checkpoint Receptor (NCR) expression in Graves' disease thyroid tissue

***D. Álvarez-Sierra**[1], A. Marín-Sánchez[2], P. Ruiz-Blázquez[1], C. Iglesias-Felip[3], P. Nuciforo[4], Ó. González-López[5], A. Casteras[6], G. Obiols[6], R. Pujol-Borrell[2];*
[1]Vall d'Hebron Research Institute, Barcelona, Spain, [2]Department of Immunology, Hospital Universitari Vall d'Hebron, Barcelona, Spain, [3]Department of Pathology, Hospital Universitari Vall d'Hebron, Barcelona, Spain, [4]Vall d'Hebron Institute of Oncology, Barcelona, Spain, [5]Department of Surgery, Hospital Universitari Vall d'Hebron, Barcelona, Spain, [6]Department of Endocrinology, Hospital Universitari Vall d'Hebron, Barcelona, Spain.

It has been reported that autoimmune thyroiditis occurs frequently after cancer immunotherapy with anti-PD-1/PD-L1.
Since PD-L1 can be induced by IFN-γ and in Graves' Disease (GD) thyroid there is a clear IFN signature, we predicted that thyrocytes, even in focal thyroiditis, would express PD-L1. Anti-PD-L1 treatment would then exacerbate focal thyroiditis and lead to clinical thyroid autoimmunity. The results here presented suggest another scenario.
Cryostat sections of GD, multinodular goitre and control lymphoid organs were stained by multicolour immunofluorescence for PD-1, PD-L1, as well as for HLAI and HLAII, Cytokeratin-18, TPO and phenotypic markers. Against our prediction, in most GD glands, PD-L1 was undetectable in thyrocytes or present at very low level, certainly much less conspicuous than HLAII. Importantly, PD1 was highly expressed by the infiltrating T cells.
Primary thyroid and thyroid-derived cell lines cultures were supplemented with increasing doses of IFNγ and stained at 24h-48h to assess HLA-I/II, PD-L1 and PD-L2 expression induction. PD-L1 and PD-L2 expression was readily induced by IFNgamma in thyrocytes cultures in a time and dose dependent manner, as assessed by flow cytometry and qPCR, demonstrating the capability of thyrocytes to express PD-1 ligands.
Overall these results suggest that the autoimmune thyroiditis linked to anti-PD-1 treatment is not due a local effect of anti-PD1/PD-L1 drugs blocking the interaction between PD-1 positive T cells and thyrocytes expressing PD-L1 o PD-L2. The factor(s) inhibiting thyrocytes PDL1 induction in vivo remain to be elucidated.

P.C1.01.02

Sexual dimorphism in mechanisms controlling development of CD4+ T cell response in collagen-induced arthritis

***B. Bufan**[1], N. Arsenović-Ranin[1], M. Dimitrijević[2], M. Nacka-Aleksić[3], D. Kosec[4], I. Pilipovic[4], M. Stojanović[3], G. Leposavić[3];*
[1]Department of Microbiology and Immunology, University of Belgrade Faculty of Pharmacy, Belgrade, Serbia, [2]Department of Immunology, Institute for Biological Research "Siniša Stanković", University of Belgrade, Belgrade, Serbia, [3]Department of Physiology, University of Belgrade Faculty of Pharmacy, Belgrade, Serbia, [4]Immunology Research Centre "Branislav Janković", Institute of Virology, Vaccines and Sera ''Torlak'', Belgrade, Serbia.

Introduction: Considering sex bias in rheumatoid arthritis prevalence, influence of biological sex on the disease development in Dark Agouti rat collagen II (CII)-induced arthritis (CIA) model of the human disease was examined. Methods: Sex bias in CD4+ T cell responses in inguinal (draining the site of immunization in preclinical CIA) and popliteal (draining inflamed joints at the peak of CIA) lymph nodes (LNs) and mechanisms controlling their development were examined using flow cytometry and/or ELISA/qRT-PCR. Results: In both inguinal and popliteal LNs greater number of CD4+CD25+Foxp3- cells, presumably activated effector T cells, was found in females compared with males, and they exhibited greater CII-specific proliferation. Consistently, more IL-17+, IFN-γ+ and IL-17+IFN-γ+ T cells were retrieved from both inguinal and popliteal female rat LNs. Moreover, more GM-CSF+ and IL-17+IFN-γ+GM-CSF+ T cells were retrieved from female compared with male rat popliteal LNs. On the other hand, lower frequency of PD-1+ cells among CD4+CD25+Foxp3+ regulatory T cells (Tregs) from female popliteal and inguinal LNs suggested lower suppressive capacity of their Tregs. Additionally, from female rat popliteal LNs fewer Tregs were recovered. Furthermore, the number of regulatory LN B10 cells was lower in females. Moreover, compared with males, in females was shifted LN INF-γ+/IL-4+ T-cell ratio towards the former, and accordingly serum CII-specific IgG2a/IgG1 antibody ratio was shifted towards pathogenic IgG2a antibodies. Conclusion: The study suggests that a less efficient control of (auto)immune Th1/Th17 cell responses during CIA development contributes to sex bias in the susceptibility to CIA. (Grant 175050, MESTD of Serbia).

P.C1.01.03

ΔdblGATA mice are resistant to experimental autoimmune encephalomyelitis

***B. Ciric**, D. Hwang, A. Rostami;*
Thomas Jefferson University, Philadelphia, United States.

GATA-binding factor 1 (GATA-1) is a transcription factor expressed in certain hematopoietic cells, governing their development and function. GATA-1 is expressed in myeloid cells but not in lymphoid cells, such as T cells. Since knockout of GATA-1 is embryonic lethal, mouse lines lacking individual enhancers to the GATA-1 gene have been generated. Lack of a particular enhancer selectively reduces, or precludes GATA-1 expression in some cell types, while in others its expression remains normal. We use mice lacking dblGATA enhancer (ΔdblGATA mice), which are devoid of eosinophils. We found that ΔdblGATA mice are resistant to both direct and adoptive EAE. ΔdblGATA mice develop weaker myelin-specific Th responses upon immunization for EAE induction, indicating a defect in priming immune responses. The resistance of ΔdblGATA mice to adoptive EAE indicates a deficiency in effector mechanisms of CNS inflammation. We have ruled out lack of eosinophils as the reason for EAE resistance of ΔdblGATA mice by demonstrating that another mouse strain (PHIL), which also lacks eosinophils, develops normal EAE. These findings show that ΔdblGATA mice have defects in both the priming and effector phases of disease. Additionally, immunized ΔdblGATA mice had fewer inflammatory monocytes and myeloid dendritic cells in blood, draining lymph nodes and the CNS. Our findings thus far suggest that an unknown defect in monocytes/dendritic cells causes resistance to EAE in ΔdblGATA mice.

P.C1.01.04

MAF expression in regulatory and conventional T cells controls gut homeostasis

***C. Imbratta**[1], M. Leblond[1], D. Velin[2], H. Bouzourène[3], D. Speiser[4], G. Verdeil[1];*
[1]Clinical Tumor Biology & Immunotherapy Group, Department of Fundamental Oncology, University of Lausanne, Epalinges, Switzerland, [2]Service of Gastroenterology and Hepatology, CHUV, Lausanne, Switzerland, [3]Unilabs, Epalinges, Switzerland, [4]Clinical Tumor Biology & Immunotherapy Group, Department of Fundamental Oncology, University of Lausanne, CHUV, Epalinges, Switzerland.

The maintenance of homeostasis in the gut is a major challenge for the immune system. In an attempt to characterize the role of the transcription factor MAF in T cells, we demonstrated that it is a key regulator of homeostasis in the gut. Mouse knocked out for *maf* in all T cells developed a spontaneous late-onset colitis, correlating with the disappearance of FOXP3+ RORγt+ T cells from the colon that normally express high level of MAF and is the major source of IL-10. We demonstrated that classical T regulatory cells inactivated for *maf* are defective in controlling colitis development in a co-transfer model and are not able to cope for the defect of RORγt+ Treg in the colon. Furthermore we show that Treg specific *maf*-KO are not sufficient to induce colitis and that the deletion of *maf* in conventional T cells is also necessary for the development of the disease.

P.C1.01.05

TCR repertoire of PD-1+ and CD137+ T-cells from synovial fluid of patients with spondyloarthropathies

***E. A. Komech**[1,2], A. D. Koltakova[3], T. V. Korotaeva[3], E. Y. Loginova[3], E. I. Shmidt[4], Y. B. Lebedev[1,2], I. V. Zvyagin[1,2];*
[1]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation, [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation, [3]Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, [4]City Clinical Hospital #1, Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Identification of auto-reactive T-cell clones could provide a useful diagnostic tool and treatment target for autoimmune diseases. To recognize clones, that are directly involved in pathologic process, we focused on TCR repertoire of activated PD-1+ and CD137+ T-cells from synovial fluid (SF) samples of patients with ankylosing spondylitis (AS) and psoriatic arthritis.
Using quantitative molecular-barcoded 5'-RACE, we performed TCRβ repertoire profiling of activated T-cells: CD3+PD-1med/hi, CD3+CD4+CD137+ and CD3+CD8+CD137+ cells, that were FACS-sorted from SF samples of patients.
From 57 to 83.7% of T-cells from SF were PD-1+, and CD137+ T-cells comprised on average 7.5% from either CD4+ and CD8+ T-cells. Clonal diversity of PD-1+ T-cells was not different from PD-1- cells. Most of CD8+CD137+ T-cells were found in PD-1+ subset of the same donor. Only a few clonotypes of activated fractions were shared between donors, including one clonotype from recently identified AS-associated TCRβ motif. In repertoire of the activated subsets we observed several low abundant clonotypes with known specificity for CMV, EBV, Influenza and melanA protein.
Our results show that the majority T-cells from synovial fluid of patients with spondyloarthropathies are activated. T-cell clonotypes of activated fractions are rather unique for each donor. Presence of clonotypes matching AS-associated TCR motif in activated T-cell subsets of synovial fluid of patients with different spondyloarthropathies supports their role in pathogenesis of the diseases.

IL-37 increases inflammation in murine immune-mediated liver diseases

***C. Lin**, Y. Chuang;*
Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, Taipei, Taiwan.

IL-37 is an emerging IL-1 family cytokine with anti-inflammatory effects on innate and adaptive immunity that shows benefit on several autoimmune diseases. Primary biliary cholangitis (PBC) is a chronic autoimmune disease that occurred in the liver with innate and adaptive immune cell infiltration in the portal triad, followed by fibrosis and cirrhosis. To investigate whether IL-37 can alleviate PBC, we used adeno-associated virus as a vector to express IL-37 in the liver of PBC mice. We found that the features of PBC, including hepatic infiltrating lymphocytes, serum autoantibody, hepatic inflammatory cytokine expression and the liver histopathology were no differences between AAV-hIL-37 or AAV-mock administered mice. However, polymorphic nuclear cells (PMNs) in liver were increased in AAV-hIL-37 injected PBC mice. To further extend whether IL-37 recruit PMN in the immune mediated liver disease, we used Concanavalin A (Con A)-induced hepatitis mouse model. Compared to AAV-mock group, Con A injected mice administered with AAV-hIL-37 had significant increases in not only PMNs but also NK, NKT, and dendritic cells in the liver. In addition, serum IFN-γ was significantly increased in AAV-hIL-37 injected Con A mice. In conclusion, IL-37 induces PMN infiltration in autoimmune cholangitis and Con A induced hepatitis and shows pro-inflammatory effects in Con A induced hepatitis.

P.C1.01.07

Deletion of the mineralocorticoid receptor in myeloid cells leads to reduced EAE severity

***F. Lühder**[1], E. Montes-Cobos[2], N. Schweingruber[1], A. Flügel[1], H. Reichardt[2];*
[1]Institute for Multiple Sclerosis Research, Göttingen, Germany, [2]Institute for Cellular and Molecular Immunology, Göttingen, Germany.

Myeloid cells play important roles in different cruial steps during the pathogenesis of multiple sclerosis and its animal model experimental autoimmune encephalomyelitis (EAE). Peripheral myeloid cells act as APCs for the initial activation of autoreactive T cells in peripheral lymphoid organs, whereas local myeloid cells are presumably responsible for their re-activation within the CNS. Myeloid cells such as monocytes and macrophages, but also local CNS-resident ones such as microglia, can differentiate towards distinct phenotypes, M1 myeloid cells being more related towards inflammation and autoimmunity and M2 myeloid cells being more related to tissue repair and anti-inflammatory processes. We generated a mouse model specifically lacking the mineralocorticod receptor (MR) in myeloid cells (MR^{LysM} mice). In these mice, the phenotype of bone marrow-derived and peritoneal macrophages was modulated towards M2 including differential phagocytic and migratory properties and NO metabolism. Furthermore, these mice presented with diminished clinical symptoms and ameliorated histological hallmarks of neuroinflammation after EAE induction by MOG_{35-55} and CFA. T cells in peripheral lymphoid organs of these mice produced less pro-inflammatory cytokines while their proliferation and the abundance of regulatory T cells were unaltered. In the CNS, the numbers of inflammatory monocytes and reactive microglia in MR^{LysM} mice were significantly lower and they also adopted an M2-polarized phenotype based on their gene expression profile, presumably explaining the ameliorated neuroinflammation. Thus, the lack of the MR in myeloid cells impacts CNS autoimmunity by either direct effects and/or modulation of the adaptive immune response.

P.C1.01.08

Tissular immune dysregulation in human autoimmune thyroiditis

***A. Mohr**[1], C. Trésallet[2], N. Monot[1], A. Bauvois[1], D. Abiven[3], L. Leenhardt[4], G. Gorochov[3], M. Miyara[3];*
[1]Sorbonne Université, Inserm, Centre d'immunologie et des maladies infectieuses – Paris (CIMI-PARIS), Paris, France, [2]Sorbonne Université, Service de Chirurgie Générale, Viscérale et endocrinienne, AP-HP Hôpital Pitié-Salpêtrière, Paris, France, [3]Sorbonne Université, Inserm, Centre d'immunologie et des maladies infectieuses – Paris (CIMI-PARIS), AP-HP Hôpital Pitié-Salpêtrière, Paris, France, [4]Sorbonne Université, Service d'endocrinologie, AP-HP Hôpital Pitié-Salpêtrière, Paris, France.

Introduction: Peripheral abnormalities in Th17 and regulatory T cells have been observed in autoimmune thyroid diseases (AITDs) that include Hashimoto's thyroiditis (HT) and Grave's disease (GD). However, it is still unclear whether such abnormalities occur in the thyroid tissue.
Materials and Methods: PBMCs and thyroid tissue infiltrating immune cells from 18 patients with HT, 10 patients with GD and 30 control donors (CD) have been analyzed by flow cytometry in order to study T cells and ILC subsets.

Results: We did not observe the previously reported increase of peripheral TH17 cells or the decrease of circulating Treg cells in HT and GD patients. $CXCR5^{+}PD1^{hi}$ TFh cells and LTi-like ILC3 were significantly increased among immune cells infiltrating thyroid from patients with both HT and GD. No modification in $FOXP3^{hi}$ effector Treg (Fr. II) cells was observed in AITDs tissue when compared to controls, while IL-2 producing $FOXP3^{low}CD4^{+}$ T (Fr. III) cells were increased. In addition, the presence of $CXCR5^{+}FOXP3^{low}CD4^{+}$ TFR-like cells with low levels of CTLA-4 was also suggestive of defective local immune dysregulation in AITDs.
Conclusion: AITDs are characterized by the occurrence of tissue immune dysregulation as the presence of TFH and ILC3, two populations involved in secondary and tertiary lymphoid organ development, and IL-2 producing $FOXP3^{low}CD4^{+}$ T (Fr. III) and $CXCR5^{+}FOXP3^{low}CD4^{+}CTLA\text{-}4^{+}$ TFR-like predominating in patients. Those abnormalities may promote the local production of autoantibodies.

P.C1.01.09

Immunological biomarkers of autoimmune liver disease in patients without clinical symptomatology

*A. Navas[1], M. López[2], **J. Molina**[3,1], A. Jurado[3,1];*
[1]Maimonides Biomedical Research Institute of Cordoba (IMIBIC)/ Reina Sofia University Hospital/ University of Cordoba, Cordoba, Spain, [2]Department of Clinical Analyses, Reina Sofia University Hospital, Cordoba, Spain, [3]Department of Allergy and Immunology, Reina Sofia University Hospital, Cordoba, Spain.

Primary biliary cirrhosis (PBC) is an autoimmune disease which results in a slow and progressive destruction of the liver small bile-ducts. PBC is more common in medium-age women and its diagnosis is usually hazard-made according to clinical symptoms, such as tiredness, itching and an increased level of liver-enzymes routinely examined. Autoantibodies against gp-210 and sp-100 are found in association with PBC, together with anti-mitochondrial antibodies. The aim of this study was to analyze demographics and clinical characteristics of serum samples screened for autoantibodies with positivity to anti-gp-210 and sp-100 antibodies.
In this study 75 patients were included. Serum sp-100 and/or gp-210 autoimmune biomarkers were detected by immune-blot according to the immunofluorescence result of autoantibodies on Hep-2 cells. Levels of transaminases were measured by chemiluminescence. The diagnostic suspicion was registered.
The 92% of patients were women. Medium-age of all patients was 59.6±13.5. Anti-sp100 and anti-gp210 were positive in 49 (65.3%) and 20 (26.7%) patients, respectively.
In 5 patients (6.7%) both antibodies were detected. Medium level of liver-enzymes was 43.9±42.3 for aspartate-aminotransferase, 43.07±50.1 for alanine-aminotransferase, 177.1±248.9 for gamma-glutamyl-transferase and 153.9±180.2 for alkaline-phosphatase. The majority of the samples came from the Rheumatology Department (29.3%), followed by those from the Digestive Department (21.3%). Only 17 (22.7%) samples belonged to patients with the clinical suspicion of PBC.
Samples from medium-age women routinely examined with an increased level of transaminases may exhibit a positivity to PBC autoantibody biomarkers. Interestingly, the majority of them are not clinically suspicious of suffering it.

P.C1.01.10

Assessment of the DFS-70 (anti-dense fine speckled 70 antibodies) specificity by CIA (Chemiluminescent immunoassay) and blot in 96 serum samples with the ICAP AC-2 immunofluorescence pattern

***D. Monzón Casado**[1], M. De Juan[1], M. Imaz Ocharan[2], M. Rey Rey[1], L. Aragón Irusquieta[1], Á. Prada Iñurrategui[1];*
[1]Osakidetza, San Sebastián, Spain, [2]Osakidetza, Bilbao, Spain.

Introduction: The nuclear dense fine speckled (ICAP AC-2) pattern in Hep-2 are observed in autoimmunity laboratories. These autoantibodies have been detected with low frequency in systemic autoimmune rheumatic diseases (SARD), in healthy individuals and in patients with other diseases.
Objective: We selected serum from 96 patients based on an immunofluorescence screening of ANA (Tittle ≥ 1/160 and ICAP AC-2 pattern). We investigated anti DFS-70 antibodies using chemiluminescence (CIA) immunoassay and blotting..
Material and Methods.
We analized 96 sera by IFA screening (Euroimmun). DFS-70: CIA (Quanta Flash Werfen) and Blot (Euroimmun). ANAs specificities: Blot (Euroimmun).
dsDNA antibodies: Enzyme immunoassay (Thermofisher) and IFA (*Crithidia luciliae*)..
Results: 1.- DFS antibodies.
From the 96 ICAP-AC2: 12/96 were positive by blot and 6/96 by CIA.
Using a binomial distribution with an uninformative beta prior, we estimated that the probability the Blot detects more positive results than the CIA is 0.9305.
2.- ANAs specificity
Three patients DFS-70 positive by blot were positive for RNP, Histones and Cenp-B.
An ICAP AC-2 positive DFS-70 negative cohort (n=14) were positive for histones (2p) nucleosomes (1p), Scl-70 (2p), Ro (4p), and others.
The ICAP AC-2 positive cohort determined by IFA (n=79) resulted negative for anti DFS-70 and other nuclear specificities.
3.- Anti-dsDNA.
All the patients were negative. .
Conclusions: 1.- DFS-70 monospecific antibodies are present in a low fraction of ICAP-AC2.
2.- The Blot has more positive results than the CIA.
3.- Besides DFS-70, other unknown specificities might show IFA AC-2 pattern.

P.C1.01.11

The role of the tetraspanin CD82 in rheumatoid arthritis synovial fibroblast migration and inflammation

***E. Neumann**[1], M. Schwarz[1], R. Hasseli[1], M. Hülser[1], S. Classen[2], M. Sauerbier[3], S. Rehart[4], U. Müller-Ladner[1];*
[1]Dept Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus-Liebig-University Giessen, Bad Nauheim, Germany, [2]Divis. Vascular Surgery, Kerckhoff-Klinik GmbH, Bad Nauheim, Germany, [3]Dept Plastic, Hand and Reconstructive Surgery, BGU, Frankfurt, Germany, [4]Dept of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt, Germany.

Introduction: Tetraspanins are membrane adaptors altering cell-cell fusion, receptor-mediated signal transduction and cell motility via interaction with membrane proteins including adhesion molecules such as integrins. CD82 is expressed in several malignant cells and a well described tumor metastasis suppressor. Rheumatoid arthritis (RA) is based on synovial inflammation and joint destruction driven in part by activated synovial fibroblasts (SF) with an increased migratory potential. CD82 is upregulated in RASF vs. osteoarthritis (OA) SF and within RA vs. OA synovial tissue. Therefore, the role of CD82 in RASF was evaluated.
Methods: Double-immunofluorescence for CD82 and integrins, proinflammatory stimuli induction of CD82, lentiviral CD82-overexpression, siRNA-mediated knockdown, RASF migration and attachment assays towards plastic/matrigel, RASF-binding assays to endothelial cells (EC), and evaluation of CD82 expression during long-term invasion in the SCID-mouse-model were performed.
Results: CD82 was significantly induced by proinflammatory stimuli (e.g. RASF: TNFα 9.55-fold; IL-1β 12.54-fold). In RA-synovium, CD82 was expressed in RASF close to vessels, lining layer, sites of cartilage invasion, and colocalized with integrins involved in tumor metastasis suppression and RASF attachment. CD82 overexpression reduced RASF migration (e.g. 46.4±15.7 vs. RFP, p=0.0004), cell-matrix (e.g. 27.8% vs. leRFP (100%), p=0.0314) and RASF-EC adhesion. CD82 knockdown increased RASF migration (CD82 174.5±70.0, NTP 74.5±70.1, p=0.044) and matrix adhesion (147.7% vs. NTP, p=0.0166) whereas RASF-EC-interaction was reduced (60.7% vs. NTP, p=0.0015). In SCID mice, the presence of CD82 on cartilage-invading RASF was confirmed.
Conclusion: CD82 contributes to RASF migration to sites of inflammation and tissue damage but also to perpetuation of RASF to articular matrix.

P.C1.01.12

Association of HLA-A alleles with vitiligo in Turkish people

*Y. Hayran, G. O. Ergen, **F. Ozmen**;*
Department of Basic Oncology, Cancer Institute, Hacettepe University, Ankara, Turkey.

Background and Aim: Vitiligo is an autoimmune disease of the skin that results in the destruction of melanocytes and the clinical appearance of white spots.The aim of this study was to investigate the association of HLA-A alleles with the extent and course of disease in patients with vitiligo. **Patients and Methods:** The study included 71 patients with vitiligo and the control group included 100 unrelated healthy donors. HLA-A typing was performed by using PCR-SSO method at low resolution level. **Results :**71(40F) patients with Vitiligo included in our study which consist of 46(64.8%) vitiligo vulgaris.Extensiveness of disease was 7.75(0.1-45)% and commence age(mean) of the disease was 26.5 years. 22.5% (n=16) male patients had positive family history. HLA-A*02 allelle frequency was found to be significantly higher in vitiligo patients than control group *(p=0.023).* Each allele increase the risk of vitiligo by two fold *(CI=1.19-3.34)*. HLA-A*02 allele frequency was similar between the sub-types of vitiligo. HLA-A*02 allele frequency was also found to significantly correlated with commence age of the disease *(p=0,026; r=0,266)*. When compared to the patient, HLA-A*11 was found to significantly higher in controls *(p=0.008)*. HLA-A*11 was found to be preventive for vitiligo disease and each allele was preventive as 3.4 folds(CI=1.31-8.88). There were no statistical correlation between HLA-A*02 allele frequency and extensiveness of the disease (VASI), degree of pigmentation, disease activity(VADI), associated auto-immune disease and the presence of vitiligo in the family. **Conclusion:** This results suggest that HLA-A*02 allele might be positively associated with vitiligo in Turkish people.

In MS, pathogenic Th-cells (mainly Th1 and Th17) recognize myelin antigens and contribute to the damage to the CNS. An important unresolved issue of MS pathogenesis is at which stage of Th-cell differentiation errors occur, at the molecular level, that result in the development of autoreactive Th-cells. We previously showed that in healthy individuals the IL-2 gene is repressed in naive Th-cells by the transcription factor Ets-2, that binds to ARRE-2 element (distal NFAT binding site) of the proximal IL-2 promoter, pointing to Ets-2 as a crucial factor influencing early events of Th-cell differentiation. Importantly, we also demonstrated that Ets-2 suppresses the expression of other genes with Ets-2 binding sites, including cytokines and HIV-1. Our results from 10 patients with remitting-relapsing MS (4M/6F, age: 24-38y, disease duration: 2-7 y, EDSS: 1-2.5), and 10 age/sex-matched healthy controls, show significantly reduced mRNA and protein synthesis of Ets-2 in naive Th-cells from MS patients, lack of Ets-2 binding to the ARRE-2 of the IL-2 promoter in vitro and in vivo, and significantly higher constitutive expression levels of cytokines in the patients' Th-cells (IL-2, IL-17 in naive Th-cells and TNF-α, IFN-γ in memory Th-cells). We also found significantly higher ets-2 expression in undifferentiated murine Th-cells compared to in vitro differentiated Th-cell populations, and elevated ets-2 expression in Th-cells from mice resistant to EAE. We suggest that in MS patients low-level synthesis and dysfunction of Ets-2 in Th-cells are responsible for downstream aberrant Th-cell differentiation resulting in the creation of pathological Th1 and Th17 cells.

Susceptibility and protection against autoimmune diseases including Rheumatoid Arthritis, Multiple Sclerosis, Type I Diabetes and Goodpasture disease (GPD) is associated with particular human leukocyte antigen (HLA) alleles. T cell responses against HLA self-epitopes are considered key drivers of autoimmunity, however the molecular mechanisms that link specific HLA alleles to the initiation or suppression of autoimmunity are presently unclear. Typically, the diversity of T cell self-epitopes and the breadth of HLA associations preclude a definititive analysis of the underlying molecular mechanisms. GPD is an HLA-linked autoimmune renal disorder, where the immune response is dominated by a single CD4+ T-cell self-epitope (α3) derived from type IV collagen. While HLA-DR15 confers a markedly increased disease risk, the HLA-DR1 allele is dominantly protective. HLA-DR15 and HLA-DR1 exhibit distinct peptide repertoires and binding preferences, and the α3 epitope is presented in different binding registers. The difference in α3 presentation is associated with functionally distinct T cell repertoires: HLA-DR15-α3 tetramer+ T cells in HLA-DR15 transgenic mice exhibit a conventional T-cell phenotype (Tconv) that secretes pro-inflammatory cytokines. In contrast, HLA-DR1-α3 tetramer+ T cells in HLA-DR1 and HLA-DR15/DR1 transgenic mice are predominantly CD4+Foxp3+ regulatory T cells (Treg cells) expressing tolerogenic cytokines. HLA-DR1-induced Treg cells confer resistance to disease in HLA-DR15/DR1 transgenic mice. Our results provide a mechanistic basis for the dominantly protective effect of HLA in autoimmune disease, whereby HLA polymorphism shapes the relative abundance of self-epitope specific Treg cells that leads to protection or causation of autoimmunity.

Staphylococcus aureus **induced Th17 cell accumulation aggravates renal autoimmune disease**

D. Reimers[1], *P. Bartsch*[2], *U. Panzer*[2], *S. Klinge*[1], *H. Rohde*[3], *C. Krebs*[2], *H. Mittrücker*[1];
[1]*Institute of Immunology - University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [2]*III. Medical Clinic and Polyclinic - University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [3]*Institute of Medical Microbiology, Virology and Hygiene - University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

CD4$^+$ Th17 cells are defined by their production of IL-17 cytokines and the expression of the transcription factor RORγt. Th17 cells are responsible for the clearance of extracellular pathogens. However, these cells also participate in autoimmune diseases such as crescentic glomerulonephritis (cGN). In our project we infect mice with *Staphylococcus aureus* and characterize the systemic and renal T cell response to infection. In addition, we induce cGN and determine the impact of prior *S. aureus* infection on the course and severity of renal disease.
S. aureus injection led to infection of the kidneys accompanied by a massive renal accumulation of T cells at day 10 post infection. Characterization of renal T cells revealed dominant populations of RORγt-positive IL-17A-secreting Th17 cells and γδ T cells. Both T cell populations were rather stable, even 10 weeks after infection increased numbers of renal Th17 and γδ T cells were still detectable. Furthermore, renal RORγt-positive T cells showed a tissue resident phenotype, defined by CD69 expression. 10 weeks after infection, cGN was induced by injection of sheep IgG binding to the glomerular basement membrane. As compared to nephritic control mice, mice with preceding *S. aureus* infection exhibited augmented renal injury with severe loss of renal function, enhanced glomerular crescents formation and massive tubulointerstitial damage.
In conclusion, our results demonstrate that renal infection and accumulation of Th17 cells correlates with an aggravated autoimmune disease. Currently, we aim to identify the underlying mechanisms.

Systemic lupus and reproduction, lessons from the animal models

G. Boneva[1], *V. Kostadinova*[1], *J. Prechl*[2], *N. Mihaylova*[1], *S. Delimitreva*[3], ***A. I. Tchorbanov***[1];
[1]*Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria,* [2]*Immunology Research Group, Hungarian Academy of Sciences, Budapest, Hungary,* [3]*Department of Biology, Medical University Sofia, Sofia, Bulgaria.*

Introduction: Systemic Lupus Erythematosus (SLE) is a polygenic autoimmune disorder involving multiple organs that can influence female fertility. Pristane-induced mouse model of SLE is very suitable to study female fertility compared to the healthy animals with the same background. Materials and Methods: Lupus-like symptoms were induced through intraperitoneal injection of hydrocarbon oil pristane in non-autoimmune Balb/c mice. Flow cytometry was used for the detection of CD25/CD69 activation markers and apoptosis assay. The levels of cytokines, autoantibodies in the sera and the number of autoantibody-producing plasmocytes were quantified by ELISA, ELISpot and protein array. Results: A single i.p. injection of pristane leads to the development of the typical SLE symptoms such as production of different autoantibodies accompanied by massive glomerular depositions of IgG-containing immune complexes in the kidneys, and proteinuria. After hormonal ovarian stimulation, ovulated oocytes were derived from oviducts. Chromatin, tubulin and actin structures were detected by Hoechst 33258, FITC-labeled alpha-tubulin antibody and rhodamine-labeled phalloidin, respectively. The total number of obtained metaphase oocytes from lupus mice was significantly lower compared to healthy controls. The maturation rate, i.e. the proportion of eggs reaching metaphase II, was also lower for Lupus mice compared to control animals. For each oocyte, four characteristics were described - spindle morphology, actin cap, chromosomal condensation and alignment. Many specific abnormalities in the lupus group were found. Conclusions: Pristane-induced mouse model of lupus exhibited numerous impairments of the reproductive system which may result due to disease activity, autoantibodies or damage in molecular mechanisms through the process of reproduction.

P.C1.01.17

Enrichment of pioneer CD4+ T cells andup regulation of CX3CR1 in Experimental Autoimmune Uveoretinitis

A. Ward, *O. H. Bell, D. A. Copland, A. D. Dick, L. B. Nicholson;*
University of Bristol, Bristol, United Kingdom.

Non-infectious uveitis is a T cell mediated intraocular inflammatory disease leading to severe visual impairment. Experimental autoimmune uveitis (EAU) is a preclinical model that shares many features of the human disease and can be induced in rodents by transfer of autoantigen specific lymphocytes. Combined high resolution clinical imaging and flow cytometric assessment, enables us to delineate the ratio of transferred and endogenous cells throughout the disease course. As the sole receptor for CX3CL1, Cx3Cr1 expression is associated with the retention and survival of CD4$^+$ T cells in the lung and skin.
To interrogate the induction of EAU by adoptive transfer of antigen-specific lymphocytes and the role of CX3CR1, cells obtained from immunized CX3CR1$^{+/GFP}$ reporter mice (Ly5.2) were transferred into naïve Ly5.1 recipients. Transferred and endogenous cells rapidly accumulate in the eye within 48 hours. As clinical disease progresses to peak (day 7), 20% of the transferred CD4+ cells were GFP positive, increasing to 50% by day 14. This demonstrates selective enrichment, as the transferred cells comprised an increasing fraction of total retinal cell infiltrate.

These studies suggest that disease-causing antigen specific cells have a long half-life in ocular tissue and/or recirculate extensively. Within the eye, a subset of CD4 cells have a tissue specific phenotype defined by the expression of CX3CR1 which promotes survival or increases retention of specific cells. Long-lived disease-causing cells are therefore a potential candidate for targeted immune-intervention.

P.C1.01.18

Polymorphisms of the cytokine genes TGFB1 and TNFA in Polish patients with inflammatory bowel disease

E. Zakoscielna[1], *M. Zagozda*[1], *A. Surowiecka-Pastewka*[1,2], *M. Durlik*[1,2];
[1]*Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland,* [2]*Central Clinical Hospital of the Ministry of the Interior and Administration, Warsaw, Poland.*

Introduction: Inflammatory bowel disease (IBD) is a chronic inflammatory condition of the gastrointestinal tract, consisting two clinical entities: Crohn's disease and ulcerative colitis. TGF-β and TNF-α are two major immunoregulatory cytokines and their signaling pathways play a critical role in IBD development and progression. The aim of the study was to analyze the TNFA and TGFB1 gene polymorphisms in Polish patients with IBD and its relationship with the secreted cytokines.
Materials and Methods: A total of 42 patients diagnosed with IBD were examined for the TNFA (-308G>A) and TGFB1 (+29C>T) SNP. As a control group, 100 healthy individuals from the same geographical region were selected. Genotyping was performed with the TaqMan assay. Cytokine levels were measured by ELISA in serum samples.
Results: A significantly increased level of TNF-α was observed in patients carrying AA variant of -308G>A polymorphism compared to control. Genotype-phenotype correlation analysis revealed that AA variant was also associated with the development of perianal fistulas. While TGF-β serum level in IBD patients was significantly higher than controls, no significant difference in TGF-β levels between different genotypes exist. Further analysis showed that patients having AA variant of +29C>T SNP suffer from severe disease condition.
Conclusions: Our data suggest that TNFA gene polymorphism participate in determination of IBD susceptibility in Polish patients. The cytokine level is significantly modulated in patients with different genotypes of TNFA gene. Further studies of additional SNPs and increasing the number of individuals should be performed to confirm the role of TNF-α and TGF-β.

Regulatory T cells (T_{reg} cells) are important for the prevention of autoimmunity and lately, their role in maintaining tissue homeostasis has been demonstrated. They exert their function via different suppressive mechanisms including soluble factors. However, how T_{reg} cells exert their function in tissue specific environments is often unknown.
Here, we show that T_{reg}-cell specific expression of hydroxyprostaglandin dehydrogenase (HPGD), which catabolizes prostaglandin E_2 (PGE_2) into 15-keto PGE_2, enforces a new suppressive mode of action through accumulation of the PPAR-γ ligand 15-keto PGE_2. PPAR-γ-dependent HPGD expression acts as the critical molecular link between prostaglandin metabolism, adipose tissue (AT)-associated T_{reg}-cell function, and maintenance of AT homeostasis. In mice, loss of HPGD results in increased numbers of non-functional T_{reg} cells, which accumulate in visceral adipose tissue resulting in increased local inflammation and systemic insulin resistance. In line with this, we could show that in type 2 diabetes (T2D) patients the peripheral blood T_{reg}-cell compartment was reduced and exhibited decreased HPGD expression, indicating that HPGD also seems to be involved in the development of T2D in humans.
These data support that Hpgd is critical for T_{reg}-cell functionality both *in vitro* and *in vivo* and that HPGD acts as a novel tissue- and context-dependent suppressor mechanism by T_{reg} cells to maintain adipose tissue homeostasis.

T-cell dynamics in *Heligmosomoides polygyrus* infection revealed by a new Timer approach

C. B. Ducker[1], *D. Bending*[2], *M. E. Selkirk*[1], *M. Ono*[1];
[1]*Imperial College London, London, United Kingdom,* [2]*University of Birmingham, Birmingham, United Kingdom.*

Heligmosomoides polygyrus (*H. polygyrus*), an intestinal nematode parasite, induces regulatory T-cells (Tregs) to persist within the murine host through secreted effector proteins. However, it is currently unknown whether and how this differs between infection phases, due to a lack of methods to study Treg dynamics and the T-cell response within the periphery. *Timer of cell kinetics and activity* (Tocky) technology allows analysis of the real-time dynamics and history of gene transcription. Here we analyse both *Foxp3*-Tocky and *Nr4a3*-Tocky mice, investigating *Foxp3* expression and TCR signalling respectively in Treg differentiation during different stages of *H. polygyrus* infection.
Nr4a3-Tocky showed that the majority of T-cells were unresponsive during the early phase of infection, while the T-cell response increased when parasites migrate to the intestinal lumen. *Foxp3*-Tocky mice revealed that de novo transcription of *Foxp3* increases in $CD4^+$ T-cells by day 7 of infection. These cells appear to then sustain *Foxp3* transcription, becoming Treg. At day 28 of infection, *Foxp3* transcription is modestly re-instated in a population. We further analysed transcriptomic responses of Tocky populations by RNA-seq.
In conclusion, two individual Treg responses appear to be occurring during *H. polygyrus* infection, depending on the phase. An initial, most likely parasite-mediated response is followed by a response of the major Treg population, possibly as a result of tissue damage. Furthermore, investigation of TCR signalling suggests a potential break in T-cell non-responsiveness during parasite migration.

P.C1.02.01

Impaired immunomodulatory function of Treg-derived exosomes in RRMS patients

M. Azimi Mohamadabadi, *M. Izad;*
Tehran university of medical science, Tehran, Iran, Islamic Republic of.

Introduction: Multiple sclerosis is an autoimmune disease which is characterized by neuroaxonal degeneration in central nervous system. Impaired function of regulatory T cells (Tregs) is believed to be an underlying pathogenic mechanism in MS. Tregs is able to release exosomes, which contain a considerable amount of protein and RNA. Exosomes are capable of transporting their content to other cells where the released content exerts biological functions. Here, we investigated whether Tregs-exosomes of RRMS patients or healthy controls might regulate the proliferation or survival of T lymphocytes.
Methods: Regulatory T cells derived from MS patients or healthy controls were cultured for 3 days and exosomes were purified from supernatants. Treg-derived exosomes were co-cultured with conventional T cells (Tconv). The percentages of Tconv proliferation and apoptosis were measured.
Result: Our findings showed that the percentage of proliferation suppression induced by exsosomes in patients compared to healthy controls was 8.04±1.17 and 12.5±1.22, respectively; p-value=0.035. Moreover, the rate of Tconv apoptosis induced by exosome of MS patient was less than healthy controls (0.68±0.12 vs. 1.29±0.13; p-value=0.015). Overall, Treg-derived exosomes from MS patients and healthy controls suppressed the proliferation and induced apoptosis in Tconv. However, the effect of MS-derived exosomes was significantly less than healthy controls.
Conclusion: Our results point to an alternative Treg inhibitory mechanism which might be important in immunopathogenesis of MS. Although, the cause of the exosomal defect in MS patients is unclear, manipulation of patients' Treg- derived exosomes to restore their suppressive activity might be considered as a potential therapeutic approach.

The blockage of NMDAr decrease the inflammatory response of T helper cells in an animal model of Multiple Sclerosis

W. N. Brandão[1], *A. C. Durão*[2], *T. T. Braga*[3], *C. Longo*[1], *C. Polinio*[1], *N. Ghabdan*[1], *L. De Oliveira*[1], *T. Marcourakis*[2], *J. S. Peron*[1];
[1]*Institute of Biomedical Sciences, São Paulo, Brazil,* [2]*Faculty of Pharmaceutical Sciences - University of São Paulo, São Paulo, Brazil,* [3]*Federal University of Paraná, Curitiba, Brazil.*

Multiple Sclerosis (MS) consists of an autoimmune disease that have its pathology due to an infiltration of immune cells in the central nervous system (CNS) promoting inflammation and death of resident cells. The factors that influence this disease are not full understanding, especially the effects of neurotransmitters on infiltrated cells. Data from our group shows that glutamate is involved in this pathology and the blockade of its receptor NMDA by MK801 in mice decreases both disease and pathogenic T cells frequency in the CNS. However, is not clear if this phenomenon is dependent of lymphocytes or cells of the innate immune response. In order to overcome this, we developed in our laboratory a model of mice that have the NMDAr blocked only in the T lymphocytes, through the crossing of C57BL/6 $CD4^+$ Cre mice with C57BL/6 Grin1 Flox. Our data shows a delay in the clinical scores of animals knockout for NMDAr in T lymphocytes. This result is associated with lower production of proinflammatory cytokines (IFN-γ and IL-17) by the leukocytes present in the draining lymph nodes during the antigen presentation period (7 days after immunization). In addition, we find a smaller amount of T helper lymphocytes present in these organs, this may be due to a lower proliferative capacity of these cells. Lastly, our data point to a direct effect the downstream of the NMDAr on the T helper lymphocyte response. Financial support CAPES

P.C1.02.03

Influence of Invariant chain and HLA-DM on the HLA-DR3 peptidome constitution

R. Farriol[1], *Y. Arribas*[1], *C. Guitart*[1], *L. Labeur*[1], *V. Casas*[2], *M. Carrascal*[2], *D. Jaraquemada*[1];
[1]*Institute of Biomedicine and Biotechnology, Autonomous University of Barcelona, Cerdanyola del Vallès, Spain,* [2]*CSIC UAB Proteomics Laboratory, CSIC-IIBB, Cerdanyola del Vallès, Spain.*

Genetic-wide-association-studies (GWAS) have pinpointed a high risk to several autoimmune diseases including type 1 diabetes, associated to certain HLA-class-II haplotypes, of which DR alleles HLA-DRB1:04:01 (DR4) and HLA-DRB1:03:01 (DR3) stand out. In a previous study, our group showed the influence of the Invariant Chain (Ii) and HLA-DM on the DR4-peptidome using a rat insulinoma cell line (RINm5f) trnsfected with DR4, Ii and HLA-DM human genes. A similar panel of four transfected cell lines (RIN -DR3DMIi, -DR3DM, -DR3Ii and -DR3) was used to dissect the individual and coordinated effects of these chaperones on the DR3-peptidome. The results showed that both Ii and DM influenced most of the peptidome characteristics, including peptide length distribution, DR3 motif compliance, predicted binding affinity and preference for endocytic degradation. In contrast, the subcellular origin of the proteins represented in the DR3-associated peptidome was independent of chaperone expression. Thus, one third of the peptides from the DR3 repertoire from all the transfectant cells derived from cytosolic degradation, i.e. were either from cytosol or nuclear proteins. The DR3-repertoire from a homozygous human B-cell line showed around 15% of such peptides. These results differ from those from the DR4 transfectants, where the frequency of cytosol-degraded peptides was only high in the HLA-DR4 single transfectants and the expression of Ii and DM normalized the subcellular origin distribution. The data thus suggested an allele dependent feature of the DR3-associated peptidome.

Thymus is a possible site of sensitization for AChR and production of autoreactive antibodies. In this study, we investigated co-stimulatory molecules on B cells as well as the response to innate or adaptive stimulations in AChR+ MG patients with or without immunosuppressive treatment and controls. Methods For this study, 45 AChR+ MG and 21 healthy controls were recruited. Also 27 thymic samples (21 AChR+ MG and 6 Non-MG) were analyzed alongside with blood samples. Peripheral blood and thymic samples were stained with CD19, CD27, CD80, CD86, CD40, HLA-DR antibodies both before and after stimulation with TLR9 agonist and IL-21 and analyzed by flow cytometry. Results CD80 and CD86 expressions on B cells were increased in the peripheral blood and in the thymus of untreated patients. Also thymic B cells had increased CD80 and CD86 compared to peripheral blood samples in both treated and untreated patients. CD86 was further amplified by IL-21 in untreated patients. CD80 expression however did not change. Conclusion A role for activated B cells, active thymic environment and IL-21 is implicated in MG.

Protein YKL-40 and neuron-specific enolase in traumatic brain injury

M. Kazakova[1], *G. Pavlov*[2], *K. Simitchiev*[3], *P. Timonov*[4], *V. Dichev*[5], *C. Stefanov*[2], *V. Sarafian*[5];
[1]*Medical University - Plovdiv, Plovdiv, Bulgaria,* [2]*Medical University - Plovdiv; 2Department of Anesthesiology, Emergency and Intensive Care Medicine; University Hospital "St. George", Plovdiv, Bulgaria,* [3]*3Department of Analytical Chemistry and Computer Chemistry, Faculty of Chemistry, University of Plovdiv, Plovdiv, Bulgaria,* [4]*Department of Forensic Medicine, Medical Faculty,Medical University – Plovdiv, Plovdiv, Bulgaria,* [5]*Department of Medical Biology, Medical Faculty, Medical University – Plovdiv, Technological Center for Emergency Medicine, Plovdiv, Bulgaria.*

Introduction: Traumatic brain injuries (TBIs) are major issue of public health. The glycoprotein YKL-40 is expressed as a consequence of a broad spectrum of inflammatory and malignant diseases. Neuron-specific enolase (NSE) is considered as a biomarker of neuronal stress and inflammatory conditions.
The purpose of this investigation is to determine the dynamics of NSE and YKL-40 levels after TBI.
Methods: We examined plasma and cerebrospinal fluid (CSF) levels of both proteins in nineteen patients – on the 24th and 96th hour after the TBI. Routine haematological and biochemical tests were also performed. As control served the CSF of age-matched suddenly deceased healthy individuals.
Results: We found no significant change between CSF levels of YKL-40 and NSE on the 24th h after TBI compared to the control group. However the interquartile range (25–75 percentile) of the YKL-40 concentrations for the control group was much lower than the one of TBI patients. NSE levels in CSF on the 24th h were higher in comparison with plasma concentrations (p=0.001), while no difference on the 96th h was observed.
Significant difference between plasma and CSF YKL-40 levels on the 24th (p=0.027) and 96th (p=0.044) in the patients with TBI was detected. No association of YKL-40 and NSE concentrations with monocytes and neutrophils counts (as percentages of WBC) was observed.
Conclusion: We assume that YKL-40 levels reflect better the inflammatory process in TBI. Acknowledgements: The financial support by the National Science Fund of Bulgaria (Contract DM 03/2 12.12.2016) is gratefully acknowledged

P.C1.02.07

Diet-induced obesity alleviates collagen-induced arthritis (CIA) in male DBA/1 male mice

K. Marcińska, ***P. Kowalczyk****, A. Strzępa, M. Majewska-Szczepanik, M. Szczepanik;*
Department of Medical Biology, Faculty of Health Sciences, Jagiellonian Univeristy Medical College, Krakow, Poland.

At present there are only a few reports concerning the effects of obesity on collagen-induced arthritis (CIA) in mice and rheumatoid arthritis in patients. Studies conducted by our team demonstrated that diet-indecent obesity (DIO) aggravates T-cell mediated immune response such as contact hypersensitivity in mice. Unexpectedly, our preliminary data employing CIA model showed that male mice with DIO develop less severe disease. To study the influence of obesity on CIA, DBA/1 mice were fed high fat diet (HFD) or normal diet for 4 or 8 weeks prior to CIA induction. Our data show that male but not female mice fed HFD for 4 or 8 weeks develop less severe disease (clinical score). Decreased disease severity in male mice correlated with reduced myeloperoxidase (MPO) activity in joint tissue. Moreover, reduced concentration of anti-COLL II IgG2a correlated with decreased disease severity in HFD-fed male mice. Observed reduction of anti-COLL II IgG2a in male HFD-fed mice is in line with decreased percentage of $CD19^+$ $B220^+$ B cells in the spleen when compared to female mice fed HFD. Further flow cytometry analysis of lymphoid organs showed increased percentage of $CD4^+IL10^+$ lymphocytes in the spleen of HFD-fed male mice that developed less severe disease. This was not observed in female mice with DIO. In summary, our data show that DIO alleviates CIA in male but not female mice suggesting that this phenomenon is determined by gender. This work was supported by grant K/ZDS/007122 to MS.

P.C1.02.08

Genetic variants in HLA and C11orf30 locus associated with breach of Immune tolerance and autoantibody production in healthyand SLE

Q. Li*, P. Raj, H. Zhu, I. Dazmorov, D. Karp, E. K. Wakeland;*
University of Texas Southwestern Medical Center, Dallas, United States.

Molecular dissection of the genetic variants from 3,903 healthy and autoimmune individuals with different levels of autoantibodies (autoAbs) revealed two major genetic loci in HLA and C11orf30 regions which are highly associated with break in immune-tolerance and autoAb production. The variants in HLA locus associated with IgG autoAbs was the same SLE risk haplotype that impact consensus binding motifs of IRF4 and CTCF in the XL9 regulatory complex and modify the transcription of MHC class-II antigen presenting genes. The HLA haplotype 3 (HAP3), which was identified to be a SLE risk haplotype, was associated with ANA positivity in healthy individuals (OR=2.1, p=0.01). High resolution autoantibody profiling showed an increased level of autoAbs against non-nuclear antigens in ANA positive healthy and incomplete lupus, while high titer of autoAbs targeting to nuclear antigens were present in most lupus patients, suggesting a target transition of IgG autoAbs during the disease development. Variants in C11orf30 locus associated with ANA in healthy but not in SLE. The carriers of C11orf30 risk haplotype demonstrated strong titers of IgG and IgA autoAbs to many common allergens i.e. cedar Red juniper pollen and whole wheat triticum. The risk haplotype of C11orf30 was associated with downregulation of its expression in EBV cells and MDMs. Whole transcriptomic analysis of B cells from ANA positive healthy donors carring the risk alleles revealed significantly upregulated BTK, SLAMF1&6, BLNK, FCRL1 and HLA-DRB1 genes, suggesting enhanced B cell signaling.

P.C1.02.09

Circulating IL-10 producing B cells in CSF of neuroimmunological disorders patients

O. Maghrebi[1], *M. belghith*[2], *K. Bahrini*[3], *S. ben Sassi*[4], *S. Blel*[4], *M. R. Barbouche*[3];
[1]*Institut Pasteur de Tunis, Belvédère Tunis, Tunisia,* [2]*Institut Pasteur de Tunis, tunis, Tunisia,* [3]*Institut Pasteur de Tunis, Belvédère tunis, Tunisia,* [4]*Institut Mongi Ben Hmida de Neurologie De Tunis, Tunis, Tunisia.*

Introduction/objective: Neuroimmunological disorders are a spectrum of diseases characterized by a chronic neuroinflammation causing neurologic lesions. The recurrent clinical course of the majority of those diseases suppose an interplay between self-reactive and immunoregulatory process. T and B cells are generally considered as effectors cells, but it is now clear that they are essential for inducing immune tolerance by regulating immune responses via IL-10 production. The aim of this work is to assess involvement of different cell subsets secreting Il-10 in the cerebrospinal fluid of patients with neuroinflammatory disease. **Material /Methods:** Blood and cerebrospinal fluid (CSF) samples from patients with CNS inflammatory diseases were collected at time of clinical relapse. Ethical clearance and written consent were obtained for all of them. Isolated PBMCs and CSF cells were immunostained with a combination of specific antibodies and then analyzed using cytometry. **Results/ conclusion:** Our results show IL-10 higher expression in CSF neuro-inflammatory diseases like Neuro-Behçet compared to neuro-autoimmune disorders. The evaluation of the eventual source of this cytokine show us an increased IL-10 producing B cells in CSF of patients compared to IL-10 producing CD4. Interestingly, the CD4 subset secretes lower levels of IL-10 in the two studied compartments of patients compared to healthy controls. In blood there was no significant difference between the two studied cells in their capacity to produce IL-10. In summary, our current findings confirm the deleterious IL-10 production by TCD4 subsets and suggest that IL-10 producing B cells are the major regulatory cells involved in neuroinflammatory environment.

P.C1.02.10

Role of the complement system in Sjögren syndrome

M. Masarwa[1], *I. Alon*[2], *A. Pikovsky*[3], *A. Livoff*[2], *B. Forer*[1];
[1]*The Department of Otolaryngology-Head and Neck Surgery, Barzilai University Medical Center (Affiliated to the Faculty of Medicine, Ben Gurion University of the Negev, Beer Sheva), Ashkelon, Israel,* [2]*The Department of Pathology, Barzilai University Medical Center, Ashkelon, Israel,* [3]*The Unit for Oral Medicine, Barzilai University Medical Center, Ashkelon, Israel.*

Sjögren syndrome (SS) is a progressive autoimmune disease characterized by a wide range of symptoms. Most patients present with mild sicca symptoms but others may develop serious systemic manifestations including vasculitis and severe vital organ dysfunction. The main pathophysiologic basis of primary SS is attributed to tissue-infiltrating T and B cell lymphocytes, triggered by concomitant inflammatory mediators and chemotactic agents. Though low levels of circulatory complement proteins are frequently observed in SS, especially in the extra-epithelial form of the disease, little is known about the contribution of the complement system to the pathogenesis of the disease. The aim of this study is to investigate the role of complement in the pathogenesis of SS.
Deposition of complement C3 and C9 proteins was examined in minor salivary gland specimens excised from SS patients (n = 16). Oral biopsies taken because of other non-inflammatory lesions and contained incidental minor salivary glands, served as controls (n = 6). Complement C3 and/or C9 deposition was observed in 93% of SS patient specimens, in contrast to 17% of controls. The sensitivity and specificity of the test herein was 93% and 83% respectively. Complement deposition was mostly seen around the ducts or within the ductal cells.
To our knowledge, this is the first time complement deposition was found in salivary glands of SS patients. These findings may pave the way for the development of new anti-complement therapeutic agents for patients with SS.

P.C1.02.11

Jmjd6 controls Aire protein expression and self-tolerance induction in the thymus

K. Matsubara[1], *T. Yanagihara*[1], *Y. Fukui*[1,2];
[1]*Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan,* [2]*Research center for Advanced Immunology, Kyushu university, Fukuoka, Japan.*

Introduction: To establish immunological self-tolerance in the thymus, medullary thymic epithelial cells (mTECs) express diverse sets of tissue-specific self-antigens (TSAs). This ectopic expression of TSAs largely depends on the transcriptional regulator Aire, yet the mechanism controlling Aire expression itself remains unknown. In this study, we examined the role of Jmjd6, a lysyl hydroxylase for splicing regulatory proteins, in Aire expression.
Material and methods: As conventional Jmjd6 KO mice die during perinatal period, 2DG-treated fetal thymi were prepared from the KO mice and control mice for FACS analyses, immunohistochemical analyses and RNAseq analyses. The 2DG-treated fetal thymi from these mice were grafted into C57BL/6 nude mice to examine its effect on self-tolerance induction. The conditional Jmjd6 KO mice (Foxn1-CRe Jmjd6$^{lox/lox}$ mice) were crossed with a diabetes mouse model (OT1+RIP-mOVA+ mice) to analyse specific tolerance induction in a more physiological condition.
Results: Although Jmjd6 deficiency did not affect abundance of *Aire* transcript in mTECs, the intron 2 of *Aire* gene was not effectively spliced out in the absence of Jmjd6. As a result, the expression of mature Aire protein and TSAs were markedly reduced in Jmjd6-deficient mTECs, and C57BL/6 nude mice grafted with Jmjd6-deficient thymi spontaneously developed multi-organ autoimmunity. In addition, we found that TEC-specific deletion of Jmjd6 exacerbated development autoimmune diabetes in a mouse model.
Conclusion: Jmjd6 expression is required in mTECs for expression of mature Aire protein and induction of self-tolerance in developing T cells.

P.C1.02.12

Role of the transcription factor Eomes in CD4 T cell functions and susceptibility to CNS autoimmunity

M. F. Michieletto[1,2,3], *E. Joulia*[1,3,2], *V. Girault*[1,3,2], *A. Saoudi*[1,3,2], *A. S. Dejean*[1,3,2];
[1]*INSERM U1043, TOULOUSE, France,* [2]*Paul Sabatier University, Toulouse, France,* [3]*CNRS UMR 5282, Toulouse, France.*

T cell responses play a crucial role in inflammation of the central nervous system (CNS) such as Multiple Sclerosis (MS). However, the molecular mechanisms conferring encephalogenic properties to CD4 T cells remain unclear. Using the Experimental Autoimmune Encephalomyelitis model (EAE), we showed that the Foxo3/Eomes axis controls pathogenic CD4 T cell polarization and susceptibility to autoimmunity. Indeed, Foxo3KO mice were resistant to EAE due to the inability of CD4 T cells to differentiate into IFN-g and GM-CSF secreting cells. At the molecular level, we identified Eomes as a direct target gene of Foxo3. *EOMES* is a susceptibility gene in MS, however, the specific functions of this transcription factor in CD4 T cells require in-depth characterization. EomesKO renders mice resistant to EAE and T cell transfer experiment showed that EomesKO CD4 T cells exhibit decreased encephalogenic properties. Using Eomes-GFP reporter mice, we showed that Eomes$^+$ CD4 T cells accumulates over time during EAE, produced more proinflammatory cytokines and displayed specific migratory capacity. *In vitro*, we showed that Eomes is expressed by a specific population of long-lived effector CD4 T cells with peculiar functions. In Human, we showed that EOMES is mostly expressed by Effector and Effector Memory CD4 T cells. Expression of EOMES allowed CD4 T cells to respond faster upon activation and to secrete high amount of pro-inflammatory cytokines such as IFN-g, GM-CSF and decreased amount IL-4 and IL-17. Altogether, our results suggest that Eomes expression might define a specific subpopulation of Th cells playing a key role in neuroinflammation.

P.C1.02.13

Immunopathogenesis of vitiligo: do cytotoxic CD8$^+$ T-cells have a role?

S. Mitra, *S. Mukherjee, S. Sengupta, A. K. Pati, A. Ghosh, S. Sen, U. Chatterjee, S. Chatterjee, M. Chatterjee;*
Institute of Post Graduate Medical Education and Research, KOLKATA, India.

Introduction: Vitiligo, an autoimmune disease is characterized by melanocyte destruction and affects 0.5-1.0% of the world population. An altered immunological milieu may contribute to disease pathogenesis and this study aimed to evaluate the status of CD8$^+$ T-cells in patients with vitiligo.
Materials and Methods: The status of CD8$^+$ T-cells in peripheral blood was evaluated in terms of Granzyme B positivity and propensity to dermal homing (CXCR3) by flow cytometry. Concomitantly, levels of circulating pro-inflammatory cytokines (IL-2, IL-6, TNF-α, IFN-γ, IL-1ß, IL-8) and chemoattractants (CXCL9, CXCL10, CXCL11) were measured using a multiplex assay. The presence of dermal CD8$^+$ T-cells was evaluated by immunohistochemistry.
Results: In peripheral blood of patients with vitiligo as compared to healthy individuals, CD8$^+$ T-cells demonstrated an increased frequency of Granzyme B and CXCR3. Additionally, levels of circulatory pro-inflammatory cytokines (IL-6, TNF-α, IL-1β, IFN-γ and IL-8), and chemokines (CXCL9, CXCL10) was enhanced. An increased presence of epidermal CD8$^+$ T-cells was demonstrated in the perilesional skin of patients with vitiligo.
Conclusions: Patients with vitiligo had higher levels of pro-inflammatory cytokines (IL-6, TNF-α, IL-1β, IFN-γ and IL-8). The increased levels of IFN-γ possibly caused upregulation of CXCR3 in CD8$^+$ T-cells, and the concomitant increment in the levels of chemokines, CXCL9 and CXCL10 facilitated the migration of CD8$^+$ T-cells to the dermal milieu which may be responsible for the destruction of melanocytes, a hallmark of the disease.

P.C1.02.14

Descriptive analysis of patients with antibodies related to systemic sclerosis

M. San Jose-Cascon[1], *A. Pérez Linaza*[2], *R. de la Varga Martínez*[3], *E. Velazquez*[4], *F. Medina Varo*[2], *C. Rodríguez*[2];
[1]*UGC Hematology, Immunology and Genetics, Hospital Universitario Puerta del Mar, Cadiz, Spain,* [2]*Hospital Universitario Puerta del Mar, Cadiz, Spain,* [3]*Hospital Universitario Virgen del Rocío, Sevilla, Spain,* [4]*Hospital Dr. Arturo Oñativia, Buenos Aires, Argentina.*

Abstract: Systemic sclerosis (SSc) is an autoimmune disease characterized by cutaneous and visceral fibrosis associated to small-vessel vasculopathy. There is evidence that both capillary anomalies and the course of disease are associated to the presence of specific autoantibodies (Ab) such as anti-centromere Ab (CENP-Ab) and anti-topoisomerase I Ab (Scl-70).
Objective: Our aim was to evaluate the diagnostic and prognostic value of CENP and Scl-70 Ab in patients diagnosed with SSc from our hospital.
Patients and methods: Patients with specific Ab of SSc were retrospectively selected from January-2012 to December-2017 (n=70). Clinical and laboratory data were collected and patients were classified according to ACR/EULAR 2013 criteria. The association between Ab and clinical parameters were assessed in the group of patients diagnosed with SSc (n=27).
Results: Among 70 patients, 58 had CENP-Ab and 12 had Scl-70 Ab. 2/3 of patients with SSc presented the limited form and the most frequent clinical manifestations were Raynaud phenomenon, digestive complaints and telangiectasias. Digital ulcers were observed in 9% of CENP-Ab vs 100% of Scl-70 positive patients ($p<0.05$, $\chi 2$). Lung involvement was present in 54% of patients with CENP-Ab vs 100% of patients with Scl-70 ($p<0.05$, $\chi 2$). Patients with anti-Scl-70 had higher levels of ESR than those with CENP Ab ($p<0.05$, $\chi 2$).
Conclusions: The presence of Scl-70 was associated with more frequent lung involvement, digital ulcers and higher levels of ESR, whereas CENP-Ab appeared in limited SSc. Therefore, anti-Scl-70 Ab are laboratory markers for identifying SSc patients with worse prognosis.

P.C1.02.15

Age related macular degeneration and innate immunity: molecular crosstalk between the complement system and the long pentraxin 3

M. Stravalaci[1,2], *M. R. Romano*[1], *F. Petroni*[2], *R. Parente*[2], *M. Gobbi*[3], *B. Bottazzi*[2], *A. Mantovani*[1,2], *A. Inforzato*[1,2];
[1]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (Milano), Italy,* [2]*IRCCS-Humanitas Clinical Research Institute, Rozzano, Italy,* [3]*IRCCS-"Mario Negri" Institute for Pharmacological Research, Milano, Italy.*

Dysregulation of the complement system is a key event in age-related macular degeneration (AMD), the leading cause of blindness in the developed world. Most of the genetic variation associated with AMD resides in genes encoding complement proteins, with the greatest risk being contributed by factor H (FH), major inhibitor of the alternative pathway of complement (AP). FH regulates complement activation both in solution and on cell surface by mediating the proteolytic cleavage of C3b, activator of the AP. One of the ligands of FH is the long pentraxin 3 (PTX3), a soluble pattern recognition molecule involved in innate immunity, tissue homeostasis and inflammation. PTX3 is locally produced in the retina pigmented epithelium (RPE), where, based on mouse models of AMD, it is believed to modulate complement activation via recruitment of FH. However how this occurs in the human eye is yet to be defined. In the present work we employed an integrated approach using *in vitro* binding assays and a cell model of RPE (ARPE-19) to investigate the PTX3-FH-C3b interactions and their effect on AP activation. In solid phase and surface plasmon resonance binding experiments we found that PTX3 specifically recognizes C3b, and this interaction is strengthened by FH. Importantly, C3b could not trigger AP activation when bound to PTX3. We extended these investigations to ARPE-19 cells under either oxidative or inflammatory conditions, to model the human disease *in vitro*. These findings point to a novel mechanism of complement regulation by PTX3 with potential implications in the etiopathogenesis of AMD.

P.C1.02.16

Human kidneys house tissue-resident B cells with a distinct phenotype and anatomical location

O. Suchanek, *J. Ferdinand, K. Loudon, A. Riding, M. R. Clatworthy;*
MRC Laboratory of Molecular Biology, Molecular Immunity Unit, University of Cambridge, United Kingdom.

Background: B cells play a central role in humoral immunity via antibody production but have also antibody-independent functions. There is an increasing appreciation of the importance of tissue-resident immune cells in generating local immune responses. To date, the question of whether B cells reside in non-lymphoid organs has received little attention. **Methods:** We examined the number, phenotype and clonality of B cells in human kidneys that were perfused to remove circulating cells, and in splenic tissue obtained from the same donor (N=10, median age 56 years (range: 23-80)). Percolled single cell suspensions from homogenized organs were analyzed using a 35-marker mass cytometry panel, and B cells were also sorted for RNA-sequencing. **Results:** The composition and size of the major renal leukocyte populations was heterogeneous between donors. The frequency of B cells in both the renal cortex and medulla was lower than that observed in spleen (8.8% and 5.8% vs. 26%, P<0.005). The renal cortex harbored five times more B cells per gram of tissue than medulla (P 0.02). Both renal cortex and medulla were significantly enriched for non-naïve B cells compared with spleen. BCR analysis showed CDR3 repertoire differences between kidney and spleen suggesting a specific antigenic exposure. **Conclusion:** Our study shows that under homeostatic conditions, the extravascular compartment of human kidneys harbors antigen-experienced B cells, mirroring studies of murine tissue-resident T cells. These kidney B cells may play a role in local immune defense or contribute to immunopathology and further studies on diseased tissues and murine models are underway.

P.C1.02.17

Highly inflammatory multiple sclerosis patients show an increase in B cell cytokine production in cerebrospinal fluid

A. Tejeda Velarde[1], *E. Rodríguez Martín*[1], *L. Costa-Frossard*[1], *Y. Aladro*[2], *S. Sainz de la Maza*[1], *M. Espiño*[1], *S. Medina*[1], *N. Villarrubia*[1], *E. Monreal*[1], *J. Álvarez-Cermeño*[1], *E. Roldán*[1], *L. Villar*[1];
[1]*Ramón y Cajal University Hospital, Madrid, Spain,* [2]*Getafe University Hospital, Madrid, Spain.*

Introduction: B cells play an important role in multiple sclerosis (MS) physiopathology. This effect may be partly mediated by mechanisms unrelated to immunoglobulin secretion. Lipid-specific IgM oligoclonal bands (LS-OCMB) identify patients with a highly inflammatory MS course. We aimed to study if these patients show different B cell profiles in cerebrospinal fluid (CSF) and peripheral blood, with a special focus in intracellular cytokine production.
Patients and methods: We analyzed CSF and blood samples of 45 relapsing-remitting MS patients. We studied LS-OCMB by isoelectric-focusing and western blot and analyzed B cell subsets and B cell cytokine production in CSF and blood by flow cytometry in a FACSCanto II. Results were expressed as percentage of CD45 mononuclear cells. Differences between patients showing and lacking LS-OCMB were studied using Mann-Whitney U test.
Results: 18% of patients showed LS-OCMB. These patients showed in peripheral blood a decrease in regulatory B cells ($p=0.027$) and a trend to increase in memory B cells ($p=0.051$). In CSF, the presence of these antibodies associated with increases in B cells producing GM-CSF ($p=0.018$), and TNFα ($p=0.048$), being the augment even higher when considering B cells producing both GM-CSF and TNFα ($p=0.007$).
Conclusions: These data show that MS patients with a highly inflammatory disease experience an increase in B cells producing pro-inflammatory cytokines within the central nervous system, thus reinforcing the role of these cells in MS physiopathology.

P.C1.02.18

The relevance of the C5a/C5aR1 axis in production of auto-antibodies in the murine immunization model of Epidermolysis bullosa acquisita

J. Tillmann[1], *B. Kovács*[1,2], *J. Figge*[1], *R. Ludwig*[2], *J. Köhl*[1,3], *C. Karsten*[1];
[1]*Institute for Systemic Inflammation Research, Lübeck, Germany,* [2]*Department of Dermatology, University of Lübeck, Lübeck, Germany,* [3]*Division of Immunobiology, Cincinnati Children's Hospital Medical Center and University of Cincinnati College of Medicine, Cincinnati, Ohio, United States.*

Epidermolysis bullosa acquisita (EBA) is a skin blistering disease caused by autoantibodies (auto-Abs) against collagen typ VII (Col7), one of the major components of anchoring fibrils in the dermal-epidermal junction. Previously, we found that deficiency of C5aR1 protects from disease development in an antibody-transfer model of EBA, demonstrating an important role for C5aR1 in the effector phase of the disease. Here, we show the importance of C5aR1 in an immunization model of EBA and redefine the view on the contribution of Fcγ-receptors (FcγR) to disease development. The active EBA mouse model is induced by subcutaneous immunization with Col7. Mice were scored and induction of Col7-specific auto-Abs was analyzed in wild type (WT) and C5aR1-deficient ($C5aR1^{-/-}$) mice, biweekly. Additionally we determined IgG pathogenicity using ROS-release-assay and assessed IgG Fc-glycosylation, which defines pro- or anti-inflammatory properties of IgGs. We observed first symptoms after 4 to 6 weeks in WT mice, whereas $C5aR1^{-/-}$ mice were protected from EBA. $C5aR1^{-/-}$ showed significantly decreased levels of pro-inflammatory agalactosylated auto-Abs compared to WT. Further, analyzing IgG pathogenicity using ROS-release-assay we found that in contrast to previous reports that FcγRIII and FcγRIV are equally important for activating neutrophils. Our findings identify the C5a/C5aR1 axis as a critical driver of EBA not only in the effector but also in the initiation phase shaping a pathogenic Ab response. Furthermore, our findings show that the previously assumed exclusive dependency on FcγRIV is not valid anymore and needs to be re-evaluated.

P.C1.02.19

Autoimmunity to beta subunit of P4Hb and glucokinase linked to insulin secretion in type 1 diabetes

M. Yang[1], *S. Horstman*[2], *R. A. Ettinger*[2], *C. Speake*[2], *E. A. James*[2], *K. Herold*[1], *M. J. Mamula*[1];
[1]*Yale University School of Medicine, New Haven, United States,* [2]*Benaroya Research Institute, Seattle, United States.*

Introduction: Inflammation and oxidative stress in pancreas amplifies various post-translational modifications (PTMs) on self-proteins. The loss of immune tolerance to PTMs within the stressed islets subsequently impacts the autoreactive T cell epitope repertoire and contributes to the destruction of insulin-producing beta cells in T1D. However, the mechanism of carbonylation and citrullination, common PTMs found in stressed islets, modulates immunogenicity and islets functions is still unclear.
Materials and Methods: Mass spectrometry was performed to map the PTM sites. Humoral responses and immunogenicity to modified islet proteins were evaluated by ELISA and HLA tetramers, respectively. Finally, proinsulin and insulin secretion upon glucose stimulation was examined in human islets in the context of beta cell PTMs.
Results: We identified six carbonyl residues within P4Hb and nineteen citrullination modifications within glucokinase. Carbonylated-P4Hb is amplified in stressed islets coincident with decreased glucose-stimulated insulin secretion and altered proinsulin to insulin ratios. Autoantibodies against both P4Hb and glucokinase arise in human T1D patients. Likewise, CD4+ T cells specific for citrullinated glucokinase are present in the circulation of T1D patients. Mature insulin is stored in the form of Zn-containing hexamers until secretion. Interestingly, anti-glucokinase antibodies correlated with anti-ZnT8, but not with other T1D autoantibodies (Insulin, GAD, IA2).
Conclusions: In beta cells, glucokinase acts as a glucose sensor to initiate glycolysis and insulin signaling. P4Hb is critical for proinsulin/insulin folding. Our studies implicate these crucial enzymes as biomarkers, providing new insights into creating autoantigens and define the impact of PTMs on the biological function of beta cells in T1D.

P.C1.02.20

Human intestinal mucosa contains a large population of CD8 resident memory T cells

R. Bartolome Casado[1], *O. Landsverk*[1], *S. Chauhan*[1], *L. Richter*[1,2], *Y. Yao*[3,4], *V. Greiff*[3], *L. F. Risnes*[3,4], *R. S. Neumann*[3,4], *S. Yaqub*[5], *O. Øyen*[6], *R. Horneland*[6], *E. M. Aandahl*[6], *V. Paulsen*[7], *L. M. Sollid*[3,4], *S. Qiao*[3,4], *E. S. Bækkevold*[1], *F. L. Jahnsen*[1];
[1]*Department of Pathology and Centre for Immune Regulation (CIR), Oslo University Hospital –Rikshospitalet, Oslo, Norway,* [2]*Core Facility Flow Cytometry, Biomedical Center, Ludwig-Maximilians-University Munich, Planegg-Martinsried, Germany,* [3]*Department of Immunology and Centre for Immune Regulation (CIR), Oslo University Hospital –Rikshospitalet, Oslo, Norway,* [4]*K.G. Jebsen Coeliac Disease Research Centre, Oslo University Hospital – Rikshospitalet, Oslo, Norway,* [5]*Department of Gastrointestinal Surgery, Oslo University Hospital - Rikshospitalet, Oslo, Norway,* [6]*Department of Transplantation Medicine, Section for Transplant Surgery, Oslo University Hospital, Rikshospitalet, Oslo, Norway,* [7]*Department of Gastroenterology, Oslo University Hospital - Rikshospitalet, Oslo, Norway.*

Recent studies in mice have described resident memory CD8 T-cells (Trm) as key immune mediators of long-lasting protective responses in non-lymphoid tissues. The gut is a large immune organ and one of the main sites of pathogen entry. However, our knowledge about CD8 Trm in the human gut is very limited. Here we examined the replacement of CD8 T-cell subsets in transplanted small intestine (SI) by flow-cytometric analysis of HLA-I mismatched donors. We found that 60% (n=15) of CD103+ CD8 T-cells both in the epithelium and lamina propria (LP) were of donor origin one year after transplantation, whereas LP CD103- CD8 T-cells were rapidly exchanged (15%, n=15). Single-cell TCR sequencing of donor CD103+ CD8 T-cells from transplanted SI revealed that a significant fraction of expanded TCR clonotypes at baseline were maintained one year after transplantation. The persistent CD103+ CD8 T-cells were CD69+ KLRG1- $CD127^{hi}$ $CD28^{lo}$ $PD1^{lo}$, and this distinctive phenotype was progressively acquired by the incoming recipient CD8 T-cells. LP CD103+ CD8 T-cell clones were highly overlapping with their counterparts in epithelium. Moreover, we found substantial clonal overlap between CD103+ and CD103-KLRG1- CD8 subsets in LP, suggesting that CD103+ CD8+ Trm might derive from CD103-KLRG1- precursors. CD103+ CD8 T cells expressed lower levels of preformed cytotoxic granules but produced more cytokines than the CD103- counterpart. In summary, we provide definitive evidence that most human intestinal CD103+ CD8 T cells persist over long periods of time and show immunogenomic, phenotypic and functional characteristics of murine CD8 Trm.

CD39/CD73 implication in neuroimmunological inflammatory disorders

k. BAHRINI[1], *M. Belghith*[1], *O. Maghrebi*[1], *S. Ben sassi*[2], *S. Belal*[2], *M. Barbouche*[1];
[1]*Insitut pasteur de Tunis, Tunis, Tunisia,* [2]*Institut Mongi ben Hamida de Neurologie De Tunis, Tunis, Tunisia.*

Introduction/Objective: Treg cells can be divided in two subsets based on the expression of CD39 an ectonucleotidase that catalyzes the conversion of pro-inflammatory extracellular ATP to adenosine which present a regulatory effect. CD39+ Tregs but not CD39-T regs have the potential to suppress the pathogenic IL-17. The purpose of our study is to characterize the CD39 population in the blood and cerebrospinal fluid (CSF) of Multiple sclerosis and Neuro-behçet disease to determine the role of this ectoenzyme in these two disorders.
Materiel and methods: We quantified, using quantitative RT-PCR, the mRNA expression of IL-10, IL-4, GATA3, Foxp3, CD39 and CD73 in the PBMC and CSF of 21 patients with relapsing remitting multiple sclerosis (RRMS), 19 patients with Neuro-Behçet disease (NBD) and 22 healthy controls. CD39 and CD73 in blood and CSF were studied simultaneously with regulatory markers by flow cytometry.
Results: Our results show no significant difference in the expression of IL-4, GATA3 and Foxp3 mRNA in the blood and CSF of the three studied groups. Concerning CD39 expression, we revealed a significant decrease of CD39 regulatory cells expressing Foxp3 and IL10 in PBMC of RRMS compared to NBD (p<0, 05). Surprisingly, in the CSF we detected a high level of CD39 in RRMS and NBD patients (p<0,001) compared to controls. CSF NBD CD39 cells aren't associated with regulatory markers. However in half of RRMS patients, CD39 is associated with IL10 and CD73. These results demonstrate a differential expression of CD39 depending on the inflammatory CNS Statue.

P.C1.03.02

IL-17 producing iNKT cells correlate positively with disease activity DAS28-ESR in rheumatoid arthritis

K. CHOWDHURY[1], *D. K. Mitra*[1], *U. Kumar*[1], *S. Das*[2];
[1]*All India Institute of Medical Sciences, Delhi, India,* [2]*Albert Einstein College of Medicine, USA., Newyork, United States.*

Rheumatoid arthritis (RA) is well established autoimmune disease mediated through various pathogenic T cells. iNKT cells constitute 0.5% of total NKT cells. The role of iNKT cells in RA animal model (collagen induced arthritis; CIA) is shown to be protective by IL-10 production. On contrary they are also shown to be secretor of IL-17 which is pathogenic to RA. There is no direct evidence of human study which shows the precise role of iNKT in disease pathogenesis or amelioration. So we intend to study CD1d restricted iNKT cells in PBL and SF of rheumatoid arthritis patients. We have recruited treatment naive activate RA patients with DAS28-score>3 (N=23) . Cells derived from peripheral blood and synovial fluid was stimulated with alpha-galactosylceramide (alpha-galcer) for 48 hours to measure cytokine production and proliferation. we have observed higher frequency of IL-17+iNKT+ cells as well as CD1d restricted iNKT in RA SF compared to autologous PBL (*p=0.001*) and positively correlates with DAS28-ESR (R=0.79). CD3+CD161+ NKT cells were also higher in RA SF. Moreover alpha-galcer stimulation up regulated IL-17+ iNKT cells instead of IL-10 in RA SF derived cells. RA synovial CD1d restricted iNKT cells are polarized towards IL-17 production instead of IL-10 upon alpha-galcer stimulation. IL-17+iNKT cells proliferates more in RA SF upon alpha-galcer stimulation and also correlates with DAS28 ESR. Taken together these findings hint towards pathogenic role of iNKT cells in RA.

P.C1.03.03

TIGIT expression identifies gut-homing effector T cells with immunomodulatory properties that are deregulated in inflammatory bowel disease patients

M. E. Joosse, *L. M. Costes, Y. Simons-Oosterhuis, R. C. Raatgeep, L. A. van Berkel, T. Cupedo, L. de Ridder, J. C. Escher, S. Veenbergen, J. N. Samsom;*
Erasmus MC, Rotterdam, Netherlands.

Inflammatory bowel disease (IBD) is characterized by intestinal infiltration of pathologic effector T-cells. The defects driving loss of normal T-cell regulation in IBD remain undefined. We could show that in healthy murine and human intestine 40-50% of gut-resident $CD38^+CD4^+$ effector T-cells express T-cell immunoglobulin and ITIM domain (TIGIT), an inhibitory receptor capable of modulating dendritic cell (DC) and T-cell function. In peripheral blood of healthy individuals, TIGIT expression was enriched on gut-homing $CD38^+$ effector T-cells while conversely, in IBD patients with active intestinal inflammation, frequencies of $CD38^+TIGIT^+$ effector T-cells were decreased and associated with severe disease course. This raised the question whether $CD38^+TIGIT^+$ effector T-cells mediate intestinal immune regulation. Bacterial colonization of germ-free mice and associated induction of regulatory immunity, increased TIGIT expression in intestinal tissue. To assess whether TIGIT is preferentially expressed by proliferating cells in mucosa-draining lymph nodes (LNs), we compared TIGIT expression on ovalbumin (OVA)-specific $CD4^+$ T-cells in murine draining LNs after OVA feed or intramuscular (i.m.) OVA injection. After OVA feed, TIGIT was most prominently expressed on T-cells in celiac LN draining the duodenum and liver when compared to T cells in peripheral LN after OVA i.m. injection. In humans, a high percentage of circulating $TIGIT^+CD38^+$ effector T-cells co-expressed the immune-regulatory molecules PD-1 or CTLA-4. Importantly, $CD38^+TIGIT^+$ effector T-cells modulated DC activation, and co-cultures with immature monocyte-derived DCs induced lower levels of *IL12p35*, *IL23p19* and *IL6* compared to co-cultures with $CD38^+TIGIT^{neg}$ cells. In sum, we have identified $CD38^+TIGIT^+$ effector T-cells as potential regulators of intestinal immunity.

RANK/RANKL Axis Regulates IL-7-Mediated Membrane-Type Matrix Metalloproteinase MMP14 Expression in Corneal Fibroblasts in GCD2

S. Kim[1], *A. Yeo*[1], *H. Lee*[1,2];
[1]*Institute of Vision Research,Department of Ophthalmology, Yonsei University College of Medicine, seoul, Korea, Republic of,* [2]*Corneal Dystrophy Research Institute, Department of Ophthalmology, Yonsei University College of Medicine, Seoul, Korea, Republic of.*

Granular corneal dystrophy type 2 (GCD2) is caused by a point mutation (R124H) in the transforming growth factor-β (TGF-β)-induced gene (*TGFBI*). The accumulation of the protein TGFBIp in the corneal stroma results in the disruption of corneal transparency and finally in a loss of vision. However, the mechanisms underlying the accumulation of TGFBIp and its clearance are poorly understood. In this study, we show that TGFBI expression was counter-regulated by interleukin-7 (IL-7) in corneal fibroblasts. IL-7 expression was significantly reduced in corneal fibroblasts from patients with GCD2. TGF-β and *TGFBI* expression were reduced upon IL-7 treatment in corneal fibroblasts, suggesting that impaired IL-7 expression in patients with GCD2 affects disease pathogenesis via a failure to control TGF-β expression. Interestingly, the interplay between TGF-β and IL-7 was regulated by the RANKL/RANK signaling cascade. We also found that IL-7 regulates the expression of a membrane-type matrix metalloproteinase (MT-MMP), which plays a crucial role in migration and neovascularization in the cornea via the RANKL/RANK axis. Taken together, we demonstrated that the RANKL/RANK axis regulates TGF-β and *TGFBI* expression via IL-7-mediated MT-MMP regulation in corneal fibroblasts; these findings improve our understanding of the pathogenesis of GCD2.

Mucosal lesions derived from oral cavity identified as lichen planus express high levels of IFN-γ and IL33

M. F. de Carvalho[1], *D. Cavalieri*[2], *S. do Nascimento*[1], *D. V. Ramos*[3], *D. C. Pasqualin*[4], *F. A. Rocha*[1], *D. Heller*[1], ***L. C. Marti***[1];
[1]*Hospital Israelita Albert Einstein - Instituto de Ensino e Pesquisa Albert Einsten, São Paulo, Brazil,* [2]*(2) Centro de Especialidades Odontológicas/Estomatologia – Unidade Alto da Boa Vista - Secretaria Municipal de Saúde de São Paulo, São Paulo, Brazil,* [3]*(3) Instituto de Responsabilidade Social- Programas Governamentais - Hospital Israelita Albert Einstein, São Paulo, Brazil,* [4]*(4) Laboratório de Patologia Clínica - Hospital Israelita Albert Einstein, São Paulo, Brazil.*

Background: Oral lichen planus (OLP) is a chronic inflammatory mucocutaneous disease that is Th1-mediated and affects skin and the oral mucosa with a variety of clinical presentations. Lesions are usually bilateral and are often sensitive or painful. Cutaneous lesions of Lichen Planus (LP) are self-limiting; however, oral lesions are chronic and rarely remissive. Interferon-gamma (IFN-γ) is an important cytokine involved in the regulation of local immune response in OLP, and it has been frequently studied in these lesions. **Aims:** Identify cytokines present in lesions suggestive of OLP and compare them to the controls. The controls were a group of patients with non-specific inflammatory lesions (NSIL). **Methods:** Histopathological image analysis, immunohistochemistry and gene expression were performed in oral mucosal tissue derived from samples suggestive of OLP and controls. All samples were obtained after patient signed an informed consent approved under CAAE number 550537165530010086. **Results:** Our preliminary results demonstrated higher numbers of lymphocytes infiltrating OLP lesions compared to controls (p=0.025) and more T CD4 lymphocytes into epithelial tissue (p=0.006). In addition, the OLP samples showed higher number of apoptotic cells compared to the control (p= 0.047). Regarding cytokine analysis, there were absence or variable expression of IL-17 in both NSIL and OLP groups, significant expression of IFN-γ and IL-33 in OLP group compared to NSIL (p<0.001; p=0.026). **Conclusion:** The lesions characterized as OLP demonstrated higher numbers of apoptotic and inflammatory cells, elevated levels of IFN-γ and IL-33 which described them as more aggressive lesions than NSIL .

Impact of skin T cell secretome on the epidermal barrier during vitiligo

C. Martins[1], *F. Lucchese*[1], *A. Taieb*[1,2], *J. Seneschal*[1,2], *K. Boniface*[1];
[1]*Inserm U1035, BMGIC, Bordeaux University, Bordeaux, France,* [2]*Department of dermatology and Pediatric Dermatology ; National Reference Center of Rare Skin disorders, hôpital Saint-André, Bordeaux, France.*

Introduction: Resident memory T cells have a key role in the development of chronic inflammatory dermatosis, such as vitiligo, the most common depigmenting disorder resulting from the loss of epidermal melanocytes. We previously showed that vitiligo skin is imprinted with resident memory CD8 T cells producing elevated levels of the inflammatory cytokines IFNγ and TNFα, while displaying moderate cytotoxic activity. We further analyzed the cytokine secretion profile of skin T cell secretome and characterized its effect on the inflammatory response and melanocyte alteration. **Materials and Methods:** The cytokine secretion profile of skin T cells was analyzed by Flow cytometry and multiplex ELISA following T cell activation. In addition, primary cultures of normal human epidermal keratinocytes and melanocytes were stimulated in the presence or absence of skin T cell supernatants and expression of genes involved in the inflammatory response, and melanocyte function was assessed by real-time PCR. **Results:** We show that T cell secretome contributes to the development and amplification of the inflammatory response by increasing the expression of chemokines and factors involved in inflammation and T cell homing, such as CXCL9 and CXCL10, by epidermal cells; while inhibiting melanocyte function, leading to the loss of melanocytes. **Conclusion:** Our results highlight the importance of skin T cell secretome in vitiligo pathogenesis, and show the role of T cell soluble factors on both the loss of melanocytes, and on the increase of the inflammatory response through an effect on both keratinocytes and melanocytes.

The effect of the first and third trimester placentas secretory factors obtained from normal pregnancy on the tube-like structure formation by endothelial cells in presence of trophoblast cells

K. L. Belyakova, ***V. A. Mikhailova****, A. R. Sheveleva, E. V. Khokhlova, S. A. Selkov, D. I. Sokolov;*
FSBSI "The Research Institute of Obstetrics, Gynecology and Reproductology named after D.O.Ott", Saint-Petersburg, Russian Federation.

Introduction: Trophoblast cells (TC) interact with endothelial cells (EC) in the uteroplacental contact area. Effects of placenta-derived factors upon local interactions between these cells remain unclear. The aim of the research was to evaluate the influence of placental factors upon formation of tube-like structures by EC in presence of TC. Materials and Methods: EC line EA.Hy926 and TC line JEG-3 were used in the experiment. Placentas were obtained after an elective pregnancy termination of normal 1st-trimester (9-11 weeks, group 1) pregnancy and after caesarean delivery of normal 3rd-trimester (38-39 weeks, group 2) pregnancy. EC and TC were cultured in 24-well-plates pretreated with Matrigel (BD, USA) in the presence of placental conditioned media (CM) with 2,5%FBS for 24 hours (37°C, 4.5%CO_2). Control wells contained DMEM, 2,5%FBS without TC. Then we assessed the number and the length of formed tube-like structures using AxioObserver.Z1 microscope and program AxioVision. Statistical analysis was performed using Mann-Whitney test. Results: In the presence of CM of placentas of both groups we observed an increase in the length and a reduction in the number of tube-like structures formed by EC in the presence of TC, comparing with a spontaneous level of their formation. Also the same parameters in the presence of CM of placentas of group 2 were different from the parameters of group 1. Conclusions: Soluble factors contained in the CM of placentas change the characteristics of the vascular network formed by EC in the presence of TC.

IL-17A is the signature cytokine of Th17 cells and plays an important role in the development of many autoimmune and inflammatory diseases such as psoriasis and in host defense against microbial organisms. The IL-17 response of Th17 cells and especially of IL-17A-producing γδ T cells is crucial for mice to fight bacterial infections. Among the 6 members of the IL-17 family, IL-17F has the greatest homology to IL-17A. Moreover, IL-17A and IL-17F signal either as homo- or as heterodimers through a dimeric receptor composed of IL-17RA and IL-17RC.
We used IL-17RA full knockout mice or mice with cell type specific deficiencies for IL-17RA to delineate which cell type needs to respond to IL-17 in order to develop Imiquimod-induced dermatitis mimicking human psoriasis. Using this approach, we could clearly define keratinocytes as cell population necessary to respond to IL-17.
Additionally to the mentioned IL-17RA deficient mice, we also analyzed IL-17AF cytokine double knock out mice. We found expanded populations of Rorγt expressing γδ T cells in the IL-17 signaling deficient mice. Furthermore, we could show that IL-17 signaling is important for defense against *Staphylococcus aureus* as the signaling deficient mice developed severe lesions composed of the coccal bacterium.
This work was funded by the DFG (CRC-TR156).

P.C1.03.09

Novel role of complement receptor C5aR2 in uterine natural killer cells during pregnancy

J. Neeb[1], *F. Mey*[1], *J. Figge*[1], *J. Köhl*[1,2], *K. Hoebe*[2], *C. Karsten*[1];
[1]*Institute For Systemic Inflammation Research, Luebeck, Germany,* [2]*Immunobiology, Cincinnati Children's Hospital Medical Center, Cincinnati, United States.*

Uterine natural killer (uNK) cells are known to be important for placental angiogenesis and development during the first trimester of pregnancy. They are the main source for IFNγ and angiogenic factors (VEGF, PLGF). Further, previous studies suggested their role in the pathogenesis of preeclampsia. We have recently shown that peripheral NK (pNK) cells express the complement receptor C5aR2, but not C5aR1. While C5aR1 acts in a pro-inflammatory manner, the function of C5aR2 is still under debate, but hinted to be anti-inflammatory. In this study we hypothesized that C5aR2 expression by uNK cells is indispensable for the development of a healthy gestation. Here, we show potentially a novel role for C5aR2 as a regulator of NK cell functions during pregnancy.
Uteri were removed on gestation day 10 and stained with DBA, CD3, CD122 to analyze NK cell compartment via flow cytometry.
We found that C5aR2 knockout mice have a significantly lower breeding efficiency shown by higher number of resorptions during pregnancy. Further, using C5aR2-tdTomato floxed reporter mice we showed that most of the uNK cells express C5aR2, whereas only subsets of pNK express this receptor. Mechanistically, we were able to show that C5aR2 knockout NK cells produce higher amounts of IFNγ after stimulation in vitro.
All in all, our findings identify a potential novel role for the anaphylatoxin receptor C5aR2 in regulating the NK cell compartment in the uterus and therefore be crucial involved in the outcome of pregnancy.

P.C1.03.10

Cell type-specific complement expression in the retina

D. Pauly[1], *N. Schäfer*[1], *S. Hauck*[2], *A. Grosche*[3];
[1]*Department of Ophthalmology, Regensburg, Germany,* [2]*Research Unit Protein Science, Helmholtz Center Munich, Neuherberg, Germany,* [3]*Department of Physiological Genomics, LMU, Munich, Germany.*

Retinal complement activity has so far been related to macrophages or to the influence of liver-derived complement components. Here we describe for the first time a liver-independent retinal complement system.
Five different cell types were isolated by immunomagnetic separation from murine and human retinae. Expression analysis of specific cell marker, housekeeping and complement component genes was performed by qRT-PCR and Western blot.
All isolated cell populations expressed *c1s*, *c3*, *cfb*, *cfp, cfh* and *cfi*. Strikingly, we distinguished retinal cell types which mainly showed inhibiting complement transcripts from cell populations which synthetized mostly complement activating mRNA. Albino mice showed an age-related change in cell type-specific complement expression levels towards a pro-inflammatory intraretinal milieu. In contrast, retinae with impaired photoreceptor recycling presented only with minimal expression changes. Major changes of local complement expression were observed after induction of a transient ischemia in the mouse retina. A very pronounced upregulation of complement activators was found in several cell types. Complement inhibitor c*fh* was down-regulated in specific cell types, while *cfi* was significantly up-regulated in all investigated cell types.
In conclusion retinal cells produce and regulate complement components independently from the liver-derived complement system in stress situations.

P.C1.03.11

Oxidative stress induces complement-dependent pro-angiogenic and -inflammatory response in retinal pigmented epithelium cells

T. Trakkides, D. Rogalski, N. Schäfer, ***D. Pauly****;*
Department of Ophthalmology, University Hospital, Regensburg, Germany.

Oxidative stress in the aging eye is associated with local inflammatory processes. In this study, we investigated the mechanisms of H_2O_2-induced, complement-dependent inflammatory processes in a human retinal pigment epithelial cell line, ARPE-19.
ARPE-19 viability and integrity were analysed. The expression of components associated with the complement system was determined by qRT-PCR, Western blot, immunofluorescence analyses and secretion of cytokines/ growth factors was measured.
We found that more than 95% of ARPE-19 treated with oxidative stress were but showed disrupted cell-cell junctions. Strikingly, senescent ARPE-19 cells upregulated complement receptors on transcript (*c5ar1*, *cr3*) and protein level (C5aR1) in response to H_2O_2. This gene modulation was associated with priming of the NLRP3 inflammasome, enhanced secretion of pro-angiogenic factors (VEGF, IL-8) and pro-inflammatory cytokine (IL-6). In the late stage of oxidative stress treatment, we observed significant more transcripts of intracellular proteases (*ctsl*, *ctsb*, *serping1*) and of the complement stabilizer (*cfp*) than in untreated controls. In contrast to previously described protective effects of Olaparib in oxidatively stressed retinae, we observed a more pronounced change towards pro-inflammation in Olaparib-treated than in untreated ARPE-19 cells.
Our results show for the first time a functional link between oxidative stress, complement receptors, pro-angiogenic and -inflammatory responses of ARPE-19 cells. These effects suggested an oxidative stress-associated mechanism of C5aR1-regulation in ARPE-19 cells in connection with upregulated intracellular proteases.

P.C1.03.12

Immunomodulatory effect of local complement regulators on retinal pigmented epithelium cells

N. Schäfer[1], *V. Enzmann*[2], ***D. Pauly***[1];
[1]*Department of Ophthalmology, University Hospital, Regensburg, Germany,* [2]*Department of Ophthalmology, University Hospital, Bern, Switzerland.*

Factor H-related 3 (FHR-3) is a complement regulator, which has been associated with retinal degeneration. The function of FHR-3 is so far not completely resolved. Here, we reveal an immunomodulatory effect of FHR-3 on the retinal complement metabolism via the retinal pigment epithelium (RPE).
The expression of complement components, inflammation-associated and metabolic signaling factors was determined in RPE cells following apical stress induced by FHR-3 or FH treatment, respectively. RPE cells were analyzed using qRT-PCR, Western Blots, immunohistology and Multiplex-ELISA.
Our data revealed for the first time a local interaction of FHR-3 with RPE cells. We showed that these cells expressed increased transcripts of *c3, cfb, cr3, nlrp3* and *il-1β* and a reduced mRNA level for *cfh*, *foxp3* and *c3ar1* after FHR-3 treatment. We detected C3, CFB and CR3 proteins in the RPE cells and found a raised secretion of C3, C4 and CFB in supernatants of FHR-3-treated ARPE-19 cells. We detected an increased pro-inflammatory cytokine IL-6 secretion following FHR-3 stress, and an anti-inflammatory IL-18 release of FH-treated RPE cells but not FHR-3 treated cells.
These novel findings reveal a direct influence of the complement regulator FHR-3 on the balance of the ocular immune privilege and indicate FHR-3 as a direct opponent of FH at the blood-retinal barrier.

P.C1.03.13

Absence of STAT1β increases Th1 differentiation and exacerbates concanavalin A-induced hepatitis

A. Puga[1], *K. Meissl*[1], *C. Lassnig*[1,2], *S. Macho-Maschler*[1], *M. Parrini*[1], *D. Hainberger*[3], *W. Ellmeier*[3], *M. Müller*[1,2], *B. Strobl*[1];
[1]*University of Veterinary Medicine Vienna, Vienna, Austria,* [2]*Biomodels Austria, University of Veterinary Medicine Vienna,, Vienna, Austria,* [3]*Institute of Immunology, Medical University of Vienna, Vienna, Austria.*

Signal transducer and activator of transcription 1 (STAT1) is a transcription factor that is crucial for gene regulation in response to all types of interferons (IFN). STAT1 has a crucial role in immunity in both men and mice: loss-of-function of STAT1 leads to a high susceptibility to infections, whereas gain-of-function mutations cause severe autoimmune diseases. Alternative splicing generates two STAT1 isoforms: the full length STAT1α and the truncated STAT1β isoform, which lacks the C-terminal transactivation domain and has compromised transcriptional activities. Using *Stat1*$^{\alpha/\alpha}$ knockin mice (i.e. mice that only express the STAT1α isoform) we show that STAT1β has important regulatory functions in T cells. CD4$^+$ and CD8$^+$ T cells, but not other cell types, from *Stat1*$^{\alpha/\alpha}$ mice have increased levels of STAT1α compared to the levels of both STAT1 isoforms in T cells from wild-type mice. In line with the crucial role of STAT1 in Th1 differentiation, *Stat1*$^{\alpha/\alpha}$ CD4$^+$ T cells had increased levels T-bet and produced considerably more IFNγ upon activation compared to wild-type cells. To investigate whether STAT1β is required to limit excessive IFNγ production *in vivo*, we challenged mice with concanavalin A, an experimental model for autoimmune hepatitis. *Stat1*$^{\alpha/\alpha}$ mice had exacerbated liver damage and higher systemic levels IFNγ compared to wild-type mice. Currently, we investigate whether CD4$^+$ T cells or NKT cells, the main drivers of ConA-induced hepatitis, cause the increased IFNγ levels in *Stat1*$^{\alpha/\alpha}$ mice. In addition, we investigate Th1 cell differentiation during viral infections. Supported by the Austrian Science Fund (FWF, DK-W1212, SFB-F6101and SFB-F6106)

P.C1.03.14

DC subsets and T cells are altered in IPAH patients

D. van Uden*, M. van Nimwegen, T. Koudstaal, P. Heukels, J. A. van Hulst, K. A. Boomars, R. W. Hendriks, M. Kool;*
Department of Pulmonary Medicine, Erasmus MC, Rotterdam, Netherlands.

Pulmonary arterial hypertension (PAH) is a cardiopulmonary disease characterized by high pulmonary arterial pressures, in which idiopathic PAH (IPAH) is the most common. Tertiary lymphoid structures (TLOs) in IPAH lungs indicate a role for immune cell activation. In TLOs, amongst other cell-types, T-cells and dendritic cells (DCs) are present, where DCs are crucial for T-cell activation and TLO maintenance. Thus, we hypothesized that DC subsets and T-cells are altered in IPAH patients.

Therefore, in-depth characterization of DCs and T-cells was performed in peripheral blood mononuclear cells (PBMCs) of IPAH patients and healthy controls (HCs) using 14-color flowcytometry.
The proportion of total conventional DCs (cDCs) was decreased in IPAH patients compared to HCs, in which the percentage of type 1 cDCs (cDC1s) increased and cDC2s was unaltered. Furthermore, decreased percentages of the recently identified T-cell-stimulatory AS-DCs were found in IPAH patients compared to HCs. Strikingly, no differences were observed in memory T-cell proportions, however IPAH T-cells showed reduced capacity to produce interferon (IFN)γ, interleukine (IL)-17 and IL-6.
In conclusion, peripheral DCs and T-cells are altered in IPAH patients, wherein cDCs and AS-DCs are decreased. As cDCs and AS-DCs are potent T-cell stimulators, this could suggest homing towards lung TLOs. Furthermore, the reduced capacity of IPAH T-cells could be a consequence of i) homing towards TLOs or ii) a negative feedback-loop due to a high pro-inflammatory cytokine milieu present in IPAH patients. These data indicate that immune cell activation could play a role in IPAH pathology.
Grant: Dutch Heart foundation (2016T052)

P.C1.03.15
RORγt inhibition selectively targets pathogenic human iNKT and γδ-T cells enriched in Spondyloarthritis while preserving IL-22 responses

K. Venken[1,2], *C. Mortier*[1,2], *M. E. Labadia*[3], *P. Jacques*[1,2], *T. Decruy*[1,2], *J. Coudenys*[1,2], *K. Hoyt*[3], *S. Van Gassen*[1,2], *J. Wahle*[3], *Y. Saeys*[1,2], *G. Nabozny*[3], *D. Elewaut*[1,2];
[1]*Ghent University, Ghent, Belgium,* [2]*VIB Inflammation Research Center, Ghent, Belgium,* [3]*Research and Development Boehringer-Ingelheim, Ridgefield, CT, United States.*

Dysregulated IL-23/IL-17 responses have been linked to inflammatory diseases including psoriasis, psoriatic arthritis and other forms of spondyloarthritides (SpA). IL-23/IL-17 inflammation is controlled by RORγt, the key Thelper17 (Th17) cell transcriptional regulator. RORγt is also expressed by subsets of innate-like T cells, including invariant natural killer T (iNKT) and γδ-T cells, but how this contributes to disorders such as SpA is still unclear. Here we describe a unique population of RORγt^{+}T-bet^{lo}PLZF^{-} iNKT and γδ-hi T cells present in healthy peripheral blood. iNKT and γδ-hi T cells showed profound IL-23 mediated Th17-like immune responses and were clearly enriched within inflamed joints. Moreover, selective depletion of iNKT and γδ-Tcells in synovial fluid mononuclear cell samples led to a significant decrease (>70%) in IL-17 responses underscoring the pathogenic features of these cells in SpA. Interestingly, unsupervised clustering analyses by FlowSOM iterations revealed a marked heterogeneity of human blood iNKT and γδ-T cells which seemed skewed in SpA patients. Strikingly, RORγt inhibition blocked γδ17 and iNKT17 cell function while selectively sparing IL-22^{+} subsets. Overall, these findings highlight a unique diversity of human RORγt^{+} T cells and underscore the potential of RORγt antagonism to modulate aberrant type 17 responses.

P.C1.03.16
IgE-Bet v 1 oligomer complexes induce specific T cell activation via CD23 mediated facilitated antigen presentation more efficiently than IgE-Bet v 1 monomer complexes

S. Villazala[1], *G. Hofer*[2], *P. Gattinger*[3], *H. Breiteneder*[3], *S. Vrtala*[3], *C. Lupinek*[3], *W. F. Pickl*[4], *W. Keller*[2], *R. Valenta*[3], *V. Niederberger*[1], *J. Eckl-Dorna*[1];
[1]*Medical University of Vienna, Department of Otorhinolaryngology, Vienna, Austria,* [2]*University of Graz, Institute for Molecular Biosciences, Graz, Austria,* [3]*Medical University of Vienna, Department of Pathophysiology and Allergy Research, Vienna, Austria,* [4]*Medical University of Vienna, Department of Cellular Immnunology and Immunohematology, Vienna, Austria.*

CD23, the low affinity receptor for IgE, mediates facilitated antigen presentation (FAP). FAP, a process known to perpetuate and amplify pathological T cell responses in allergy, is initiated by the binding of IgE-allergen complexes to CD23. Those complexes are endocytosed and peptides from those antigens are displayed on MHC II to be recognised by specific T cells. Our aim was to study the effects of different types of IgE-Bet v 1 complexes on FAP. Epstein Barr virus transformed B cells were incubated with different concentrations and ratios of chimeric Bet v 1 specific Bip 1 IgE (CB1 IgE) and recombinant Bet v 1 in monomeric or oligomeric form.
Primed cells were incubated with Jurkat T cells, which expressed a T cell receptor (TCR) specific for Bet v 1 and a luciferase reporter gene under the control of IL2 promotor. Equimolar concentrations of CB1 IgE-oligomer Bet v 1 complexes induced higher specific T cell activation when compared to CB1 IgE-Bet v 1 monomer complexes, independently of their ratio. Likewise 25-125 fold lower concentrations of CB1 IgE-Bet v 1 oligomer than CB1 IgE-Bet v 1 monomer complexes were sufficient to induce specific T cell activation. Blocking of CD23 using anti-CD23 antibody completely abrogated specific T cell activation triggered by IgE-Bet v 1 complexes. In conclusion, IgE-Bet v 1 oligomer complexes provoke specific T cell activation more efficiently than IgE-Bet v 1 monomer complexes. These data indicate that the oligomerisation state of IgE-allergen complexes greatly affects FAP and subsequent allergen-specific T cell activation.

P.C1.03.17
Foxp3^{+} RORγT^{+} regulatory T cells depend on CD27/CD70 costimulation

I. Vogel, *V. Acolty, M. Moser;*
Laboratory of Immunobiology, IBMM, Université Libre de Bruxelles (ULB), Gosselies, Belgium.

CD27/CD70 costimulation enhances T-cell survival, expansion and effector function. However, in Th17 cells, which express the transcription factor RORγT, CD27 signalling specifically suppresses the production of the proinflammatory cytokine IL-17. Consequently, mice lacking CD27 or its ligand CD70 have a higher number of IL-17 producing RORγT^{+} Th17 cells compared to WT mice and display exacerbated experimental autoimmune encephalomyelitis (EAE). This suggests a tight regulation of the effector function of RORγT expressing cells by CD27/CD70 signalling.
Recently, so called T-regulatory-17 (Tr17) cells have been described which express the transcription factors Foxp3 and RORγT and specifically suppress Th17 cells during EAE. To examine if Tr17 cells are equally dependent on CD27 costimulation, we induced EAE in CD27 and CD70 knock-out (KO) mice. While KO mice have overall less Foxp3^{+} Treg cells in a steady state, their number rapidly increases in response to immunization to the level of WT mice. Tr17 cells were present in the peripheral lymph nodes of both WT and KO mice. However, we found a significant reduction of this Treg subset in the central nervous system (CNS) of mice lacking CD27 or CD70. Tr17 cells in the periphery of KO mice displayed a more active phenotype (CTLA-4^{high}, CD103^{high}) compared to WT mice suggesting that activated cells are trapped in the lymph nodes and unable to migrate to the CNS.
Transcriptomic (single-cell) profiling and functional analysis of Tr17 cells in KO *vs.* WT mice will further elucidate the role of CD27/CD70 signalling in RORγT^{+} Treg cells and discover downstream signals.

P.C1.03.18
The role of S100A8 and S100A9 in murine keratinocytes

C. Weise[1], *J. Latzel*[1], *K. Loser*[2], *J. Roth*[1];
[1]*Institute of Immunology, Münster, Germany,* [2]*Department of Dermatology, Münster, Germany.*

Introduction: S100A8 and S100A9, also known as myeloid-related protein-8 (MRP8) and MRP14, are damage-associated molecular pattern molecules (DAMPs). Both proteins are highly up-regulated in autoimmune diseases of human skin like psoriasis as well as in certain *in vivo* models (e.g. Imiquimod induced psoriasis like phenotype).
Methods: Keratinocytes collected from adult tail skin of either wildtype or S100A9-/- mice were differentiated under high calcium conditions (1 mM CaCl2). Furthermore keratinocytes of both mice strains were stimulated with different inflammatory mediators. Cells were harvested at different time points and analysis of gene or protein expression was performed.
Results: Both, wildtype and S100A9-/- cells, show a typical expression pattern of genes responsible for differentiation. During differentiation an increased gene expression of both S100 proteins could be detected in wildtype but not in S100A9-/- (here only S100A8) cells. On protein level S100A9-/- cells show no expression of S100A8 and S100A9 whereas wildtype cells express both proteins in increasing amounts during differentiation. Wildtype keratinocytes stimulated with IL-1α, IL-17A, IL-17F, TNFα and Flagellin show a significant elevation of S100A8 and S100A9 on mRNA and protein level compared to unstimulated or IL-13 treated cells.
Conclusion: Both wildtype and S100A9-/- keratinocytes show the same gene expression pattern of proteins known for differentiation, indicating no direct correlation of S100 proteins and keratinocyte differentiation. Surprisingly S100A9-/- keratinocytes do not express S100A8 although mRNA level were increasing during differentiation and stimulation with inflammatory mediators. These results indicate an inflammation and differentiation dependent mechanism of S100 protein expression.

P.C1.03.19
Thymus-derived Foxp3+ regulatory T cells upregulate RORgt expression under inflammatory conditions

J. YANG[1], *M. Zou*[1,2], *J. Pezoldt*[1], *X. Zhou*[2], *J. Huehn*[1];
[1]*Helmholtz Centre for Infection Research, Braunschweig, Germany,* [2]*Key Laboratory of Pathogenic Microbiology and Immunology, University of the Chinese Academy of Sciences, Beijing, China.*

Foxp3^{+} regulatory T cells (Tregs) co-expressing the Th17-lineage specification factor RORγt represent a unique Treg subpopulation that has been reported to be induced upon response to gut microbiota within the intestinal immune system. Hence, RORγt^{+} Tregs are considered to solely consist of peripherally-induced Foxp3^{+} Tregs (pTregs), and the possibility that also thymus-derived Treg (tTregs) can upregulate RORγt expression and contribute to the pool of RORγt^{+} Tregs was largely ignored. Here, we expand our knowledge on the origin of RORγt^{+} Tregs by demonstrating that also tTregs can attain RORγt expression. In transgenic Foxp3$^{\Delta CNS1Cre}$ reporter mice, a substantial fraction of CNS1-independent Tregs, predominantly consisting of tTregs, was found to coexpress RORγt. In additon, genuine tTregs isolated from thymi of Foxp3^{hCD2}RAG^{GFP} reporter mice initiated RORγt expression both *in vitro* and *in vivo*, particularly under inflammatory conditions. In conclusion, our data demonstrate that tTregs can upregulate RORγt expression under inflammatory conditions and that hence RORγt^{+} Tregs can be regarded as a heterogeneous population consisting of both pTregs and tTregs.

P.C1.03.20
Evolution of CD4+ T cell immunity to viral infection: analysis of systemic and local responses

***B. J. Meckiff**, H. M. Long;*
Institute of Immunology and Immunotherapy, Birmingham, United Kingdom.

BACKGROUND: Most studies investigating the immune response to viral infection have focussed on systemic immunity. However, mounting evidence suggests that immunity also involves localised non-circulating resident memory populations retained in specific anatomic compartments. To date, there is limited knowledge of resident memory $CD4^+$ T cells induced by natural virus infection in humans.
Here we compare systemic $CD4^+$ T cell immunity against the common herpesvirus Epstein-Barr virus (EBV) with the immune response at the site of infection, the tonsils. Clinical identification of Infectious Mononucleosis (IM) patients undergoing primary infection has enabled investigations of acute primary infection through to persistent carriage. A greater understanding of resident T cell memory in humans is paramount for the development of vaccine strategies.
METHODS: Matched PBMCs and tonsillar UMs were collected from patients suffering from acute IM or from healthy EBV carriers undergoing tonsillectomy. We used EBV-MHCII tetramers, representing a range of viral $CD4^+$ T cell epitopes, to investigate the frequency and phenotype of virus-specific $CD4^+$ T cells in both compartments.
RESULTS: Primary infection induces expanded populations of activated virus-specific $CD4^+$ T cells in the blood of IM patients, but only low frequencies are detected in the tonsils. Following resolution of IM symptoms, EBV-specific $CD4^+$ T cells are maintained in memory at a low frequency in both the circulation and at the site of infection. Furthermore, in long-term virus carriage, some virus-specific $CD4^+$ T cells in the tonsil express resident memory-associated markers. Therefore EBV infection induces a population of virus-specific $CD4^+$ T cells that are retained within the tonsil, with a different phenotype to circulating cells.

Kidney disease alters the intestinal microbiota and regulates intestinal inflammation

***K. Aono**, K. Nishiyama, H. Nakajima, T. Takeuchi, Y. Azuma;*
Laboratory of Veterinary Pharmacology, Osaka Prefecture University Graduate School of Life and Environmental Science, Izumisano, Japan.

A number of organ-organ crosstalk is involved in homeostasis. Considering gastrointestinal symptoms are common in patients with renal failure, the aim of this study was to elucidate the relationship between gastrointestinal motility and gastrointestinal symptoms in chronic kidney disease. We performed studies with C57BL/6 mice with chronic kidney disease following 5/6 nephrectomy. Gastrointestinal motility was evaluated with ex vivo responses of ileum and distal colon strips to electrical field stimulation. Feces were collected from mice and the composition of the gut microbiota was analyzed by 16S rRNA sequencing. Mice with chronic kidney disease after 5/6 nephrectomy showed the decreased number of fecal and this constipation is correlated with the suppressed contraction response in the ileum motility and decreased relaxation responses in the distal colon motility. Spermine, one of the uremic toxins, inhibited the contraction response in the ileum motility, but 4 kind of uremic toxins showed no effect on the relaxation responses in the distal colon motility. 5/6 Nephrectomy mice had the disturbed balance of gut microbiota. The motility dysregulation and constipation were cancelled by antibiotic treatments. Expression levels of IL-6, TNF-alpha, and iNOS in 5/6 nephrectomy mice were increased in the distal colon but not in the ileum. In addition, macrophage infiltration in 5/6 nephrectomy mice were increased in the distal colon but not in the ileum. We found 5/6 nephrectomy to alter the gastrointestinal motility and cause constipation by changing the gut microbiota and colonic inflammation. These findings indicate that renal failure was remarkably associated with gastrointestinal dysregulation.

P.C1.04.02
Interleukin-19 protects Th2-mediated IBD model mice

***Y. Azuma**, T. Takeuchi;*
Laboratory of Veterinary Pharmacology, Osaka Prefecture University Graduate School of Life and Environmental Science, Izumisano, Japan.

IL-19 was originally found by sequence homology to IL-10, and is a member of the IL-10 family. However, little is known about the exact immunological role of IL-19 in the regulation of inflammatory bowel disease. Ulcerative colitis (UC) involves the superficial mucosal and submucosal layers of the colon and is driven by Th2 cytokines, such as IL-4, IL-5, and IL-13. In this study, we investigated the role of IL-19 in oxazolone-induced colitis which is useful for the study of the Th2 inflammatory response and resembles the symptom seen in UC. Balb/c genetic background IL-19 knockout mice (KO) were used. To presensitize mice, 150 µL of a 4% oxazolone in 100% ethanol was applied in the shaved abdominal skin. Seven days after presensitization, colitis was induced by intrarectal administration with 100 µL of 3% of oxazolone in 50% ethanol using a plastic catheter. The colitis was evaluated by analyzing body weight loss and histology of the distal colon. IL-19KO showed severe weight loss. Histological analysis revealed that the distal colon in IL-19KO exhibited increased numbers of infiltrating cells and a general loss of tissue architecture. In IL-19KO, oxazolone treatment increased colonic MPO activity. Serum IgE levels and the number of circulating eosinophil were significantly elevated in IL-19KO. CD4-positive T-cells isolated from lymph node of IL-19KO produced elevated amounts of IL-4 and IL-9, but not IL-5 and IL-13. IL-19 plays an anti-inflammatory role in the Th2-mediated colitis model, suggesting that IL-19 may represent potential therapeutic target for reducing colonic inflammation.

P.C1.04.03
Anti-IL-17A therapy resolves skin lesions and vascular dysfunction in mouse models of psoriasis

***A. Brand**[1], R. Schüler[1,2], C. Wohn[3], P. Wenzel[2], A. Waisman[1], S. Karbach[1,2], B. E. Clausen[1];*
[1]Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, 55131 Mainz, Germany, [2]Center for Thrombosis and Hemostasis, University Medical Center of the Johannes Gutenberg-University Mainz, 55131 Mainz, Germany, [3]Department of Immunology, Erasmus MC, 3015 GE Rotterdam, Netherlands.

Introduction: Besides skin inflammation, patients with severe psoriasis suffer from an increased risk of cardiovascular mortality. We hypothesized that Interleukin (IL)-17A is a key cytokine connecting the pathogenesis of psoriasis to the development of cardiovascular disease. Indeed, we previously demonstrated that high-level overexpression of IL-17A in keratinocytes leads to severe psoriasis-like skin disease and drives vascular inflammation, endothelial dysfunction and arterial hypertension in mice.
Methods: To further determine the role of IL-17A in the correlation of psoriatic skin inflammation and cardiovascular disease, we targeted IL-17A expression to all $CD11c^+$ myeloid cells and assessed the development of psoriatic skin lesions and vascular dysfunction in these CD11c-$IL17A^{ind}$ mice. In addition, we investigated whether neutralization of IL-17A can protect CD11c-$IL17A^{ind}$ mice from the concurrent development of skin lesions and cardiovascular disease.
Results: Constitutive low-level expression of IL-17A by $CD11c^+$ cells resulted in the gradual development of chronic skin lesions, resembling macroscopic, histologic and genetic hallmarks of psoriatic plaques. The onset and incidence but not the severity of cutaneous disease was IL-17A dose dependent. Similarly, vascular dysfunction correlated with peripheral IL-17A levels. Notably, successful anti-IL-17A treatment of psoriatic skin lesions diminished peripheral oxidative stress levels, pro-inflammatory cytokines and vascular inflammation.
Conclusion: These data highlight the pivotal role of IL-17A linking plaque formation and vascular disease in psoriasis. Moreover, neutralization of IL-17A can rescue both the skin and cardiovascular phenotype. Hence, CD11c-$IL17A^{ind}$ mice represent a valuable tool to investigate the effects of biologics on chronic skin and cardiovascular disease in psoriasis.

P.C1.04.04
PD-1-dependent dysregulation of type-2 innate lymphoid cells in a murine model of obesity

*G. Oldenhove[1], E. Boucquey[1], A. Taquin[1], V. Acolty[1], L. Bonetti[1], B. Ryffel[2], M. Le Bert[2], **K. Englebert**[1], L. Boon[3], M. Moser[1];*
[1]IBMM, Department of Molecular Biology, Université Libre de Bruxelles, Gosselies, Belgium, [2]INEM, UMR7355, Molecular Immunology, University and CNRS, Orléans, France, [3]Bioceros, Yalelaan 46, 3584 CM, Utrecht, Netherlands.

Recent observations have clearly highlighted the critical role of type 2 innate lymphoid cells in maintaining the homeostasis of adipose tissues in humans and mice. This cell population promotes beiging and limits adiposity directly and indirectly by sustaining a Th2-prone environment enriched in eosinophils and alternatively activated macrophages. Accordingly, the number and function of ILC2s are strongly impaired in obese individuals. In this work, we sought to determine the factor(s) leading to ILC2 destabilization upon high fat feeding. We identified the PD-1/PD-L1 pathway as a negative checkpoint of ILC2 homeostasis and function. TNF appears to play a central role, triggering IL-33-dependent PD-1 expression on ILC2s and recruiting/activating PD-$L1^{hi}$ M1 macrophages. PD-1 blockade partially restored the type 2 innate axis, raising a possibility to restore tissue homeostasis.

P.C1.04.05

A novel humanized mouse model to study skin immunology

*M. M. Klicznik[1], **L. M. Gail**[1], R. Holly[1], A. Benedetti[1], A. Sir[2], R. Reitsamer[2], E. M. Murauer[3], D. J. Campbell[4], I. K. Gratz[1,3];*

Human skin is a complex barrier organ with elaborate immune functions to prevent infection by pathogens and reactions against harmless antigens. Numerous immune cells reside in human skin and communicate with each other as well as with the skin tissue cells (e.g. epidermal keratinocytes) in order to mediate appropriate immune responses. We hypothesize that these interactions are crucial to maintain homeostasis within the skin and aim to investigate them. Because murine and human skin differ in structure and cell composition we established a skin-humanized xeno-graft mouse model to investigate immune mechanisms in vivo. In the model we generate a simplified skin tissue consisting of fibroblasts and keratinocytes only, thus featuring a minimal organotypic skin tissue. This can be reconstituted with different immune cell types, allowing for the study of e.g. T cell-APC, T cell-keratinocyte or T-cell-microbe cross-talk. We can successfully follow T cell infiltration of the skin, started to characterize local T cell - APC interactions and found that these lead to improved T cell infiltration of the skin and local T cell proliferation in the presence of a microbial antigen. Further on we will use this model to study the mechanisms of maintenance and recruitment of the numerous skin T cells and their immunological and tissue regenerative function. M.M.K. is supported by a DOC-fellowship from the Austrian Academy of Science. The project was supported by a Debra International Grant awarded to E.M.M. and I.K.G. and a grant from the National Institute of Health (R01AI127726) awarded to D.J.C. and I.K.G..

P.C1.04.06

Hallmark features of atopic skin disease affect keratinocyte-derivedexosomal compartment

***L. Hovhannisyan**[1], A. Łuczak[1], A. Kobiela[1], X. Wang[2,3], H. Sheldon[4], E. Giannoulatou[5], S. Taylor[5], G. Ogg[2], D. Gutowska-Owsiak[1,2];*
[1]Institute of Biotechnology UG, Intercollegiate Faculty of Biotechnology of University of Gdańsk and Medical University of Gdańsk, Gdańsk, Poland, [2]MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, [3]State Key Laboratory of Military Stomatology, Department of Oral Medicine, School of Stomatology, The Fourth Military Medical University, Xi'an Shaanxi Province, China, [4]Cancer Research UK Molecular Oncology Laboratories, Weatherall Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom, [5]Computational Biology Research Group, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom.

INTRODUCTION: Atopic dermatitis (AD) is a common skin disease combining skin barrier dysfunction and aberrant epidermal differentiation with inflammation. Recent milestone discoveries highlighted the importance of a keratinocyte protein, filaggrin, linking insufficiency in epidermal barrier with inflammatory state and induction of allergic phenotype resulting in sensitisation to allergens.
Exosomes are secreted vesicles acting as messengers between cells; they have functional impact on recipient cells by delivery of a protein, lipid or nucleic acid cargo. Published data suggest changes in the secretion of vesicles upon cellular maturation, differentiation and exposure to cytokines. Here, we investigated whether the two hallmarks of allergic skin disease, i.e. keratinocyte differentiation/epidermal barrier dysfunction and inflammatory *milieu* induce changes in keratinocyte exosomal compartment.
METHODS: We used filaggrin knock-down keratinocytes and allergic mediators (histamine; IL-4/IL-13; IL-17A and IL-22) followed by mRNA profiling and enrichment analysis (FunRich tool) to observe changes in keratinocyte-derived exosomal compartment. We isolated exosomes from conditioned keratinocyte medium (by ultracentrifugation) and analysed exosomal output by WB with the use of common exosomal markers.
RESULTS: Expression of genes encoding exosome-enriched proteins was altered in both filaggrin-insufficient keratinocytes and keratinocytes exposed to inflammatory mediators enriched in atopic skin. Western blot analysis confirmed the impact of keratinocyte differentiation state and stimulation on exosome production.
CONCLUSIONS: Hallmarks of atopic skin disease, i.e. inflammation and barrier dysfunction affect quantitatively and qualitatively keratinocyte-derived exosomal pool, suggesting changes in inter-cellular communication across skin barrier. These are likely to contribute to pathogenesis of AD. The mechanisms remain largely elusive and warrant further study.

P.C1.04.07

Telomeres of T cells as a marker of type 1 diabetes progression in children

***D. Iwaszkiewicz-Grzes**[1], M. Gliwinski[1], A. Woloszyn-Durkiewicz[2], J. Sakowska[1], M. Żalińska[2], M. Hennig[2], M. Myśliwiec[2], P. Trzonkowski[1];*
[1]Department of Clinical Immunology and Transplantology, Medical University of Gdansk, Gdansk, Poland, [2]Department of Pediatric Diabetology and Endocrinology, Medical University of Gdansk, Gdansk, Poland.

Introduction: Type 1 diabetes (T1D) is a chronic disease caused by autoimmune destruction of beta-cells in pancreatic islets, which is followed by hyperglycaemia and clinical symptoms. Genetical and environmental factors play an important role in pathogenesis of T1D. Chronic inflammation associated with autoimmune diseases influences the immune system affecting the replication of lymphocytes. It has been observed that in relation to chronic inflammation, immune cells proliferate more intensively, which causes acceleration of cell-aging. Cellular age can be estimated by measuring the telomeres length. In somatic cells, telomeres get shorter with every cell division and as a result, they are the indicator of the cellular senescence.
Materials and Methods: Samples from were collected from 29 patients with newly diagnosed and 25 patients with long-standing type 1 diabetes. CD4+ and CD8+ T cells were isolated from fresh peripheral blood mononuclear cells. We measured telomeric sequences in vertebrate interphase hematopoietic cells. We used MOLT-4 cells as a reference.
Results: There was an association between age, time of diagnose and telomere length in CD4+ and CD8+ T cells in children, which was especially evident in CD4+ T cells.
Conclusions: The duration of the disease influences the length of telomeres in lymphocytes.
This work has been supported by National Centre for Research and Development, Poland: LIDER/160/L-6/14/NCBR/2015 and STRATEGMED1/233368/1/NCBR/2014.

The effect of progesterone on MMP7 and MMP13 expression in mouse model of systemic sclerosis

***e. izady**[1], F. Vafashoar[1], M. Assarehzadegan[1], H. Poormoghim[2], j. Kuhpayehzadeh[3], N. Mojtabavi[4];*
[1]Immunology department,Iran university medical science, Tehran, Iran, Islamic Republic of, [2]Scleroderma Study group, Firuzgar Hospital,Iran University of medical sciences,, Tehran, Iran, Islamic Republic of, [3]Community Medicine and Public health research center, Iran University of medical sciences, Tehran, Iran, Islamic Republic of, [4]Immunology department, Iran University of medical sciences,Iran university medical science, Tehran, Iran, Islamic Republic of.

Background: Gender medicine is a new era of science which focuses on the impact of sex hormones and gender on normal physiology, pathobiology and clinical features of diseases. In our previous study we showed that supra physiological dose of progesterone exacerbate the lung fibrosis in a mouse model of scleroderma. Matrix metalloproteinases are a group of enzymes which play a role in tissue remodeling and fibrosis. Whereas the abnormal expression of MMP2 and MMP9 are indicated in the pathogenesis of systemic sclerosis, fewer studies are done on MMP13 and MMP7 which are expressed by epithelial cells, fibroblasts and macrophages of the lungs. They are involved in the pathogenesis of COPD, IPF and different lung diseases therefore we aimed to investigate the effect of progesterone on the expression of these two enzymes in lungs of mouse model of scleroderma.
Method: Female mice received progesterone for 28 and 21 days in addition to 28 days bleomycin. On day 29 mice were sacrificed and the expressions of these two enzymes in lungs were analyzed by real time PCR.
Result: We found that bleomycin significantly downregulated the expression of MMP7 and MMP13 and co-administration of progesterone and bleomycin declined the expression of these enzymes but not in a significant manner.
Conclusion: While progesterone cannot reduce the expression of MMP7 and MMP13 in a mouse model of lung fibrosis more investigation on other player of fibrosis are necessary.
Keywords: Systemic sclerosis, Progesterone, Fibrosis, Bleomycin, MMP7, MMP13

P.C1.04.09

IL-36 signalling modulates CD4$^+$ T cell responses involved in the pathogenesis of IBD

***G. Leon**[1,2], S. O'Neill[1], M. Gogarty[1,2], S. Hussey[1], P. T. Walsh[1,2];*
[1]National Children's Research Centre, Crumlin, Dublin, Ireland, [2]Dept of Clinical Medicine, Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland.

Despite significant therapeutic advances the global incidence of Inflammatory Bowel Diseases (IBD) continues to rise. Aberrant lymphocyte and immune cell activation and infiltration into the colonic mucosa of patients are characteristic of inflammation in IBD and has been demonstrated to occur due to inappropriate innate signalling.
In this study we demonstrate increased levels of the pro-inflammatory innate cytokine IL-36α in the serum of paediatric patients with IBD. Importantly, the elevated levels of IL-36α observed are negatively correlated with expression of IL-36Ra, indicating an environment permissive to enhanced IL-36 signaling among these patients. Pathogenic autoimmune T cell responses play a pivotal role in the pathogenesis of IBD and we demonstrate that IL-36 exerts potent effects on specific CD4+ T cell lineages implicated in disease. Specifically, IL-36α directly enhances murine naïve CD4+ Thelper cell (T_H), T_H1, T_H2 and T_H9 effector lineage responses, independently of potent IL-2 induction during early T_H cell activation. In contrast, IL-36α directly inhibits the differentiation of non-pathogenic T_H17 and iTreg cells. Critically, the absence of the IL-36 receptor, specifically on CD4+ T cells, results in altered T cell activation *in vivo* while conferring significant protection from disease progression in a T cell driven model of colitis.
These data indicate an important role for IL-36 family members in T_H cell-mediated inflammation in the context of IBD, thus rendering these cytokines attractive targets for therapeutic intervention.

P.C1.04.10
The role of IL-19 in CCl_4-induced liver fibrosis

***M. Miki**, H. Nakajima, T. Takeuchi, Y. Azuma;*
Laboratory of Veterinary Pharmacology, Osaka Prefecture University Graduate School of Life and Environmental Science, Izumisano, Japan.

IL-19 is a member of the IL-10 family and is an anti-inflammatory cytokine produced mainly by macrophages. Liver fibrosis results from chronic liver injury-mediated inflammation and activation of hepatic stellate cells. However, the involvement of IL-19 in liver fibrosis is not yet fully understood. We investigated the immunological role of IL-19 in carbon tetrachloride (CCl_4)-induced liver fibrosis model mice. Balb/c genetic background IL-19 knockout (KO) mice and age-matched wild-type (WT) mice were used. Liver fibrosis was induced by CCl_4 injection (0.2 mL of 50% solution/kg, 2 times per week) for 8 weeks. Histological evaluation in the liver was assessed by HE staining, Azan staining, and α-SMA immunohistochemistry. mRNA expression in the liver was analyzed by quantitative real-time PCR. In CCl_4-induced liver fibrosis, serum analysis revealed that level of ALT was decreased in L-19 KO mice compared with WT mice. IL-19 KO mice presented exacerbated fibrosis by the morphometric assessment of the total area positively stained with Azan. Moreover, α-SMA expression were increased in liver sections of IL-19 KO compared with WT mice. Additionally, mRNA expression levels of TGF-β and α-SMA were increased in IL-19 KO mice compared with WT mice. These findings indicate that IL-19 has previously undocumented roles in the progress of fibrosis. Enhancement of IL-19 signaling pathway may present therapeutic treatments of liver fibrosis.

P.C1.04.11
Biomarkers in Immune response of fungi inoculated mice

***A. J. Odebode**[1], A. Adekunle[2], E. Farombi[3];*
[1]Faculty of Science, University of Lagos, Akoka, Lagos, Nigeria, [2]Department of Botany, Faculty of Science, University of Lagos, Akoka, Lagos, Nigeria, [3]Faculty of Basic Medical Science, University of Medicine, Ibadan., Ibadan., Nigeria.

Fungi are an increasing public health problem worldwide because they have a great impact on human health. A mouse model was devised to compare the adverse effects provoked by four most abundant fungi isolated from southwest, Nigeria.Sixty Balb/b albino mice were grouped into nine treatments of six per cage with a control group. The animals were exposed intranasally to the spores of *A. flavus, A. penicilloides, Penicillium citrinum* and *Penicillium chrysogenum* at 2.3×10^7 and 3.2×10^5 m/L for 24hours. Both dose-response, time-course inflammatory and toxic responses were investigated after a single dose of the microbes. The spores of *A. flavus,* and *A. penicilloides* provoked a very intense acute inflammation indicated by production of increased malondialdehyde, myeloperoxidase, protein in the lungs. The inflammatory cell response in the lungs was more severe and varies with each organism. White blood cells were significantly higher in *Penicillium funiculosum*, *Aspergillus terreus* and *P. chrysogenum* inoculated mice compared to control. All the fungi inoculated resulted in significant ($p<0.05$) increase in the monocyte and basophils cell. *P. citrinum* significantly increased the eosinophils as *A. terreus* increased the lymphocytes. The neutrophils content was higher in the *A. penicillioides, P. chrysogenum* and *P. citrinum* incoculated treatments. Both haemoglobin and red blood cell count were significantly increased in the mice inoculated with *A. funiculosum*, *P. chrysogenum* and *A. flavus* compared to control group. The results show that the selected microbes have potential to cause inflammatory and toxic responses after airway exposure in mice.

P.C1.04.12
Cutaneous drug eruptions

***L. Pajaziti**, S. Sopjani, A. Krasniqi, O. Vogel, A. Pajaziti;*
University Clinical Center of Kosovo, Prishtina, Kosovo, Republic of.

Drug reactions are common. Their frequency increases with the increased use of drugs. The intensity of the reactions is different and ranges from mild forms that are more frequent to life-threatening. Clinical manifestations of these reactions are different. The aim of this study is to explore some of the characteristics of the drug reactions in our hospitalized patients: the most common clinical forms of the cutaneous drug eruptions, the identification of the causative drugs, circumstances, and the possible correlation of a drug with a given clinical type. In this study, 128 patients (58 women and 70 males) with cutaneous drug eruption were included.
Six types of reaction were observed: erythema multiforme / Steven-Johnson syndrome, urticaria, exanthematous drug eruption, fixed drug eruption, erythema nodosum, and angioedema. Of them, the dominant pattern was erythema multiforme (34.37%), followed by urticaria (31.25%), and exanthematous reactions (19.53%). Nonsteroidal anti-inflammatory drugs and acetaminophen were the most common cause of drug reactions, followed by antibiotics (39.06%). A drug may cause some clinical patterns of reaction. Uncontrolled use of nonsteroidal anti-inflammatory drugs increases the likelihood of drug eruptions.

P.C1.04.13
IL-35 maintains regulatory T cells phenotype to suppress diabetic nephropathy

*E. Eriksson[1], Z. Luo[2], S. Varli[1], M. Mejia-Cordova[1], D. Espes[1], L. Thorvaldson[1], M. Blixt[1], P. Carlsson[1], P. Hansell[1], S. Sandler[1], **K. Singh**[3];*
[1]Dept of Medical Cell Biology, Uppsala University, Uppsala, Sweden, [2]Dept. of Medical Cell Biology, Uppsala University, Uppsala, Sweden, [3]Uppsala University, Uppsala, Sweden.

Diabetes causes an elevation of the blood glucose level and a long-term hyperglycemia that contributes to kidney damage, i.e. diabetic nephropathy (DN). DN exhibits signs of inflammation and kidney infiltration of mononuclear-cells. RegulatoryT-cells (Treg-cells) maintain the homeostasis of the immune system, specifically by producing anti-inflammatory cytokine IL-35. Despite intensive research the role of both Treg-cells and IL-35 is not yet clear. Herein, we determined the proportions of Treg-cells, IL-35$^+$Treg-cells and IL-17a$^+$Treg-cells in type 1 diabetes (T1D) patients with or with out DN, and matched them for age, sex and body mass index with healthy controls (HC). Treg-cells and IL-35$^+$Treg-cells was decreased in DN and T1D patients, whereas IL-17a$^+$Treg-cells were increased compared to HC. To further advocate the role of Treg-cells in DN of Treg cells in the kidneys of multiple low dose streptozotocin (MLDSTZ) treated mice and in NOD female mice were determined. We found an increase in the numbers of Treg-cells and an infiltration of mononuclear-cells in the kidneys of MLDSTZ, and NOD mice. Thus, our data reveal that Treg-cells are increased in kidneys of mouse models of T1D. However, the upregulation of Treg-cells did not protect against both hyperglycemia and infiltration of mononuclear-cells in kidneys. In addition, IL-35 treatment prevented the mononuclear cell infiltration and maintained the phenotype of Treg-cells in kidneys of MLDSTZ and NOD diabetic mice, and albumin creatinine ratio was lowered in IL-35 treated mice compared to vehicle mice, suggesting that IL-35 could be investigated to prevent mononuclear-cell infiltration in kidneys and perhaps in DN.

P.C1.04.14
The role of interleukin-19 in NAFLD/NASH mice model

***Y. Ushikai**, K. Hirota, H. Nkajima, T. Takeuchi, Y. Azuma;*
Laboratory of Veterinary Pharmacology, Osaka Prefecture University Graduate School of Life and Environmental Science, Izumisano, Japan.

IL-19 is a member of the IL-10 family and is an anti-inflammatory cytokine produced mainly by macrophages. Nonalcoholic fatty liver disease (NAFLD) is highly associated with the metabolic syndrome, and occurs as a more serious form of the disease, nonalcoholic steatohepatitis (NASH). NASH is diagnosed pathologically by histological evaluation of fibrosis, inflammation, and other features, such as hepatocyte ballooning. However, the involvement of IL-19 in liver inflammation and liver fibrosis is not well understood. We investigated the immunological role of IL-19 in diet-induced NAFLD/NASH model mice. IL-19 knockout mice (KO) and wild-type mice (WT) were fed a choline-deficient and high-fat diet (60kcal% fat) with 0.1% methionine and 2% cholesterol for 2 months. Histological evaluation in the liver was assessed by HE staining and Azan staining. mRNA expression in the liver was analyzed quantitative real-time PCR. IL-19KO showed significantly weight loss compared with WT mice. Liver weight was significantly less in IL-19KO. Histological analyses of WT showed moderate steatosis, mild inflammation, and no fibrosis, indicating that WT have steatohepatitis. IL-19KO showed significantly high ALT level compared with WT. Moreover, IL-19KO showed weaker steatosis and more severe inflammation. Specifically, IL-19KO showed pericellular fibrosis that is one of the features of NASH. Additionally, mRNA expression levels of TNF-alpha and IL-6 were significantly increased in IL-19KO. Our findings indicate that IL-19 has previously undocumented roles in the progress of fibrosis and the elimination of inflammation in the liver. IL-19KO may be a valuable tool to study the NAFLD/NASH mice model.

P.C1.04.15
Continual exit of human skin resident memory CD4 T cells that seed distant tissue sites

*M. M. Klicznik[1], P. A. Morawski[2], B. Hoellbacher[2], T. Duhen[2], S. Motley[2], **S. R. Varkhande**[1], M. Rosenblum[3], D. J. Campbell[2], I. K. Gratz[1];*
[1]University of Salzburg, Salzburg, Austria, [2]Benaroya Research Institute, Seattle, WA, United States, [3]University of California, San Francisco, San Francisco, CA, United States.

As a barrier organ the skin harbors immune cells that not only provide protection against a myriad of pathogens but also support tissue homeostasis and repair. A large proportion of these immune cells in skin are resident memory Tcells (TRM) with unique skin-tropic signatures that are thought to permanently reside in the tissue and not recirculate.
We have identified a novel population of circulating CD4$^+$CLA$^+$CD103$^+$cells in the blood of healthy humans. Using a multidimensional mass cytometry approach (CyTOF) we found that these cells have a unique skin-tropic phenotype reminiscent of skin TRM. Phenotypic and transcriptional similarities determined by conventional flow cytometry and RNA sequencing further highlighted the close relationship between CD4$^+$CLA$^+$CD103$^+$TRM and circulating CD4$^+$CLA$^+$CD103$^+$cells. Their unique cytokine production profile of IL-22 and IL-13, and low production of IL17a and IFN-γ indicates a function in skin homeostasis and repair. The presence of this unique population in circulation suggests recirculating TRMs, mobilized potentially to seed remote tissue sites.

To test this hypothesis, we performed xeno-graft experiments, by transferring human full thickness skin onto immunodeficient mice that carried an engineered human skin graft devoid of TRM. We found that CLA^+CD103^+TRM could be mobilized from the skin, enter circulation and seed a distant skin site, while preserving their phenotype. Further, upon transfer of human PBMC we detected CLA^+CD103^+cells that had seeded an engineered human skin graft. Thus, we propose that $CD4^+CLA^+CD103^+$cells found in the human blood represent a migrating population of skin TRM.

P.C1.04.16
Defining the targets of autoimmune disease-associated variation in human Regulatory T cells

Y. Y. Wong;
University of Adelaide, North Adelaide, Australia.

Chromatin structure is known to have a major influence on gene expression by controlling transcription factor (TF) access to binding sites in non-coding regulatory enhancers and promoters. Studies have shown that majority of the autoimmune disease risk associated genetic variations are found in non-coding regions of the genome such as enhancers. Our lab has been working on the functional validation of cell-specific enhancers located at autoimmune disease risk loci, in order to explain how genetic variations at these loci contribute to disease. In view of this, identifying the TFs bound to enhancers and promoters is critical for understanding how these elements work and how disease-associated single nucleotide polymorphisms (SNPs) may influence this activity. Currently our ability to predict genomic binding sites from sequence alone is limited and functional TF binding sites needs to be experimentally validated. ATAC-seq, which simultaneously probe chromatin structure and importantly transcription factor binding, requires relatively few cells making it amenable to use on rare population and small clinical samples.

Functional characterization of T lymphocytes in coeliac patients with dermatitis herpetiformis: evidence of cross reactivity between tissue and epidermal transglutaminases

M. Capone, M. Caproni, M. Rossi, A. Mazzoni, B. Rossettini, G. Montaini, G. Lami, ***L. Maggi****, A. Calabrò, L. Cosmi, F. Liotta, F. Annunziato;*
University of Florence, Florence, Italy.

INTRODUCTION: Dermatitis herpetiformis (DH) is considered the cutaneous manifestation of coeliac disease (CD), however why only few coeliac patients develop this disorder is still unknown. Epidermal transglutaminase (TG3) has been recently described as the main autoantigen of DH. Here we propose to study phenotypic features and antigen specific response of T cells towards both tissue (TG2) and epidermal transglutaminases in DH compared to CD patients. METHODS: Mononuclear cells from peripheral blood (PBMNC), skin and gut biopsies of 14 DH patients and 8 CD patients were policlonally expanded and evaluated by flow cytometry for expression of Th1, Th2 and Th17 cells associated markers. PBMNCs were also cultured in the presence of TG2 or TG3 and antigen specificity of expanded T cells has been evaluated after 15 days of culture. RESULTS: Flow cytometric evaluation showed an increased frequency of TNF-alpha producing T cells in skin of DH patients compared to CD, thus confirming the inflammatory status in the epidermal district. More interestingly, antigen specificity assays revealed that a cross reactivity occurs between TG2 and TG3 specific T cells, more in DH than in CD patients. CONCLUSIONS: Our data, even if preliminary, provide possible explanation to the mechanisms leading to DH only in some CD patients. Moreover, based on the finding of the increased production of TNF-alpha at skin level, new possible treatments should be proposed, including biological therapy, being DH very slow to respond to gluten free diet.

P.C1.04.18
Linking diet, gut immunity and microbiota in the pathogenesis of Type 1 Diabetes

I. Cosorich[1]*, L. De Giorgi*[1]*, A. Bolla*[2]*, R. Ferrarese*[1]*, E. Bosi*[2]*, R. Zuppardo*[1]*, A. Mariani*[2]*, D. Esposito*[2]*, M. Falcone*[1]*;*
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*San Raffaele Hospital, Milan, Italy.*

Recent data indicate that gut immunity and the mechanisms that regulate effector and regulatory T cell differentiation in the intestine are instrumental to maintain immune tolerance towards self-tissues and to prevent extra-intestinal autoimmune diseases. This observation led to the hypothesis that environmental factors as diet and microbiota modifications, affect the pathogenesis of autoimmune Type 1 Diabetes (T1D).
To this aim, we analyzed gut mucosal immunity in tissue samples isolated from the small intestine of T1D patients and healthy controls (HC). A phenotypical analysis of gut mucosal immune cell subsets has been performed. We observed a statistically significant increase of Th22cells and CD1c+CX3CR1+DCs in the gut of T1D. In order to find if there is a correlative link between diet and Th subsets, we are collecting a 3-days-food record questionnaire from T1D patients. Gut microbiota of brushing material from duodenum was analyzed by 16S rRNA sequencing.
We also investigated if different type of diet can influence autoimmunity in preclinical models of T1D. In particular if an anti-inflammatory diet enriched in fibres and omega3 can reduce gut inflammation and protect NOD mice from T1D. We demonstrated a lower gut permeability in NOD mice fed with omega3 diet, compared to NOD mice fed with control diet.
We further aim at elucidating the link of gut immunity alterations and environmental factors that might have a strong impact on T1D.

P.C1.04.19
Lymph node stromal cells confer location-dependent tolerogenic properties to dendritic cells

J. Pezoldt[1]*, M. Szente-Pasztoi*[2]*, M. Zou*[1]*,* ***C. Wiechers***[1]*;*
[1]*Helmholtz Centre for Infection Research, Braunschweig, Germany,* [2]*Biomedical Center, Ludwig-Maximilians University, Munich, Germany.*

The balance between regulatory T cells (Tregs) and effector T cells is key for the maintenance of immune homeostasis. To dissect the contribution of lymph node (LN) stromal cells to T cell differentiation and peripheral *de novo* Treg induction in gut-draining mesenteric lymph nodes (mLNs), LN transplantation experiments have been utilized in a mouse model. Remarkably, the high Treg-inducing capacity of mLNs was retained after transplantation into the popliteal fossa, a non-tolerogenic, skin-draining site, although the hematopoietic compartment was completely replaced after 8 weeks, suggesting mLN stromal cells were stably imprinted with the tolerogenic properties. Additionally, the composition of incoming resident (res) dendritic cells (DCs) and their transcriptional signatures in transplanted mLN closely resemble resDCs from endogenous mLNs. Furthermore, co-cultures of resDCs re-isolated from transplanted mLN with naïve $CD4^+$ T cells from DO11.10 mice resulted in a high Treg induction, demonstrating that resDCs can get modulated by LN stromal cells after their LN entry, and that mLN stromal cells via modulation of resDCs affect local T cell differentiation and particularly *de novo* Treg induction. Finally, single-cell RNAseq data from either pLN or mLN $CD45^-CD24^-$ stromal cells revealed a to date underappreciated location-dependent heterogeneity. To discern the imprinted tolerogenic properties of stromal cells from different LNs, *in vitro* experiments of pLN vs mLN stromal cell subsets with precursor-DCs (pre-DCs) are currently underway. In conclusion, our recent data demonstrated a cross talk between LN stromal cells and resDCs, which is in turn affecting the generation and/or homeostasis of the Treg compartment.

P.C1.04.20
Fine characterization of healthy conjunctiva: main findings when comparing IELs and peripheral blood fine lymphocytes subsets

A. Corell[1]*, J. Zarzuela*[1]*, C. Martin*[2]*, A. Armentia*[1]*, R. Reinoso*[1]*, S. Rubio*[1]*, M. Cano*[1]*, A. Vallelado*[1]*, J. Herreras*[1]*;*
[1]*Universidad de Valladolid, Valladolid, Spain,* [2]*Centro de Hemoterapia y hemodonación Castilla y León, Valladolid, Spain.*

Introduction: As occurs in other mucosal tissues —for example gut, bronchi and nose—, ocular mucosa holds a conjunctiva- associated lymphoid tissue (CALT). It is well known that MALT (Mucosa Associated Lymphoid Tissue) has morphological and functional variations across tissues. Therefore, a thorough analysis of lymphoid populations might render useful information on ocular surface conditions. **Objectives:** The aim of this study is to improve the knowledge of human immune system within the conjunctiva in healthy and different ocular surface conditions. **Material and methods:** Twenty-five healthy volunteers were recruited. Peripheral blood lymphocytes were obtained by venipuncture while intraepithelial lymphocytes (IELs) from eye conjunctival mucosa were obtained by brush cytology. Major and fine subsets were characterized by flow cytometry.Memory, naïve, γδ T cells, $CD8^+$ (**Tc, NKT subtypes**), $CD4^+$(**Th0, Th1, Th2, Th17,Th1/Th17, Th22** and **Treg** subsets), B cells (**B_1** and **B_2**) and **NK cells** —regulatory and cytotoxic— subsets were analyzed in both conjunctival mucosa and peripheral blood. **Results:** Age and sex seemed to determine few differences in some lymphocyte subsets: Th1 cells might be age-influenced whereas Th22 might be sex-influenced. As expected, no strong correlations between peripheral and conjunctival lymphocytes were found. Conjunctival T cells seemed to be mainly CD8+ and TCRγδ+, while they were only a minor population in peripheral blood. Memory CD4+ T cells, NKT, B1, Tregs and regulatory NK cells had higher values in conjunctiva. **Conclusions:** Some known differences (increased TCRγδ cells) were found, whereas others are apparently new (increased B1, NKT, Tregs and regulatory NK lymphocytes) in conjunctival MALT. These suggest specialized functions (including regulatory) in the area.

P.C1.05.01
Neutrophil activation by immunoglobulin A exacerbates pathogenesis of inflammatory bowel disease

***A. Bos**, M. Bögels, R. Mebius, M. van Egmond;*
VU medical center, Amsterdam, Netherlands.

Immunoglobulin A (IgA) is the most prominent antibody in the mucosa and important for maintaining homeostasis. However, altered IgA repertoires have been found in chronic inflammatory diseases. For instance, patients with inflammatory bowel disease (IBD) have altered IgA against commensal bacteria. Therefore, this study aims to determine the contribution of IgA on IBD pathology.
We used a DSS-induced colitis model to investigate the development of colitis in human IgA x human IgA Fc receptor (hIgA$^+$/hFcαRI$^+$) mice. Compared to control mice, hIgA$^+$/hFcαRI$^+$ mice showed more severe inflammation, reduced body weight and worse survival. Additionally, massive accumulation of intra-intestinal FcαRI$^+$ neutrophils was observed. Similarly, inflamed patient biopsies revealed significant infiltration of neutrophils, together with a destroyed epithelial lining. Therefore we assessed the effect of IgA-activated neutrophils on epithelial cell line co-cultures. We observed that IgA-activated neutrophils from IBD patients form neutrophil extracellular traps (NETs) that capture epithelial cells. Importantly, we assessed IBD plasma for the presence of anti-epithelial antibodies and found specifically IgA antibodies recognizing epithelial cell lines. Nevertheless, no enhanced IgG or IgM antibodies were found against epithelial cells within these patients.Thus, we propose that anti-epithelial IgA contributes to IBD pathology by binding to the human epithelial lining, which activates neutrophils and initiates perpetual neutrophil activation, which results in massive tissue damage.

P.C1.05.02
Tissue resident memory cells T cells in the human conjunctiva and immune signatures in human ocular surface diseases.

***T. Bose**[1], L. Tong[2], G. K. Chandy[3];*
[1]Ludwigs-Maximilians-Universität, München, Germany, [2]Singapore Eye Research Institute, Singapore, Singapore, [3]Lee Kong Chian School of Medicine, Singapore, Singapore.

Non-recirculating resident memory (T_{RM}) and recirculating T cells mount vigorous immune responses to both self and foreign antigens in barrier tissues like the skin, lung and gastrointestinal tract. Using impression cytology followed by flow cytometry we identified two T_{RM} subsets and four recirculating T-subsets in the healthy human ocular surface. In dry eye disease, principal component analysis (PCA) revealed two clusters of patients with distinct T-cell signatures. Increased conjunctival central memory and naïve T cells characterized Cluster-1 patients, and increased CD8$^+$ T_{RM}s and CD4$^+$ recirculating memory T cells characterized Cluster-2 patients. Interestingly, these T-cell signatures are associated with different clinical features: the first signature correlated with increased ocular redness, and the second with reduced tear break up times. These findings open the door to immune-based characterization of ocular surface disease and T-subset specific immunotherapies to suppress T-subsets involved in disease. They may also help with patient stratification during clinical trials of immunomodulators.

P.C1.05.03
The local microenvironment drives the identity of tissue-resident lymphocytes

***S. Christo**[1], M. Evrard[1], D. Newman[1], S. L. Park[1], J. E. Prier[1], F. R. Carbone[1], F. Ginhoux[2], A. Kallies[1], L. K. Mackay[1];*
*[1]The Peter Doherty Institute, Melbourne, Australia, [2]Signapore Immunology Network (SIgN) Agency for Science, Technology and Research (A*STAR), Singapore, Singapore.*

Tissue-resident memory T (T_{RM}) cells are a population of non-recirculating lymphocytes that permanently reside in non-lymphoid organs. Together with other tissue-resident lymphocytes, these cells are critical for controlling infection and cancer, and are implicated in promoting tissue repair and autoimmunity. Although T_{RM} cells possess a common molecular signature distinguishing them from their circulating counterparts, the transcriptional identity of these cells differs vastly between organs. We found that organ-specific gene signatures are conserved between different subsets of resident lymphocytes within a given tissue, partly reflective of local cytokine imprinting. We show that whilst T_{RM} cells in different tissues exhibit differential cytokine and molecular requirements for their development, locally-derived factors cooperate to globally suppress tissue-egress genes in resident cells across all organs. Collectively, our data demonstrate the adaptation of T_{RM} cells to specific tissue microenvironments. Exploiting such commonalities and differences in T_{RM} cell regulation will inform new strategies designed to target these cells in a site-specific manner.

P.C1.05.04
Resident T cells trigger disease-associated tissue responses that stratify clinical outcome in human psoriasis

*I. Gallais-Sérézal, S. Cheuk, **L. Eidsmo**;*
Department of Medicine Solna, Stockholm, Sweden.

Resident T cells provide barrier immunity in murine models of viral infections. In contrast, alteration in functionally distinct subsets of resident T cells is implicated in human focal skin diseases. We recently reported that CD49a marks CD8+ T cells poised to cytotoxicity and IFN-gamma production, while IL-17 producing T cells form localised disease memories in resolved psoriasis. However, if and how these cells cause human pathology is not known. Here, we investigated the consequences of T cell activation on tissue response patterns. T cell activation induced type-1 interferon tissue responses in explanted skin tissue and psoriasisform, IL-17-related responses were selectively induced in psoriasis-derived skin. Our data indicates that local T cell activation induce clinically relevant tissue responses and stratification of these responses in resolved psoriasis were correlated to clinical outcome. Finally, our data indicates that microbial interplay with genetically predisposed keratinocytes may shape the local pool of resident T cells.

P.C1.05.06
***Helicobacter hepaticus* as disease driver in a novel CD40-mediated spontaneous colitis-model**

***V. Friedrich**[1,2], C. Barthels[1], A. Ogrinc[1], D. Garzetti[3], B. Stecher[3], I. Forné[4], A. Imhof[4], T. Brocker[1];*
[1]Institute for Immunology, Biomedical Center, Ludwig-Maximilian-University, Munich, Germany, [2]Graduate School of Quantitative Biosciences (QBM), Ludwig-Maximilian-University, Munich, Germany, [3]Max von Pettenkofer-Institute, Ludwig-Maximilian-University, Munich, Germany, [4]Protein Analysis Unit, Biomedical Center, Ludwig-Maximilian-University, Munich, Germany.

The mammalian gastrointestinal tract is shaped by microbiota. To maintain mucosal homeostasis, a balance between appropriate immune responses to invading pathogens and tolerance to food and commensal-derived antigens is essential. Disturbed balances can result in severe inflammatory disorders like Inflammatory Bowel Disease. Dendritic cells (DCs) play a key role in this regulation as they can induce both, immunity and tolerance. To investigate the role of the CD40L-CD40 axis in tolerance vs. immunity and the role of DCs therein, we generated a murine model with constitutive CD40-signaling in DC. CD40-signaling leads to migration of CD103$^+$ DCs from the colonic lamina propria to draining lymph nodes, followed by DC-apoptosis. This loss of CD103$^+$ DCs caused lack of RORγt$^+$Helios$^-$ induced regulatory T cells and an increase of Th1/Th17 effector cells in the colon, resulting in breakdown of mucosal tolerance and severe colitis.
We used sera from these mice to isolate fecal antigens recognized by mice with colitis, but not control mice and studied changes of the microbiota during disease development. We detected *Helicobacter hepaticus (H.h.)*-specific antibodies in transgenic mice and could protect them from disease onset by rendering them *H.h.*-free. Upon *H.h.*-reinfection of transgenic mice, rapid disease onset was observed. Our data suggest that *H.h.* is the disease driver in a CD40-mediated spontaneous colitis-model, allowing us to study T cell specificities and differentiation plasticity during inflammation more in detail.

P.C1.05.07
Canonical and non-canonical functions of tyrosine kinase 2 during liver inflammation

***D. Gogova**[1], C. Lassnig[1,2], S. Knapp[3], A. Puga[1], M. Müller[1], B. Strobl[1];*
[1]Institute of Animal Breeding and Genetics, Vienna, Austria, [2]Biomodels Austria, University of Veterinary Medicine Vienna, Vienna, Austria, [3]CeMM (Research Center for Molecular Medicine of the Austrian Academy of Sciences) and Laboratory of Infection Biology, Department of Medicine I, Medical University, Vienna, Austria.

Tyrosine kinase 2 (TYK2) belongs to the Janus kinase family of receptor-associated tyrosine kinases and is an integral part of signalling cascades utilized by many cytokines with important immune regulatory activities. Mice deficient for TYK2 (*Tyk2*$^{-/-}$) or expressing enzymatically inactive TYK2 (*Tyk2*^{K923E}) allow us to distinguish between kinase-dependent and independent functions in immune responses.
We found that TYK2 and its kinase activity are required to protect from *Escherichia coli*-induced liver injury, which correlated with diminished systemic and hepatic levels of interleukin-22 (IL-22). IL-22 signals through TYK2, is produced by innate and adaptive immune cells upon stimulus with various cytokines and growth factors and has been reported to have hepatoprotective effects. Next, we employed the concanavalin A (ConA)-induced acute hepatitis model to further study the role of TYK2 in IL-22 production and signalling, as previous studies showed increased disease severity in *Il22*$^{-/-}$ mice. We show that *Tyk2*$^{-/-}$ mice have significantly increased liver damage parameters and decreased systemic and hepatic levels of IL-22 compared to wild-type mice. Surprisingly, despite diminished levels of IL-22, *Tyk2*^{K923E} mice showed liver damage comparable to wild-type mice. Analysis of disease-driving cytokines revealed that hepatic *Ifng* mRNA expression was almost completely abolished in *Tyk2*^{K923E} and *Tyk2*$^{-/-}$ mice, whereas *Tnfa* expression was specifically reduced in *Tyk2*^{K923E} animals.
Taken together, we show that TYK2 protects from infection- and inflammation-induced hepatitis and that TYK2^{K923E} is capable to prevent inflammatory TNFα production and ameliorate liver injury.
Supported by FWF grants P25642-B22, SFB-F6101 and SFB-F6106.

A single nucleotide polymorphism in the promoter region of the inhibitory immune receptor SIRL-1 controls its surface expression on mononuclear phagocytes

D. Gollnast[1], *T. van Capel*[2], *B. Giovannone*[1], *M. van der Vlist*[1], *D. Hijnen*[3], *E. de Jong*[2], *L. Meyaard*[1];
[1]*Laboratory of Translational Immunology (UMCU), Utrecht, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands,* [3]*Dermatology and Allergology (UMCU), Utrecht, Netherlands.*

Signal inhibitory receptor on leukocytes-1 (SIRL-1) is expressed highly on human blood granulocytes and monocytes and low on circulating myeloid dendritic cells (mDCs) and basophils. SIRL-1 ligation inhibits innate effector mechanisms such as production of FcR-induced reactive oxygen species in monocytes and neutrophils and NETosis in neutrophils. We show that the single nucleotide polymorphism (SNP) rs612529T/C, located in the SIRL-1 promoter region, abrogates SIRL-1 expression in monocytes and dendritic cells, whereas expression levels in neutrophils and eosinophils remain unaffected.
Using targeted association analysis, rs612529T/C could be associated to the skin inflammatory disease atopic dermatitis. By FACS analysis we found that in healthy skin, SIRL-1 is restricted to very low expression on subpopulations of skin-resident DCs. By RT-PCR analysis of FACS-sorted skin-resident immune cells we identified SIRL-1 mRNA exclusively in dermal mDCs with elevated levels in $CD14^+$ DC-like macrophages. In individuals that carry the rs612529C allele, SIRL-1 transcripts were undetectable in these dermal cell types, indicative of similar transcriptional regulation of SIRL-1 in skin-resident DCs as in blood-resident monocytes and mDCs.
In contrast to skin, high expression of SIRL-1 was detected on 30-50% of tissue-resident immune cells in healthy lung tissue samples derived from tumor-removal surgery. SIRL-1 was expressed on interstitial macrophages, monocytes, and mDC subsets.
These results suggest a role of SIRL-1 in immune regulation of mononuclear cells, including monocytes, DCs and macrophages. Immune inhibitory functions of SIRL-1 may be important to circumvent the manifestation of inflammatory diseases in human barrier tissues and may be of particular importance in lung.

P.C1.05.09

Massive and organized B-cell infiltrates in the aorta of LV-GCA patients

J. C. Graver*, M. Sandovici, E. A. Haacke, A. M. Boots, E. Brouwer;*
University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Giant cell arteritis (GCA) is the most common type of systemic vasculitis and can be classified into cranial(C)-GCA and large-vessel (LV)-GCA. GCA is postulated to be T-cell-mediated and in temporal artery infiltrates, T-cells clearly outnumber B-cells. However, our report on a disturbed homeostasis of B-cells in newly diagnosed GCA patients shows evidence for a putative role of B-cells. So far, the role of B-cells is underexplored and the presence of B-cells in the vessel wall of LV-GCA patients is unknown. Therefore, this study assessed the presence of B-cells in the aorta of LV-GCA patients.
Aorta tissue samples of 9 histologically-proven LV-GCA patients who underwent surgery due to an aortic aneurysm were studied by immunohistochemistry. Staining was performed with antibodies against CD20 (B-cells), CD3 (T-cells), CD21 (follicular dendritic cells (FDC)), bcl6 (germinal centers), and CD138 (plasma cells). None of the patients received immunosuppressive treatment at the time of surgery. Aorta tissue from age- and sex-matched atherosclerosis patients with an aneurysm were included as controls.
Aorta tissues of LV-GCA patients showed massive infiltration of B-cells, mainly in the adventitia. In contrast to the temporal artery, B-cells outnumbered T-cells in the aorta. B-cells organized into artery tertiary lymphoid organs; there was co-localization of B- and T-cells, FDCs, germinal centers and plasma cell niches.
Aorta tissues from patients with histologically-proven LV-GCA showed massive and organized B-cell infiltrates in the adventitia. The mere presence of B-cells at the site of inflammation prompts further investigation into the role of B-cells in GCA.

P.C1.05.10

Tryptophan metabolism in inflammatory bowel disease - Distribution and regulation of enzymes, metabolites and target structures in a multidimensional model

M. Huhn[1], *M. Herrero San Juan*[1], *R. Boll*[2], *J. Pfeilschifter*[1], *P. Weller*[2], *H. Radeke*[1];
[1]*pharmazentrum frankfurt, Frankfurt am Main, Germany,* [2]*Institute for Instrumental Analysis and Bioanalytic, Mannheim, Germany.*

The immune pathogenesis of inflammatory bowel diseases leads to a perpetuating mucosal inflammation based on an imbalance of pro- and anti-inflammatory cytokines. While tryptophan (TRP) and kynurenine have been examined in detail, neither downstream enzymes nor other cells involved in chronic inflammation have been studied in detail. Therefore, we sought to complete the knowledge of downstream enzymes in all cell types involved in chronic inflammation. We performed a multidimensional metabolome TRP analysis in primary colon cell lines, cancer cell lines and immune cells of healthy donors by LC-MS/MS and qRT-PCR. Cells of the innate immune system, especially monocytes, dendritic cells and macrophages, were proven to be the main producers of TRP metabolites. In addition, mRNA of indoleamine 2,3-dioxygenase 1 (IDO1) was expressed in cytotoxic CD8+ T cells and B cells. Colon cells revealed no constitutive expression of IDO1 and IDO2 mRNA. Tryptophan 2,3-dioxygenase (TDO) and Kynurenine 3-monooxygenase (KMO) mRNA were detected in cancer cell lines CaCo-2 and DLD-1, but not in primary colon cell line CCD841 CoN. Furthermore, mRNA expression of G protein-coupled receptor (GPR35) was shown to be increased in CaCo-2 and DLD-1. However, only low expression levels of GPR35 mRNA were detected in CCD841 CoN. Our findings reveal an altered TRP metabolism, with an increased activity caused by inflammatory conditions. Taken together, we identified TDO, KMO and GPR35 as potential biomarkers for colorectal cancer. These results point to a major role in the development and progression of chronic diseases like cancer. Funded by the Arbeitsgemeinschaft-industrieller-Forschungsvereinigungen Germany.

A trauma and victimization history associate with Immune barrier dysregulation in women

A. S. Kohlmeier[1], *L. B. Haddad*[2], *K. A. Brookmeyer*[1], *J. M. Baker*[3], *K. Chi*[1], *C. Y. Chen*[1], *E. N. Kersh*[1], *J. A. Johnson*[1], *M. M. Herbst-Kralovetz*[4], *M. Hogben*[1], *I. Ofotokun*[2], *J. E. Kohlmeier*[2];
[1]*CDC, Atlanta, United States,* [2]*Emory University, Atlanta, United States,* [3]*The University of Arizona, Pheonix, United States,* [4]*The University of Arizona, Phoenix, United States.*

Background: A growing body of literature suggests women who have experienced psychological traumas such as violence victimization, are more vulnerable to sexually transmitted infections (STIs). Though this susceptibility has been associated with sexual behaviors, a biological impact on STI risk through long-lasting immune changes at sites of STI exposure has not been investigated. We examined immune barrier composition and lifetime trauma and victimization history (LTVH) by characterizing critical cellular immune mediators at the apical lumen of the lower FRT. Results: Samples from high (n=20) compared to low (n=22) LTVH scoring participants presented alterations in barrier homeostasis and cell composition at the FRT lumen. Specifically, we found increased detection of MHC class II+ antigen presenting cells, expressing increased frequencies of CCR5 and CD103. Corresponding to this observation local T cell populations, expressed reduced frequencies of the tissue retention marker CD69 and increased frequencies of lymphoid trafficking marker CCR7. Additionally, genes involved in maintaining tight junctions and epithelial barrier integrity ALOX12, OCLN, LCE3D were decreased in FRT epithelial cells. Conclusions: Repeated exposures to trauma and violence victimization was associated with alterations in barrier homeostasis and cell composition. While low scoring participant samples expressed characteristics of a healthy immune-restricted barrier, samples from high-scoring participants exhibited immune perturbations that evidence compromised immune defenses to initial pathogen encounter. These data indicate that alterations in immune mediators at the FRT may directly contribute to an increased risk of STIs among women who endure greater trauma and violence victimization.

P.C1.05.12

Understanding the crosstalk between immune and epithelial cells in the development of the "TTP-deficiency" syndrome

C. La[1], *B. De Toeuf*[2], *A. Assabban*[1], *H. Shehade*[1], *P. J. Blackshear*[3], *L. Van Maele*[1], *C. Gueydan*[2], *G. Oldenhove*[2], *S. Goriely*[1];
[1]*Institute for Medical Immunology, Gosselies, Belgium,* [2]*Laboratory of Molecular Biology of the Gene, Institut de Biologie et de Médecine Moléculaire, Gosselies, Belgium,* [3]*Duke University Medical Center, Durham, United States.*

Introduction. Interactions between epithelial barriers and environmental stimuli are essential for a functional immunity, to maintain homeostasis and avoid tissue damage. Tristetraprolin (TTP, encoded by *Zfp36*) is an RNA-binding protein, regulating inflammatory genes (eg. *Tnf*, *Il23a*, *Cxcl2)*. TTP deficient mice develop a spontaneous inflammatory syndrome, which had been largely attributed to dysregulated function of myeloid cells. However, mice harboring conditional TTP deletion in myeloid (LysM-*Zfp36*$^{fl/fl}$) or dendritic cells (CD11cCre-*Zfp36*$^{fl/fl}$) do not develop any spontaneous pathology. In sharp contrast, TTP deletion in keratinocytes (K14Cre-*Zfp36*$^{fl/fl}$) is sufficient to trigger the "TTP-deficiency" syndrome. Our goal is to further define the role of environmental factors in this pathology and the role of TTP in gut homeostasis. **Results.** 1) This syndrome was more severe under conventional housing compared to SPF facility. 2) Unexpectedly, TTPKO mice derived on MyD88- or Caspase1-deficient backgrounds, involved in key signaling pathways towards microbial recognition, developed more severe inflammation, pointing to a potential role of dysbiosis and inadequate response at epithelial barriers. 3) We observed an overgrowth of the *Enterobacteriaceae* family in the gut of TTPKO mice. 4) There was no overt intestinal inflammation histologically but mRNA expression of cytokines and inflammatory markers was increased in the ileum. We thus hypothesize that absence of TTP might also activate regulatory mechanisms controlling this subclinical inflammation. Indeed we observed higher levels of IL-22 and increased Tregs in the lamina propria. **Perspectives.** To further study the role of TTP in epithelial (using VillinCre-*Zfp36*$^{fl/fl}$ mice) and immune cells and the involvement of the gut microbiota.

ASC in CD4$^+$ T cells intrinsically limits their proliferation capacity and is required to maintain intestinal homeostasis

*H. Javanmard Khameneh[1], **A. Mortellaro**[1,2];*
*[1]Singapore Immunology Network (SIgN), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [2]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS San Raffaele Scientific Institute, Milan, Italy.*

The apoptosis-associated speck-like protein containing a CARD (ASC or Pycard) plays a pivotal role in the assembly and activation of the inflammasome complex. Inflammasome activation is essential for caspase-1 activation in response to diverse danger and pathogen-associated signals, which leads to proteolytic cleavage and release of the pro-inflammatory cytokines IL-1beta and IL-18. ASC has been shown to play important roles in the context of inflammation, cell death, and tumorigenesis. While ASC has been broadly implicated in inflammasome activation in myeloid cells, such as macrophages and neutrophils, little is known about its contribution in lymphocyte biology. Here, we found that Asc is expressed in naïve T cells and its loss resulted in increased proliferation *in vitro* and *in vivo*, indicating that ASC intrinsically fine-tunes proliferative capacity of CD4$^+$ T cells. Using a mouse model of induced chronic colitis, we found that ASC expression in CD4$^+$ T cells intrinsically suppresses their colitogenic capacity, facilitating the maintenance of gut homeostasis by the mucosal adaptive immune system. Further analysis of Asc$^{-/-}$ CD4$^+$ T cells revealed a stronger TCR signaling and an altered metabolic profile in these cells compared to wild-type CD4$^+$ T cells. In conclusion, ASC in CD4$^+$ T cells has crucial non-inflammasome functions to modulate T-cell biology and maintenance of mucosal immune homeostasis in the gut.

The co-inhibitory molecule PD-L1 contributes to regulatory T cell-mediated protection in murine crescentic glomerulonephritis

***K. Neumann**[1], A. Ostmann[1], P. C. Breda[1], A. Ochel[1], F. Tacke[2], H. Paust[1], U. Panzer[1], G. Tiegs[1];*
[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]RWTH-University Hospital Aachen, Aachen, Germany.

Introduction: Crescentic glomerulonephritis is a severe glomerular disease mediated by inappropriately regulated cellular and humoral immune responses subsequently leading to development of end-stage renal failure. Previously, we demonstrated a crucial role for regulatory T cells (Treg) in controlling the inflammatory Th1 immune response during nephrotoxic nephritis (NTN), the murine model of crescentic glomerulonephritis. Here, we aim at investigating the role of the co-inhibitory molecule PD-L1 in Treg-mediated protection from NTN.
Methods: NTN was induced by i.p. injection of nephrotoxic serum. Analysis was done eight days later. Kidney damage was analyzed by quantification of crescent formation and determination of albumin-to-creatinine ratio. Tregs from nephritic PD-L1$^{-/-}$ and WT mice were transferred into Rag1$^{-/-}$ mice one day before NTN induction. Cytokine expression was analyzed by quantitative RT-PCR and flow cytometry.
Results: We demonstrated that Foxp3$^+$ Tregs expressing PD-L1 infiltrate the kidney during NTN. In nephritic *PD-L1$^{-/-}$* mice, the frequency of renal Tregs was increased compared to nephritic WT mice. However, *PD-L1$^{-/-}$* mice developed more severe NTN associated with a strongly elevated renal Th1 immune response. The same findings were shown after blockage of PD-L1 in WT mice. Moreover, neutralization of IFNγ in PD-L1$^{-/-}$ mice ameliorated NTN. Interestingly, lack of PD-L1 profoundly altered the gene expression profile of Tregs in homeostasis and kidney inflammation. Functionally, Tregs from nephritic PD-L1$^{-/-}$ mice had impaired suppressive capacity *in vitro* and did not protect from NTN *in vivo*.
Conclusion: PD-L1 displays a protective role in NTN, which is related to Treg-mediated suppression of the Th1 immune response.

MicroRNAs as a regulator of development and progression in inflammatory bowel diseases among the Polish population.

***A. Surowiecka-Pastewka**[1,2], E. Zakościelna[1], M. Zagozda[1], M. Durlik[1,2];*
[1]Mossakowski Medical Research Centre of the Polish Academy of Sciences, Warsaw, Poland, [2]Department of Gastroenterological Surgery and Transplantation, Warsaw, Poland.

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are inflammatory bowel diseases(IBD) characterized by chronic inflammation of the gastrointestinal tract. The immunopathogenesis of the diseases is still not completely understood, however it has been proven that miRNAs have a key regulatory role in the development of IBD. Therefore, the aim of this study was to compare the expression of selected miRNAs with clinical data within patients with IBD. **Materials and Methods:** This study consisted of 60 IBD patients, as well as 50 healthy controls. The expression patterns of the circulating miRNA in serum were quantitatively assayed using reverse transcription and real-time RT-PCR.
The results were analyzed using Statistica software. **Results:** We detected significantly up-regulated expression of miR-21 in a serum isolated from IBD patients. Genotype-phenotype correlation analysis revealed thatmiRNA expression was associated with severe form of the disease.
Moreover, miRNA expressionwas associated with the development of perianal fistulas compared to control. **Conclusions:** Changes in the levels of miR-21 may suggest its involvement in the development and progression IBD. We demonstrate that circulating miRNAs correlate with disease activity and may be considered as potential tool for the further biomarker research in IBD. However, a thorough confirmation of these mechanism require further investigation.

P.C1.05.16

Gammapathy, immunodeficiency and autoimmunity: when the immune system turns against us

***P. E. Walo Delgado**, P. Lapuente-Suanzes, I. Nieto-Gañan, A. Carrasco-Sayalero;*
Servicio de Inmunología. Hospital Universitario Ramón y Cajal, Madrid, Spain.

Introduction. The immune system helps to keep homeostasis. It is capable of recognizing, controlling and eliminating pathogens as well as neoplastic cells. When a dysfunction of any of its components exists, immune tolerance, as well as other pathways of the immune system, may result affected in a non-specific manner, predisposing to the appearance of autoimmune disease, immunodeficiencies, allergies and lymphoproliferative disorders.
Description: We present the case of a 54-year-old man with no relevant medical history who attended to the emergency department with temporal-spatial disorientation and seizures during the course of an influenza A H1N1 infection. Anti-amphiphysin antibodies were identified, without evidence of neoplasm after thorough testing was performed. Also, biclonal IgG kappa and lambda gammapathy was detected by isoelectric focusing, associated with pan-hypogammaglobulinemia of polyclonal IgG, IgA and IgM, with decreased circulating memory B-cells measured by flow cytometry. One year later, he suffered an ischemic stroke and status epilepticus that was ruled to be of possible autoimmune etiology; however, no anti-neuronal antibodies were identified this time. In the following years, he has developed several episodes of encephalitis and recurrences of disseminated herpes zoster.
Conclusion. Despite not being able to find a clear causal correlation between the episodes of autoimmune encephalitis and the several other immunological alterations shown by the patient, it could be hypothesized that the presence of autoimmunity, as well as hypogammaglobulinemia in this case – causing increased susceptibility to infections- is found in the context of biclonal gammopathy, thus constituting a well-known, classical association between autoimmunity and immunodeficiency.

P.C1.05.17

Characterizing intraepithelial lymphocytes in human bile ducts

***C. L. Zimmer**[1], E. Von Seth[2,3], O. Strauss[1], L. Berglin[1], U. Arnelo[2], M. Hansson[2], A. Bergquist[2,3], N. K. Björkström[1];*
[1]Center for Infectious Medicine, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [2]Department of Hepatology, Karolinska University Hospital, Stockholm, Sweden, [3]Unit of Gastroenterology and Rheumatology, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

The bile duct is a mucosal barrier tissue connecting the liver with the small intestine. Intraepithelial lymphocytes (IELs) typically reside in epithelial layers of barrier tissues and are thought to play a role in the immunopathogenesis of diseases in bile ducts, such as primary sclerosing cholangitis (PSC), a chronic inflammatory disease with unknown etiology. However, the composition and function of immune cells localizing to bile ducts remain unexplored. Using endoscopy, we obtained brush-samples from the bile duct mucosal surface and carried out an extensive flow cytometric analysis of the biliary immune system. Our results revealed major differences in immune cell composition in bile ducts as compared to peripheral blood. This included the presence of a sizeable population of CD69$^+$CD103$^+$ IELs that was varified using immunofluorescencent microscopy. These IELs had a TCRαβ$^+$CD8αβ$^+$ effector memory T cell phenotype, presented with a gut and liver homing chemokine receptor profile, and were highly functional. Taken together, the characterization of the biliary immune system increases our understanding of immune responses at this previously unexplored site and sheds new light on the immunopathogenesis of PSC.

P.C1.05.18

Dynamic transcriptional and epigenetic response of CD8 + intraepithelial lymphocytes (IELs) to proinflammatory cytokines

M. M. Zorro Manrique[1], *R. Aguirre-Gamboa*[1], *T. Mayassi*[2], *C. Ciszewski*[2], *C. Wijmenga*[1], *S. Withoff*[1], *B. Jabri*[2], *Y. Li*[1], *I. Jonkers*[1];
[1]*UMCG, Groningen, Netherlands,* [2]*University of Chicago, Chicago, United States.*

Cytokine deregulation contributes to the development of autoimmune diseases (AIDs) by eliciting the activation of immune cells, including cytotoxic CD8⁺ T cells. These cells are located in mucosal and intestinal tissues, where they detect and destroy pathogens, but are also known to damage the intestinal barrier under disease conditions. Limited recovery from intestinal biopsies has hampered study of CD8⁺ Intra Epithelial Lymphocytes (IELs). To elucidate the molecular pathways involved in activation of these cells by AID-related cytokines, we investigated the dynamic transcriptomic and epigenetic changes and cytokine production of CD8⁺ IELs derived from the intestine of patients in response to IL-15, IL-21 or IFNβ at different time points (0h, 30min, 3h, 4h, and 24h).
Our results show unique gene expression profiles for each cytokine. IL-21 promoted moderate gene expression changes (838 differentially expressed genes (DEGs) after 3h), most related to immune pathways. IL-15 and IFNβ provoked strong activation of IELs. IFNβ induced a robust interferon immune response mediated by STAT1, followed by a drastic increase in gene expression of cell cycle genes. Conversely, IL-15 induced immune- and RNA-processing genes, likely mediated by AP-1 and EGR1, which were mostly restored to resting state after 24 h. Although the secretion of cytokines did not follow the patterns of expression of their encoding genes, the transcriptional profiles were mirrored by changes in H3K27Ac profiles at genes and enhancers that regulate DEGs.
In conclusion, these cytotoxic IELs show great plasticity in both epigenetic and transcriptomic profiles in response to the inflammatory milieu

P.C1.05.19

Mature naive B cells accumulate in intervillous space of term placenta and positively associate with specific chemokines

A. Lundell[1], *M. Solders*[2], *L. Gorchs*[2], *S. Gidlöf*[3], *E. Tidblad*[3], *H. Kaipe*[2];
[1]*Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, Gothenburg, Sweden,* [2]*Dept of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden,* [3]*Dept of women's and children's health, Karolinska Institutet, Stockholm, Sweden.*

Introduction: Total B cell numbers in the circulation decrease during late pregnancy compared to post-partum and to non-pregnant controls, but the underlying mechanisms for this is unknown. The aim of this study was to examine if the proportions of total B cells and B cell subsets at different maturational stages differ in peripheral blood (PB) compared to placental intervillous blood (IVB) at delivery. **Methods:** From 23 paired samples of PB and IVB following uncomplicated full term pregnancies, total B cells as well as transitional, mature/naïve and memory B cells were identified by flow cytometry. Chemokine levels in blood were analyzed using a luminex assay. **Results:** We found that the proportions of total B cells, as well as the fraction of mature/naïve B cells, were significantly higher in IVB relative to PB. In contrast, the proportions of immature transitional B cells and memory B cells were higher in PB compared to IVB. Multivariate factor analysis demonstrated that a specific profile of chemokines in IVB, including CCL20, positively associated with higher proportions of mature/naïve B cells in the intervillous space. Although all B cells expressed CCR6, the corresponding receptor for CCL20, mature/naïve B cells expressed the highest levels of this receptor. Migration assays further showed that B cells migrate towards placental explant-derived supernatants. **Conclusion:** these results suggest that B cells, and mature/naïve B cells in particular, home to the placenta in response to certain chemokines produced by this tissue during late pregnancy.

Effects of terminating treatment with ADSC-derived exosomes on obesity

Q. WANG, *H. Zhao;*
School of Basic Medical Sciences, Shandong University, Jinan, China.

We have recently reported that exosomes from adipose-derived stem cells (ADSCs) attenuate adipose inflammation, insulin resistance or even obesity development in mice fed on high-fat diet. ADSC-derived exosomes drive the polarization of macrophages into anti-inflammatory M2 phenotypes through transactivation of arginase 1, which further mediate beiging of white adipose tissue. To optimize the protocol for exosome treatment, the administration of ADSC-derived exosomes was ended in high-fat diet-fed mice that received 6-8 weeks of exosome injection, the adipose tissue inflammation and insulin resistance were evaluated. After 6-8 weeks of exosome treatment, the mice showed significant improvement on glucose tolerance; while 3 weeks after terminating treatment, ADSC-derived exosomes showed no more protection against insulin resistance in obese mice. Four weeks after terminating treatment with exosomes, the mRNA level of arginase 1 in stromal vascular fraction from epididymal fat pad showed no significant elevation despite an increasing trend, while the mRNA level of TNF-α was still significantly decreased; additionally, no obvious decreases in fat mass were observed. These findings suggest that termination of treatment partially reduces the beneficial effects of ADSC-derived exosomes on obesity-associated adipose tissue inflammation and metabolic disorders, which need to be considered during the exosome treatment for obesity. This study is supported by National Natural Science Foundation of China 81471065, 81770838 and Shandong Major Research Program 2016GSF201005.

Tipping the scale - how a shift in the presentation of self-antigen can prime for autoimmunity

J. Petersen[1], *J. D. OOi*[2], *H. Reid*[1], *J. Rossjohn*[1], *R. Kitching*[3];
[1]*Monash University, Clayton, Australia,* [2]*Centre for Inflammatory Diseases, Clayton, Australia,* [3]*Department of Nephrology, Clayton, Australia.*

The T cell repertoire of each individual is shaped to finely balance the recognition of foreign antigen against potential autoimmunity. This balance is determined in the thymus, where the interactions between HLA presented self-antigens and maturing T cells drive T cell selection and further determine their differentiation into effector and regulatory T cells. Goodpasture disease is strongly associated with HLA-DR15, whereas individuals carrying HLA-DR1 are dominantly protected. Our recent data provides insight into how specific HLA class II alleles impact on the functional bifurcation of the T cell repertoire towards a single a self antigen, thus lending protection or predisposing for autoimmune disease (Ooi Petersen et al., Nature 2017).

Characterizing the role of lymphatics in contact hypersensitivity

P. Aradi, *Z. Horváth, É. Kemecsei, Z. Jakus;*
Department of Physiology, Semmelweis University School of Medicine, Budapest, Hungary.

Contact hypersensitivity (CHS) reaction, the mouse model of human allergic contact dermatitis, can be induced by repeated exposure to contact allergens. The lymphatic system is a critical player for the regulation of the immune responses in infectious diseases in the skin but the possible role of lymphatics in the development of allergic contact dermatitis remains unclear.
In our studies *Flt4*$^{kd/+}$ mice carrying a germline point mutant kinase dead Vegfr3 allele were used. CHS was initiated by the exposure of the skin to TNCB (2,4,6-trinitrochlorobenzene) followed by a second treatment. The disease progression was monitored by the measurement of ear thickness. The ears were collected for paraffin-based histology followed by H&E staining and immunostaining against lymphatic and immune cell markers.
We found the complete lack of lymphatics in the skin including the ear of *Flt4*$^{kd/+}$ mice, while the lymphatic structures were present in the lung and small intestine. We characterized the development of CHS in *Flt4*$^{+/+}$ and *Flt4*$^{kd/+}$ mice and our experiments have revealed reduced inflammation in the ear of the *Flt4*$^{kd/+}$ mice. CHS development induced dynamic changes in lymphatic morphology and resulted in unexpected lymphatic growth in *Flt4*$^{kd/+}$ ears.
Our results revealed that dynamic changes of lymphatic morphology occur in CHS, and the inflammation is reduced in the Flt4$^{kd/+}$ mice lacking lymphatics in the ears. They also suggest that distinct mechanisms regulate the developmental and inflammatory lymphangiogenic program. Our findings define novel aspect of the interactions between the immune and lymphatic in allergic diseases.

P.C1.06.02

Relative efficiencies of peptidylarginine deiminase (PAD) 2 and 4 in generating target sites in fibrinogen, alpha-enolase and histone H3 for anti-citrullinated protein antibodies

D. Damgaard[1], *M. Bawadekar*[2], *L. Senolt*[3], *A. Stensballe*[4], *M. A. Shelef*[2,5], *C. H. Nielsen*[1];
[1]*Institute for Inflammation Research, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark,* [2]*Department of Medicine, University of Wisconsin, Madison, United States,* [3]*Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic,* [4]*Department of Health Science and Technology, Aalborg University, Aalborg, Denmark,* [5]*William S. Middleton Memorial Veterans Hospital, Madison, United States.*

Introduction: Peptidylarginine deiminase 2 (PAD2) and PAD4 are expressed in the synovium of rheumatoid arthritis (RA) patients and catalyze citrullination of arginine residues in proteins targeted by anti-citrullinated protein antibodies (ACPAs). Little is known about the relative importance of PAD2 and PAD4 in generating citrullinated self-antigens. Here we investigate the ability of PAD2 and PAD4 to generate citrullinated targets of ACPAs in four human proteins.

Materials and Methods: Synovial fluid (SF) and plasma were collected from 42 RA patients. Human fibrinogen, human alpha-enolase (ENO1), human histone H3, and human serum albumin (HSA) were citrullinated *in vitro* by PAD2 and PAD4. The total degree of citrullination was determined using the anti-modified citrulline approach. Antibody binding to native and citrullinated proteins was measured by ELISA.
Results: ACPAs within pooled SF from multiple RA patients reacted equally well with PAD2- and PAD4-citrullinated fibrinogen, at any PAD and SF concentration used. Accordingly, ACPAs from most individual patient SF and plasma samples bound equally well to PAD2- and PAD4-citrullinated fibrinogen and ENO1. Native ENO1 was also targeted substantially by autoantibodies. When histone H3 was used as target, PAD4 was generally superior in generating epitopes recognized by ACPAs. Despite adequate citrullination, no binding to citrullinated HSA was observed.
Conclusion: In most patients, PAD2 and PAD4 are equally efficient in generating citrullinated target sites in fibrinogen and ENO1. The binding of autoantibodies to histone H3 was generally higher after citrullination with PAD4 than with PAD2. Citrullinated HSA is not a target for ACPAs.

P.C1.06.03
Autoantibodies against the basal cell layer recognize keratin 14 and keratin 5 in patients withhepatitis delta virus

J. Delgado de la Poza, *C. García Miralles;*
Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí I3PT. Universitat Autònoma de Barcelona, Sabadell, Spain.

Introduction: Hepatitis delta is the most severe viral hepatitis leading to hepatic decompensation and hepatocarcinoma rapidly. Zauli D et al. in 1984 described antibodies to the basal cell layer (BCL) in patients with hepatitis delta virus (HDV). To date, anti-BCL antibodies have not been identified.
Methodology: 176 serum samples, from patients diagnosed with HDV in the Ospedale Aggiore Policlinico in Milan, and 30 sera from healthy donors were tested. An indirect immunofluorescence (IIF) on sections of monkey esophagus were realized. Antigen characterization was performed with human and rat epidermal extracts. To confirm the results a capture ELISA has been designed with monoclonal antibodies against recombinant keratin 14 (K14) and keratin 5 (K5).
Results: 49 of the 176 HDV samples (27.8%) have anti-BCL antibodies by IIF and 1 control serum (3.3%). 1 dimension immunoblot on human and rat extracts reveals the presence of a 51 kDa band which, upon sequencing, gave significant identifications for keratins 1, 5, 9, 10, 14 and 16. Only keratins 5 and 14 are present in epidermis BCL, then we design a capture ELISA for K14 and K5 to confirm these antigenic specificities. 114 HDV sera (65.5%) were positive for K14 and 112 HDV sera (64.4%) were positive for K5 and 2 (6.7%) and 1 (3.3%) control sera were positive for K14 and K5 respectively.
Conclusion: The present study has identified K14 and K5 as main target antigens that recognize autoantibodies against BCL. This identification has been confirmed through a capture ELISA with recombinant K14 and K5.

P.C1.06.04
Extra-criteria antiphospholipid antibodies in seronegative antiphospholipid syndrome of central nervous system with small vessel brain lesions

M. A. Estévez[1,2], *A. Molina-Fuentes*[1,2], *A. López-Gómez*[1,2], *M. R. Jiménez*[1,2], *N. Lanio*[1,2], *M. Montes*[1], *M. R. Fuster*[1], *J. Rascón*[1], *S. Tur*[1], *M. Picado*[1], *L. Sáez*[3], *S. Sánchez*[4], *L. Pallarés*[1], *M. R. Julià*[1,2];
[1]Hospital Universitario Son Espases, Palma de Mallorca, Spain, [2]Institut d'Investigació Sanitària Illes Balears (IdISBa), Palma de Mallorca, Spain, [3]Hospital Universitario Miguel Servet, Zaragoza, Spain, [4]Hospital Fundación Alcorcón, Madrid, Spain.

Background. Seronegative Antiphospholipid Syndrome (SNAPS) refers to patients with clinical profile suggestive of APS but persistently negative for antiphospolipid antibodies (aPL) included in APS classification criteria: anticardiolipin (ACA), anti-beta2Glycoprotein I (B2GP) (both IgG or IgM), and lupus anticoagulant.
Patients and methods. We studied 65 patients with small vessel brain lesions (SVBL), MRI and clinical manifestations compatible with APS and negative for aPL included in APS criteria. We also tested 24 autoimmune controls. We performed:
1-ELISA assays for B2GP and ACA (IgA); anti-phosphatidylserine/prothrombin (PS/PT), phosphatidylethanolamine, prothrombin (PT) (IgG, IgM) and anti-annexin V (IgG).
2-Chemiluminiscence assay for antibodies to Domain 1 of B2GP IgG.
Results. We found 13 patients positive for extra-criteria aPL: 2 (3.1%) for B2GP IgA; 4 (6.1%) for PT IgG, 1 of them was low positive; 4 (6.1%) for PT IgM , 2 were low positive for PS/PT
IgM (3.1%) and 1 was low positive for PT IgG and PS/PT IgM (1.5%). Only 3 controls were positive: 1 for PS/PT IgM, 1 for PT IgG and 1 for Annexin V, all of them low positive. Excluding low positive results, we detected 9 patients and 0 controls positive.
Conclusions. The presence of Abs to B2GP (IgA) and to PT (IgG and IgM) allowed us to identify as aPL-positive 13.8% of seronegative SVBL patients presenting MRI and clinical findings compatible with APS. Follow-up of these patients and additional studies will confirm our results.
This work was funded by a grant from the Spanish Society of Internal Medicine (ref: SAFSN-SNCpv).

Pro-inflammatory histidyl-tRNA synthetase-specific CD4$^+$ T-cells are enriched in the lung of patients with inflammatory myopathies and antisynthetase syndrome

A. S. Galindo-Feria[1,2], *I. Albrecht*[1,2], *C. Fernandes-Cerqueira*[1,2], *A. Notarnicola*[1,2], *E. A. James*[3], *J. Herrath*[1,2], *M. Dastmalchi*[1,2], *T. Sandalova*[4,5], *K. Tandre*[6], *L. Rönnblom*[6], *P. Jakobsson*[1,2], *M. Fathi*[7], *A. Achour*[8,9], *J. Grunewald*[10], *V. Malmström*[1,2], *I. E. Lundberg*[1,2];
[1]Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [2]Center for Molecular Medicine, Stockholm, Sweden, [3]Benaroya Research Institute at Virginia Mason, Seattle, Washington, United States, [4]Science for Life Laboratory, Department of Medicine Solna, Karolinska Institute, Stockholm, Sweden, [5]Department of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden, [6]Department of Medical Sciences, Rheumatology, Science for Life Laboratory, Uppsala University, Institutet, Karolinska University Hospital, Uppsala, Sweden, [7]Department of Respiratory Medicine and Allergy, Karolinska University Hospital, Stockholm, Sweden, [8]Science for Life Laboratory, Department of Medicine Solna, Karolinska Institute,, Stockholm, Sweden, [9]Department of Infectious Diseases, Karolinska University Hospital, Solna, Stockholm, Sweden, [10]Respiratory Medicine Unit, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Objectives To investigate immunity against histidyl-tRNA synthetase (HisRS) in blood and lungs of idiopathic inflammatory myopathy (IIM)/anti-synthetase syndrome (ASS) patients. **Methods** Bronchoalveolar lavage fluid (BALF) cells, and peripheral blood mononuclear cells (PBMCs) from IIM/ASS patients (n=24) were stimulated with full-length HisRS-protein and/or a HisRS-peptide representing a potential T-cell epitope (amino acids 11-23). Controls were cells from sarcoidosis patients (n=16), and HLA-matched healthy subjects (HCs n=18). Antigen-specific activation of CD4$^+$T-cells was assessed by CD40L up-regulation and cytokine expression using flow cytometry. Anti-Jo1 antibodies in serum and BALF were investigated by ELISA. CD3$^+$ T-cells and CD138$^+$ plasma cells were investigated by immunohistochemistry in lung biopsies from IIM and obstructive pulmonary disease patients. **Results** Increased CD40L up-regulation was detected in BALF cells from 2 out of 3 IIM/ASS patients stimulated with HisRS-peptide (median-fold [IQR]: 27 [1-148]) and in PBMCs from 14/18 patients with HisRS-protein (5[2-26]). Elevated CD40L expression in BALF cells stimulated with HisRS-protein and HisRS-peptide was observed in 2/7 sarcoidosis patients; and in 1/12 PBMCs from HLA-DRB1*03-HCs stimulated with HisRS-protein. Activated HisRS-specific T-cells in IIM/ASS displayed a Th1 phenotype in BALF when compared to PBMCs (production of IFN-γ$^+$: 60% vs 10%). Anti-Jo1 antibodies were detected in BALF and germinal center-like structures in lung biopsies of anti-Jo1$^+$ patients. **Conclusions** We report HisRS-reactive CD4$^+$ T-cells in both PBMCs and BALF cells of IIM/ASS patients. This together with anti-Jo1 antibodies in BALF and CD138$^+$ cells in lung tissue indicates that immune activation against HisRS might be triggered in the lungs of anti-Jo1$^+$ IIM patients.

P.C1.06.06
Clinical relevance of the new auto-antibodies in dermatomyositis/polimyositis

D. Garcia-Cuesta[1], *M. Vilches-Moreno*[1], *C. Collantes-Rodriguez*[2], *D. Jimenez-Gallo*[2], *L. Ossorio-García*[2], *M. Linares*[2], *C. Rodriguez*[1];
[1]UGC Hematology, Immunology and Genetics. Hospital Puerta del Mar., Cádiz, Spain, [2]UGC Dermatology. Hospital Puerta del Mar., Cádiz, Spain.

Introduction: Dermatomyositis and polymyositis (PM/DM) are inflammatory myopathies characterized by muscular weakness and inflammation. Some patients also present with characteristic skin changes, interstitial lung disease (ILD) or cancer, among other symptoms. Myositis-specific and myositis-associated autoantibodies (autoAb) have been found in patients. In addition, new specific AutoAb have been included in the diagnostic panels.
Objective: To asses the clinical value of the new PM/DM-specific AutoAb in defining clinical phenotypes in our patients diagnosed with PM/DM.
Materials and methods: All patients with a suspicion of PM/DM admitted to Hospital Puerta del Mar (Cadiz, Spain) for the last 18 months were tested for anti-TIF1-γ, anti-NXP2, anti-MDA5 and SAE-1 AutoAb (New DM/PM-autoAb) by using immunoblot (Euroimmun, Germany). Clinical features were recorded.
Results: New DM/PM-AutoAb were detected in 3 patients. Patient 1 had anti-TIF1-γ AutoAb and showed an exclusive cutaneous phenotype. Neither ILD nor cancers were found. Patient 2 had anti-MDA5 AutoAb and showed a skin rash with progressive ILD. Patient 3 had Anti-NXP2 AutoAb and presented with severe skin changes without ILD or cancer. Patients did not show evident muscular weakness, although muscle enzymes were elevated in patients 2 and 3.
Conclusions: In our patients, anti-MDA5 AutoAb was a good marker for ILD and NXP2 AutoAb indicated severe skin disease. Neither TIF1-γ nor NXP2 were markers for associated cancer in PM/DM. These results support the role of the new DM/PM-AutoAb in defining the clinical phenotype and the prognosis of DM/PM patients.

P.C1.06.07

Frequency of anti-nuclear antibody and anti dsDNA antibodies in subjects of oral addictive habits

M. Kashif[1], *N. Afzal*[1], *S. Minhas*[2], *M. A. Anwar*[1], *F. S. Khan*[1], *S. Jahan*[1];
[1]*University of Health Sciences, Lahore, Pakistan,* [2]*Akhtar Saeed Medical and Dental College, Lahore, Pakistan.*

Background: People with addictive habits are prone to both infectious and non-infectious diseases. Conflicting results have been reported about propensity of these individuals for development of autoimmune diseases. Therefore, a study was planned to determine the frequency of anti-nuclear antibody (ANA) and anti-dsDNA (dsDNA) antibody in the serum of habitual smokers, paan (areca nut) chewers and other oral addictive habits as compared to subjects without such addictive habits.
Methods: Blood samples from 90 subjects (45 with addictive habits and 45 without any addiction) were taken by random sampling after getting written informed consent. Enzyme linked immunosorbent assay (ELISA) was used to test the sera for ANA and anti dsDNA.
Results: One subject in the addictive group had ANA and dsDNA antibodies, whereas in the control group, two subjects had anti dsDNA while none of them had ANA. No significant association of these antibodies was observed between the two groups.
Conclusions: Addictive habits do not predispose the subjects to develop autoimmune diseases.

P.C1.06.08

Functional role of CD83 expressed by Foxp3$^+$ regulatory T cells in the context of inflammatory bowel disease.

C. Koenig*, A. Steinkasserer, M. Lechmann;*
Department of Immune Modulation at the Department of Dermatology, University Hospital Erlangen, Erlangen, Germany.

Inflammatory bowel disease (IBD) is still a significant health problem characterized by chronic and recurrent inflammation of the gastrointestinal tract. Unfortunately, available treatment options for IBD are not satisfactory and therefor, a great need for new and more efficient therapeutic strategies exists. Interestingly, using murine IBD models our group showed that activated Tregs rapidly upregulate CD83 expression and that the application of soluble CD83 ameliorates the clinical symptoms in the DNBS-induced colitis model. To investigate the underlying mechanisms, we generated CD83 conditional KO animals (CD83cKO), whereby CD83 expression has been specifically deleted on Tregs only. Using these animals we investigated in detail whether deletion of CD83 modulates the suppressive function and/or development of Tregs in steady state and in the context of IBD. The clinical impact of CD83 expression on Tregs was monitored using histology, weight loss and endoscopy. Phenotypically, these Tregs were characterized by FACS-, RT-PCR- and CBA. Body weight and health status revealed an aggravated colitis in CD83cKO mice which correlated with a highly increased mortality rate in these mice. In addition, elevated expression of pro-inflammatory mediators and reduced numbers of Foxp3$^+$CD103$^+$ and Foxp3$^+$KLRG1$^+$ Tregs were observed in CD83cKO mice. In addition, we are currently evaluating the therapeutic potential of sCD83 as new strategy for the treatment of IBD by using the murine transfer colitis model.
Our results provide first detailed insights into the mechanistic role of CD83 expressed on Tregs and represent the basis for the development of new specific therapies for patients suffering from autoimmune disorders.

P.C1.06.10

β-Catenin signaling in CD11c$^+$myeloid cells regulates immune homeostasis in the intestine

C. Kurz[1], *A. Brand*[1], *F. Bauer*[1], *A. Jiang*[2], *I. Mellman*[3], *J. Ober- Blöbaum*[1], *B. E. Clausen*[1];
[1]*Institute of Molecular Medicine, Mainz, Germany,* [2]*Department of Immunology, Roswell Park Cancer Institute, Buffalo, NY 14263, United States,* [3]*Research Oncology, Genentech, South San Francisco, CA 94080, United States.*

Introduction: Chronic inflammation in the intestine arises from a loss of tolerance towards harmless environmental antigens like nutrients or commensal bacteria. Myeloid antigen-presenting cells (APC), including macrophages (MØ) and dendritic cells (DC), play essential roles balancing immunity and tolerance. β-Catenin is the central component of the canonical Wnt signaling pathway and has previously been demonstrated to promote a tolerogenic DC phenotype *in vitro*. Hence, CD11c-specific β-catenin deficiency aggravates disease in a mouse model of DSS-induced colitis, suggesting that β-catenin is a key regulator of myeloid cell function *in vivo*. Whether β-catenin in APC is able to attenuate intestinal inflammation remains elusive.
Methods: To further investigate the role of CD11c-specific β-catenin signaling in the regulation of intestinal immune homeostasis, we generated mice with either a deletion (CD11c-βcat^{DEL}) or expressing a stabilized form of β-catenin (CD11c-βcat^{EX3}). Subsequently, these mice were analyzed in the steady-state as well as in DSS-induced colitis.
Results: In steady-state mesenteric lymph nodes (mLN), CD11c-βcat^{EX3}mice exhibited higher numbers of DC and regulatory T cells (Tregs) as compared to controls, whereas DC and Treg numbers in mLN of CD11c-βcat^{DEL}mice remained unchanged. Moreover, CD11c-βcat^{EX3}mice were less susceptible to DSS-induced colitis accompanied by increased numbers of Foxp3$^+$Tregs.
Conclusion: Our data indicate that activation of β-catenin signaling in CD11c$^+$myeloid cells supports their tolerogenic function via the induction of Tregs. In ongoing experiments we are dissecting the molecular mechanism(s) by which β-catenin enables distinct MØand DC subsets to regulate intestinal immune homeostasis in the steady-state and during inflammation.

A deep analysis of the intestinal immune cell compartment in dextran sodium sulfate (DSS) induced colitis

M. Letizia[1,2,3], *Y. Rodriguez Sillke*[1], *F. Schmidt*[1], *R. Glauben*[1], *C. Weidinger*[1], *B. Siegmund*[1];
[1]*Charité, Berlin, Germany,* [2]*Humboldt-Universität zu Berlin, Berlin, Germany,* [3]*ZIBI Graduate School Berlin, Berlin, Germany.*

Crohn's disease is characterized by epithelial barrier breaches and a subsequent translocation of bacteria from the intestinal lumen into the adjacent mesenteric fat, inducing the hyperplasia of adipose tissue as well as the recruitment of various immune cells. However, the functional role of mesenteric fat in intestinal immunity and the immunologic imprinting occurring upon epithelial barrier defects is currently unknown. One of the most used mouse model of experimental colitis employs DSS treatment. Although the immune cell composition of colon lamina propria has been investigated, little is known about DSS induced changes within the mesenteric fat. Therefore, we analyzed the immune cell compartment of colon lamina propria in comparison with the mesenteric fat compartment. C57BL/6 mice were fed 2.5% DSS in their drinking water for 5 days to induce acute colitis or 1.5% DSS for 5 days followed by 7 days water in 4 cycles to induce chronic colitis. Immune cells were isolated from mesenteric fat, gonadal fat, mesenteric lymph nodes and lamina propria and analyzed by flow cytometry or mass cytometry. Our data give for the first time a comprehensive characterization of immune cells in colon lamina propria and mesenteric fat in DSS induced colitis and suggest an immune-modulatory function of mesenteric fat in chronic but not in acute intestinal inflammation. Further analyses are needed in order to assess whether the DSS-induced colitis model is able to mimic the role of mesenteric wrapping fat in Crohn's disease adequately.

P.C1.06.12

Induction of antibodies to citrullinated protein antigens (ACPAs) by stressed neutrophils

T. Li*;*
Karolinska Institutet, Stockholm, Sweden.

There are very interesting findings published by Mariana J. Kaplan showing that stressed neutrophils can induce mitochondrial ROS, activation of PAD4 and the formation of neutrophil extracellular traps (NETs). They have also shown that NETs containing citrullinated peptides are internalized by fibroblast-like synoviocyte (FLS) through a RAGE-TLR9 pathway, promoting FLS inflammatory phenotype and their up-regulation of major histocompatibility complex (MHC) class II. Once internalized, arthritogenic NET peptides are loaded into FLS MHC class II and presented to antigen-specific T cells. HLA-DRB1*04:01 transgenic mice immunized with mouse FLS loaded with NETs develop antibodies specific to citrullinated forms of relevant autoantigens implicated in rheumatoid arthritis (RA) pathogenesis as well as cartilage damage. These results implicate FLS as notable mediators in RA pathogenesis, through the internalization and presentation of NET citrullinated peptidesto the adaptive immune system, leading to pathogenic autoimmunity and cartilage damage. Therefore, it will be interesting to study whether proteins from stressed neutrophils can be used to immunize the humanized mouse strains to induce ACPA production. To link periodontal infection to ACPA, we will use leukotoxin A (LtxA), a toxin from Aggregatibacter actinomycetemcomitans (Aa), which has been shown to induce hypercitrullination in host neutrophils. We have cultured FLS in vitro successfully and verified that these FLS have the ability to present antigens to CD4$^+$ T cells. Next we plan to immunize DRB1*0401. Ncf1*/* mice with cit-peptides loaded FLS and detect whether can induce the production of ACPAs and RA.

Compartmentalized tissue adaptation of human colonic CD4⁺ T cells

L. Lutter[1], *D. P. Hoytema van Konijnenburg*[2], *J. J. ter Linde*[1], *A. Petrelli*[3], *N. R. Lansu*[1], *J. ten Hove*[1], *M. van der Wal*[1], *V. Meij*[1], *H. H. Fidder*[1], *M. Mokry*[1], *B. Oldenburg*[1], *F. van Wijk*[1];
[1]*University Medical Centre Utrecht, Utrecht, Netherlands,* [2]*Rockefeller University, New York, United States,* [3]*IRCCS San Raffaele Scientific Institute, Milan, Italy.*

The mucosal barrier of the gut is home to numerous intraepithelial (IE) and lamina propria (LP) T cells adapted to the local environment in order to maintain homeostasis. Recent work on tissue T cells has focused on CD8⁺ "tissue resident memory cells" (Trm); however, the human colon also harbors different, less characterized, CD4⁺ T cell populations. Tissue resident T cells have been suggested to play important roles in relapsing-remitting inflammatory diseases including inflammatory bowel disease; hence, we FACS-sorted human CD4⁺ IE and LP T cell populations for RNA sequencing. We show that LP CD4⁺CD8aa⁺ resemble the murine cytotoxic CD4⁺CD8aa⁺ IE T cells (e.g. expression of GZMA, GZMB, PRF1, and IFNG), and LP CD4⁺CD25⁺ cells are similar to classical regulatory T cells. CD4+CD25+ are similar to CD4⁺CD8aa⁺ IE T cells with upregulation of immune regulatory pathways, and both populations are quite different from their LP counterparts.
Furthermore, IE and LP CD4⁺CD8aa⁺ possess hallmarks of Trm cells, but do not fully recapitulate the phenotype as described in the literature for CD8⁺ Trm. During inflammation, flow cytometry analyses showed an increased IE and LP CD4⁺:CD8⁺ ratio compared to remission values, as well as an increase in CD4⁺ T cells expressing lower or no amounts of CD69. Additionally, we found a trend towards relative decreased CD4⁺CD8aa⁺ and increased CD4⁺CD25⁺ T cell presence both in the LP and IE compartment during inflammation. This loss of compartmentalized tissue adaptation of human colonic CD4⁺ T cells can have potential detrimental effects on barrier maintenance and continued inflammation.

Immunological findings in patients with recurrent aphthous stomatitis

J. Petanova[1,2], *R. Cermakova*[3], *M. Libanska*[3], *J. Bartova*[3], *Z. Jiraskova Zakostelska*[4], *Z. Stehlikova*[4], *H. Tlaskalova-Hogenova*[4], *L. Izakovicova-Holla*[5,6], *S. Slezakova*[5,6], *P. Borilova Linhartova*[5,6], *P. Kuklínek*[7];
[1]*General University Hospital in Prague, Institute of Immunology and Microbiology, Prague 2, Czech Republic,* [2]*Charles University, Institute of Immunology and Microbiology, Prague, Czech Republic,* [3]*General University Hospital in Prague, Institute of Clinical and Experimental Dental Medicine, Prague 2, Czech Republic,* [4]*Institute of Microbiology, The Czech Academy of Sciences, Prague, Czech Republic,* [5]*Clinic of Stomatology, Institution Shared with St. Anne's Faculty Hospital, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [6]*Department of Pathophysiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [7]*Department of Clinical Immunology and Allergology, Institution Shared with St. Anne's Faculty Hospital, Faculty of Medicine, Masaryk University, Brno, Czech Republic.*

The etiology of recurrent aphthous stomatitis is not yet clear, immunopathologic states like autoimmunity, allergy or deficiency are mentioned either. We analyzed the immunological status of 73 patients with recurrent aphthous stomatitis (28 men, 45 women, aged 18-72 years). The following parameters were studied: humoral immunity (serum concentration of immunoglobulin IgG, IgA, IgM, IgE, IgG subclasses, complement components C3 and C4, acute phase protein CRP, selected autoantibodies), cellular immunity (total number of lymphocytes, T lymphocytes subpopulations, B lymphocytes, natural killer cells). The immunological parameters in cellular immunity were in normal ranges. In humoral immunity we found in 13 patients slightly decreased or increased serum concentrations of IgG (4), IgA (6), IgM (3), elevated IgE levels occurred in 14 patients. Antinuclear antibodies were slightly positive or positive in 15 patients (21%). Eighteen (38%) of 48 patients had slightly positive antibodies to desmogleins. The clinical periodontal finding and in some cases mucosal biopsy with histopathological findings excluded autoimmune blistering diseases in all tested patients. We found high inter-individual variability in anamnestic and laboratory data in the group of patients with recurrent aphthous stomatitis. The positivity of antibodies to desmogleins is not specific, positive results can be found in different inflammatory mucosal or cutaneous states. More specific tests have to be performed together with specialized periodontal clinical findings. The work was supported by Ministry of Health of the Czech Republic, grant nr.15-29336A.

P.C1.06.15

The impact of food antigens on the intestinal homeostasis and inflammation in inflammatory bowel disease

Y. Rodríguez Sillke[1,2], *U. Steinhoff*[3], *M. Schumann*[1], *C. Bojarski*[1], *D. Lissner*[1], *F. Branchi*[1], *B. Siegmund*[1], *R. Glauben*[1];
[1]*Charité - Universitätsmedizin Berlin, Medical Department (Gastroenterology, Infectious Diseases, Rheumatology) Campus Benjamin Franklin, Berlin, Germany,* [2]*Institute of Nutrition, University of Potsdam, Nuthetal, Germany,* [3]*Institute for Medical Microbiology and Hygiene, University of Marburg, Marburg, Germany.*

One of the hallmarks of inflammatory bowel diseases (IBD) is a dysregulation of the intestinal immune system. Although nutritional therapy with the elemental diet proves to be effective, little is known about its mechanism. Murine data indicate that food antigens induce an activation and subsequent apoptosis of the CD4⁺ T-cells in the Peyer's Patches (PP) thus maintaining the healthy balance of the mucosal immune system.
PP T-cells were characterized for patients of Crohn´s disease (CD) and Ulcerative colitis (UC) as well as healthy controls. Gluten served as a model food antigen. Thus gluten activated CD4⁺ T-cells in the peripheral blood of these patients were analysed by a magnetic enrichment of CD154⁺ cells and a subsequent cytometric antigen-reactive T-cell analysis (ARTE technology).
CD4⁺ T cells isolated from PP of CD patients revealed a significantly reduced apoptotic rate compared to UC patients and healthy controls. This was accompanied by an increased expression of the survival marker Bcl-2. Further characterization identified an up-regulation of FoxP3 as marker for regulatory T-cells, as well as the activation marker, Helios in CD patients. Moreover, there was a higher frequency of gluten antigen-specific T-cells (CD4⁺CD154⁺) in the peripheral blood of CD patients expressing pro-inflammatory cytokines.
The decreased apoptosis in parallel to an enhanced survival of CD4⁺ T-cells in PP of CD patients suggests a pathological T-cell hyperactivation followed by a disturbed immune homeostasis. Additionally, our data provide evidence that the IBD dependent disruption of the intestinal barrier suffices to induce food-antigen specific pro-inflammatory T-cells in the periphery.

P.C1.06.16

Anti-GP2 antibodies in blood and feces of children with inflammatory bowel diseases.

A. Toptygina[1,2], ***E. Semikina***[3,4], *S. Petrichuk*[5];
[1]*G.N.Gabrichevsky Research Institute for Epidemiology and Microbiology, Moscow, Russian Federation,* [2]*Lomonosov Moscow State University, Moscow, Russian Federation,* [3]*Federal State Autonomous Institution, Moscow, Russian Federation,* [4]*Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [5]*Federal State Autonomous Institution "National Medical Research Center of Children's Health", Moscow, Russian Federation.*

Inflammatory bowel diseases (IBD), such as Crohn's disease (CD) and ulcerative colitis (UC), are associated with considerable morbidity and reduced quality of life. Anti-glycoprotein2 (GP2) antibodies were found in the blood of CD-patients. The aim was to examine the anti-GP2 antibody levels in blood and feces of CD and UC-patients. Serum and coproextract probes from 110 children (64 boys and 46 girls) aged 12.3(2.6-17.9) years old were examined: 36 CD-patients, 30 UC-patients, and 44 control patients with intestinal dysbiosis (DB). IgG and IgA anti-GP2 antibodies were tested by ELISA. Cut-off calculated for children's IgG anti-GP2 antibodies for IBD versus non-IBD was 13.8U/ml (sensitivity 63.2%, specificity 100%). Cut-off for IgA was 5.63U/ml (sensitivity 60.5%, specificity 78.8%). Among 36 CD-patients 10(27.7%) had IgG and 15(41.7%) had IgA anti-GP2 antibodies. In 30 UC-patients 5(16.6%) had IgG and 10(33.3%) had IgA anti-GP2 antibodies. None of 44 DB-patients had IgA and only 1(3.3%) had IgG (15.5U/ml). The level of anti-GP2 antibodies in the serum of CD-patients was significantly higher in comparison to UC-patients ($p<0.05$) and control group ($p<0.01$). The feces levels of anti-GP2 IgG were elevated in CD(23.5U/ml) and UC(20.45U/ml) patients versus 1.99U/ml in DB ($p<0.01$). No differences in anti-GP2 IgA levels between IBD-patients and DB were found. However IBD-patients had higher level of sIgA, and the ratio of anti-GP2IgA/sIgA was significantly lower in CD(0.326) and UC(0.327) than in DB(2.332) patients ($p<0.01$). Differences in anti-GP2 IgG and IgA profiles between IBD and DB patients reflect the peculiarities of disease immunopathogenesis.

P.C1.06.17

***In situ* expression of IgA and IgG in intestinal mucosa of algerian patients with inflammatory bowel disease**

R. Toumi[1], *I. Soufli*[1], *S. Ait Younes*[2], *C. Touil-Boukoffa*[1];
[1]*University of Sciences and Technology Houari Boumedienne, Algiers, Algeria,* [2]*Anatomic Pathology Service, Mustapha Pacha Hospital, Algiers, Algeria, Algiers, Algeria.*

The intestinal mucosa is home to the largest population of Antibody-secreting plasma cells. The antibodies released by these cells constitute a first line of protection but could also be involved in autoimmune processes. Although the role of immunoglobulins in triggering inflammatory bowel disease (IBD) has not yet been established, there is many data to support this hypothesis. IBD including Crohn diseases (CD) and Ulcerative colitis (UC) is chronic multi-factorial disorder affecting the gastrointestinal. In this study, we investigated by immunohistochemical study the expression of IgA and IgG in the intestinal mucosa of Algerian patients with CD and UC. Our results revealed the presence of a significantly high number of IgA + and IgG + cells for both categories of patients compared with healthy mucosa ($p<0.05$). The analysis of IgA and IgG expression at different regions of intestine of the patients did not show a significant difference. However our data, showed the presence of high number of IgA+ cells in the colonic mucosa of patients with CD in comparison with UC. This result could be explained by the strong expression of NOS-2 and TNF-α in MC that maintain IgA-producing plasma cells in the intestine. Moreover, a slight predominance of IgG + cells in the colonic mucosa of patients with CD was observed. This can be explained by the nature of the immune profile characterizing both pathologies. In summary, the current study provides additional evidence for the Involvement of plasma cells secreting IgG and IgA in the pathophysiology of IBD.

P.C1.06.18

HMGB1 released from intestinal epithelia damaged by cholera toxin adjuvant contributes to activation of mucosal DCs and induction of intestinal CTLs and IgA

***A. Wakabayashi**, M. Shimizu, E. Shinya, H. Takahashi;*
Nippon Medical School, Tokyo, Japan.

Oral administration of OVA plus cholera toxin (CT), but not the CTA or CTB subunit, induces OVA-specific $CD8^+$ cytotoxic T lymphocytes (CTLs) in intraepithelial lymphocytes (IELs). The intestinal OVA-specific CTLs were not induced in $CD11c^+$ dendritic cell (DC)-depleted CD11c-DTR mice. $CD8^+CD103^+CD11c^+CD11b^-$ DCs and $DCIR2^+CD103^+CD11c^+CD11b^+$ DCs were distributed in the intestinal lamina propria and mesenteric lymph nodes, both DC subsets expressed DEC-205, and the expression of costimulatory molecules such as CD80 and CD86 was enhanced in both DC subsets after oral administration of intact CT but not the CTA or CTB subunit. Intestinal DCs activated by the oral administration of OVA plus CT cross-presented OVA antigens, and DCs that captured OVA antigen through DEC-205, but not DCIR2, could cross-present antigen. We found that oral administration of intact CT, but not the CTA or CTB subunit, enhanced cell death, cytoplasmic expression of high mobility group box 1 protein (HMGB1) in epithelial cell adhesion molecule $(EpCAM)^+CD45^-$ intestinal epithelial cells (IECs) and HMGB1 levels in fecal extracts. HMGB1 dose-dependently enhanced the expression of CD80 and CD86 on DCs *in vitro*, and intravenous or oral administration of glycyrrhizin, an HMGB1 inhibitor, significantly suppressed activation of mucosal DCs and induction of intestinal OVA-specific CTLs and IgA by oral CT administration. These results showed that oral administration of intact CT triggers epithelial cell death in the gut and the release of HMGB1 from damaged IECs and that the released HMGB1 may mediate activation of mucosal DCs and induction of CTLs and IgA in the intestine.

P.C1.06.19

Alterations in Immune cell subsets in patients with chronic silicosis caused by artificial quartz agglomerates

*G. Jimenez-Gomez[1], A. Hidalgo-Molina[1], A. Perez-Alonso[2], J. M. Morales-Morales[3], J. A. Cordoba Doña[4], A. Leon Jimenez[5], **A. Campos-Caro**[1];*
[1]Hospital Universitario Puerta del Mar, Cádiz, Spain, [2]Preventive Medicine Service, Cádiz, Spain, [3]Hospital Universitario Puerto Real, Cádiz, Spain, [4]Public Health Service, Cádiz, Spain, [5]Hospital Universitario Puerta del Mar, Cadiz, Spain.

Background: Silicosis produced by Artificial Quartz Agglomerates (AQA) evolves more aggressively than the classical form of miners. This entity is emerging worldwide and a significant group of cases has been detected in the province of Cádiz (Spain) in recent years. The role of the cellular immune response in the pathogenesis of silicosis by AQA has not been previously studied. **Objective:** to analyse cell populations present in peripheral blood from patients with silicosis by AQA and and compare them with the ones obtained from healthy volunteers. **Methods:** 48 patients diagnosed with silicosis by AQA and 18 healthy controls were studied. The blood cells populations were quantified by flow cytometry. **Results:** No differences were found in the total number of leukocytes or granulocytes. However, a significant increase in monocytes cell number and a clear lymphocytopenia were observed in the blood from patients compared to healthy controls. Almost all the lymphocyte subsets studied - B lymphocytes, T lymphocytes and NK cells ("Natural Killers") - were decreased compared to healthy controls. Particularly, a significant decrease in the total cell number was observed in the following subsets: memory B lymphocytes; T-helper lymphocytes, naïve and memory T-lymphocytes, T-regulatory lymphocytes and $CD56^{Brigth}$ NK cell subpopulations. However, there was a significant increase in the TH1 and TH17 subsets as well as in plasma cells in patients. **Conclusions:** These alterations in blood cell populations could reflect different states of inflammatory and fibrotic activity in these patients.

P.C1.07 Maintenance and local regulation of tissue specific immunity - Part 7

P.C1.07.02

G protein-coupled receptor 15 is associated with smoking and relapsing remitting multiple sclerosis

***C. Ammitzbøll**, M. R. von Essen, L. Börnsen, E. Petersen, O. McWilliam, H. B. Søndergaard, F. Sellebjerg;*
Danish Multiple Sclerosis Center, Copenhagen, Denmark.

Background: Smoking is an established risk factor associated with autoimmune diseases including multiple sclerosis (MS). We have studied the effect of smoking on circulating immune cells and found *GPR15* mRNA expression upregulated in healthy smokers and patients with relapsing remitting MS (RRMS). The protein expression of GPR15 was related to smoking but not RRMS. *GPR15* encodes a G protein-coupled receptor on lymphocytes, which together with the recently identified GPR15L, is involved in immune homeostasis in the skin and colon.
Objective: To study GPR15L and GPR15 expressing cells in the cerebrospinal fluid (CSF) of smokers and patients with RRMS.
Results: By flow cytometry we found higher frequencies of GPR15+ T cells in CSF compared with blood. In smokers, blood- and CSF frequencies of GPR15+ T cells were significantly increased and were in the CSF associated with chemokine receptors CCR6 and CXCR3 compared with GPR15- T cells. ELISA analyses showed lower concentrations of GPR15L in CSF than in blood and concentrations were unaffected by smoking or RRMS. In patients with RRMS, GPR15L were positively correlated with CD4+GPR15+CCR6+CXCR3+ T-cells, myelin basic protein (MBP) and functional disability measured by the expanded disability status scale (EDSS).
Conclusion: In the present study we suggest a novel cell type in MS pathogenesis, linked to smoking. Smoking increases circulating GPR15+ T cells with CNS migration potential (CCR6 and CXCR3 expression). In patients with RRMS, these cells (from the CD4+ T cell population) are associated with GPR15L in the CSF, damage of the myelin sheaths and functional disability.

P.C1.07.03

The HLA-DR3 peptide repertoire in epithelial cells versus the conventional antigen processing

***Y. Arribas**[1,2], J. A. Collado[1], R. Farriol[1,2], V. Casas[2], M. Carrascal[2], D. Jaraquemada[1];*
[1]Cellular Immunology, Institute of Biotechnology and Biomedicine, Cerdanyola del Vallès, Barcelona, Spain, [2]CSIC/UAB Proteomics Laboratory, IIBB-CSIC, Cerdanyola del Vallès, Barcelona, Spain.

HLA-DR3 (HLA-DR17, DRB1*0301/DRA1*0101) is an HLA-DR allele associated to a high number of autoimmune diseases, including type 1 diabetes or Graves' disease. Previous work on HLA-DRB1*0301-positive Graves' thyroid tissues revealed the presence of peptides from tissue-specific antigens in the HLA-DR-associated repertoire. The peptide repertoires of human $DR3^+$ spleen samples were then processed and compared with thyroid tissue. The results showed a clear tissue-specific bias in the spleen repertoire, where a large frequency of peptides derived from blood borne proteins. In addition, the overall affinity of the peptides from the spleen was higher than that of thyroid peptides. In order to identify possible mechanisms of differential HLA-II processing in $MHC\text{-}II^+$ epithelial cells versus canonical APCs, peptide repertoires were studied from a human HLA-DR3, -Ii and -DM transfected rat insulinoma epithelial cell line compared with a homozygous $DR3^+$ lymphoblastoid B cell line. The results showed little differences between both repertoires in parameters such as affinity or hydrophobicity. Tissue specificity was evident in the epithelial repertoire. We identified several peptides derived from proteins restricted to neuroendocrine tissues, including T1D autoantigen ICA512 or autoimmune uveitis-related calpain-5. In contrast, the peptides found in EBV were mostly derived from ubiquitous proteins. Interestingly, a high frequency of cytosolic-degraded peptides was found in the DR3 repertoires, both from epithelial cells, B-LCLs and spleen cells, to a maximum of 40% in the spleen samples. This contrasts with the B-LCL repertoires associated to most HLA-DR alleles, which usually contain around 20% of such peptides.

P.C1.07.05

Rapid isolation of functional ex vivo human skin resident memory T cells

***W. Du**[1], C. Cendon[1], A. Schulz[1], E. Zhang[2], J. Bodo[3], H. Chang[1], A. Radbruch[1], J. Dong[1];*
[1]German Rheumatism Research Center Berlin, Berlin, Germany, [2]Sankt Gertrauden Krankenhaus, Berlin, Germany, [3]Plastische und Ästhetische Chirurgie, Berlin, Germany.

Introduction
In mice, skin-resident memory T (T_{RM}) cells have been shown to provide rapid local protection. To further dissect human skin T_{RM} cells, various isolation approaches have been applied, e.g. EDTA isolation, collagenase P digestion, and skin explants. However, these protocols either suffer from low yield or require long ex vivo culture periods. We established a modified collagenase IV digestion protocol for rapid isolating high yield viable T_{RM} cells while preserving intact epitopes of interest.
Materials and Methods
Skin samples were obtained from healthy donors under plastic surgeries. Subcutaneous fat were removed and the remaining tissue was minced and incubated in digestion medium at 37°C for 6 hours. Subsequently, the digested skin fragments were dissociated and the cell suspension was filtered and stained with various surface markers. Viable cells were counted; the expressions of CD45 and resident memory T cell markers were analyzed. In parallel, this protocol was compared with other protocols such as whole skin dissociation and collagenase P digestion.
Results and Conclusions
In terms of yield and cell viability, the modified collagenase IV digestion protocol resulted in at least 1.5 times more T cells per cm^2 with relatively higher viability than other protocols. Moreover, this modified protocol could well preserve critical surface marker expressions (e.g. CD4, CD8 and CD69), as opposed to other protocols. Therefore, the modified collagenase IV digestion protocol is suitable for further functional assays which acquire relative high amount of viable skin T cells, providing an opportunity for better understanding of human skin T_{RM} cells.

P.C1.07.06

FOXO1-activity controls CD8 T cell effector function and prevents liver immune pathology during viral hepatitis and non-alcoholic steatohepatitis

M. Dudek;
Institute of Molecular Immunology and Experimental Oncology, Munich, Germany.

Introduction: Upon antigen-recognition, cytotoxic-T-lymphocytes (CTLs) eliminate infected cells. Cellular co-regulation of metabolism and immunity is known to influence effector function, but the mechanisms controlling organ-specific immunity in tissues rich in nutrients such as liver remained unclear. Here we identify FOXO1-activity in CTLs as critical regulator of their metabolic activation during liver disease states. **Material and Methods:** Extracellular flux analysis, cytokine expression, cytotoxicity assays were performed to study CTL co-regulation of metabolism and immunity and its dependence on FOXO1. Murine models of viral hepatitis and non-alcoholic steatohepatitis (NASH) were used to explore FOXO1-dependent T cell immunopathology. **Results:** We previously discovered that FOXO1 was required for memory CD8 T cell-differentiation through cross-priming liver-sinusoidal-endothelial-cells by downsizing cell metabolism. Here we report that, FOXO1-activity also controlled metabolism in effector CTLs. Upon FOXO1-inhibition, CTLs showed augmented metabolic activity, increased gene-expression of nutrient transporters, augmented nutrient-uptake, upregulation of IFN-γ, GzmB and FasL and enhanced effector-functions. Adoptive-transfer of FOXO1-inhibited virus-specific CTLs into mice with viral infection of the liver caused liver immunopathology but failed to control viral infection demonstrating dysbalance between antigen-recognition and execution of effector function. In NASH, hepatic CTLs showed decreased FOXO1-levels and increased cytotoxic potential. Since RNA sequencing did not reveal presence of particular hepatic CTL-clones in NASH, we assume that increased CTL metabolic activation in absence of FOXO1-control caused hepatic immunopathology. **Conclusion:** Our results provide evidence for a critical role of FOXO1 in controlling metabolic CTL-activation required to maintain tissue homeostasis and prevent immunopathology but also to allow for functional tissue immune-surveillance.

P.C1.07.07

The regulation of ZC3H12A and ZC3H12B expression during sterile neuroinflammation

A. Kasza[1]*, D. D. Biswas*[2]*, A. S. Gupta*[2]*, M. Wawro*[1]*, T. Kordula*[2]*;*
[1]*Faculty of Biochemistry, Biophysics and Biotechnology, Cracow, Poland,* [2]*Virginia Commonwealth University, Richmond, United States.*

During sterile neuroinflammation, microglia and astrocytes become activated and release a plethora of pro-inflammatory cytokines such as IL-1β and IL-6. We asked whether activation of astrocytes also triggers a feed-back mechanism, which depends on the synthesis of RNases than degrade pro-inflammatory transcripts. We focused on the regulation of expression of two proteins from ZC3H12 family, namely ZC3H12A/MCPIP1 and ZC3H12B/MCPIP2. The amount of mRNA for Zc3h12a and Zc3h12b was analyzed in the spinal cords of LPS-treated mice as well as during experimental autoimmune encephalomyelitis, a mouse model of multiple sclerosis. In both experimental models, the level of Zc3h12a was increased whereas the level of Zc3h12b was decreased. Similarly, treatment of mouse microglia and astrocytes with IL-1β or LPS or human astrocytes with IL-1β, elevated expression of ZC3H12A. However, pro-inflammatory stimuli did not change the level of ZC3H12B. Moreover, these ZC3H12 family members were actively modulating the course of neuroinflammation. Knock-down of ZC3H12A or ZC3H12B up-regulated expression of IL-1β and IL-6 in IL-1-activated astrocytes. Thus, mechanisms, which induce expression of pro-inflammatory cytokines, also activate expression of ZC3H12A, which elicits a feed-back mechanism by regulating pro-inflammatory transcripts turn-over. Regulation of ZC3H12B activity during neuroinflammation remains elusive and needs further investigation.
FUNDING: This work was supported by grant from the Polish National Science Center UMO-2014/15/B/NZ2/03379 (to A.K.) and the Polish-U.S. Fulbright Commission (to A.K.)

TxT-induced MDSCs alter the early systemic pro-inflammatory response and inhibit the antigen-specific T-cell proliferation

Y. Hüsecken[1]*,* ***M. Kustermann***[1]*, M. Huber-Lang*[2]*, K. Debatin*[1]*, G. Straußß*[1]*;*
[1]*Department of Pediatric and Adolescent Medicine, 89075 Ulm, Germany,* [2]*Department of Trauma Surgery, Hand, Plastic and Reconstructive Surgery, 89075 Ulm, Germany.*

Introduction: Trauma activates a strong inflammatory immune response, which is counterbalanced by immunosuppression characterized by an impaired adaptive immune response. Inflammation triggers the induction of myeloid-derived suppressor cells (MDSCs) a heterogeneous population of immature myeloid cells, which suppress various T-cell functions. Thus, induction of MDSCs after an experimental blunt chest trauma (TxT) and their subsequent influence on innate and adaptive immunity was investigated.
Methods: C57BL/6 mice underwent a blast wave to induce TxT. At 6h up to 5d after TxT, increase in MDSCs in lung and spleen and their suppressive capacity in MLR and in vivo after SEB activation was determined. Alterations in the secretion of cytokines and chemokines caused by TxT-induced MDSCs were analyzed in bronchoalveolar lavage (BAL) fluid and blood serum samples.
Results: In TxT-animals, MDSC numbers were preferentially enhanced in the lung until 48h after trauma, while total cell numbers and lymphocyte composition in spleen and lung were not affected. Although, no strong increase in MDSC numbers was detected, splenic MDSCs isolated after TxT suppressed the proliferative capacity of antigen-stimulated T-cells in vitro. Moreover, trauma-induced MDSCs inhibited T-cell proliferation of SEB activated T-cells in vivo and they supported the production of Th1-associated cytokines. TxT-induced MDSCs decreased the systemic levels of IL-6, G-CSF and MCP-1 but didn´t substantially influence the expression of pro-inflammatory factors in BAL fluid.
Conclusions: Thus, our results indicate that TxT promotes the induction of T-cell suppressive MDSCs, which might contribute to trauma-induced immunosuppression.

P.C1.07.09

Development of tissue-resident mucosa-associated invariant T (MAIT) cells in human renal fibrosis and chronic kidney disease (CKD)

B. M. P. Law[1,2]*, R. Wilkinson*[1]*, X. Wang*[1]*, K. Kildey*[1]*, K. Giuliani*[1]*, K. Beagley*[2]*, H. Healy*[1]*, A. J. Kassianos*[1,2]*;*
[1]*Royal Brisbane and Women's Hospital, Brisbane, Australia,* [2]*Queensland University of Technology, Brisbane, Australia.*

MAIT cells are a specialised lymphocyte population associated with chronic inflammatory disorders in peripheral tissues. To date, MAIT cell research has focused primarily on mucosal tissue, with limited studies on non-mucosal organs such as kidneys. In this study, we evaluated MAIT cells in native human kidneys with tubulointerstitial fibrosis, the pathological hallmark of CKD. MAIT cells were identified, enumerated and phenotyped from human kidney tissue by multi-colour flow cytometry. Localisation of MAIT cells were performed by immunofluorescence microscopy. MAIT cells and human primary proximal tubular epithelial cells (PTEC) were cultured under hypoxic (1% O2) conditions to examine mechanistic tubulointerstitial interactions. We detected significantly elevated numbers of MAIT cells (TCR-Vα7.2+ CD161++) in diseased biopsies with interstitial fibrosis compared with diseased biopsies without fibrosis and healthy kidney tissue. The increased numbers of MAIT cells correlated significantly with loss of kidney function (eGFR). MAIT cells in fibrotic biopsies expressed development markers (IL-7Rα, IL-18Rα), activation receptor (NKG2D), extravasation marker (CD44) and tissue-resident markers (CD69, CD103, and CD49a). Immunofluorescent staining of fibrotic kidney tissue localised the accumulation of MAIT cells within the tubulointerstitial compartment, adjacent to PTEC. Notably, PTEC under in vitro pro-fibrotic/hypoxic conditions up-regulates tissue-resident markers CD69 on MAIT cells. We provide the first characterisation of MAIT cells in human kidney tissue. Collectively, our data suggest that human MAIT cells are retained as tissue-resident lymphocytes and are positioned to contribute the fibrosis process via complex interactions with PTEC. Further dissection of kidney MAIT cells offers a novel pathway of disrupting the mechanisms of CKD.

P.C1.07.10

***Eomes*controls the development of Th17-derived (non-classic) Th1 cells during chronic inflammation**

A. Mazzoni[1]*, L. Maggi*[1]*, F. Siracusa*[2]*, M. Ramazzotti*[1]*, M. Rossi*[1]*, V. Santarlasci*[1]*, G. Montaini*[1]*, M. Capone*[1]*, B. Rossettini*[1]*, R. De Palma*[3]*, A. Kruglov*[2]*, H. Chang*[2]*, R. Cimaz*[1]*, E. Maggi*[1]*, S. Romagnani*[1]*, F. Liotta*[1]*, L. Cosmi*[1]*, F. Annunziato*[1]*;*
[1]*University of Florence, florence, Italy,* [2]*German Rheumatism Research Center, Berlin, Germany,* [3]*University of Campania, Naples, Italy.*

Th17 cells are a highly plastic cell subset that can be easily directed towards the Th1 phenotype in *in vitro* and also *in vivo* during inflammation. Instead, there are more concerns regarding the opposite plasticity (i.e. from Th17 to Th1). We show here that ectopic ROR-γt expression can restore or initiate IL-17 expression by non-classic (Th17-derived) or classic Th1 cells, respectively, while common pro-Th17 cytokine cocktails are ineffective. We found that the stability of the Th1 phenotype is at least partially due to the presence of a molecular machinery governed by the transcription factor Eomes, which promotes IFN-γ secretion and inhibits ROR-γt and IL-17. By using a mouse model of T cell-dependent colitis we demonstrate that Eomes controls non-classic Th1 cell development also *in vivo* and promotes their pathogenic potential. Eomes expression associates to a highly inflammatory phenotype also in humans. Indeed, it favors the acquisition of a cytotoxic signature, and promotes the development of IFN-γ$^+$GM-CSF$^+$ cells that have been described to be pathogenic in chronic inflammatory disorders. Finally, our data show an enrichment of Eomes$^+$IFN-γ$^+$ cells in the synovial fluid of patients affected by juvenile idiopathic arthritis.

Human bone marrow resident natural killer cells have a unique transcriptional profile resembling resident memory CD8$^+$ T cells

***J. E. Melsen**, G. Lugthart, C. Vervat, S. M. Kielbasa, S. A. van der Zeeuw, H. P. Buermans, M. M. van Ostaijen-ten Dam, A. C. Lankester, M. W. Schilham;*
Leiden University Medical Centre, Leiden, Netherlands.

Human lymphoid tissues harbor, in addition to circulating CD56^{bright} and CD56^{dim} natural killer (NK) cells, a third NK cell population: CD69$^+$CXCR6$^+$ lymphoid tissue (lt)NK cells. To obtain more insight in the characteristics of ltNK cells, RNA sequencing was performed on the three NK cell populations from bone marrow and blood. 700-900 genes were differentially expressed between individual populations in blood or marrow. Among the downregulated ltNK cell genes, we identified *S1PR1*, *SELPLG* and *SELL*. By flow cytometry we confirmed that the adhesion molecule (e.g. CD49e$^-$, CD29^{low}, CD81^{high}, CD62L$^-$, CD11c$^-$) and transcription factor profile (e.g. Eomes^{high}, Tbet^{low}) of ltNK cells significantly differed from their circulating counterparts. ltNK cells were characterized by enriched expression of inhibitory receptors TIGIT and CD96, and low expression of DNAM1 and cytolytic molecules (e.g. *GZMB*, *GZMH*, *GNLY*). Their proliferative capacity was reduced compared to the circulating NK cells. Gene set enrichment analysis revealed the transcription factor EGR2 and phosphatase DUSP6 as potential regulators of the ltNK cell transcriptome. Remarkably, comparison of the ltNK cell and published human spleen-resident memory CD8$^+$ T(rm) cell transcriptome revealed a shared transcriptional program. Moreover, the phenotypical profile of ltNK cells resembled that of bone marrow CD8$^+$ Trm cells. Together, we provide molecular data that clearly distinguish ltNK cells from both the circulating CD56^{bright} and CD56^{dim} NK cells and substantiate the view that ltNK cells are tissue-resident and functionally restrained in killing. Our findings underscore the existence of a core gene signature shared between CD8$^+$ Trm and resident NK cells in lymphoid tissues.

P.C1.07.12

Blockade of the T cell ecto-enzyme ARTC2.2 *in vivo* preserves the vitality and function of isolated liver tissue resident-memory T cells

***B. Rissiek**[1], M. Lukowiak[1], F. Raczkowski[2], T. Magnus[1], H. Mittrücker[2], F. Koch-Nolte[2];*
[1]Department of Neurology, Hamburg, Germany, [2]Institute of Immunology, Hamburg, Germany.

On murine T cells, the GPI-anchored ADP-ribosyltransferase 2.2 (ARTC2.2) ADP-ribosylates the P2X7 ion channel at arginine 125 in response to nicotinamide adenine dinucleotide (NAD$^+$) released from damaged cells. We have previously reported that this pathway is activated also by NAD$^+$ released during the preparation of liver leukocytes, where sustained gating of P2X7 by ADP-ribosylation can severely compromise the vitality and function of primary regulatory T cells (Tregs) and NKT cells that co-express high levels of ARTC2.2 and P2X7. In our present study, we evaluated the expression of ARTC2.2 and P2X7 by effector and memory T cells in the liver of mice seven weeks after infection with Listeria monocytogenes (Lm). We found that CD4$^+$ KLRG1$^+$/CD69$^+$ and CD8$^+$KLRG1$^+$/CD69$^+$ tissue-resident memory T cells (Trm) in the liver express high levels of ARTC2.2 and P2X7. Isolation of liver Trm and further incubation at 37°C resulted in cell death of the majority of CD4$^+$ and CD8$^+$ Trm. Injection of the ARTC2.2-blocking nanobody s+16a 30 min prior to organ harvesting prevented ADP-ribosylation of P2X7 during cell preparation and thereby protected Trm from NAD-induced cell death (NICD) when cells were incubated at 37°C. Consequently, preserving Trm vitality by s+16a injection enabled sensitive analyses of the *in vitro* cytokine expression profile of primary liver Trm. In conclusion, *in vivo* blockade of ARTC2.2 during cell preparation by systemically injected nanobody s+16a represents a valuable strategy to study the role and function of liver Trm in mice.

P.C1.07.13

Diagnostic algorithm for the detection of anti-SOX1 antibodies

***R. Ruiz-García**[1], M. García-Ormaechea[1], M. Español-Rego[1], E. Martínez -Hernández[2,3], C. San Bartolomé-Belloch[1], L. Sabater[2], L. Querol[4], I. Illa[4], F. Graus[3,2];*
[1]Immunoloy Department, CDB, Hospital Clínic de Barcelona, Barcelona, Spain, [2]Neuroimmunology Program, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain, [3]Neurology Department, Hospital Clínic de Barcelona, Barcelona, Spain, [4]Neuromuscular Disorders Unit, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Introduction: The Lambert-Eaton myasthenic syndrome(LEMS) is a neuromuscular disorder with an associated cancer inup to 50% of patients, mostly lung cancer(LC). The detection of anti-SOX1 antibodies is useful in thediagnosis of paraneoplastic LEMS, although they had been detected sporadically in idiopathic neuropathiesby immunoblot/ ELISA.Currently, there are commercial immunoblots for the detection of anti-SOX1 antibodies but comparisonwith a specific technique is lacking and their sensitivity is unknown. **Methods:** We studied 203 serum samples using cell based assay (CBA), rat cerebellar immunohistochemistry(IHQ) and commercial immunoblot(IB). We included 64 patients with anti-SOX1 antibodies and 139 as diseasecontrols **Results:** 79.7% anti-SOX1 positive patients were male. Mean age was 64 years. 98.4% patients had cancer (61 lung,1 prostate and 1 breast); 25% presented cerebellar degeneration; 22% LEMS; 22% limbic encephalitis; 11%encephalomyelitis; 11% neuropathy/neuronopathy; 3% Stiff-man syndrome; 6% LC without anyneurological syndrome and 2% cerebellar syndrome without cancer. 10.9% anti-SOX1 positive serumsamples by CBA were negative by IHQ but positive by IB (IHQ false negatives) and another 10.9% werenegative by IB (IB false negatives). Regarding the 139 controls, only 1 patient, with sensitive neuropathy andparotid cancer, was positive for SOX1 by IB but seronegative by CBA and by IHQ (IB false positive). Anti-SOX1 abs were detected by all three tests in 78% of patients. **Conclusions:** Anti-SOX1 antibodies are LC markers. It is important to assess the risk of LC in samples negative by IB(>40 years, smoking, classic paraneoplastic syndrome), since 11% of patients have anti-SOX1 antibodies byCBA. False positive results are rare and should be confirmed by CBA if clinical picture is discordant.

P.C1.07.14

Familial multiple sclerosis with autosomal recessive pattern inheritance linked to a region on chromosome 7p

***z. salehi**[1], M. Keramatipour[2], S. Talebi[3], M. Sahraian[4], A. Naser Moghadasi[4], M. Izad[1];*
[1]Department of Immunology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [2]Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [3]Department of Medical Genetics and Molecular Biology, Faculty of Medicine, Iran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [4]MS Research Center, Neuroscience Institute, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: The prevalence rate of familial multiple sclerosis (MS) is recently increasing among Iranian population which endorses the heritability of the disease. On the other hand, hereditary disease gene analysis in consanguineous families with multi-incidence of MS could be highly effective in finding mutations underlying disease pathogenesis in an ethnic group. Because of the high rate of consanguinity among Iranian population, we propose to examine genetic mutations in an Iranian family with an autosomal recessive inheritance of relapsing-remitting MS (RRMS).
Materials and Methods: We performed whole exome sequencing (WES) in a family with five patients and four healthy individuals of four generations. Sanger sequencing was done to confirm the found variants. We also performed homozygosity mapping to determine the genomic region linked to the disease.
Results: We described novel homozygous rare variants in *AMPH*, *POLM*, *POLD2* and *TNS3* genes in the affected members. Interestingly, all the variants were located on chromosome 7p arm. Especially, using homozygosity mapping, we found a long continues stretch of homozygosity (LCSH) at chromosome 7p12.3-14.1, spanned more than 10 Mbp, which included four identified variants in the affected proband, his affected father/ sibling.
Conclusion: Our results identify chromosome 7p arm as a genetic region of interest for familial multiple sclerosis susceptibilities which could be considered for the identification disease-causing mutations to solve missing heritability of MS.

P.C1.07.15

A case of autoimmune glial fibrillary acid protein astrocytophaty and a-GFAP autoantibodies

***C. San Bartolomé Belloch**[1], M. Romera Forné[2], M. Antón Monleón[2], L. Ballester-Marco[3], D. Escudero[4], F. Graus[4,5], R. Ruiz-García[2];*
[1]Immunology department CDB, Hospital Clínic de Barcelona., Barcelona, Spain, [2]Immunology department CDB, Hospital Clínic de Barcelona, Barcelona, Spain, [3]Neurology department, Hospital Comarcal de Alcañiz, Teruel, Spain, [4]Neurology department, Hospital Clínic de Barcelona, Barcelona, Spain, [5]Neuroimmunology Program Institut d'Investigació Biomèdica August Pi i Sunyer (IDIBAPS), University of Barcelona, Barcelona, Spain.

INTRODUCTION: Glial fibrillary acidic protein (GFAP) is an intracellular protein located between the smaller microfilaments and larger microtubules in astrocytes and is a target and biomarker for astroglial pathology in neurological diseases. This astrocytopathy is a novel autoimmune central nervous system disorder. The pathogenesis of this disorder is poorly understood and predominantly affects the meninges, brain, spinal cord and optic nerve.
PATIENT AND METHODS: We present a 71 years old patient which showed signs of weakness, tremor, fluctuating episodes of disorientation and bradypsychia. MRI was negative for acute pathology. Lumbar puncture showed presence of leukocytes and elevated protein level. Clinical examination suggested bilateral optic neuritis and lymphocytic meningitis. Serum and cerebrospinal fluid (CSF) samples were tested for antibodies using immunohistochemical assays on rat cerebellum and brain tissues. Antibody specificity was confirmed with an *In house* cell based assay.
RESULTS: Patient's CSF presented a characteristic immunostaining pattern in the rat cerebellum, compatible with a-GFAP antibodies, which were confirmed by indirect immunofluorescence (IFI) with GFAP-transfected HEK293T cells. However, the serum sample did not present any anti-neuronal antibody specificity.
CONCLUSIONS: Here we described a novel case of this rare neurological disease associated with meningoencephalitis and a-GFAP antibodies. We demonstrated, in this case, the intrathecal synthesis of GFAP antibodies by the analysis of both biological samples. It is highly recommended to perform a study as broad and specific as possible in both samples for establish an appropriate diagnosis and treatment.

Apoptosis of food-activated T cells in Peyer´s patches is a hallmark of healthy intestines

U. Steinhoff[1], *S. Hartmann*[1], *K. Rajalingam*[2], *B. Siegmund*[3], *Y. Rodriguez Sillke*[3], *R. Glauben*[3], *A. Visekruna*[1];
[1]*Institute for Microbiology and Hospital Hygiene, Marburg, Germany,* [2]*Institute for Immunology, Mainz, Germany,* [3]*Charité-Medical Department for Gastroenterology, Berlin, Germany.*

It is well known that development of the intestinal immune system is shaped by the microbiota. However little information exists about the impact of dietary antigens on development and homeostasis of the intestine. We studied the impact of dietary proteins on the fate of intestinal immune cells. Data from mice and humans show that continuous exposure to dietary protein antigens leads to highly activated Helios$^+$ Foxp3$^-$ CD4$^+$ T cells in Peyer´s Patches (PP), independently of the intestinal microbiota. Food protein activated, Helios$^+$ CD4$^+$ T cells in PP undergo PD-1 mediated apoptosis and removal of dead cells by macrophages induces local IL-10 production. Further studies in patients with inflammatory bowel diesease revealed significantly reduced frequencies of apoptotic CD4$^+$ T cells as compared to healthy controls. These findings demonstrate that continous activation and subsequent apoptosis of diet-reactive CD4$^+$T cells is a hallmark of the healthy intestine.

P.C1.07.17

Age dependent changes in T cell subsets in multiple sclerosis patients

A. Tejeda Velarde[1], *E. Rodríguez-Martín*[1], *L. Costa-Frossard*[1], *Y. Aladro*[2], *S. Sainz de la Maza*[1], *J. Fernández*[1], *S. Medina*[1], *N. Villarrubia*[1], *E. Monreal*[1], *J. Álvarez-Cermeño*[1], *E. Roldán*[1], *L. Villar*[1];
[1]*Ramón y Cajal University Hospital, Madrid, Spain,* [2]*Getafe University Hospital, Madrid, Spain.*

Introduction: T cells have an important role in multiple sclerosis (MS) physiopathology. CD4 trigger the inflammatory cascade and recruit immune cells into the central nervous system, while CD8 contribute to induce axonal damage. However, age dependent changes in these T cell subsets remain unknown. We aimed to study age dependent changes in CD4 and CD8 subsets in cerebrospinal fluid (CSF) and blood of MS patients.
Patients and methods: We analyzed CSF and blood of 102 MS patients (91 relapsing-remitting and 11 primary progressive) in a FACSCanto II cytometer. We studied: naïve, central memory (CM), effector (Including effector memory, EM, and terminally differentiated, TD), resident memory T cells (T_{RM}), regulatory T cells (Treg), PD-1+ cells and PD-L1+ cells. Results were expressed as percentage. Nonparametric Spearman's correlation was performed to analyze association with age.
Results: In blood, we observed an age dependent decrease in naïve CD8 (r=-0.41; p<0.0001), accompanied by an increase in effector CD8 (r=0.35; p=0.0006), especially in TD CD8 (r=0.33; p=0.0013). We also found an increase in PD1+ CD4 (r=0.48; p=0.0265). These associations were not found in CSF. However, in the CSF we observed an increase in both CD4 (r=0.34; p=0.0017) and CD8 (r=0.25; p=0.0273) $T_{RM.}$ We did not find any association with Treg, but we observed an increase in CD4 PD-L1+ (r=0.56; p=0.0146) in the CSF.
Conclusions: Our data show that the distribution of T cell subsets in CSF and blood changes along the time in MS, and this could have some implications in the prognosis of these patients.

P.C1.07.18

Intra-cerebral T-cells in multiple sclerosis patients recognize EBV-infected cells, but notcandidate disease-associated autoantigens

G. M. G. Verjans*, G. P. van Nierop, R. Q. Hintzen;*
Erasmus MC, Rotterdam, Netherlands.

Introduction. Association between Epstein-Barr virus (EBV) and multiple sclerosis (MS) may involve intracerebral EBV-specific T-cell responses targeting the virus or indirectly, candidate MS-associated autoantigens (cMSAg). We determined the differentiation status and Ag-specificity of T-cells in (i) cerebrospinal fluid (CSF) of early diagnosed MS patients (n=13) and (ii) paired blood, CSF and (non-)affected brain tissue of deceased patients with progressed MS (n=27). **Methods**. T-cells were phenotyped ex-vivo by flowcytometry. Short-term T-cell lines (TCL) were generated from clinical samples by mitogenic stimulation and assayed by intra-cellular cytokine flowcytometry for reactivity towards autologous EBV-infected B-cells (autoBLCL) and transformed autoBLCL expressing eight human cMSAg. **Results**. Intrathecal T-cells in early MS patients are directed to lytic EBV antigens, but not cMSAg. In late stage MS patients, local T-cell responses mainly involved oligoclonal effector-memory cytotoxic CD8 T-cells expressing markers of chronic antigenic stimulation, but not senescence. TCRVß repertoire correlated between paired MS lesions, but with paired unaffected brain tissue, CSF and blood. Whereas no substantial cMSAg-specific T-cell reactivity was detected, brisk CD8 T-cell reactivity was detected in multiple lesion-derived TCL towards autoBLCL. In one MS patient, the autoBLCL-specific T-cell response in paired intra-lesional TCL was dominated by TCRVβ2+CD8+ T cells, which were localized in the parenchyma of the respective tissues expressing a polarized TCR and CD8 expression suggesting immunological synapse formation in-situ. **Conclusions**. The data suggest the involvement of effector-memory cytotoxic CD8 T-cells recognizing antigens expressed by autoBLCL, most likely EBV antigens, but not the assayed human cMSAg in both early and late stage MS patients.

P.C1.07.19

Functional tagging of autoaggressive CD8$^+$ T cells in the animal model of multiple sclerosis

M. Walkenhorst*, A. Willing, E. Luu, N. Kursawe, J. B. Engler, M. A. Friese;*
Institut für Neuroimmunologie und Multiple Sklerose, Zentrum für Molekulare Neurobiologie Hamburg, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.

Multiple sclerosis (MS) is the most common inflammatory disease of the central nervous system (CNS) that is characterised by CNS-infiltrating CD8$^+$ and to a lesser extent also CD4$^+$ T cells. However, the mouse model of MS, experimental autoimmune encephalomyelitis (EAE), is almost entirely driven by autoreactive CD4$^+$ T cells. Therefore, current EAE models only partially reflect the pathogenesis of MS. Accordingly, the role of CD8$^+$ T cells in MS remains elusive and requires a functional characterization of CD8$^+$ T cell responses in EAE that will instruct us on how to genetically engineer a CD8$^+$ T cell-driven model. Here, we genetically and irreversibly labelled activated CD8$^+$ T cells in EAE by using an inducible granzyme B (gzmB) reporter mouse. We found that during EAE onset CD8$^+$ T cells are activated in the periphery and labelled CD8$^+$ T cells were enriched in the CNS compared to draining lymph nodes in the acute phase of the disease. Sequencing the T cell receptor (TCR) of tagged CD8$^+$ T cells in EAE will allow us to identify myelin oligodendrocyte glycoprotein-specific CD8$^+$ T cells. Eventually, we aim to transgenically express identified TCRs to develop a mouse model that enables us to study the pathogenic role of naturally occurring encephalitogenic CD8$^+$ T cells. Therefore, results in this model might allow better translatability to MS.
This work is supported by the Bundesministerium für Bildung und Forschung (BMBF), Krankheitsbezogenes Kompetenznetz Multiple Sklerose (KKNMS).

Uterine immune dynamics assessed from pre-pregnancy endometrium to delivery

M. Benner[1], *D. Feyaerts*[1], *C. Cartagena Garcia*[1], *G. Ferwerda*[1], *W. Shadmanfar*[2], *O. W. van der Heijden*[1], *I. Joosten*[1], *R. G. Van der Molen*[1];
[1]*Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands,* [2]*Mildred Clinics, Arnhem, Netherlands.*

Introduction: The importance of local immunity for correct placental development and healthy pregnancy is evident. Various studies focusing on a particular cell type and time points during pregnancy suggest gestational immune shifts. However, methodological differences between studies make it impossible to fully assess when and to what extent changes in placental immune signature are induced. Here, we examined >30 different lymphocyte (sub)populations and their dynamics during gestation. Methods: Deep immune flowcytometry phenotyping was performed on lymphocytes isolated from the uterine mucosa throughout gestation. Pre-pregnancy endometrial lymphocytes, isolated from menstrual blood, lymphocytes from placenta at different time points (5-11.6wk, 12-14wk and >37wk) and peripheral blood mononuclear cells were processed immediately. Results: NK cells were enriched in endometrium up until the 2nd trimester of pregnancy, while the percentage of T cells in placenta rises after >17wk gestation. Various subpopulations of NK and T cells revealed gestation-dependent shifts. We observed a well-defined B cell population in 1st and 2nd trimester placentae, with highest levels in the 2nd trimester. Especially CD24^{Hi}CD38^{Hi} B cells were increased in 2nd trimester decidua. Currently, we are assessing the nature and putative specificity of these cells. Conclusion: Uterine mucosal immunity changes extensively after the induction of pregnancy. Gestation-dependent local B cell function deserves attention. Contrary to a common believe that decidual B cells are almost absent or only present in pathological conditions, our results highlight possible functional implications in early to mid gestation. Investigation of decidual tolerance-mediating B cells might reveal key mechanisms of how placental immunity is maintained.

A novel human CD3$^+$CD56$^+$regulatory cells: role in the pathogenesis of type 1 diabetes

S. Bruzzaniti[1], *V. Rubino*[2], *C. La Rocca*[1], *A. Giovazzino*[2], *A. Palatucci*[1], *V. De Rosa*[1], *P. de Candia*[3], *S. De Simone*[1], *A. Franzese*[2], *E. Mozzillo*[2], *G. Terrazzano*[4], *G. Ruggiero*[2], *G. Matarese*[2], *M. Galgani*[1];
[1]*Istituto per l'Endocrinologia e l'Oncologia Sperimentale- Consiglio Nazionale delle Ricerche, Naples, Italy,* [2]*University of Naples "Federico II", Naples, Italy,* [3]*Istituto di Ricovero e Cura a Carattere Scientifico MultiMedica, Milan, Italy,* [4]*University of Potenza, Potenza, Italy.*

Regulatory T cells play a cardinal role in the control of immune response and homeostasis. Here, we reported that a circulating T cell population, co-expressing CD3 and CD56 markers (here defined as CD3$^+$CD56$^+$ cells), identifies a novel human regulatory T cell subset, not expressing the fork-head-box-P3 (Foxp3) transcription factor and distinct from NKT cells. Flow-sorted CD3$^+$CD56$^+$ cells showed that CD3$^+$CD56$^+$ cells were able to suppress cytotoxicity and IFN-γ production when co-cultured *in vitro* with CD8$^+$ effector cells. Regulatory function of human CD3$^+$CD56$^+$ cells required cell-to-cell contact and associated to a reduction of intracellular reactive oxygen species (ROS) in CD8$^+$ target cells. Furthermore, through a microarray analysis, we characterized the transcriptional profile of CD3$^+$CD56$^+$ cells, clustering independently from other circulating T cell subset. Finally, these data were corroborated in human autoimmune condition; indeed, peripheral frequency and suppressive function of CD3$^+$CD56$^+$ cells were significantly reduced in a large cohort of children with type 1 diabetes, at diagnosis. Taken together, our findings unveil a previously unrecognized regulatory T cell population specifically controlling CD8$^+$ effector functions, which may play a critical role in the control of immunological tolerance and autoimmune diseases in humans.

Tissue specialization of human Tfr cells

R. Correia[1], *V. R. Fonseca*[1,2], *A. Agua-Doce*[1,3], *L. Graca*[1,3];
[1]*Instituto de Medicina Molecular João Lobo Antunes, Lisboa, Portugal,* [2]*Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, Lisboa, Portugal,* [3]*Instituto Gulbenkian de Ciência, Oeiras, Portugal.*

The recent discovery of a follicular regulatory T (Treg) cell subset, called T follicular regulatory (Tfr) cell, has revealed a new and specialized mechanism for germinal centre (GC) regulation and prevention of autoimmunity. Tfr cells gain access to the GC and suppress follicular helper T (Tfh) cells and B-cell responses. In humans, blood Tfr cells are not fully competent in suppressing humoral responses. However, full knowledge of human Tfr cell biology have been challenged by the difficulty to study secondary lymphoid organs.
We studied Tfr cells in human lymph nodes and tonsils. We found that the presence of GC reactions impacts the phenotype of Tfr cells. While in human lymph nodes without GC reactions (identified by Bcl-6 immunohistochemistry), Tfr cells resemble their blood counterparts, GC presence is associated with the emergence of activated Tfr cells, as the ones usually found on human tonsils.
Taken together, these results suggest that human Tfr cells follow a tissue compartment specialization accordingly to the presence of ongoing humoral responses. A detailed phenotypical and functional analysis of Tfr cells in different human tissues is critical to understand the biology of these cells.

Potential role of CD4+T cell-derived extracellular microRNAs in the loss of immune tolerance during multiple sclerosis

S. Garavelli[1], *F. Buttari*[2], *F. Carbone*[3], *C. Procaccini*[3], *V. De Rosa*[3], *D. Centonze*[2], *G. Matarese*[3], ***P. de Candia***[1];
[1]*IRCCS Multimedica, Milan, Italy,* [2]*IRCCS Istituto Neurologico Mediterraneo (INM) Neuromed, Pozzilli, Italy,* [3]*Istituto di Endocrinologia e Oncologia Sperimentale, Consiglio Nazionale delle Ricerche (IEOS-CNR), Naples, Italy.*

Introduction: CD4$^+$ T regulatory (Treg) cells control inflammation by inhibiting the growth and cytokine production of CD4$^+$ T conventional (Tconv) cells. We showed that, upon stimulation, T cell subsets release extracellular vesicles (EVs), containing distinct patterns of microRNAs with the capability of modulating specific mRNA targets upon cellular up-take. Objective of the present work was to evaluate whether the T cell-derived extracellular microRNA signatures may get dysregulated in autoimmunity with a potentially different impact on the transcriptome of EV receiving cells. Materials and Methods: To this aim, human CD4$^+$ T cell subsets were purified from peripheral blood of naïve to treatment relapsing-remitting multiple sclerosis (RRMS) patients and healthy controls. Tconv- and Treg cells were *in vitro* stimulated and released EVs were characterized by nanoparticle tracking analysis and RT-qPCR to analyze size distribution and microRNA content. Results: Compared to healthy, both Tconv and Treg cells from patients showed a differentially expressed set of microRNAs with crucial regulatory function in the immune system. By a mRNA sequencing approach, we have then demonstrated that the treatment of naïve T cells with Treg- (but not Tconv-) EVs caused the specific repression of genes involved in the proteasome-dependent proteolytic process, known to be crucial for T cell activation, and that in RRMS, Treg-derived EVs may have lost this capability. Conclusions: Our results unveil a novel molecular mechanism for Treg-mediated maintenance of self-tolerance and its potential alteration in multiple sclerosis. Grants: National Multiple Sclerosis Society NMSS (PP-1606-24687) and Fondazione Italiana Sclerosi Multipla FISM (2016/R/10) to PdC.

The role of regulatory T cells in the development of obesity in MIF-KO mice

D. Gajić, *I. Koprivica, M. Vujičić, I. Stojanović, T. Saksida;*
Institute for Biological Research "Siniša Stanković", Belgrade, Serbia.

Obesity is a disorder characterized by a pro-inflammatory environment in visceral adipose tissue (VAT) due to increased infiltration of pro-inflammatory macrophages and a drop in regulatory T (Treg) cells. Macrophage migration Inhibitory Factor (MIF) is a pro-inflammatory cytokine with versatile functions in innate and adaptive immunity. Although it has a predominantly pro-inflammatory role in the organism, its innate absence in MIF-KO mice leads to obesity. VAT in MIF-KO mice is larger in mass and the infiltration of immune cells per gram of VAT is not different than in WT controls. Also, MIF-KO VAT has the same distribution of immune cells (CD3+, CD4+, CD8+, CD19+ cells, M1 and M2 macrophages), but a higher expression and secretion of TNF-α and IL-1β. Surprisingly, Treg cells are more abundant in VAT of MIF-KO mice. Proliferation of Treg cells in VAT measured by BrdU incorporation is the same in both strains, suggesting that their increased number is not due to enhanced *in situ* division. Cytokines responsible for Treg suppressive action, IL-10 (denoted as CD4+IL-10+FoxP3+ cells) and TGF-β (secreted from VAT infiltrating cells), are underrepresented in VAT of MIF-KO mice. Based on these results, we can assume that Treg cells in VAT of MIF-KO mice are, albeit extensively present, less functional. This situation may be responsible for obesity development in the absence of MIF. *Supported by Ministry of Education, Science and Technological Development, Republic of Serbia (#173013)*

Exploratory study on the association of Vγ9Vδ2Tcells with Chlamydial cervico-vaginal infection in women with Recurrent Spontaneous Abortions

I. Voskakis[1], *C. Tsekoura*[1], *T. Keramitsoglou*[1], *E. Deligeoroglou*[2], ***I. Gkougkourelas***[3], *E. Glynou*[4], *M. Varla-Leftherioti*[1];
[1]*Dept. of Immunology and Histocompatibility "Helena Venizelou" Hospital, Athens, Greece,* [2]*National and Kapodistrian University of Athens. School of Medicine. Aretaieio Hospital, Athens, Greece,* [3]*2nd Dept. of Internal Medicine, Aristotle University of Thessaloniki, Hippokratio GHTH, Thessaloniki, Greece,* [4]*Dept. of Microbiology "Helena Venizelou" Hospital, Athens, Greece.*

Introduction: We have previously reported a significant association of Vγ9Vδ2T cells with cervico/vaginal *Chlamydia trachomatis*(*Ct)*infection in women with RSA. This association raises questions on the chlamydial antigens that activate γ9δ2 T cells to develop an anti-trophoblast response as well as the factors that enhance it. In the present study, we try to answer if the γ9δ2-mediated anti-trophoblast activity is related to the length of the infection by analyzing the γ9δ2T cells in aborters who have received or not anti-clamydial treatment.**Patients-Methods:** The percentage of γ9δ2T cells in PB was analyzed by flow cytometry in 76 positive for *Ct* infections (*Ct*+) RSA women (A), within 10 days after a new miscarriage. 35 of them had received anti-*Ct* treatment upon diagnosis (T) and 41 were not treated (NT). Fertile women without Ct infection (*C*) served as controls(C=82). **Results:** A highly statistically significant difference of mean percentages of γ9δ2T cells was shown between Tand C groups (58.95 vs 61.92, p<0.00001). The analysis performed in T and NT aborters revealed that the mean percentage was 58.95% and 83.29% respectively (p=0.0002) and that 53% of NT women had >80% γ9δ2T cells (only 20% of T women, p=0.0017). **Conclusions:** The increased levels of PB γ9δ2T cells in untreated cases support the hypothesis that the persistence of *Ct* in the cervic/vaginal tract favors the recognition by γ9δ2T cells *Ct* antigens sharing common epitopes with antigens (HSP?) expressed on the embryonic tissues which results in the activation of anti-embryonic responses and possibly abortions.

Sertoli cells have non-canonical functional inflammasome network able to perturb testis niche immune tolerance and to inflict cell death

K. Todorova, E. Avramska, L. Sezer, A. Apostolova, ***S. Hayrabedyan****;*
Institute of Biology and Immunology of Reproduction, Bulgarian Academy of Sciences, Sofia, Bulgaria.

Sertoli cells are pivotal in protecting auto-immunogenic germ cells by establishing an immune privileged environment, but eventually they could also serve as germline damage sentinels. We have recently showed a functional Nrp3 inflammasome in mouse Sertoli cells, both primary and cell line, where challenging of NOD1/NOD2 and TLR4, in ATP presence activated caspase-1, incurring cell death and mature IL-1β, IL-6, IL-23 secretion.
We explored if the caspase-1 mediated cell death was pyroptosis-like and it was only Nlrp3 regulated.

Surprisingly, we found an even larger non-canonical innate immunity inflammasome network elicited by TLR4/NOD1/ATP challenge (NGS RNA-Seq: intact Sertoli vs. Ma, Illumina; challenged vs. intact Sertoli cells, Oxford Nanopore), that was preserved in metabolic stress (caspase-1, RT-qPCR) and consisted of several inflammasomes and adaptors. Caspase-1 inflammasomes Aim2 (9000 fold), Nlr10 (7000 fold), Nlrp3 (200 fold) and Nlrc4 (100 fold) upregulation overwhelmed anti-apoptotic Naip1 (100 fold). The importance of metabolic preference for glycolysis (Agilent Seahorse) was supported by the role of MAPK1 for NF-κB upregulation upon challenge (MAPK1 siRNA in stable 15P-1 cell line with pNIFTY2-SEAP reporter). Sertoli cells undergo partial pyroptosis-like cell death (PI imaging, flow cytometry), with membrane leakage (LDH assay), blebbing (live imaging, fluorescent reporter), but without pyroptosis-like membrane shredding.
Inflammasome network serves as sentinel for germline genome stability by sensing DAMP/PAMP/metabolic stress, acting through caspase-1 axis, a notion coinciding with clinically observed semen IL-1β/IL-18 finding in male infertility patients, suggesting new therapy avenues.

The alarmin IL-33 drives a ST2$^+$ Treg-mediated anti-inflammatory immune response during immune-mediated hepatitis

***F. Heinrich**, A. Ochel, G. Tiegs, K. Neumann;*
University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Introduction: During Concanavalin A (ConA)-induced immune-mediated hepatitis, the alarmin IL-33 is released by necrotic hepatocytes and induces immune responses by signaling through the IL-33 receptor ST2. We have shown previously that IL-33 pre-treatment prevents development of immune-mediated hepatitis suggesting an immunosuppressive function for IL-33 in liver disease. Since regulatory T cells (Tregs) respond to IL-33, we aimed to investigate the IL-33-driven Treg response in the inflamed liver.
Methods: C57BL/6 mice were treated either with IL-33 or PBS alone or received ConA after 3-day IL-33/PBS treatment. Mice were analyzed 24 hours after hepatitis induction. The phenotype of Foxp3$^+$ Tregs was determined by flow cytometry.
Results: We showed that the frequency of hepatic Foxp3$^+$ Tregs was significantly increased in IL-33-treated mice compared to PBS-treated mice. Within the Treg population, the frequency of Tregs expressing ST2 was highly elevated. Compared to ST2$^-$ Tregs, hepatic ST2$^+$ Tregs displayed an activated phenotype with up-regulated expression of CD25, KLRG1, and ICOS as well as enhanced expression of the functional markers CTLA-4, TIGIT, and GITR. During immune-mediated hepatitis, the frequency of hepatic ST2$^+$ Tregs was elevated compared to healthy mice and was further strongly increased by IL-33 pre-treatment. Interestingly, hepatic ST2$^+$ Tregs also have an activated phenotype in liver inflammation that was not altered by IL-33 pre-treatment.
Conclusion: The immunosuppressive function of IL-33 in immune-mediated hepatitis might be driven by expansion and recruitment of a highly activated Treg population expressing ST2.

Dendritic cells as predictors for embryo implantation

***C. Kyvelidou**, A. Geisler, B. Toth, C. Heufler, S. Hofer-Tollinger;*
Medical University of Innsbruck, Innsbruck, Austria.

The immunological processes surrounding implantation and pregnancy are still under investigation. Promising players are dendritic cells (DC), major controllers of the immune system and key immune cells in the human endometrium. We hypothesize that the mechanisms for the establishment of maternal tolerance are generated even before implantation, are highly depended on DC for their initial activation, and that embryo-produced bioactive factors trigger DC for tolerance. Discarded medium (SM) from human single-embryo cultures was collected in order to perform a large scale protein array and also to be used for the treatment of DC. Our goal was to compare the outcomes between medium from embryos that resulted in pregnancy (prSM) and the ones that did not (npSM). Preliminary results so far show a different protein expression pattern in the SM which can be associated with a positive or a negative pregnancy outcome. Furthermore, several DC genes were found to be regulated by the SM. VCAM-1, CXCL2, CCL19, CXCL10, CXCL8, RELB, and NFKB1 were found upregulated by the prSM, while CCL2 was found upregulated by the npSM. These results indicate that indeed preimplantation embryos are able to produce bioactive factors that can affect DC. The elevated number of DC during pregnancy and their ability to interact with T regulatory and natural killer cells render DC a very promising target in the field of maternal tolerance and their study can offer new insights in the immunological events surrounding implantation and early pregnancy and inspire novel immunomodulatory strategies and treatment options for infertility.

Myeloid-specific molecular mediators of subchondral bone damage in antigen-induced arthritis

***N. Lukač**[1,2], M. Fadljevic[1], I. Radanovic[1], E. Lazic Mosler[3,4], A. Sucur[1,5], D. Flegar[1,5], T. Kelava[1,5], V. Katavic[1,2], D. Grcevic[1,5], N. Kovacic[1,2];*
[1]Laboratory for Molecular Immunology, Croatian Institute for Brain Research, University of Zagreb School of Medicine, Zagreb, Croatia, [2]Department of Anatomy, University of Zagreb School of Medicine, Zagreb, Croatia, [3]General Hospital Dr. Ivo Pedišić, Sisak, Croatia, [4]Catholic University of Croatia, Zagreb, Croatia, [5]Department of Physiology and Immunology, University of Zagreb School of Medicine, Zagreb, Croatia.

Introduction: Rheumatoid arthritis (RA) is marked by subchondral bone destruction, joint deformations and disability. Available therapeutics improve the prognosis, but with limited effect on bone destruction. Using antigen-induced arthritis (AIA), animal model of RA, we found that mice deficient for Fas gene (Fas-/-) develop non-destructive arthritis, marked by lower frequency of myeloid cells in joints. We aim to identify mediators of bone resorption in arthritis, by analyzing differentially expressed genes in sorted myeloid population from wild-type (WT) and Fas -/- mice with AIA.
Materials and methods: AIA was induced by intra-articular injection of methylated bovine serum albumin to immunized mice. Bone resorption was assessed by µCT. Synovial cells were released by collagenase, labeled with anti-mouse CD45-FITC, CD11b-PE, Gr1-PECy7, B220/CD3/NK1.1/CD31/TER119-APC, and CD51-APCeF780. CD11b+Gr-1+ population was sorted using BD FACSAria, RNA extracted by Trizol, and hybridized to Affymetrix ST 2.0 arrays. Differences in gene expression found on arrays were confirmed by qRT-PCR.
Results: Synovial CD11b+Gr1+ cells were transcriptionally similar in Fas -/- and WT mice with AIA. Samples split into two hierarchical clusters consisting predominantly of Fas -/- or WT samples. WT-dominant cluster revealed up-regulated genes related to cell cycle progression and mitosis, suggesting higher proliferation. Mid1 and Erdr1 genes were down-regulated in joints from Fas -/- mice with AIA, which was confirmed by PCR.
Conclusions: Resorptive AIA is marked by higher myeloid proliferation potential. Mid1 gene is a potential novel mediator for targeting inflammation-mediated joint destruction in arthritis.
Grants: This work was supported by the Croatian Science Foundation project number 7406.

Functional analysis of inflammation associated parameters in a patient with NEMO deficiency

***N. Sürücü**[1], B. Kayaoglu[1], E. Alpdündar Bulut[1], I. C. Ayanoglu[1], E. Dünüroglu[1], M. Acar[1], B. Sözeri[2], A. Kıykım[3], E. Karakoç-Aydıner[3], S. Barıs[4], A. Özen[3], M. Gürsel[1];*
[1]Middle East Technical University, Department of Biological Sciences, Ankara, Turkey, [2]Health Sciences University Ümraniye Teaching and Research Hospital, Pediatric Rheumatology Clinic, İstanbul, Turkey, [3]Marmara University Hospital, Pediatric Allergy and Immunology Department, İstanbul, Turkey, [4]Marmara University Hospital, Pediatric Allergy and Immunology Department, Istanbul, Turkey.

NEMO (NF-κB essential modulator, IKK-γ), is a regulatory component of the IKK (inhibitor of NF-κB kinase) complex and has a central role in the activation and subsequent translocation of the nuclear factor (NF)-κB transcription factor. NEMO deficiency, is a rare type of primary immune deficiency which has also been associated with autoinflammatory manifestations. This study aimed to investigate underlying mechanisms of inflammation in a patient with NEMO deficiency that presented with recurrent fever, perivascular and interstitial neutrophilic infiltrates and nodular skin lesions. PBMC and neutrophils were isolated from peripheral blood and used for functional assays and gene expression analysis using the NanoString inflammation panel. PBMC of the patient and healthy controls were stimulated with various TLR ligands or anti-CD3/anti-CD28. Results showed decreased cytokine responses in the patient (IL-1β, IL-6, IL-17, IFNγ) compared to healthy individuals. However, type I IFN responses to cytosolic nucleic acids was uncompromised. Low density granulocytes (LDG) in the PBMC fraction were abnormally increased in the patient and gene expression analysis subsequently confirmed a striking increase in MMP9 expression. NanoString pathway analysis showed a decreased score for IKK and NF-κB signaling pathway but an upregulation of type I interferon related genes MX1 and IFI44 and an elevated JAK/STAT pathway score. Consistently, cytometric bead array (CBA) analysis of plasma showed a sixty-fold increase in circulating IP-10 levels in the patient compared to healthy controls. Collectively, these results suggest that inflammation-associated symptoms in the patient might stem from elevated type I interferons and LDGs, leading to granulocyte dysregulation.

Hypoxia and rheumatoid phenotype decrease the T helper cell suppressive capacity of synovial fibroblasts

*N. Kaul[1], S. R. Mohapatra[2], T. Tretter[1], C. A. Opitz[2], H. Lorenz[1], **L. Tykocinski**[1];*
[1]University of Heidelberg, Heidelberg, Germany, [2]German Cancer Research Center (DKFZ), Heidelberg, Germany.

Introduction: The pathogenesis of rheumatoid arthritis (RA) is linked to functional changes in synovial fibroblasts (SF) and local infiltration of T lymphocytes. Increased synovial inflammation is also associated with a hypoxic microenvironment. Oxygen levels in the joints of RA patients are significantly decreased (mean oxygen tension: 3.2%) compared to those of osteoarthritis (OA) patients. So far, little is known about the effects of hypoxia on the interaction between fibroblasts and T cells and its implications on the pathophysiology of RA. Methods: SF of OA or RA patients were co-cultured with Th cells under normoxic or hypoxic (3% O_2) conditions. Th cell proliferation was determined by flow cytometry, cytokine secretion by ELISA, indoleamine 2,3-dioxygenase 1 (IDO1) expression was analysed by Western Blot and real-time PCR, tryptophan/ kynurenine levels were quantified by HPLC. Results: Under normoxic conditions, SF strongly inhibited the proliferation of co-cultured Th cells by an IDO1-mediated depletion of tryptophan. RASF showed a significantly lower IDO1 expression, tryptophan metabolism and a significantly weaker capacity to suppress the proliferation of Th cells compared to OASF. Under hypoxic conditions, the expression of IDO1, the tryptophan metabolism and the Th cell suppressive capacity of both OASF and RASF were significantly reduced. Conclusions: The IDO1-mediated suppression of Th cell growth may play an important role in preventing inappropriate Th cell responses under normal conditions. The reduced tryptophan metabolism under hypoxia together with the inferior efficiency of RASF to restrict T cell proliferation likely supports the development of synovitis in RA.

P.C1.08.14

Increase of aerobic glycolysis mediated by activated T helper cells drives synovial fibroblasts towards an inflammatory phenotype

*P. Kvacskay[1], M. M. Souto-Carneiro[1], R. Carvalho[2], K. D. Klika[3], H. Lorenz[1], **L. Tykocinski**[1];*
[1]University of Heidelberg, Heidelberg, Germany, [2]University of Coimbra, Coimbra, Portugal, [3]German Cancer Research Center (DKFZ), Heidelberg, Germany.

Introduction: There is growing evidence for a dysregulated glucose metabolism of synovial fibroblasts (SF) in rheumatoid arthritis (RA) being a prerequisite for their aggressive phenotype. As yet, little is known about the influence of immune cells on the metabolism of SF although local infiltration of leucocytes constitutes a hallmark in the pathogenesis of RA. Here, we investigated the effect of Th cells on the glucose metabolism and cytokine production of non-inflammatory (osteoarthritis (OA)) and inflammatory (RA) SF. Methods: RASF and OASF were cultured in the presence of a stable glucose isotope ($U^{-13}C$) and stimulated with culture supernatants (SN) of activated Th cells. Glucose and lactate levels were determined by proton nuclear magnetic resonance spectroscopy (H-NMR). Cytokine secretion was quantified by ELISA. Janus kinases (JAKs) were blocked by Baricitinib or Tofacitinib, glycolysis was inhibited by 3-Bromopyruvate or Fx11. Results: Resting RASF showed a significantly higher production of lactate, IL-6 and MMP-3 compared to OASF. Stimulation by activated Th cells strikingly changed the metabolic profile of both SF by inducing a shift towards aerobic glycolysis with strongly increased lactate production. In parallel, a significant increase in IL-6 and MMP-3 secretion was induced. Interestingly, blocking of either JAKs or of glycolysis significantly reduced both the production of lactate and the secretion of inflammatory cytokines. Conclusions: A Th cell-mediated metabolic switch towards aerobic glycolysis in SF could likely be an important step in the pathogenesis of RA. Targeting this mechanism by JAK- or glycolytic inhibitors may provide a new strategy in RA therapy.

P.C1.08.15

Mammary gland involution stimulates severe local inflammation that promotes breast cancer tumourigenesis

***A. Unsworth**[1], R. Anderson[2], N. Haynes[3], K. Britt[3];*
[1]Peter MacCallum Cancer Centre, Department of Oncology, Melbourne, Australia, [2]Olivia Newton-John Cancer Wellness & Research Centre, Heidelberg, Australia, [3]Sir Peter MacCallum Cancer Centre, Department of Oncology, Melbourne, Australia.

During reproduction the breast undergoes significant structural changes to prepare for breastfeeding. Once breastfeeding ceases, the mammary gland undergoes rapid tissue remodeling, which is likened to a wound-healing response. While this process is tightly controlled, the wound-healing environment during involution is also known to be ideal for tumor development. Preliminary transcriptional analysis suggests the immune system may play a critical role in increasing breast cancer risk during involution, as inflammatory markers are significantly up-regulated in the involuting mammary gland.
Our study aims to examine the specific composition of immune cells in the mouse mammary gland during reproduction, specifically involution (repair) and parous (resting) using a multi-panel flow cytometry approach and cytokine bead analysis. To determine the effects of these reproductive environments on breast tumor development, syngeneic mammary tumor cells were introduced orthotopically into involuting, parous and nulliparous mice.
The involuting mammary gland exhibits a significant increase in myeloid cells, coupled with decreases in T and B-lymphocytes and expansion of pro-inflammatory cytokines compared to nulliparous glands. This inflammatory environment stimulates mammary tumor growth at a faster rate compared to that of a resting nulliparous gland. The parous mammary gland (assessed 9-weeks post-involution) showed complete resolution of this inflammatory microenvironment, consequently having no effect on tumor growth rate in mice.
The involuting mammary gland exhibits a strong inflammatory microenvironment, which we show promotes the development of breast cancer. We are currently investigating immune targeted therapeutics that could be used to reduce this local inflammation and consequently decrease breast cancer risk during involution.

P.C1.08.16

Human myometrial CD4 T cells at the maternal-fetal interface are tissue-resident memory T cells, which show site-specific adaptation within the uterus

***J. Wienke**[1], L. Brouwers[1], T. E. Vogelvang[2], A. Franx[1], B. B. Van Rijn[1], F. Van Wijk[1];*
[1]UMC Utrecht, Utrecht, Netherlands, [2]Diakonessenhuis, Utrecht, Netherlands.

Introduction: The uterine myometrium is a unique immune environment, capable of harboring a 'foreign' fetus without eliciting an immune response. We aimed to investigate the presence, adaptation and function of human myometrial CD4 T cells at the maternal-fetal interface in uncomplicated pregnancy.
Methods: Myometrial biopsies were obtained at caesarean section from placental and incision site. Lymphocytes were isolated through dissection and digestion with collagenase IV. CD4 T cells were analyzed by flow cytometry or FACS sorted for RNA sequencing by CEL-seq protocol. Suppression assays were performed with FACS sorted uterine regulatory T cells (Tregs).
Results: 70-80% of myometrial CD4 T cells were CD69+, suggesting a tissue-resident memory (TRM) phenotype. RNA sequencing confirmed a TRM-like profile in CD69+ cells, with high expression of CD49a, CXCR6, DUSP6, PD-1 and low expression of CD62L, KLF2/3 and S1PR1 compared to blood memory CD4 T cells. Interestingly, expression of negative costimulatory molecules such as PD-1, TIGIT, Lag3, TIM-3 and CTLA4 on the CD4 T cells, as well as the percentage of Treg cells, was higher at the placental site compared to the incision site of the uterus. Suppression assays confirmed the suppressive capacity of myometrial Tregs.
Conclusion: Myometrial CD4 T cells at the maternal-fetal interface are TRM cells with a high expression of negative costimulatory molecules and a high abundance of functional Tregs. The topographical distribution of these immunoregulatory features indicates that T cells may not only adapt to a tissue, but also to specific sites within one tissue, possibly depending on the local micro-environment.

P.C1.08.17

Defective Regulatory T cells and B cell Subsets Are Associated with Autoimmunity in Common Variable Immunodeficiency Patients

***R. Yazdani**, G. Azizi, H. Abolhassani, F. Kiaee, A. Mirshafiey, A. Aghamohammadi;*
Research Center for Immunodeficiencies (RCID), Tehran, Iran, Islamic Republic of.

Introduction: Common variable immunodeficiency (CVID) is one of the most prevalent symptomatic primary immunodeficiencies (PIDs), which manifests a wide clinical variability such as autoimmunity, as well as T cell and B cell abnormalities. **Methods:** A total of 72 patients with CVID were enrolled in this study. Patients were evaluated for clinical manifestations and classified according to the presence or absence of autoimmune disease. We measured regulatory T cells (Tregs) and B-cell subsets using flow cytometry, as well as specific antibody response (SAR) to pneumococcal vaccine, autoantibodies and anti-IgA in patients. **Results:** Twenty-nine patients (40.3%) have shown at least one autoimmune manifestation. Autoimmune cytopenias and autoimmune gastrointestinal diseases were the most common. A significant association was detected between autoimmunity and presence of hepatomegaly and splenomegaly. Among CVID patients, 38.5% and 79.3% presented a defect in Tregs and switched memory B-cells, respectively, whereas 69.0% presented CD21low B cell expansion. Among patients with a defect in Treg, switched memory and CD21low B cell, the frequency of autoimmunity was 80.0%, 52.2% and 55.0%, respectively. A negative correlation was observed between the frequency of Tregs and CD21low B cell population. 82.2% of patients had a defective SAR which was associated with the lack of autoantibodies. **Conclusion:** Autoimmunity may be the first clinical manifestation of CVID, thus routine screening of immunoglobulins is suggested for patients with autoimmunity. Lack of SAR in CVID is associated with the lack of specific autoantibodies in patients with autoimmunity. It is suggested that physicians use alternative diagnostic procedures.

P.C1.08.18

Regulatory function of B cells on T cell immunity during viral infection is controlled by the surface receptor Toso

***J. Yu**, N. Föger, K. Lee;*
Inflammation Research Group, Institute of Clinical Chemistry, Hannover Medical School, Hannover, Germany.

The immune system is tightly controlled by regulatory processes that allow for the elimination of invading pathogens, while limiting immunopathological damage to the host. In this study, utilizing conditional gene deletion, we demonstrate a critical immunoregulatory role of the cell surface receptor Toso, that, via a B cell-inherent mechanism, provides protective T cell immunity against viral infection. Employing conditional gene deletion, our study revealed that impaired anti-viral T cell responses in Toso deficient mice, were not due to T cell inherent defects, but rather induced by a previously unrecognized function of Toso in B cells. We specifically demonstrated that the deletion of Toso in B cells results in impaired inflammatory T cell responses, such as production of TNFα and IFNγ, in response to influenza A infection. Further studies showed that Toso deficiency in B cells results in a strong increase of IL-10-competent B cells *in vivo*, and, as we further demonstrate through adoptive transfer experiments, this specific subtype of B cells mediates immunosuppressive activity on T cell immunity during influenza A infection. Thus, Toso exhibits its immunoregulatory function by controlling a pool of IL-10-competent regulatory B cells. In addition, we demonstrate that during influenza A-induced pulmonary inflammation the application of Toso-specific antibodies selectively induces IL-10-competent B cells at the site of inflammation and results in decreased proinflammatory cytokine production by lung T cells. These findings suggest that Toso may serve as a novel therapeutic target to dampen pathogenic T cell responses via the modulation of IL-10-competent regulatory B cells.

P.C1.08.19

Roquin deficiency in T cells induces early stages of pancreatic cancer

***T. Raj**[1], J. Zöller[2], D. Hu[1], G. Bianco[2], M. Heikenwälder[2], V. Heissmeyer[1,3];*
[1]Biomedical Center Munich, Institute for Immunology, LMU Munich, Planegg - Martinsried, Germany, [2]Department of Chronic Inflammation and Cancer, German Cancer Research Center, Heidelberg, Germany, [3]Research Unit Molecular Immune Regulation, Helmholtz Zentrum München, Munich, Germany.

Our immune system not only prevents cancer development by eliminating transformed cells, it can also drive chronic inflammation causing tissue insult and the development of cancer. Acute and chronic pancreatitis are strongly implicated in the development of pancreatic ductal adenocarcinoma (PDAC), the most frequent form of pancreatic cancer and one of the leading causes of cancer deaths worldwide.
Investigating mice with combined Roquin-1 and Roquin-2-deficiency in T cells we show that chronic T cell activation can lead to autoimmune pancreatitis, acinar-to-duct metaplasia (ADM) and formation of PanIN1A (pancreatic intraepithelial neoplasia) lesions in mice. Pancreatic damage increases with age, with half of the mice aged 10 - 20 weeks exhibiting precursor lesions. Pancreata were infiltrated with inflammatory cells and pSTAT3 levels were strongly increased, pointing towards a potential role of IL-6 mRNA deregulation in T cells during the development of Roquin mediated pancreatic pathology. These mice produced autoantibodies against pancreatic antigens, suggesting an involvement of Tfh cells. Combined genetic inactivation of the Roquin encoding alleles as well as of its target Ox40 lead to a partial rescue and an improved phenotype. Currently, we are investigating the contributions of Tfh and Th17 cells to the pancreatic pathology. Furthermore, we are evaluating antibodies against Roquin dependent surface antigens as potential biomarkers for PDAC in mice and humans.
We propose that mice with conditional Roquin deletion in T cells are a useful model to study how chronic inflammation and autoimmune pancreatitis trigger the development of neoplasia and pancreatic cancer.

Expression Pattern of TIPE1 Insights into its Functions

***S. Liu**, J. Shao, Y. Li, G. Jin, C. Gao;*
Department of Immunology, Ji'nan, China.

Members of the tumor necrosis factor-alpha-induced protein-8 (TNFAIP8 or TIPE) family play important roles in immune homeostasis and cancer. TIPE1 (TNFAIP8-like 1) is a new member of the TIPE family that may regulate cell death. We found that TIPE1 protein was detected in a wide variety of tissues in C57BL/6 mice and a variety of cells of the epithelial origin, particularly those with secretory functions. High levels of TIPE1 mRNA were detected in most human carcinoma cell lines. TIPE1 is also detectable in endothelial cells, which can induce endothelial dysfunction when exposed to oxidative stress and resulting in atherogenesis in ApoE-/- mice.

P.C1.08.21

Characteristics of gamma/delta T cells at the feto-maternal interface of murine pregnancy

***J. M. Nörenberg**[1], M. Meggyes[1,2], P. Jáksó[3], A. Barakonyi[1,2];*
[1]Department of Medical Microbiology and Immunology, Medical School, University of Pecs, Pécs, Hungary, [2]János Szentágothai Research Centre, Pécs, Hungary, [3]Department of Pathology, Medical School, University of Pécs, Pécs, Hungary.

Pregnancy is an immunological enigma where paternal antigens are present at the feto-maternal-interface. What regulates the local immunotolerance which is necessary to prevent rejection of the conceptus is still under strong investigation. Gamma/delta T cells are believed to play a role in the local regulation of this immunotolerance towards the semi-allogenic fetus. Gamma/delta T cells from uterus and spleen of pregnant and non-pregnant mice were analyzed by flow cytometry.The ratio of γδT cells in the decidua associated lymphoid tissue increases during the course of murine pregnancy. Those decidual γδT cells are in large part $\gamma\delta TCR^{dim}/CD4^{+}$, whereas $\gamma\delta TCR^{bright}$cells are mainly $CD4^{-}$. Furthermore, compared to peripheral γδT cells, a greater proportion of decidual γδT cells express CD107a, TIM-3 and TIM-1, by contrast no difference in the expression of CD160 was detected. Within lymphocytes expressing CD107a, TIM1 or CD160, the rate of γδT cells is significantly higher in the decidua. Accordingly, γδT cells seem to influence the Th1-Th2 balance, which is crucial to provide protection against pathogens, while mediating tolerance towards the semi-allograft.This study was supported by a grant from the University of Pécs (AOK-KA/13-03/34039) and by TÁMOP 4.2.4. A/2-11-1-2012-0001. The present scientific contribution is dedicated to the 650th anniversary of the foundation of the University of Pécs, Hungary.

P.C2.01.01

Identification and characterization of novel toll-like receptor 3 mutations in patients with autoimmune Addison's disease

***S. Aslaksen**, E. Bratland, E. Husebye;*
Department of Clinical Science and KG Jebsen Center for autoimmune diseases, Bergen, Norway.

Autoimmune Addison's disease (AAD) is a classic organ-specific autoimmune disease characterized by an immune-mediated attack on the adrenal cortex. As most complex autoimmune diseases, AAD is believed to be caused by a combination of genetic and environmental factors. Prolonged or persistent viral infections have been suggested to play an important role in triggering the autoimmune destruction, by invoking increased inflammation and autoimmunity. Such infections can be caused by aberrations in innate immunity, including mutations in Toll-like receptor 3 (TLR3). TLR3 recognizes double stranded RNAs, and is therefore a major factor in antiviral defense. It is expressed and functional in the adrenal cortex, which has been suggested to serve as a reservoir of infection for several viral species. Here we report two novel missense mutations, F351I and G221R, as well as three previously described mutations, T59N, R867Q and L412F, in TLR3 in patients with AAD. Their biological implications on TLR3's function were evaluated in cell-culture models, revealing a devastating effect of F351I and R867Q. F351I was present in two Norwegian patients with AAD, but was not found in 379 Norwegian blood donors or in the Exome Aggregation Consortium (ExAC) database. Together, these findings suggest a potential role for TLR3 in the pathogenesis of AAD.

P.C2.01.02

The anti-inflammatory neuropeptide cortistatin plays a critical role in the development and progression of atherosclerosis

***R. Benítez**[1], I. Forte-Lago[1], F. O'Valle[2], M. Delgado[1];*
[1]Institute of Parasitology and Biomedicine Lopez Neyra, CSIC, Granada, Spain, [2]Department of Pathology, School of Medicine, University of Granada, Granada, Spain.

Atherosclerosis is a chronic inflammatory and autoimmune cardiovascular disease that causes important adverse circulatory events and is responsible of high mortality worldwide. Cortistatin is a neuropeptide produced by immune cells and expressed in the vascular system and atherosclerotic plaques that inhibits inflammation in different experimental models of autoimmune diseases, including atherosclerosis. Here, we investigated whether a deficiency in cortistatin predisposes to suffer exacerbated atherosclerosis by using established preclinical mouse models. We generated mice that lack of apolipoprotein E ($apoE^{-/-}$) and are totally ($CST^{-/-}$, KO) or partially ($CST^{+/-}$, HET) deficient in cortistatin. Mice were subjected to carotid partial ligation and fed a hyperlipidemic diet for four weeks to induce acute localized plaques, or alternatively were fed a normal or hypercholesterolemic diet for various weeks to induce chronic atherosclerotic plaques in aorta and aortic sinus. We observed that $apoE^{-/-}$CST-ko and $apoE^{-/-}$CST-het mice developed higher (number and size) atherosclerotic plaques in carotid artery, heart, aortic arch and aorta than $apoE^{-/-}$CST-wt mice fed a high-lipid diet. Interestingly, total or partial deficiency in cortistatin predisposed significantly to increased mortality during the progression of this disease.

Even with normal diet, apoE$^{-/-}$CST-ko and apoE$^{-/-}$CST-het mice showed early severe atherosclerotic plaques in heart and aortic arch. Lack of cortistatin did not change serum cholesterol, but increased the presence of lipid-loaded macrophages and of Th1 and Th17 cells in plaques and draining-lymph nodes and of inflammatory M1 macrophages in peritoneum. Our findings demonstrate the endogenous role of cortistatin in the regulation of and potential predisposition to inflammatory cardiovascular disorders.

The effect of HLA on autoantibody isotypes & cytokine production in myasthenia gravis with autoantibodies to muscle specific tyrosine kinase (MuSK-MG)

M. CEBI[1], *H. DURMUS*[2], *S. YENTUR*[1], *V. YILMAZ*[1], *F. AYSAL*[3], *Y. PARMAN*[2], *P. OFLAZER*[2], *F. DEYMEER*[2], *G. SARUHAN-DIRESKENELI*[1];
[1]*ISTANBUL UNIVERSİTY, ISTANBUL MEDICINE FACULTY, DEPARTMENT OF PHYSIOLOGY, İSTANBUL, Turkey,* [2]*ISTANBUL UNIVERSİTY, ISTANBUL MEDICINE FACULTY, DEPARTMENT OF NEUROLOGY, İSTANBUL, Turkey,* [3]*Bakırköy Sadi Konuk State Hospital, İSTANBUL, Turkey.*

A small subset of myasthenia gravis (MG) develops with autoantibodies against muscle-specific kinase (MuSK). These anti-MuSK autoantibodies are predominantly of IgG4 isotype. MuSK-MG is strongly associated with *HLA-DQB1*05* with *HLA-DRB1*14* or *HLA-DRB1*16*. In this study, the effect of these HLA-associations on the anti-MuSK IgG autoantibody isotype and antibody-related cytokine production was investigated.
Among all patients with MG who were followed at the Neuromuscular Unit of the Department of Neurology of Istanbul Medical Faculty, 80 patients with anti-MuSK antibodies were selected. Disease-associated HLA types were detected in the collected DNA samples. Anti-MuSK-IgG1, -IgG2, -IgG3 and -IgG4 antibody titers and levels of IL-6, IL-17A and IL-10, measured in the sera by ELISA, compared between the groups with or without *HLA-DQB1*05, HLA-DRB1*14* or *HLA-DRB1*16* by non-parametric tests.
Anti-MuSK-IgG4 titers were significantly higher than -IgG1, -IgG2 and -IgG3 isotypes ($p< 0.0001$, $p< 0.0001$, $p< 0.0001$) in the whole group of patients. Anti-MuSK-IgG1 titers were also relatively higher than -IgG2 and -IgG3 titers ($p< 0.0001$, $p< 0.0001$). When the titers were compared between HLA subgroups, *DRB1*14 (+)* MuSK-MG patients had higher IgG4 and IgG1 titers than *DRB1*14 (-)* patients ($p= 0.017$, $p= 0.0002$). Higher IL-10 ($p= 0.048$) and lower IL-17A ($p= 0.011$) levels were measured in *DRB1*14* (+) patients compared to *DRB1*14 (-)* patients. No other differences were detected.
Higher titers of anti-MuSK-IgG4 and -IgG1 autoantibodies in *HLA-DRB1*14* (+) patients suggest the role of HLA in isotype switching. Differences of IL-17A and IL-10 in *HLA-DRB1*14* subgroups strengthen the role of *DRB1* in this autoimmune response.

P.C2.01.05

A diet high in fibre can moderate inflammation and kidney pathology in a model of systemic lupus erythematosus

T. A. Gottschalk*, E. Tsantikos, M. L. Hibbs;*
Monash University, Melbourne, Australia.

Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease mediated by the deposition of immune complexes in tissues including the kidney, with the ensuing inflammatory cascade driving progressive tissue damage and dysfunction. Mice lacking Lyn tyrosine kinase (Lyn$^{-/-}$ mice) develop an autoimmune disease similar to SLE, driven by dysregulation of the immune system, immune complex deposition in tissue and systemic inflammation culminating in progressive glomerulonephritis. The gut microbiome has been shown to have an immunoregulatory effect on the development of autoimmune and inflammatory diseases, in large part due to the production of short chain fatty acids from the fermentation of dietary fibre. To determine whether dietary fibre could moderate systemic autoimmune and inflammatory pathology, Lyn$^{-/-}$ mice and control C57BL/6 mice were fed a high fibre diet (HFD) or a standard control diet from weaning until 42 weeks old. On the control diet, Lyn$^{-/-}$ mice developed lymphopenia, splenomegaly from enhanced splenic myelopoiesis, immune cell hyperactivation, and pathogenic IgG anti-dsDNA autoantibodies resulting in glomerulonephritis.
These hallmarks of inflammation and autoimmune disease were significantly moderated in HFD fed Lyn$^{-/-}$ mice, indicating that dietary intervention is effective at dampening chronic systemic inflammation and glomerular pathology. These findings highlights the contribution of diet and the gut microbiome in regulating systemic immune responses and controlling autoimmunity, inflammation, and preventing the progression of immunopathology and suggests that fibre supplementation may improve outcomes for those living with SLE or other chronic systemic inflammatory diseases. This work was funded by grants from the NHMRC of Australia and Monash CCS.

P.C2.01.06

CD11b regulates inflammation, autoimmunity and associated pathology in a model of systemic lupus erythematosus

T. A. Gottschalk*, E. Tsantikos, M. L. Hibbs;*
Monash University, Melbourne, Australia.

Systemic Lupus Erythematosus (SLE) is a complex, heterogeneous autoimmune disease characterized by circulating self-reactive antibodies that deposit in tissues including the kidneys, alongside a chronic inflammatory response that leads to progressive tissue damage and impaired function. Genome-wide association studies have identified a number of receptors and signal transduction molecules specific for the immune system that predispose to the development of SLE. A loss-of-function single nucleotide polymorphism in the *Itgam* gene encoding leukocyte integrin CD11b (rs1143679) has been identified which associates with an increased incidence of SLE, implicating CD11b as a protective factor against disease development. To understand the role that CD11b plays in controlling autoimmune disease, we crossed CD11b deficient mice (CD11b$^{-/-}$) with Lyn deficient (Lyn$^{-/-}$) mice, a well-studied, robust model of human SLE. Double knockout Lyn$^{-/-}$CD11b$^{-/-}$ mice were analysed over time for development of autoimmune disease and inflammation. While aged mice lacking CD11b alone did not develop autoimmune disease, deficiency of CD11b on the Lyn-deficient autoimmune-prone background exacerbated disease, driving splenomegaly and lymphadenopathy, extramedullary haematopoiesis, autoantibody production and glomerulonephritis, which heavily impacted survival. These findings confirm that CD11b is an autoimmune susceptibility gene that when mutated can exacerbate the severity of disease on a susceptible genetic background. This work highlights an important role for CD11b in regulating and controlling the progression of inflammation and autoimmune disease. This work was funded by grants from the NHMRC of Australia and Monash CCS.

P.C2.01.07

Integration of genome-wide DNA methylation and transcription uncovered aberrant methylation-regulated genes and pathways in the peripheral blood mononuclear cells of systemic sclerosis

Q. Li[1], *H. Zhu*[2], *C. Zhu*[1], *W. Mi*[1], *H. Luo*[2], *X. Zuo*[2];
[1]*University of Texas Southwestern Medical Center, Dallas, United States,* [2]*Xiangya Hospital, Central South University, Changsha, China.*

Objectives: The aim is to delineate the interaction network between gene transcription and DNA methylation in PBMC of systemic sclerosis (SSc) patients and to identify methylation-regulated genes involved in the pathogenesis of SSc. Methods: Genome-wide mRNA transcription and global DNA methylation analysis were performed on PBMC from 18 SSc patients and 19 matched normal controls (NC) using Illumina BeadChips. Differentially expressed genes (DEGs) and differentially methylated positions (DMPs) were integratively analyzed to identify methylation-regulated genes and associated molecular pathways. Results: Transcriptome analysis distinguished 453 DEGs (269 up- and 184 down-regulated) in SSc from NC. Global DNA methylation analysis identified 925 DMPs located on 618 genes. Integration of DEGs and DMPs revealed 20 potential methylation-regulated DEGs (MeDEGs), including 12 up-regulated genes (ELANE, CTSG, LTBR, C3AR1, CSTA, SPI1, ODF3B, SAMD4A, PLAUR, NFE2, ZYX and CTSZ) and eight down-regulated genes (RUNX3, PRF1, PRKCH, PAG1, RASSF5, FYN, CXCR6 and F2R), are predominantly involved in the migration, proliferation, activation and inflammation of immune cells. Support vector machines analysis identified six out of the 20 MeDEGs, including F2R, CXCR6, FYN, LTBR, CTSG and ELANE, which clearly distinguished SSc from NC with 100% accuracy. The expression for four MeDEGs, F2R, FYN, PAG1 and PRKCH, significantly decreased in SSc with interstitial lung disease (ILD) compared with NC or SSc without ILD. Conclusion: The identified MeDEGs may represent novel candidate factors in the etiology and pathology of SSc and may lead to the abnormal activation of immune regulatory pathways and potentially contribute to the pathogenesis of SSc.

P.C2.01.08

C1q restrains autoimmunity and viral infection by regulating CD8$^+$T-cell metabolism

G. Ling[1], *G. Crawford*[1], *N. Buang*[1], *I. Bartok*[1], *K. Tian*[1], *N. Thielens*[2], *I. Bally*[3], *J. Harker*[1], *P. Ashton-Rickardt*[1], *S. Rutschmann*[1], *J. Strid*[1], *M. Botto*[1];
[1]*Imperial College London, London, United Kingdom,* [2]*University Grenoble Alpes, Grenoble, France,* [3]*University Grenoble Aples, Grenoble, France.*

Deficiency of complement C1q, the first component of the classical pathway, is strongly associated with the development of systemic lupus erythematosus (SLE). Explaining this strong association in terms of abnormalities in the classical complement pathway alone remains problematic because C3 deficiency does not predispose to SLE. Here we demonstrate, using a chronic graft-versus-host-disease (cGvHD) lupus model, that C1q, but not C3, restrains the immune response to self-antigens by controlling effector CD8$^+$ T cells. In the absence of C1q, the turnover of the memory precursor effector CD8$^+$T cells was accelerated because the mitochondrial spare respiratory capacity, which provides bioenergetic advantage for survival, was reduced. This C1q-mediated metabolic effect favoured the expansion of the short-lived effector CD8$^+$T cells which are the main source of granzyme B that can generate unique autoantigen fragments. Furthermore, depletion of CD8$^+$T cells limited the propagation of the autoimmune response in cGvH-induced *C1qa*$^{-/-}$mice, indicating the direct contribution of these cells to the disease progression. Consistent with the findings in the SLE-cGvHD model, C1q deficiency also triggers an exuberant effector CD8$^+$ T-cell response to chronic lymphocytic choriomeningitis virus infection leading to lethal immunopathology. Our results demonstrate that C1q, independently of complement activation, operates as a key determinant in the development of a balanced effector CD8$^+$ T response.These data establish a link between C1q and CD8$^+$T-cell metabolism and may explain how C1q protects against lupus, with implications for the role of viral infections in the perpetuation of autoimmunity.

P.C2.01.09

Exploiting annexin-mediated immunosuppression to induce antigen-specific tolerance

***C. S. Link**, F. Bujupi, H. Weyd, P. H. Krammer;*
German Cancer Research Center (DKFZ), 69120 Heidelberg, Germany.

Apoptotic cells mediate immunosuppression of dendritic cells (DC) and inhibit immune responses. Thereby, apoptotic cells facilitate the induction of peripheral tolerance and the prevention of autoimmune diseases. We investigate the influence of apoptotic cells on DC and identified the cell surface exposure of the evolutionary conserved annexin core domain (Anx) as a specific signal, which binds to specific receptors on DC and antagonises Toll-like receptor signalling. To further test this tolerogenic capacity of Anx for potential downregulation of antigen-specific immune responses, we generated beads harbouring Anx as well as the model antigen ovalbumin (OVA). Treating BMDC with either Anx-OVA beads (OAB) or with OVA-beads (OB) as a control and subsequent co-culture with OVA-specific $CD4^+$ T cells, we could show diminished T cell activity in the presence of Anx. Furthermore, Anx leads to reduction of cytokine secretion (IL-2, IFN-γ) and of proliferation that suggests induction of T cell anergy by the OAB treatment. These results indicate that coupling of Anx and a defined antigen or allergen in a therapeutic bead preparation might be used as a new approach to downregulate pathologic immune responses in the context of autoimmunity and allergy.

P.C2.01.10

Selective inhibition of gelatinases in CD4+ T-cells reduces clinical severity in a murine model of multiple sclerosis

***L. Onwuha-Ekpete**, D. Tokmina-Roszyk, G. B. Fields;*
Florida Atlantic University, Jupiter, United States.

Introduction: MMP-2 and MMP-9 are the gelatinase members of the matrix metalloproteinase (MMP) family of proteolytic enzymes that mediate the degradation of extracellular matrix components. MMPs are essential for normal physiological processes, but their dysregulation is associated with various pathologies including multiple sclerosis (MS). Experimental autoimmune encephalomyelitis (EAE) is a well-established murine model of MS. In EAE, CD4+ T-cells activated in the periphery penetrate the blood-brain barrier (BBB), recruit immune cells, initiate destruction of the myelin sheath, and cause axonal loss. The gelatinases are required for these various processes. Recent studies have implicated the gelatinases in normal T-cell activation; however, the mechanism of action is not known. Materials and Methods: For *in vitro* assays, CD4+ T cells were activated with CD3/CD28 mAb beads after prior treatment with a gelatinase inhibitor. For *in vivo* assays, EAE mice were treated daily from Day 7 with vehicle or inhibitor and disease progression monitored. Results: Upon activation, CD4+ T-cells treated with inhibitor demonstrated a reduced ability to enter cell cycle, proliferate, and produce cytokines. In addition, RNA-seq analysis highlighted key proteins associated with the T-cell receptor signaling pathway that are impacted. Furthermore, treatment of EAE mice with an MMP-2/MMP-9 inhibito resulted in reduced clinical severity. Conclusion: In our studies, we demonstrated that the gelatinases are important for homeostatic maintenance as well as a robust antigenic stimulation. These results emphasize the importance of gelatinases as therapeutic targets in CD4+ T-cell mediated autoimmune diseases.

P.C2.01.11

Hyperglycemia-dependent NF-kappaB O-GlcNAcylation acts as a molecular switch regulating T cell and T reg cell function in autoimmunity

***P. Ramakrishnan**, T. de Jesus, L. Liu;*
Case Western Reserve University, Cleveland, United States.

Type 1 diabetes is an autoimmune disease associated with hyperglycemia. Adverse pathological effects of hyperglycemia include posttranslational modification of proteins by the sugar N-acetyl glucosamine (GlcNAc) in a process called O-GlcNAcylation. We found that hyperglycemia induces O-GlcNAcylation of NF-kappaB protein c-Rel, which is a critical regulator of T cell function and T regulatory cell development. O-GlcNAcylation of c-Rel at serine 350 activates c-Rel-dependent transcription of proautoimmune cytokines and inhibits the expression of T regulatory cell specific transcription factor FOXP3. Thus, c-Rel O-GlcNAcylation may serve as a key regulatory switch with dual, but reciprocal, roles in positively regulating autoimmune T cell and negatively regulating immunosuppressive T regulatory cell function. The net result of these two opposing effects may exacerbate autoimmunity in type 1 diabetes. This study reveals c-Rel O-GlcNAcylation as a disease-dependent novel molecular mechanism regulating autoimmunity and a potential therapeutic target to control autoimmunity in type 1 diabetes.

P.C2.01.12

High-throughput screening for Lck-coreceptor coupling inhibitor

***K. Ruppova**, V. Horkova, O. Stepanek;*
Institute of Molecular Genetics of the ASCR, Prague, Czech Republic.

TCR-mediated activation of T lymphocytes is the key event for the initiation of adaptive immune response that is directed against pathogens but also against self-antigens in the case of autoimmune diseases. The initiation of TCR signaling is promoted by coreceptors CD4 and CD8 that mediate the interaction of TCR signaling complex with Lck kinase which triggers downstream signaling. We developed a functional model to study Lck-coreceptor coupling. Our data show that Lck-coreceptor coupling is especially important for T cell activation by low affinity antigens and that T cell activation increases with increased Lck-coreceptor coupling. Moreover, it was shown that, in contrast to foreign antigens, self-antigens are recognized with low affinity by TCR of autoreactive T cells that escaped negative selection in thymus. Thus, we assume that inhibiting of Lck-coreceptor interaction should prevent activation of autoreactive T cells that are the main cause of autoimmune diseases while leaving the protective immunity against foreign antigens unaffected.
The association of Lck and coreceptor is mediated by a unique protein-protein interaction where two cysteines from each partner are coordinated by a zinc cation. Thus, we will perform a high-throughput screening to find an inhibitor of this interaction using peptides derived from Lck and CD4 or CD8. Candidate molecules will be tested to inhibit the interaction in living cells using FRET technique and later to inhibit TCR signaling using luciferase reporter system. Selected molecule(s) will be finally tested to inhibit autoimmunity in mouse models.

P.C2.01.13

Thymol blunts experimental autoimmune orchitis-induced reproductive failure in BALB/c mice

*E. Yarahmadi, **A. Shalizar-Jalali**, G. Najafi, M. Abtahi-Foroushani;*
Faculty of Veterinary Medicine, Urmia University, Urmia, Iran, Islamic Republic of.

Introduction: Autoimmune orchitis as an autoimmune aggression to testis can result in male subfertility and/or infertility. This study was aimed to scrutinize the possible repro-protective activity of thymol (TML) against experimental autoimmune orchitis (EAO)-induced alterations in testicular histoarchitecture and epididymal sperms characteristics and *in vitro* fertilizing potential in mice.
Materials and Methods: In this experimental study, 36 adult male BALB/c mice were randomly categorized to six equal groups including untreated, TML (100 $mgkg^{-1}$BW/day; orally for 5 weeks), antigen (100 µl; subcutaneously) and *Bordetella pertussis* (10^9 bacteria at the day of antigen injection and 48 hours later; intraperitoneally) control groups, EAO and EAO + TML. The EAO was induced through testicular homogenate plus complete Freund's adjuvant plus *B. pertussis* injection. All animals were euthanized after 5 weeks and testicular histoarchitecture as well as epididymal sperms characteristics and *in vitro* fertilizing ability were analyzed.
Results: The EAO caused significant reductions in the seminiferous tubules diameter, germinal epithelium height, quality and maturation along with severe testicular morphological alterations including spermatogenic cells maturation arrest, seminiferous tubules depletion and also multinuclear giant cells formation compared to control, TML, antigen and *B. pertussis* groups. Moreover, EAO resulted in epididymal sperms quantity, quality and fertilizing potential reduction as well as embryo development impairment. While, TML co-administration led to remarkable amelioration of EAO-induced reproductive disorders.
Conclusions: These findings revealed that TML has repro-protective activities against EAO-evoked disorders in male mice reproductive system.
This study was funded by Urmia University, Urmia, Iran.

Paquinimod prevents development of diabetes in the non-obese diabetic (NOD) mouse

***S. Tahvili**[1], M. Törngren[2], D. Holmberg[1], T. Leanderson[1], F. Ivars[1];*
[1]Lund university, Lund, Sweden, [2]Active Biotech AB, Lund, Sweden.

Introduction: Quinoline-3-carboxamides (Q compounds) are immunomodulatory compounds that have shown efficacy both in autoimmune disease and cancer. We have in here investigated the impact of one such compound, paquinimod, on the development of diabetes in the NOD mouse model for type I diabetes (T1D).Methods and Results: In cohorts of NOD mice treated with paquinimod between weeks 10 to 20 of age and followed up until 40 weeks of age, we observed dose-dependent reduction in incidence of disease as well as delayed onset of disease. Further, in contrast to untreated controls, the majority of NOD mice treated from 15 weeks of age did not develop diabetes at 30 weeks of age. Importantly, these mice displayed significantly less insulitis, which correlated with selectively reduced number of splenic macrophages and splenic $Ly6C^{hi}$ inflammatory monocytes at end point as compared to untreated controls. Conclusion: Collectively, these results demonstrate that paquinimod treatment can significantly inhibit progression of insulitis to T1D in the NOD mouse. We propose that the effect of paquinimod on disease progression may be related to the reduced number of these myeloid cell populations. Our finding also indicates that this compound could be a candidate for clinical development towards diabetes therapy in humans.

P.C2.01.15

Astrocytic ShcC/Rai supports the function of autoreactive T cells during EAE by modulating adenosine-dependent CTLA4 expression through the inhibition of CD39 and CD73 activity

C. Ulivieri[1], *D. De Tommaso*[1], *F. Finetti*[1], *B. Ortensi*[2], *G. Pelicci*[3], *M. D'Elios*[4], *C. Ballerini*[4], *C. T. Baldari*[1];
[1]*University of Siena, Siena, Italy,* [2]*European Institute of Oncology, Milano, Italy,* [3]*University "Amedeo Avogadro" Novara, Novara, Italy,* [4]*University of Florence, Florence, Italy.*

Autoreactive T cell recruitment and activation in the central nervous system (CNS) are two recognized pathogenic processes in Multiple Sclerosis (MS). Recent data indicate, however, that the interplay between cells resident in the CNS, including astrocytes, and infiltrated T cells is instrumental for disease onset and progression. In this context, while the impact of astrocytes on the T cell dependent autoimmune response has been partially addressed, how autoreactive T cells modulate astrocytes during experimental autoimmune encephalomyelitis (EAE) has not been explored. We have recently demonstrated that ShcC/Rai is as a novel astrocytic adaptor whose loss in mice accounts for a milder EAE notwithstanding a higher frequency of CNS infiltrated autoreactive T cells. Here we have explored and characterized the molecular mechanism that underlies the reciprocal modulation of astrocytes and autoreactive T cells, focusing on the role of ShcC/Rai. We found that astrocytes respond to autoreactive T cellsinjury by upregulating the ectonucleotidases CD39 and CD73 through both contact-dependent and -independent mechanisms. We also demonstrate that Rai dampens the enzymatic activity of CD39 and CD73 in astrocytes, thereby preventing the degradation of pro-inflammatory extracellular ATP to its immunosuppressive metabolite adenosine and hence supporting the pathogenic potential of autoreactive T cells. Accordingly, we found that the microenvironment shaped by Rai deficient astrocytes inhibited T cell proliferation and TCR signaling more efficiently compared with control astrocytes by promoting adenosine-dependent CTLA4 upregulation in recently activated T cells. Collectively, we have identified a new mechanism by which astrocytes sustain the pathogenic potential of autoreactive T cell.

New insights into Cyclin D3 signaling involved in beta cell wellness and survival

C. Vived*, C. Santos-Rosendo, M. de la Torre, L. Egia-Mendikute, M. Corral-Pujol, E. Rosell-Mases, J. Verdaguer, C. Mora;*
University of Lleida/IRB Lleida, Lleida, Spain.

Introduction: Autoimmune diabetes is caused by the destruction of insulin producing pancreatic beta cells. Cyclin D3 is involved in CDK-dependent cell cycle progression. Nevertheless, our group has reported that cyclin D3, which is downregulated in beta cells upon inflammation, is essential for protecting beta cells in front of the inflammation-induced apoptosis and for maintaining proper function of beta cells, both in a cell-cycle independent fashion. Materials and Methods: We have identified by the yeast two-hybrid technology (Y2H) a number of molecules other than the CDKs that physically interact with cyclin D3 to unveil potential signaling pathways responsible for the protective role of cyclin D3 in front of the autoimmune insult. Results: We have observed that cyclin D3 interacts with proteins involved in diverse physiological processes. We are assessing the physical interaction between cyclin D3 and the different candidates in eukaryotic cell models by different experimental approaches. Conclusion: We focus on the molecules obtained from Y2H that are not involved in the cell cycle, in order to dissect metabolism and viability and cell cycle. In this way, we can analyse this unknown role of cyclin D3 in the viability and fitness of beta-pancreatic cells and it helps the translation into future therapeutic targets for T1D.

P.C2.01.17

Trained autoimmunity as a driver in the pathogenesis of Systemic Lupus Erythematosus

C. Yanginlar*, N. Rother, J. van der Vlag;*
RIMLS, Radboudumc, Nijmegen, Netherlands.

Introduction: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by autoantibodies against chromatin. Elevated levels of circulatory chromatin are detected in SLE patients, which may be a result of aberrancies in apoptosis or neutrophil extracellular trap (NET) formation or insufficient clearance of apoptotic material or NETs. Recently, we showed that SLE-derived PBMCs appeared more sensitive to apoptotic microparticles (MPs) than those from controls, for which there is no clear explanation yet. Recently the concept of trained immunity was described, meaning that innate immune cells can develop a memory after first exposure to disease/pathogen associated molecular patterns (DAMPs/PAMPs) which results in a stronger response after subsequent exposures. We hypothesized that sources of nuclear antigens in SLE, including MPs and NETs, can train PBMCs, thereby inducing trained autoimmunity.
Methods: PBMCs from healthy volunteers were trained 24 hours with different stimuli (untrained, heat killed *C. albicans*, MPs, NETs). After 6 days of resting, cells were stimulated with TLR2 (Pam3CSK4) or TLR4 (LPS:B5) antagonists for 24 hours and IL-6 and TNF-α levels were measured.
Results: NETs induced PBMC training dose dependently, which was based on secretion of higher levels of IL-6 and TNF-α in response to LPS:B5 or Pam3CSK4 after the resting period. Training by NETs was comparable to that induced by *C. albicans*. MPs, on the other hand, induced training at a lesser extent.
Conclusions: Innate immune cells can be trained by MPs and NETs, which may play an important role in the pathogenesis of SLE and lupus nephritis.

Dysregulated T cell activity in systemic lupus erythematosus

H. Zhou, T. Wu, J. LI, B. LI, ***F. Yu****;*
Affiliated Hospital of Guizhou Medical University, Guiyang, China.

Background: Accumulating evidence indicates a critical role for T lymphocytes and relavant cytokines in the pathogenesis of Systemic lupus erythemotosus (SLE). However, the specific contribution of T lymphocytes together with the related circulating cytokines in disease pathogenesis and organ involvement is still not clear. Methods: Blood samples were collected from 49 SLE patients and 22 healthy controls (HC). Expressions of HLA-DR and co-stimulatory molecules on T cells were evaluated by flow cytometry. Concentrations of serum C-reactive protein, erythrocyte sedimentation rate, anti-double-stranded DNA (anti-dsDNA) antibody, total IgG, complement 3, complement 4 were measured. Serum cytokines and chemokines were measured by a cytometric beads array assay. Results: Elevated frequencies of HLA-DR$^+$T cells and ICOS$^+$T cells were observed in SLE patients with positive anti-dsDNA antibodies compared with those in HC. The expression of HLA-DR$^+$T cells was positively correlated with SLEDAI. Furthermore, levels of serum IL-6, MCP-1, TNFRI, IL-10 and IL-12 were detected higher in SLE patients compared with HC. In addition, patients with hematologic manifestations displayed elevated frenquencies of HLA-DR$^+$-, ICOS$^+$- but lower TIGIT$^+$CD4$^+$-T cells. Patients with renal manifestations displayed decreased levels of serum CCL20 and MCP-1 but an increased frenquency of HLA-DR$^+$T cells. Conclusion: SLE subjects exhibited dysregulated T cell activity and the cytokine expression profile. Furthermore, we developed a chemokine and cytokine profiling strategy to predict the activity of SLE, which has clinical implication for monitoring the flares and remission during the course of SLE in order to improve clinical outcomes.

A novel animal model for systemic sclerosis induced by immunization ofangiotensin II receptor 1

X. Yue[1], *F. Petersen*[1], *X. Wang*[1], *J. Yin*[1], *H. Heidecke*[2], *G. Wallukat*[3], *S. Ingolf*[3], *A. Philippe*[4], *D. Dragun*[4], *G. Riemekasten*[5], *X. Yu*[1];
[1]*Research center borstel, Borstel, Germany,* [2]*CellTrend GmbH, Luckenwalde, Germany,* [3]*Berlin Cures GmbH, Berlin, Germany,* [4]*Department of Nephrology and Critical Care Medicine, Berlin, Germany,* [5]*University Hospital Lübeck, Lübeck, Germany.*

Background and Objectives: Systemic sclerosis (SSc) is a complex connective tissue disease which is characterized by autoimmunity, vasculopathy and fibrosis. Our recent study showed that the progression of SSc was strongly associated with the autoantibodies against angiotensin II receptor I (AT1R), suggesting a role of autoimmunity to AT1R in the pathogenesis of the disease. In this study, we aimed to investigate the role of AT1R in the pathogenesis of SSc in mice. **Methods:** C57BL/6J mice were immunized with membrane extract (ME) of CHO cell overexpressing human AT1R or with ME of CHO cells as control. Serum, lung and skin samples were collected and assessed 63 days after immunization for autoantibody production, inflammation and fibrosis, which are hallmarks for SSc. **Result:** Immunization with hAT1R induced the production of autoantibodies against the receptor in mice, and autoantibody deposition was found in the lung.
Histologically, mice immunized with hAT1R showed a SSc-like disease, including perivascular infiltrates and fibrosis in the skin as well as pulmonary inflammation. The inflammation in the skin and the lung were characterized by infiltration of T- and B-cells. **Conclusion:** This study demonstrates that immunization with hAT1R can induce a SSc-like disease, thus showing a pathogenic role of autoimmunity to AT1R and providng a novel mosue model for the diseases. Furthermore, this study also introduces a new immunization strategy to generate functional autoantibodies against receptors on the cell membrane.

P.C2.01.20

INS1007, a reversible dipeptidyl peptidase 1 inhibitor, reduces human neutrophil membrane-bound proteinase 3 expression and neutrophil serine protease activities

***J. Zhang**, J. Basso, D. LaSala, W. R. Perkins, K. DiPetrillo;*
Insmed Incorporated, Bridgewater, NJ, United States.

Introduction: Granulomatosis with polyangiitis (GPA) is a form of vasculitis characterized by necrotizing granulomatous inflammation. In most patients, this autoimmune disease is associated with anti-neutrophil cytoplasmic antibodies binding to membrane-bound proteinase 3 (mPR3) on neutrophils and stimulating degranulation and release of neutrophil serine proteases (NSPs) that damage tissues. Dipeptidyl peptidase 1 (DPP1) is a key enzyme that converts pro-PR3 to an active form. We hypothesized that inhibiting DPP1 activity with INS1007 could decrease mPR3 expression and NSP activities in neutrophils.
Methods: Human stem cells from either cord blood (CB) or bone marrow (BM) were differentiated into neutrophils *in vitro* in the presence of increasing INS1007 concentrations. mPR3 expression was assessed qualitatively by fluorescence microscopy and quantitatively by flow cytometry. Activities of NSPs, including neutrophil elastase (NE) and PR3, were measured in enzymatic assays using exogenous peptide substrates.
Results: Compared to untreated differentiated neutrophils, INS1007 concentration-dependently (0.000153 -10 μM) reduced both mPR3 levels and the percentage of cells expressing detectable mPR3. Additionally, INS1007 concentration-dependently decreased both PR3 (CB EC_{50} = 0.70 μM, BM EC_{50} = 0.28 μM) and NE (Both EC_{50} = 0.36 μM) activities in differentiated neutrophils, with greater than 90% reductions of enzyme activities at 10 μM.
Conclusions: INS1007 effectively lowered mPR3 expression and reduced NSP activities in *in-vitro*-differentiated neutrophils. Considering the central role of mPR3 as the autoantigen in GPA and the tissue damage and inflammation resulting from NSP activities, the multiple mechanisms by which INS1007 affects neutrophil function make it a potential therapy for treating GPA patients.

Systemic immunophenotyping and cytokine profiling reveals inflammatory signature of alopecia areata

***K. Bain**[1], E. McDonald[1], I. McInnes[1], S. Holmes[2], A. Astrand[3], S. W. Milling[1];*
[1]Intistute of Infection, Immunity and Inflammation, Glasgow, United Kingdom, [2]Queen Elizabeth University Hospital, Glasgow, United Kingdom, [3]AstraZeneca, Gothenburg, Sweden.

Alopecia Areata (AA) is a T cell mediated autoimmune disease causing hair loss. AA can have profound psychological effects on affected individuals. Therapeutic options are limited, and a positive response is often followed by relapse upon treatment cessation. JAK inhibitors offer promise, but may cause significant immunosuppression. Human and murine studies have implicated $CD8^+NKG2D^+$ T cells in hair follicle damage, but little is known about the specific pathways and mediators involved in promoting and sustaining this response. Peripheral blood was obtained from consented volunteers at our dedicated research clinic. Peripheral blood mononuclear cells (PBMCs) were analysed using 11-parameter flow cytometry to identify $CD4^+$ T cell, $CD8^+$ T cell, dendritic cell (DC), natural killer (NK) cell and B cell populations. Multiplex analysis was performed to determine the plasma concentrations of inflammatory cytokines. Flow cytometric immunophenotyping revealed a significant increase in the number of circulating $CCR6^+$ $CD4^+$ T cells. We also observed altered frequencies of $CD4^+CXCR3^+$ T cells expressing the skin homing marker cutaneous lymphocyte antigen (CLA). Importantly, these changes are enhanced in participants with more extensive hair loss (alopecia totalis and alopecia universalis) evaluated by SALT score. Multiplex cytokine profiling revealed a strong inflammatory signature, characterised by a significant increase in the levels of circulating IL-17A, IL-33, IL-25, TNFalpha and IL-6. We have generated the first comprehensive immunophenotype in AA, and have not only discovered changes in circulating $CD4^+$ T cell populations, but have also revealed a strong systemic inflammatory/Th17 signature in these individuals.

Functional elimination of autoreactive T and B cells by anti-annexin A1 antibody therapy in MRL/lpr murine model of systemic lupus erythematosus

***S. Bradyanova**[1], N. Mihaylova[1], P. Chipinski[1], S. Chausheva[1], Y. Manasiev[2], M. Herbáth[3], D. Kyurkchiev[4], J. Prechl[3], A. Tchorbanov[1,5];*
[1]Laboratory of Experimental Immunology, Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria, [2]Department of General Microbiology, Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria, [3]MTA-ELTE Immunology Research Group, Hungarian Academy of Sciences, Budapest, Hungary, [4]Laboratory of Clinical Immunology, University Hospital 'Sv.I.Rilski', Medical University Sofia, Sofia, Bulgaria, [5]National Institute of Immunology, Sofia, Bulgaria.

Introduction: Systemic lupus erythematosus is an autoimmune syndrome characterized by the development of autoantibodies to a wide range of antigens and multiple organ involvement. Together with B cells, respective self-reactive T cells have an important contribution in disease progression as being responsible for inflammatory cytokines secretion, B cell activation, and promoting amplification of the autoimmune and inflammatory response. Annexin A1 is expressed by many cell types and binds to phospholipids in a Ca^2+ dependent manner. Abnormal expression of annexin A1 was found on activated B and T cells in both murine and human autoimmunity suggesting its potential role as a therapeutic target. Materials and Methods: Groups of lupus-prone MRL/lpr mice were treated with an anti-annexin A1 monoclonal antibody and the disease activity and survival of the animals were monitored. ELISA and ELISpot assays, RT-PCR, cell proliferation assay, flow cytometry, histological and immunofluorescence kidney analyses were used to determine the levels of cytokines, anti-dsDNA antibodies and kidney injuries. Results: Administration of anti-annexin A1 monoclonal antibody resulted in suppression of IgG anti-dsDNA antibody production and of proteinuria, modulation of cytokine production, improved kidney histology, decreased disease activity and prolonged survival compared to the control group. Conclusions: The anti-ANX A1 antibody therapy described here obviously targets over-activated autoreactive cells and has a beneficial effect on earlier stage of lupus development. The administration of ANX A1 antibody strongly suppresses the ongoing autoimmune disease in lupus-prone MRL/lpr mice and by using such a therapy it is possible to down-regulate the activity of lupus-associated lymphocytes.

P.C2.02.03

Transcriptomic analysis of CD4+ and CD8+ T cells from lupus nephritis patients clustered them into type I IFN-high and IFN-low expressing patients irrespective of their disease activity

***N. B. Buang**, G. Ling, L. Stephens, F. Doyle, M. Pickering, M. Botto;*
Imperial College London, London, United Kingdom.

Systemic Lupus Erythematosus (SLE) is a relapsing-remitting autoimmune disease and we lack biological parameters with which to monitor and predict disease flares. Recent studies have postulated that exhaustion signatures from CD8+ T cells can be used as a biomarker to predict long-term prognosis in SLE. To investigate if the T cell transcriptomic signatures can be utilised to define disease activity, mRNA from CD4+ and CD8+ T cells from active (SLEDAI > 4, n=12) and inactive (SLEDAI < 4, n=16) Lupus Nephritis (LN) patients was sequenced and correlated with 84 clinical criteria. Principle Component Analysis shows overlapping global gene expression between active and inactive LN patients. Unsupervised hierarchical clustering of all differentially expressed genes between LN patients and healthy controls grouped patients into two groups: individuals expressing high type I Interferon (IFN) (active LN n=8, inactive LN n=6) and those with low IFN signatures (active LN n=4, inactive LN n=10). No difference in SLEDAI, BILAG, and anti-dsDNA levels could be observed between the 2 IFN groups. Gene Set Variation Analysis identified larger gene sets (200) to correlate with disease activity in CD8+ T cell gene signatures compared to CD4+ T cells (59), indicating CD8+ T cell signatures may be more informative to predict disease activity than CD4+ T cells. These signatures are involved in cell cycle, peroximl lipid metabolism, mitochondrial and proteasome pathways. Furthermore, there was no correlation between disease activity and the degree of the IFN signatures indicating that IFN may not play a key role in driving LN flares.

P.C2.02.05

Treg-of-B cells attenuated the progression of primary biliary cholangitis via modulating the activation of antigen-presenting cells

***Y. Chen**, B. Chiang;*
Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.

Introduction. Primary biliary cholangitis (PBC), a liver-specific autoimmune diseases, is characterized by the presence of antimitochondrial antibody (AMA) and chronic progressive destruction of intrahepatic bile ducts with infiltrating mononuclear cells. Regulatory T cells (Tregs) attenuated the maturation of antigen-presenting cells (APCs) which play an important role to initiate immune responses. ducts with infiltrating mononuclear cells in the portal tract. chronic progressive destruction of small intrahepatic bile ducts with infiltrating mononuclear cells in the portal tract. chronic progressive destruction of small intrahepatic bile ducts with infiltrating mononuclear cells in the portal tract. Materials and Methods. In our study, splenic B cells without additional cytokines or chemicals induced the generation of Treg-like cells which referred to as Treg-of-B cells for the treatment of PBC. Results. Treg-of-B cells suppressed the proliferation of T cells, showed high expressions of LAG3 and CTLA-4, without expressing Foxp3. After incubation with Treg-of-B cells for 24 hr, LPS treated dentritic cells reduced productions of IL-6 and TNF-α and expressions of costimulatory molecules (CD80 and CD86). The inhibitory effect was dependent on cell-cell contact manner via CTLA-4 pathway. In mouse model of PBC, Treg-of-B cells were intravenously injected during the progression of disease. The level of AMAs, the cell infiltrations of APCs and lymphocytes, and the degree of fibrosis were significantly reduced in Treg-of-B cells treated group. Conclusion. Our results demonstrated that Treg-of-B cells can alleviate the inflammatory processes of PBC. It is suggested that Treg-of-B cells might be a potential therapeutic approach for autoimmune disease.

P.C2.02.06

The HLA class II risk genes associated to celiac disease are preferentially expressed compared to non-associated HLA genes either in *cis* and in *trans* configuration: implication for the pathogenic anti-gluten T-cell response

*C. Gianfrani[1], L. Pisapia[2], S. Picascia[2], F. Farina[2], R. Spettrini[2], **G. Del Pozzo**[2];*
[1]Instiitute of Protein Biochemistry-CNR, Naples, Italy, [2]Instiitute of Genetics and Biophysics-CNR, Naples, Italy.

Introduction We have recently studied the expression of DQA1*05 and DQB1*02 alleles, encoding the DQ2.5 molecule presenting the gluten peptides. We discovered that specialized Antigen Presenting Cells (APC) either DR3-DR3 homozygous or DR1-DR3 heterozygous show similar level of DQ2.5 transcripts and surface molecules. As a consequence, DQ2.5 APC induced similar activation level of gluten-specific T lymphocytes (DOI: 10.1016/j.jaut.2017.12.0). **Methods** We measured the quantity of DQA1* and DQB1* mRNAs by RT-qPCR, the DQα1*05 and DQβ1*02 surface proteins in APC by flow cytometry and the magnitude of gluten-specific $CD4^+$ T cell activation by INFγ ELISA. **Results** We found that DQA1*05 and DQB1*02 risk alleles were more expressed than non CD-predisposing alleles also in B cells with DQ2.5 genes in *trans* (DR5/DR7) configuration. The differential expression between CD-associated and non-associated alleles was significant also in the APC from non-affected subjects, although in these latters the increments was much lesser than in CD patients. The quantification of DQα1*05 and DQβ1*02 proteins by specific monoclonal antibodies confirmed these findings. Furthermore, we assessed that B cells carrying the DQ2.5 genes in *trans* and in *cis* configurations induce a comparable activation of specific $CD4^+$ T cell response to gluten epitopes. **Conclusions** Our findings indicated that the high level of HLA class II risk genes expression, independently by the gene dosage, strongly influence immune response against gluten in the intestinal mucosa of subjects with CD. Our results have a general relevance as the high expression of predisposing HLA alleles may favour the establishment of autoimmunity.

P.C2.02.07

Clinical manifestations and anti-TNF alpha treatment of juvenile Behçet's disease in Taiwan: A retrospective study.

***Y. Hu**, Y. Lin, Y. Yang, B. Chiang;*
Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan.

Background. Behçet's disease (BD) is a rare vasculitic disorder affecting all sizes of vessels. Patients with diagnosed age younger than 16 years old is defined as juvenile BD, which only accounts for 4 to 25 percent among all BD patients. This study aimed to evaluate the incidence change, clinical manifestation and treatment including anti-TNF alpha agents of patients with juvenile BD patients in Taiwan.
Methods. We retrospectively reviewed the patients younger than 16 years old with diagnosis of Behçet's disease in National Taiwan University Children's Hospital between 2008 to 2017.
Results. Total 66 patients were included in the study. The mean age at onset was 10.4 4.2 years. The most common clinical presentation was recurrent oral aphtosis (98.5%), which was also the most common initial symptoms. The most frequently used treatments were colchicine (57.6%) and systemic steroid (66.7%). Among 66 patients, 6 of them received anti-TNF alpha treatments due to refractory or severe BD. The BD patients with anti-TNF alpha agents have younger age at disease onset (7.0 v.s. 11 years, p=0.027) and diagnosis, (7.5 v.s. 13 years, p=0.012). All of the 6 patients were free of steroid use at the 1st year after treatment. Anti-TNF alpha therapy was well tolerated in all cases.
Conclusions. Juvenile BD was a rare disease but the incidence seemed increased recently. Patients with younger age, presenting gastrointestinal symptoms and arthritis might tend to have more severe disease. Anti-TNF alpha therapy might be an effective and safe treatment for pediatric patients with refractory BD.

P.C2.02.08

Therapeutic potential of immunosuppressive A151 ODN loaded liposomes in bleomycin induced mouse scleroderma model

***G. Kilic**, O. Bulut, M. Yildirim, G. Gucluler, T. Kahraman, B. Bayyurt Kocabas, I. Gursel;*
Bilkent University, Ankara, Turkey.

Introduction: Scleroderma (SSc) is an autoimmune disease which is characterized by vascular abnormalities, inflammation and fibrosis due to accumulation of extracellular matrix proteins. Although there are treatments for organ-specific complications of scleroderma, little is known concerning the therapy options related to resolution of ongoing fibrosis. In this study we investigated the immunosuppressive and anti-fibrotic effects of TLR antagonist A151 ODN in bleomycin induced fibrosis model.
Methods: NIH3T3 cells were stimulated with bleomycin and A151; fibrotic gene levels were assessed with qPCR. Inflammasome activation of mouse bone marrow derived macrophages upon p(dA/dT) stimulation in the absence or presence of A151 ODN was monitored via IL-1β levels of the culture supernatants. Lastly, to investigate whether A151 has a preventive effect on the development of scleroderma, mice were injected with A151 in free and liposomal forms 3 days before intratracheal bleomycin administration.
Results: Data revealed that TGFβ gene expression levels along with IL-1β production and expression of CD80 and CD86 from NIH3T3 and BMDMs were reduced in response to A151 treatments. A151 was able to decrease Col1a1 and Col1a2 gene levels from lung tissues as well as IL-6 and IL-12 production from BALF in mouse model of scleroderma.
Conclusion: These data indicated the preventive effect of A151 ODN on inflammation and fibrosis *in vitro* and in the mouse model of scleroderma. Current work focuses on demonstrating as a therapeutic value of A151 in established fibrosis.

P.C2.02.09

IL17- and IL22-producing γδ-T cells in the pathogenesis of systemic juvenile idiopathic arthritis

***B. Malengier-Devlies**[1], H. Engels[1], M. Imbrechts[1], J. Vandenhaute[1], T. Mitera[1], N. Berghmans[1], O. Burton[2], C. Wouters[3], P. Matthys[1];*
[1]Rega Institute, Laboratory of Immunobiology, Leuven, Belgium, [2]VIB-KU Leuven Center for Brain & Disease Research, Laboratory of Genetics of Autoimmunity, Leuven, Belgium, [3]University Hospitals Leuven, Leuven, Belgium.

Systemic juvenile idiopathic arthritis (sJIA) is a severe childhood immune disorder characterised by quotidian fever, rash, arthritis and splenomegaly and is associated with anaemia, neutrophilia and thrombocytosis. Although the aetiology of sJIA is poorly understood, the disease is considered as an autoinflammatory disorder driven by innate immune cell and cytokines. By using a novel mouse model for sJIA that rely on immunisation of Balb/c mice with complete Freund's adjuvant (CFA), we demonstrate in the present study a key role for innate γδ-T cells in the development of the disease. $CD27^{neg}$ γδ-T cells were dramatically increased in CFA-challenged mice and depletion of γδ-T cells ameliorated disease outcome. Intracellular cytokine staining identified γδ-T cells as a major source of IL-17 and IL-22, and neutralisation of each of these cytokines inhibited sJIA-like disease pathology. We further presented evidence for the involvement of γδ-T cells in the myelopoiesis of neutrophils and in the production of IL-1 and IL-6, and these are two key cytokines in the pathogenesis of sJIA for which their targets are currently used in the clinic. In conclusion, in a mouse model for sJIA, we provide evidence for a role of γδ-T cells in the aetiology and pathogenesis of this autoinflammatory disease. The data are clinically relevant as increased numbers of γδ-T cells were recently demonstrated in blood and joints of sJIA patients with active disease.

P.C2.02.10

Selective depletion of pro-inflammatory Th1 cells in chronic inflammation by targeting microRNA-148a with antagomirs

***P. Maschmeyer**[1], G. Petkau[1], F. Siracusa[1], J. Zimmermann[2], F. Zügel[1], A. A. Kühl[3], K. Lehmann[1], S. Schimmelpfennig[1], M. Weber[1], C. Haftmann[1], R. Riedel[4], M. Bardua[1], G. A. Heinz[1], C. L. Tran[1], B. F. Hoyer[5], F. Hiepe[3], S. Herzog[6], J. Wittmann[7], N. Rajewsky[8], F. Melchers[1], H. D. Chang[1], A. Radbruch[1], M. F. Mashreghi[1];*
[1]German Rheumatism Research Center (DRFZ) Berlin, Berlin, Germany, [2]Maurice Müller Laboratories (DKF), Bern, Switzerland, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]Max Planck Institute for Evolutionary Biology, Plön, Germany, [5]Universitätsklinikum Schleswig-Holstein, Kiel, Germany, [6]Medical University Innsbruck, Innsbruck, Austria, [7]Nikolaus-Fiebiger-Center, University of Erlangen-Nürnberg, Erlangen-Nürnberg, Germany, [8]Berlin Institute for Medical Systems Biology, Berlin, Germany.

CD4+ T helper (Th) cells contribute to the induction and maintenance of chronic-inflammatory diseases (CIDs). While depletion of Th cells with anti-CD4 antibodies significantly ameliorates disease activity in CID patients, this treatment also ablates Th cells that are protective against infections. Currently, a treatment that selectively targets CID-maintaining Th cells is still lacking.
The microRNA-148a (miR-148a) is expressed in CD4+ T helper type 1 (Th1) cells that reside at inflamed sites in patients with CIDs. Among Th cells, miR-148a expression is specifically upregulated in repeatedly-activated Th1 cells and promotes their survival by inhibiting the expression of the pro-apoptotic molecule Bim.
Here, we investigated whether miR-148a-targeting oligonucleotides (antagomir-148a) can be used to selectively deplete pro-inflammatory Th1 cells of chronic inflammation.
In the murine model of transfer colitis, antagomir-148a treatment reduced the number of Th1 cells in the colons of colitic mice by 50%. Moreover, antagomir-148a treatment inhibited miR-148a expression by 71% in colonic Th1 cells, while expression of the miR-148a target Bim was increased. Antagomir-148a-mediated reduction of Th1 cells resulted in a significant amelioration of colitis. The effect of antagomir-148a was selective for chronic inflammation. Antigen-specific memory Th cells that were generated by an acute immune reaction to nitrophenylacetyl-coupled chicken gamma globulin (NP-CGG) were not affected by treatment with antagomir-148a, both during the effector and the memory phase. In addition, antibody titers to NP-CGG were not altered. Thus, antagomir-148a might qualify as an effective drug to selectively deplete pro-inflammatory Th1 cells of chronic inflammation without affecting the protective immunological memory.

P.C2.02.11

The genetic regulation of the immune system in health and disease

V. Orrù[1], *M. Steri*[2], *C. Sidore*[2], *V. Serra*[1], *M. Marongiu*[1], *G. Sole*[2], *M. Pala*[2], *S. Lai*[1], *M. Dei*[1], *A. Mulas*[1], *M. Zoledziewska*[2], *M. Marongiu*[1], *M. Lobina*[1], *M. G. Piras*[1], *S. Olla*[2], *M. Floris*[3], *E. Fiorillo*[1], *F. Cucca*[2,3];
[1]*Institute for Genetic and Biomedical Research, Lanusei, Italy,* [2]*Institute for Genetic and Biomedical Research, Cagliari, Italy,* [3]*University of Sassari, Sassari, Italy.*

The immune system is a complex biological network of specialized cells and molecules that evolved to defend against pathogens and, in healthy condition, distinguishes between self and non-self antigens. Despite its relevance for human health, only a few studies have systematically evaluated the genetic influence on immune cells[1,2,3]. Some years ago, we completed the first GWAS assessing the genetic control of 95 leukocytes subsets in 2,870 general population individuals from the SardiNIA cohort. We identified multiple variant-trait associations at 13 loci, four of which overlapping with disease risk variants, revealing parameters potentially involved in disease pathogenesis[1]. The efficacy of this approach was demonstrated by our group that identified and clarified the mechanism of action of a complex variant, in the 3'UTR of the *BAFF* gene, associated with 18 immune endo-phenotypes and predisposing for multiple sclerosis and systemic lupus erythematosus[4]. Here we extended the previous characterization of immune cells to about 2,500 traits, related to the levels of 300 immune cell subtypes assessed in up to 4,000 volunteers from the SardiNIA cohort. We performed a GWAS, interrogating >26M variants, identifying 135 independent associations in 69 genetic loci (p-value<$6.9x10^{-11}$). Among these, 30 association signals are shared between immune traits and diseases. These data will help to understand the biological mechanisms underlying the links between pathologies and immune cells and to identify new therapeutic targets for personalized medicine. 1.Orrù V. *et al*, Cell 2013; 2.Roederer M. *et al*, Cell 2015; 3.Patin E. *et al*, Nat Immunol 2018; 4.Steri M. *et al*, NEJM 2017

P.C2.02.12

Effect of pregnancy hormones on CD4+ T cell activation and their possible use as treatment in multiple sclerosis

G. Papapavlou*, S. Hellberg, J. Raffetseder, J. Brynhildsen, M. Jenmalm, J. Ernerudh;*
Linköping Univesrity, Linköping, Sweden.

Multiple sclerosis (MS) is an autoimmune inflammatory disorder of the CNS with variable patient response to treatment. Intriguingly, women with MS show a transient improvement during pregnancy. Although little is known on the exact underlying mechanisms, the observed amelioration is most likely a result of immunological and hormonal interactions. The pregnancy hormones progesterone and estrogen could be involved in the systemic immune modulation as their levels coincide with disease amelioration and aggravation during and soon after pregnancy, respectively. Since a dysregulated activation of peripheral CD4+ T helper cells is considered to be a key event in MS pathogenesis, we examined the direct *in vitro* effects of these pregnancy hormones on CD4+ T cell activation derived from female healthy donors. The cells were stimulated for 24h with anti-CD3 and anti-CD28 antibodies and incubated in the presence of different concentrations of the hormones. Flow cytometry assessed the level of activation based on the expression of CD69 and CD25. Our preliminary data suggests that the hormones exert opposite effects, with progesterone hampering CD4+ cell activation ($n=4$, $p < 0.01$) and estrogen increasing it ($n=3$, $p > 0.05$), both in a dose-dependent manner. Our findings so far suggest that progesterone could be considered as a potent candidate of add-on treatments in MS, which so far has failed in the case of estrogen.

P.C2.02.13

Wiskott-Aldrich syndrome protein regulates endosomal architecture & TLRs signalling in DCs

G. M. Piperno[1]*, A. Naseem*[1]*, G. Silvestrelli*[1]*, N. Caronni*[1]*, K. E. Cervantes-Luevano*[1]*, N. Liv*[2]*, J. Klumperman*[2]*, H. Ali*[1]*, F. Graziano*[3]*, P. Benaroch*[3]*, H. Haecker*[4]*, R. Hanna*[5]*, F. Benvenuti*[1]*;*
[1]*International Centre for Genetic Engineering and Biotechnology, Trieste, Italy,* [2]*Section Cell Biology, Center for Molecular Medicine, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands,* [3]*Institute Curie Laboratoire Immunité et Cancer – INSERM U932 Transport Intracellulaire et Immunité, Paris, France,* [4]*Department of Infectious Diseases, St. Jude Children's Research Hospital, 262 Danny Thomas Place, Menphis, United States,* [5]*Respiratory, Inflammation and Autoimmunity, MedImmune LLC, Gaithersburg, United States.*

Wiskott-Aldrich syndrome (WAS) is a rare immune deficiency caused by mutations in WAS protein (WASp), an actin nucleation promoting factor (NPFs) of the WASp/WAVE family, expressed exclusively in cells of the hematopoietic system. WAS mutated innate cells secrete excessive amount of cytokines in response to Toll-like receptor stimulation, contributing to autoimmune manifestations that often develop in WAS. However, the precise cellular mechanism of Toll-like receptor regulation by WASp remains elusive. Here we found that WASp nucleates actin around endosomes and promotes sorting and maturation of endolysosomes into degradative compartments in dendritic cells. Lack of WASp causes stalling of TLR9 and its ligands in hybrid, maturation-defective compartments, preventing degradation of signalling complexes. Delayed receptor and cargo degradation lower the threshold for receptor activation rendering DCs sensitive to little concentration of TLR9 agonists. These data elucidate how WASp negatively regulates endosomal TLRs signalling, contributing to explain disease pathogenesis.

P.C2.02.14

The regulation of IL-17 receptor signaling by kinases TBK1 and IKKε

D. Polatova*, H. Draberova, S. Janusova, K. Ruppova, A. Drobek, O. Stepanek, P. Draber;*
Institute of Molecular Genetics, Prague, Czech Republic.

Inflammation is an important reaction of the immune system in response to the infection and to the disruption of integrity of the organism. It is a way the organism immediately reacts to the damage or pathogen presence. Amongst important mediators of immune inflammatory response are members of interleukin 17 (IL17) family. IL-17 is a pivotal regulator of inflammatory immune reaction. Binding of IL-17 to its specific receptor leads to the production of pro-inflammatory cytokines such as IL-6, CXCL1, CXCL2, CCL20 or CCL2 which then promote an immune defense of the organism by recruitment of macrophages and neutrophils to the site of inflammation. The absence of IL-17 signaling leads to increased sensitivity to some pathogens (e.g. *Candida albicans*). On the other hand, the dysregulation of this signaling pathway results into severe autoimmune disorders such as psoriasis, rheumatoid arthritis or multiple sclerosis. Currently, antibodies blocking IL-17 or its receptor are approved for the treatment of psoriasis and psoriatic arthritis. As clinical therapy by antibodies has numerous limitations and brings many side effects, the elucidation of the precise mechanism of yet not completely understood signaling via IL-17 receptor is a possible way to reveal new potential drug targets for therapeutic treatment. Here we aimed to understand the role of kinases TBK1 or IKKε in propagating IL17 receptor-triggered signaling pathways and to elucidate whether the inhibition or ablation of these kinases can be used to modulate the IL17-induced cellular responses.

P.C2.02.15

Imbalance of blood Tfh and Tfr cells in systemic and organ-specific human autoimmunity

F. Ribeiro[1,2]*, V. R. Fonseca*[1,3]*, A. Agua-Doce*[1,2]*, V. Romao*[1,3]*, E. Nobre*[3]*, M. J. Bugalho*[3]*, J. E. Fonseca*[1,3]*, L. Graca*[1,2]*;*
[1]*Instituto de Medicina Molecular João Lobo Antunes, Lisboa, Portugal,* [2]*Instituto Gulbenkian da Ciência, Lisboa, Portugal,* [3]*Centro Hospitalar Lisboa Norte – Hospital de Santa Maria, Lisboa, Portugal.*

Many autoimmune diseases are mediated by self-reactive antibodies produced during disturbed B-T cell interactions in the germinal center (GC). The balance between T follicular helper (Tfh) cells and T follicular regulatory (Tfr) cells have a significant impact on GC outcome: while Tfh cells support the production of high-affinity antibodies, Tfr cells limit the production of self-reactive antibodies. We have recently found that the balance between circulating Tfh and Tfr cells is altered in human systemic autoimmunity. In order to investigate whether such dysregulation is also observed in organ-specific autoimmunity, we compared Sjögren Syndrome (SS) and Hashimoto's Thyroiditis (HT) patients.
We analyzed peripheral blood Tfh and Tfr cells of those two distinct autoantibody-mediated autoimmune diseases. We found a significant increase in Tfr/Tfh ratio in peripheral blood of SS patients compared to age-matched healthy donors, contrary to HT patients where a considerable decrease in Tfr/Tfh ratio was observed. However, circulating Tfh cells in both diseases expressed GC-related activation markers, suggesting greater Tfh cell activation in autoimmune patients regardless of the underlying disease.
Our results show that SS and HT are characterized by dysregulation of Tfh/Tfr ratio, possibly implicated in the loss of self-tolerance and emergence of autoantibodies. However, the imbalance of circulating Tfr and Tfh cells is distinct in these diseases, suggesting they do not share common mechanisms of GC dysregulation. Our results suggest that the blood Tfr/Tfh ratio may constitute a novel biomarker for autoantibody-mediated autoimmunity, potentially identifying patients with greater benefit for therapeutic approaches targeting B-T cell interactions.

P.C2.02.16

Pro-survival phenotype of human endothelial cells exposed to neutrophil-derived extracellular vesicles

M. Surmiak[1]*, S. Polanski*[2]*, J. Kosalka*[1]*, M. Sanak*[1]*;*
[1]*Department of Internal Medicine, Jagiellonian University Medical College, Krakow, Poland,* [2]*University Hospital, Krakow, Poland.*

Introduction In autoimmune vasculitis syndromes like granulomatosis with polyangiitis (GPA) neutrophils can damage multiple organs. In this study we measured transcriptional response of human endothelial cells to extracellular vesicles from neutrophils activated with IgG anti-PR3 antibodies. **Material and methods** Anti-PR3 antibodies were isolated form serum of patients with GPA by affinity chromatography. Neutrophils from healthy volunteers were primed with TNF-α (2ng/mL) and stimulated with anti-PR3 (200 ng/mL) for 2h. Extracellular vesicles (EV) were collected from culture by ultracentrifugation, characterized by flow cytometry (CD9, CD63, CD81) and nanoparticle tracking analysis. After 6 hours stimulation of human umbilical vein endothelial cells (HUVEC) by EV, RNA was isolated, reverse transcribed and measured by real-time quantitative PCR method (TaqMan Inflammation and Apoptosis Panels).

Results Transcripts were compared between primed only and EV stimulated HUVEC. Significant up-regulation (>2 fold change, p<0.05) was present for 8 transcripts. Some were inhibitors of apoptosis (*BIRC1*, *BIRC2*) and NF-κB modulators (*CARD6* and *NALP*), others regulated vascular adherence or leak (*VCAM1*, *PTGIS*, *KLK14, IL1R2*). Significant down-regulation was consistent with apoptosis inhibition (*CASP8, HRK, BCL2)* and also present for 2 other transcripts (*HTR3A, KLKB1)*. **Conclusions** This in vitro model of neutrophil-derived EV influence on endothelium in autoimmune vasculitis revealed unexpected changes in genes expression. Pro-survival phenotype was suggested by altered transcripts, accompanied by increase of prostacyclin synthase and shift in kallikreins. We conclude, that observed reprogramming of endothelial phenotype can enhance granulocyte transmigration and maintain microvascular perfusion in damaged tissue. P.C2.02.17
the kinase MAP4K3/GLK is a novel therapeutic target for IL-17A-mediated autoimmune diseases

*H. Chuang, **T. Tan**;*
Natioanl Health Research Institutes, Zhunan, Taiwan.

T-cell receptor signaling activates the kinase MAP4K3 (also named GLK) by inducing its direct interaction with the upstream adaptor protein SLP-76. Activated GLK directly phosphorylates and activates PKC-θ, which is required for NF-κB activation in T cells. Moreover, GLK-deficient mice show impaired Th17 differentiation and are resistant to IL-17A-mediated experimental autoimmune encephalomyelitis (EAE). Consistently, autoimmune SLE and rheumatoid arthritis (RA) patients show significantly increased GLK levels in T cells; the percentage of GLK-overexpressing T cells is correlated with autoimmune disease severity.
Recently, we generated and characterized T-cell specific GLK transgenic mice and found that these transgenic mice spontaneously developed autoimmune diseases with an induction of systemic inflammation and an increase of autoantibodies (ANA, anti-dsDNA, rheumatoid factor). We found that GLK signaling specifically induced IL-17A transcription in the T cells of GLK transgenic mice. GLK-mediated IL-17A induction has been studied using biochemical approaches, genetically modified mice, and autoimmune patient T cells. We will present the data on a novel signal transduction mechanism of IL-17A transcriptional activation by GLK in autoimmune T cells and activated T cells. Collectively, MAP4K3/GLK is a diagnostic biomarker and therapeutic target for IL-17A-mediated autoimmune diseases.

***Ex-vivo* beneficial effect of interferon-β treatment on the secretion profile of inflammatory mediators via suppression of iNOS signaling pathway in patients with primary Sjögren's syndrome**

*S. Benchabane[1], M. Belkhelfa[1], H. Belguendouz[1], S. Zidi[1], A. Boudjelida[2], **C. Touil-Boukoffa**[1];*
[1]Cytokines and NO Synthases Group. Faculty of Biological Sciences,, Algiers, Algeria, [2]Internal medicine department, Maillot Hospital, Algiers, Algeria.

Introduction Primary Sjögren's syndrome (pSS) represents a chronic, systemic autoimmune disorder, characterized by lymphocytic infiltration of exocrine glands. Increasing evidence had revealed that inflammatory mediators, such as nitric oxide (NO) and pro-inflammatory cytokines are critical in the development and perpetuation of pSS. In our study, we investigate the *ex vivo* immunomodulatory effect of interferon-β on iNOS expression, as well as on pro-inflammatory (tumor necrosis factor (TNF)-α, interleukin (IL)-6) and immunoregulatory (IL-10) cytokines production. Furthermore, we examined potential associations between the influence of IFN-β treatment on NO production and pSS clinical and serological manifestations. ***Methods*** In 41 pSS patients documented for their clinical and serological features, NO and cytokines levels were measured by the Griess method and enzyme-linked immunosorbent assay, respectively.
Inducible nitric oxide synthase expression was analyzed by fluorescence immunostaining assay, using peripheral blood mononuclear cells (PBMCs) isolated from healthy controls and pSS patients. ***Results*** Our results revealed a strong down-modulating effect of IFN-β in the secretion of pro-inflammatory mediators including TNF-α, IL-6, and NO production. Interestingly, IFN-β exerts an increase in IL-10 levels. The most suppressive effect exerted by IFN-β on NO production was importantly reported for patients with neurological manifestation. This immunomodulatory effect of IFN-β on NO production is highly related to the decrease of inducible nitric oxide synthase (iNOS) expression. ***Conclusion*** Our findings highlight a consistent *ex vivo* inhibitory effect of IFN-β on pro-inflammatory cytokines production and NO pathway in pSS patients. Our data suggest that IFN-β could represent a potential candidate for targeting inflammation during pSS.

Investigating genetic variation in the control of human T cell activation

***C. Williams**, T. Hou, L. Faulkner, D. Sansom;*
Institute of Immunity and Transplantation, London, United Kingdom.

Despite the identification of vast numbers of genetic loci implicated in autoimmune susceptibility achieved through GWAS, interpretation of the functional consequence of these loci is complicated by; the polygenetic nature of complex autoimmunity, the haplotype structure of SNPs in linkage disequilibrium and the high frequency of causal variants in non-coding regions of DNA. Enrichment of risk loci has been observed in T cell enhancers, specifically those associated with stimulation. This implies T cell activation as an integral element of autoimmunity through which functional aberration as a result of genetic variation may be observed. The two signal model of T cell activation describes the response of a T cell as a function of the dose of two signals mediated through TCR and CD28. Thus, fine tuning of T cell stimulation may expose functional diversity between individuals bearing different SNPs. The polygenetic nature of autoimmunity suggests that multiple risk variants integrate into functional pathways. As strongly deleterious mutations would likely be selected against, these variants likely also confer subtle (non-disease-causing) effects in T cell responses in healthy individuals. We have set up defined T cell stimulation assays in an attempt to identify functionally relevant SNPs through analysis of inter-individual variation in T cell responses from healthy donors. These assays have demonstrated a considerable degree of variability regarding T cell phenotype and proliferative response thereby indicating differential sensitivity to TCR and CD28 co-stimulation. Combining genetic and functional analysis will allow us to identify SNPs associated with specific T cell outcomes to stimulation.

Microglia are myelinogenic and neuroprotective macrophages of the CNS

***A. Wlodarczyk**, A. Benmamar--Badel, K. Nolling Jensen, T. Owens;*
Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark.

Microglia are central nervous system (CNS)-resident macrophages. They are implicated in neuroinflammatory and neurodegenerative diseases including multiple sclerosis. We have shown that numbers of microglia expressing CD11c, normally almost undetectable in adult CNS, significantly increase in experimental autoimmune encephalomyelitis (EAE). These are effective antigen presenting cells, but poor inducers of Th1 or Th17 responses. Interestingly, CD11c$^+$ microglia express high levels of neuroprotective insulin-like growth factor 1 (IGF1), suggesting a neuroprotective rather than proinflammatory role. We have recently shown that CD11c+ microglia cells predominate in primary myelinating areas of the developing brain and express genes for neuronal and glial survival, migration and differentiation, and they control primary myelination via IGF1 production.
Here we show that upon adoptive transfer into the cerebrospinal fluid of adult mice with symptomatic EAE, neonatal microglia migrate to the inflammatory lesions in the spinal cord. This intervention suppressed disease symptoms and reduced leukocyte infiltration and demyelination. Although unfractionated neonatal microglia suppressed disease, the CD11c+ microglial subset was significantly most effective. We therefore identify a unique phenotype of neonatal microglia that have re-myelinating and anti-inflammatory potential. Understanding mechanism for these protective effects will enable therapy for neuroinflammatory disease.

Combined actions of Type 1 diabetes associated HLA genes, alleles and residues

***A. Alansari**, S. Al-Badi, M. Al-Balushi, H. Al-Riyami, S. Al-Yaarubi;*
Sultan Qaboos University, Al-Khoud, Oman.

Introduction. Genetic susceptibility and environmental factors determine the onset of type 1 diabetes (T1D). The identification of human leukocytes antigen (HLA) high risk alleles, genotypes and haplotypes is beneficial for understanding their roles in T1D pathogenesis and intervention practices. Also, it could help in developing new assays and immunotherapy. Aim. The aim of the study is identify associations between HLA genes and T1D in Oman. Materials and methods. Our case-control study included 100 diabetic children (mean age 9.19±3.94 years) and 110 controls (mean age 10.77±3.36 years). HLA-DRB1, DQA1 and DQB1 alleles were genotyped using sequence specific primer polymerase chain reaction (SSP-PCR). Results. B*08, DQB1*02, DRB1*03 and DRB1*04 alleles were associated with T1D susceptibility, while C*16, B*51, DQB1*05 and DQB1*06 alleles were associated with protection. HLA- DRB1*03 and DQB1*02 alleles showed the strongest risk association among all alleles. Six DRB1 residues (Glu-9, Ser-11, Ser-13, Tyr-30, Val-70, Lys-71) were significantly associated with TID susceptibility and analysis indicated that they have combined actions. Heterozygous genotypes, HLA-DRB1*03/*04 and DQB1*02/*03 were associated with T1D susceptibility significantly (p=0.021, OR=15.909). Furthermore, HLA-DRB1*03 and DQ*02 found to be in LD and have significant combined action in the disease (p=5.21E-13, OR 12.11). Conclusions. Significant association of HLA I and II alleles, genotypes and haplotypes were identified in Omani TID patients. Similar associations were reported from Arab and non-Arab populations. Results indicated significant combined actions predisposing to TID at the genes, alleles and resides levels.

Annexin A1 (ANXA1): potential regulator of adaptive immune response in Multiple Sclerosis (MS)

A. Colamatteo[1], *E. Maggioli*[2], *G. Cali*[3], *S. Cassano*[3], *M. Galgani*[3], *D. Bruzzese*[4], *G. Maniscalco*[5], *G. Matarese*[1], *E. Solito*[2], *V. De Rosa*[3];
[1]*Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Napoli, Italy,* [2]*William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom,* [3]*Istituto di Endocrinologia ed Oncologia Sperimentale, Consiglio Nazionale delle Ricerche, Napoli, Italy,* [4]*Dipartimento di Sanità Pubblica, Università degli Studi di Napoli "Federico II", Napoli, Italy,* [5]*Dipartimento di Neurologia, Centro Regionale Sclerosi Multipla, Azienda Ospedaliera "A. Cardarelli", Napoli, Italy.*

ANXA1 is a glucocorticoid-regulated anti-inflammatory protein, which acts as an endogenous regulator of innate immunity by limiting neutrophils extravasation and blocking monocytes migration. ANXA1 is also expressed in brain microvascular endothelial cells, where it regulates blood brain barrier (BBB) integrity. Recently, a selective loss of ANXA1 in the plasma and cerebrovascular endothelium of multiple sclerosis (MS) subjects has been reported.
Our aim was to investigate whether ANXA1 could have also a role in the modulation of immune tolerance in naive-to-treatment relapsing-remitting (RR)-MS subjects. We analysed whether its plasma levels correlated with disease severity and progression. Moreover, we measured ANXA1 expression in different T cell subsets: regulatory T (Treg), conventional T (Tconv) and Th17 cells. We also investigated the migratory capacity of Treg and Tconv cells from RRMS and healthy subjects. Finally, we assessed whether recombinant (r)-human ANXA1 treatment could affect T cell activation, proliferation and metabolic engagement *in vitro*.
We observed that ANXA1 plasma levels inversely correlated with EDSS and relapses number in RRMS subjects. Its expression was significantly lower in Treg, Tconv and Th17 cells from RRMS compared to healthy subjects. This finding correlated with a higher degree of adhesion and migration of both Treg and Tconv cells *in vitro*. Rh-ANXA1 treatment profoundly reduced proliferation, expression of several activation markers and glycolytic engagement of PBMCs from healthy subjects, with a mild effect in RRMS subjects. Understanding the molecular mechanism accounting for the reduced ANXA1 expression should provide relevant informations on the key events leading to RRMS onset and progression.

Dimethyl fumarate induces an anti-inflammatory shift in follicular T cells in multiple sclerosis

V. Cunill[1,2], *M. Massot*[1], *A. Clemente*[2], *C. Callles*[1], *V. Andreu*[2], *C. Capó-Serrra*[2], *V. Núñez*[1], *A. López-Gómez*[1,2], *R. Díaz*[1], *M. Jiménez*[1], *J. Pons*[1,2], *C. Vives*[2], *J. Ferrer*[1,2];
[1]*Hospital Universitari Son Espases, Palma de Mallorca, Spain,* [2]*Fundació Institut d'Investigació Sanitària Illes Balears, Palma, Spain.*

Introduction: Although Multiple sclerosis (MS) is considered a T cell-mediated autoimmune disease, several evidences demonstrate the involvement of B cells in its etiology. Follicular helper (Tfh) cells are essential in the regulation of humoral immunity. Alterations in circulating(c)Tfh function and/or distribution associate with autoimmune diseases including MS. Dimethyl fumarate (DMF) is a recently approved first-line treatment for relapsing-remitting MS(RRMS) patients. The aim of our study was to evaluate cTfh subpopulations in RRMS patients, the impact of DMF treatment on cTfh distribution and their clinical evolution. **Methods:** We analyzed, by flow cytometry, the distribution of cTfh1(CXCR3+CCR6-), cTfh2(CXCR3-CCR6-), cTfh17(CXCR3-CCR6+) and cTfh17.1(CXCR3+CCR6+) in CD4+ follicular T cells (CD45RA-CXCR5+) subpopulations from 29 untreated RRMS patients and 6 and 12 months after DMF treatment. We also evaluated these subpopulations in CD4+ non-follicular T cells (CD45RA-CXCR5-). **Results:** Untreated RRMS patients presented higher percentages of cTfh17.1 cells and lower percentages of cTfh2 cells consistent with a pro-inflammatory bias compared to controls. DMF treatment induced a progressive increase in cTfh2 cells 6 and 12 months after treatment, accompanied by a decrease in cTfh1 and the pathogenic cTfh17.1 cells. Similar decreases of non-follicular Th1 and Th17.1 cells in addition to an increase in the anti-inflammatory Th2 subpopulation were also detected. Interestingly, we identified three non-responders DMF patients unable to normalize the deviation of cTfh subpopulations. **Conclusions:** RRMS have a pro-inflammatory profile, defined by high cTfh17.1 and low cTfh2 subpopulations, which can revert after DMF treatment. Monitoring cTfh subsets during treatment may become a biological marker of DMF effectiveness.

P.C2.03.04

Reciprocal modulation of human Th1 and Th17 cells by beta2-adrenergic receptor agonists

P. J. Darlington[1], *M. Tabatabaei Shafiei*[2], *T. Daigneault*[1], *C. M. Carvajal Gonczi*[1];
[1]*Concordia University, Montreal, Canada,* [2]*McGill University, Montreal, Canada.*

Introduction: T helper (Th) 1 and Th17 cells are essential for host protection and have been linked to various autoimmune diseases. The beta2-adrenergic receptor (β2AR) pathway regulates physiological reactions in response to catecholamines hormones such as epinephrine and norepinephrine. Little is known about how catecholamines alter Th cell balance in health and disease in humans. **Methods:** Peripheral blood mononuclear cells (PBMC) from healthy human donors, and Th cells purified with magnetic columns, were activated *in vitro* with anti-CD3 and anti-CD28, and treated with β2AR pharmacological agonists (terbutaline, or nebivolol) and antagonist (ICI-118,551). Proliferation was measured by flow cytometry and cytokines were measured by enzyme linked immunosorbent assay. Common polymorphisms of β2AR (*ADRB2*) were determined by Sanger sequencing. **Results:** Th17 cells expressed β2AR. Terbutaline raised the level of Th17 cell cytokine IL-17A ($p<0.01$) while lowering the level of Th1 cell cytokine IFNγ ($p<0.01$). Nebivolol, an inverse agonist, lowered IL-17A but raised IFNγ which was opposite to the terbutaline effect. Only a slight proliferative change was observed on Th cells ($p<0.001$). The cAMP analog (dbcAMP) raised IL-17A ($p<0.05$) while lowering IFNγ ($p<0.001$) similar to the terbutaline effect. Samples from donors who were *ADRB2* Arg16 heterozygotes responded significantly to terbutaline ($p<0.01$) while Gln/Glu27 had no interaction with agonist response. **Conclusion:** Cell signaling through β2AR alters the balance of Th17 and Th1 cytokines and may be linked to common polymorphisms. These results suggest that β2AR agonists differentially modulate adaptive immune responses and may influence autoimmunity. Research funded by NSERC Discovery grant (418522-2013)

P.C2.03.05

Identification and characterization of HDAC1 interaction networks in Th17 cells

P. Hamminger[1], *L. Hess*[2], *L. Göschl*[1], *T. Preglej*[1], *M. Hartl*[3], *C. Seiser*[2], *W. Ellmeier*[1];
[1]*Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria,* [2]*Center for Anatomy and Cell Biology, Division of Cell and Developmental Biology, Vienna, Austria,* [3]*Mass Spectrometry Facility, MFPL, Vienna, Austria.*

The differentiation and function of $CD4^+$ T helper (Th) subsets has to be tightly regulated, since their dysregulation is linked with immune-mediated diseases. Th cell differentiation is accompanied by reversible changes in histone acetylation, mediated by the opposing activity of histone acetyltransferases (HATs) and histone deacetylases (HDACs), however many non-histone targets are emerging, indicating that HAT/HDACs act beyond the regulation of chromatin. Results of my laboratory demonstrate an essential role for HDAC1 in regulating Th17 cell effector function and that loss of HDAC1 in T cells protects mice from the development of experimental autoimmune encephalitis. This clearly indicates essential roles for HDAC1 in the control of T cell-mediated autoimmunity. Since HDAC1 is part of larger multiprotein complexes, it is tempting to speculate that the crucial role of HDAC1 is mediated by targeting factors that are key regulators of Th17 cells. The aim of my PhD thesis project is to test this hypothesis.

P.C2.03.06

In-depth mapping of transcriptomic dysregulation in circulating pDCs from patients with Sjögren's Syndrome associated with increased production of pro-inflammatory cytokines

M. R. Hillen, *A. Pandit, S. L. Blokland, S. A. Hartgring, K. van der Wurff-Jacobs, A. A. Kruize, M. Rossato, J. A. van Roon, T. R. Radstake;
University Medical Center Utrecht, Utrecht, Netherlands.*

Introduction: Primary Sjögren's syndrome (pSS) is an autoimmune disease characterized by lymphocytic infiltration of the exocrine glands. Type-I interferons (IFN) are thought to play an important role in pSS pathogenesis, suggesting a role for pDCs. We performed RNA sequencing on isolated circulating pDCs from patients with pSS, non-Sjögren's sicca (nSS) patients, and healthy controls (HC).
Methods: Peripheral blood pDCs were isolated from two independent cohorts (each n=31) of patients and controls using MACS and RNA sequencing was performed. ±20 million paired-end sequencing reads per sample were obtained using using Illumina HiSeq 2500 platform. For *in vitro* experiments, pDCs were isolated from 22 pSS and 17 HCs and cultured for 3h with loxoribine or CPG-C.
Results: 3144 genes were consistently differentially expressed (p-value <0.05) between all groups in both cohorts. We generated gene modules from both cohorts and found 5 gene clusters that were consistently dysregulated. Pathway analysis showed that these clusters contain genes associated with cellular activation, including IFN-signalling and viral sensing. pDCs from pSS patients produced significantly more IFN-a and IFN-b *in vitro* and cytokine levels correlated with the expression of genes that were present in the RNAseq gene clusters.
Conclusions: We identified gene clusters that are robustly replicated in two independent cohorts. nSS patients showed similar transcriptomic dysregulation to pSS patients at an intermediate level. The increased production of type-I IFN by pSS pDCs confirms their activated phenotype and the association between cytokine production and gene expression suggests that these transcriptomic difference may underpin pDC dysregulation in pSS.

P.C2.03.07
Effects of ROS-insensitive PTPN22 on autoimmunity

***J. James**, C. Marquina, A. Saxena, R. Holmdahl;*
Karolinska Institute, Solna, Sweden.

Autoimmune diseases present an ever-growing health concern and affect millions around the globe, particularly in Western countries. An allelic variant of PTPN22 (protein tyrosine phosphatase, non-receptor type 22) is highly associated with several autoimmune diseases such as rheumatoid arthritis, SLE and type 1 diabetes. PTPN22 acts a negative regulator of signalling in B and T cells by dephosphorylating immunoreceptor-proximal proteins. Furthermore, PTPs act as redox sensors and inactivation of PTPs via oxidation plays an important role as a regulatory mechanism. While studies have focused on the disease-associated PTPN22 R620W variant, the oxidative regulation of PTPN22 in autoimmunity has not been investigated yet.
To this purpose our lab has developed a mouse strain where a point mutation (C129S) in the PTPN22 gene results in insensitivity to redox regulation. Preliminary results show similar PTPN22 expression levels in splenic B cells and thymocytes and comparable immune cell profiles in spleen, thymus and bone marrow between wild-type and PTPN22^{C129S} mice. Phosphorylation of target proteins downstream of PTPN22 is unaffected by the mutation. However, GPI-induced arthritis and DTH (delayed-type hypersensitivity) models show increased arthritis severity in the PTPN22 mutant. How PTPN22 function is regulated by ROS remains to be further investigated.

P.C2.03.08
The properties of integrin α4β7+ CD4 T cells are altered in multiple sclerosis

***M. Nguyen Ky**[1], A. Ruet[2], A. Bru[1], C. Dulau[2], M. Deloire[2], K. Kounkou[2], J. Déchanet-Merville[1], P. Blanco[1], B. Brochet[2], N. Schmitt[1];*
[1]ImmunoConcEpT CNRS UMR 5164, University of Bordeaux, Bordeaux, France, [2]Neurology department, CHU Bordeaux Hospital, Bordeaux, France.

Multiple sclerosis (MS) is a neurodegenerative autoimmune disease of the central nervous system (CNS). Mouse studies suggest that gut-derived CD4 T cells might be an important player in MS pathogenesis. CD4 T cells primed in the gut are characterized by their expression of integrin α4β7. α4β7+ CD4 T are negative for the expression of the brain-homing molecule integrin α4β1 but express the other main brain homing molecule LFA-1 proposed to play an important role in the migration of CD4 T cells such as Th17 into CNS in mouse models.
We found that the proportion of Th17 cells was significantly increased in α4β7+ CD4 T cells in the blood of MS patients compared to controls. Following polyclonal stimulation, we observed an increased proportion of IL-2 and a decreased proportion of IFNγ and MIP-1α-secreting cells in α4β7+ CD4 T cells in MS compared to controls while IL-17 and IL-10 levels were not altered. Importantly, these modifications were more marked in α4β7+ CD4 T cells compared to α4β7- CD4 T cells.
We next assessed whether the capacity of α4β7+ CD4 T cells to migrate into the CNS might be altered by Natalizumab (NZB), a monoclonal antibody targeting integrin α4, which efficiently prevents the migration of pathogenic CD4 T cells into the CNS. We found that NZB indirectly decreased the expression of LFA-1 on α4β7+ CD4 T cells suggesting that NZB treatment might reduce their migration to the CNS.
Altogether, these results suggest the involvement of α4β7+ CD4 T cells in MS pathogenesis.

P.C2.03.10
***KIR* genes and autoantibodies levels in rheumatoid arthritis**

***I. V. Reyes-Pérez**[1], P. E. Sánchez-Hernández[1], J. F. Muñoz-Valle[2], G. E. Martínez-Bonilla[3], S. Gutiérrez-Ureña[3], S. Cerpa-Cruz[3], V. González-Díaz[3], T. García-Iglesias[1], J. Polanco-Cruz[3], K. M. García-Osuna[3], E. E. Velarde-De la Cruz[1], M. G. Ramírez-Dueñas[1];*
[1]Laboratorio de Inmunología, Universidad de Guadalajara, Guadalajara, Mexico, [2]Instituto de Investigación en Ciencias Biomédicas, Universidad de Guadalajara, Guadalajara, Mexico, [3]Servicio de Reumatología, Hospital Civil Fray Antonio Alcalde, Guadalajara, Mexico.

Introduction Rheumatoid arthritis (RA) is an autoimmune disease characterized by inflammation of the diarthrodial joints and production of different autoantibodies such as RF, anti-CCP, anti-MCV and anti-PADI4. *KIR* genes encode receptors that regulate the function of NK cells and T cell subpopulations, which may be involved in the activation of B cells. **Aim** To identify the association of *KIR* genes with RF, anti-CCP, anti-MCV and anti-PADI4 levels in rheumatoid arthritis **Methodology** Peripheral blood samples were obtained from RA patients (RA, n=90) and healthy subjects (HS, n=70). gDNA was extracted by Miller modified technique and 16 KIR genes were typed by PCR-SSP. RF was quantified by turbidimetry. Anti-CCP, anti-MCV, and Anti-PADI4 were quantified by ELISA kit. The data were analyzed with chi-square and t-student tests with a significant p <0.05. **Results** *KIR2DL2* and *KIR2DS4del* were found more frequently in patients than in healthy subjects (p = <0.0001; p = <0.003, respectively). RF (HS=6.7 U/mL, AR=62.3 U/mL, p=0,0001), anti-CCP (HS=0.6 U/mL, AR=150.6 U/mL, p=0,0001), anti-MCV (HS=10.1 U/ml, AR=1418.0, p=0.0001) and anti-PADI4 (HS=2.57 ng/mL, AR=4.04 ng/mL, p=0.0001) were higher in subjects with RA than in HS. *KIR2DL2- / 2DS4del+* genotype obtained a tendency to increase anti-PADI4 levels in comparison to *KIR2DL2+/2DS4del+ (p*=0.07). **Conclusions** *KIR2DL2* and *KIR2DS4del* could act as risk factors in the AR development. An association between *KIR* genes and autoantibodies levels has not been found yet, but the data shows a tendency of higher levels of anti-PADI4 in patients with *KIR2DL2+/2DS4del+* genotype.

Altered Toll-like receptor -7 and -9 signaling in patients with primary Sjögren's syndrome: a single-cell network analysis by mass cytometry

***I. Sarkar**[1], R. Davies[1], D. Hammenfors[1,2], B. Bergum[1], A. K. Aarebrot[1], S. M. Solberg[1,3], P. Vogelsang[1], J. G. Brun[2,4], R. Jonsson[1], S. Appel[1];*
[1]Broegelmann Research Laboratory, Department of Clinical Science, University of Bergen, Bergen, Norway, [2]Department of Rheumatology, Haukeland University Hospital, Bergen, Norway, [3]Department of Dermatology, Haukeland University Hospital, Bergen, Norway, [4]Department of Clinical Science, University of Bergen, Bergen, Norway, Bergen, Norway.

Introduction: Primary Sjögren's syndrome (pSS) is a chronic, inflammatory, systemic autoimmune disorder characterized by dysfunction of exocrine glands, mainly salivary and lacrimal, leading to dry mouth and eyes. The dryness and other clinical manifestations result in a significant decrease in life quality of the patients, 90 % of them being women. Currently there is no cure or effective treatment for pSS due to the pathogenic complexity of the disease, with genetic predisposition, hormonal and environmental factors all contributing to the disease etiology. Enhanced activation potential of signaling pathways may play a crucial role in the pathogenesis of pSS. In our previous work using phospho-flow cytometry, we had analysed MAPK/ERK and JAK/STAT signaling networks in peripheral blood mononuclear cells (PBMCs) and observed altered signaling profiles in pSS patients. Methods: Mass cytometry was used to validate and refine our previous results. Phosphorylation status of MAPK/ERK and JAK/STAT signaling networks in Toll-like receptor (TLR) -7 and -9 stimulated PBMCs from 25 female pSS patients and 25 age and sex-matched healthy donors were analysed. Results: Stimulation of PBMCs with TLR-7 and -9 ligands resulted in significant differences in the phosphorylation profiles between patients and healthy donors. Principal component analysis (PCA) including clinical parameters showed that it was possible to subgroup the patients. Conclusion: Patients with pSS have an increased signaling potential in PBMCs upon TLR-7 and -9 stimulation. Funding: This work was supported by the EU H2020 contract HarmonicSS (H2020-SC1-2016-RTD/731944), Broegelmann Foundation, Western Norway Regional Health Authorities (grant nr. 912065) and University of Bergen.

P.C2.03.12
Expanding systemic antigen specific regulatory networks to treat liver autoimmunity

***C. Sokke Umeshappa**, S. Singha, K. Shao, R. Hebbandi Nanjundappa, J. Lee, J. Yamanouchi1, Y. Yang, P. Santamaria;*
University of Calgary, Calgary, Canada.

Peptide-major histocompatibility complex class II (pMHCII)-based nanomedicines trigger the formation of multi-cellular regulatory networks by re-programming autoantigen-experienced CD4+ T-cells into tissue-specific T-regulatory type 1 cells (TR1). Here, we show that pMHCII-based nanomedicines displaying liver autoimmune disease-relevant, yet ubiquitous mitochondrial, endoplasmic reticulum or cytoplasmic, antigens can blunt multiple liver autoimmune diseases, Primary Biliary Cholangitis (PBC), Autoimmune Hepatitis (AIH), and Primary Sclerosing Cholangitis (PSC). The therapeutic effect occurred in an autoimmune-disease as well as non-disease-but-organ-specific manner, wherein PBC-relevant pMHCII nanomedicines blunted not only PBC but also AIH and PSC, and AIH-relevant pMHCII nanomedicines blunted not only AIH but also PBC and PSC. These data indicate that hepatocyte and biliary epithelial cell destruction in liver autoimmunity results in the activation of subdominant T-cells recognizing systemically-expressed antigens not known to partake in these diseases. Mechanistically, nanomedicines-expanded TR1 cells suppressed autoantigen-loaded antigen-presenting cells and drove cognate B cells differentiation into disease-suppressing B regulatory cells locally, without suppressing immunity against infections or cancer. From the clinical point, the therapeutic effect was superior to Ursodeoxycholic acid, the current standard of care for PBC. Thus, the current study represents an unmet clinical need for three complex liver autoimmune diseases.

P.C2.03.13

Changes in natural killer cells and monocytes during the third trimester of pregnancy in multiple sclerosis

***H. B. Søndergaard**, L. Börnsen, J. R. Christensen, B. R. Nielsen, A. Oturai, F. Sellebjerg;*
Danish Multiple Sclerosis Center, University of Copenhagen, Rigshospitalet, Copenhagen, Denmark.

Pregnancy affects the disease course in the autoimmune disease multiple sclerosis (MS), particularly in the third trimester, where the relapse rate is reduced by as much as two thirds. This study aimed at identifying specific changes in biomarkers of immune activation in pregnant MS patients. Flow cytometry analysis was performed on mononuclear blood cells stained with antibodies directed against, among others, PD-L1 and PD-L2, antigen-presenting cells (APCs), NK-cells, NKT-cells, CD4+- and CD8+ T-cells and subsets of these cell types. Pregnant MS patients had a highly significant increase in the percentage of monocytes and a decrease of NK-cells and myeloid dendritic cells (mDCs) compared to non-pregnant MS patients. No changes were found in NKT- and regulatory T-cells, CD4+- and CD8+-T-cells, plasmacytoid dendritic cells (pDCs) or B-cells. The percentage of mDCs and pDCs expressing PD-L1 was increased and the percentage of monocytes and pDCs expressing PD-L2 was increased in pregnant patients. PD-L1 and PD-L2 are known to bind PD-1 expressed on T cells with an inhibitory effect on T-cell proliferation and increase in the production interleukin-10. Also, we confirm previous reports of a relative increase in CD56-bright NK cells and a decrease in CD56-dim NK cells in the last trimester of pregnancy in MS patients. Thus, decreased immune activation in the third trimester of pregnancy coincides with an increased number of circulating monocytes and lower numbers of NK-cells together with a more immunoregulatory APC phenotype. This research was funded by the Danish Council for Strategic Research and the Danish Multiple Sclerosis Society.

P.C2.03.14

New insights into inflammatory myopathies using microarray data analysis

***C. Sordo-Bahamonde**, S. Lorenzo-Herrero, A. López-Soto, E. deAndrés-Galiana, J. Fernández-Martínez, S. González;*
Universidad de Oviedo, Oviedo, Spain.

Introduction: Idiopathic inflammatory myopathies comprise a heterogeneous group of disorders characterized by muscle inflammation that include Polymyositis (PM) and Inclusion Body Myositis (IBM). PM is considered as a T cell-mediated autoimmune disease and IBM is characterized by a combination of T cell-mediated disease and myofiber degeneration.
Materials and Methods: The most discriminatory genes of IBM and PM phenotypes were determined using previously reported microarray data from muscle biopsies of patients by using a combination of fold change, Fisher's Ratio and a new machine learning algorithm.
Results: Our data support the well-known relevance of Major Histocompatibility Complex (MHC) class I molecules in PM and IBM, accessory molecules involved in MHC class I presentation and function, as well as transcription factors that promote cytotoxic CD8 T cell-mediated immune responses, such as STAT1, IRF7 and IRF9,. Additionally, our study unveils the potential relevance of novel genes involved in the pathogenesis of PM, including *OSBPL10*, *GOLM1* and *SIK1*; and IBM (*RPS4Y*, *S100A4*, *S100A6* and *CAPN3*).
Conclusions: IBM and PM remain as incurable autoimmune diseases. Our study confirms the relevance of molecules and pathways widely accepted to play a role in inflammatory myopathies, but it also provides new insights into the pathogenesis of PM and IBM. The role in inflammatory myopathies of the new molecules detected in our study deserves future investigation since they may be potential new therapeutic targets in these type of diseases.

P.C2.03.15

Prevalence and age association of autoantibodies in a Greek healthy adult cohort

*K. Ampelakiotou, E. Synodinou, K. Soufleros, S. Pomoni, A. Lemoni, **A. Tsirogianni**;*
Immunology-Histocompatibility Dept. "Evaggelismos" General Hospital, Athens, Greece.

The aim of this study was to investigate the prevalence of autoantibodies (aabs) in 187 healthy adults classified in 3 groups: group I (18-40 years), group II (41-64) and group III (65-87). Anti-nuclear (ANA), anti-dsDNA, anti-neutrophil cytoplasmic (ANCA), anti-mitochondrial (AMA), anti-smooth muscle (ASMA), anti-liver/kidney microsomal type 1 (anti-LKM1) and anti-parietal cells (APCA) aabs, were studied. Indirect Immunofluorescence (IIF) assay was used initially while positive samples, by Line Immunoassay (LIA), were further analyzed. Positive ANA were detected in 31 of 187 samples (16,6%), 25 out of 116 women (21,6%) and 6 out of 71 men (8,5%). In group I, 10 out of 67 (14,9%) samples, in group II, 12 out of 73 (16,4%) and in group III, 9 out of 47 (19,1%). Anti-dsDNA were not detected in any sample while in only one ANA positive sample anti-Mi-2 were identified. Regarding ANCA, atypical pattern (a-ANCA) was observed in 5 (2,7%) samples without anti MPO/PR3 specificity. ASMA were detected in 3 samples (1,6%), APCA in 9 (4,8%), whereas AMA and LKM1 were not identified. In this studied cohort the sera of 44 (23,5%) individuals had at least one autoantibody while 3 (1,6%) had more than one. In conclusion, it is suggested that in Greek healthy adults the prevalence of autoantibodies increases with age. However, it is lower than in other studies performed worldwide. This might mean that genetic and epigenetic factors, HLA, diet and climate in particular, affect our findings.
*This study has been submitted to the AESKU IFA Prize Competition 2017.

P.C2.03.16

HLA typing and autoantibodies screening among family members of Celiac Disease Greek patients

*V. Kitsiou, D. Kouniaki, K. Soufleros, T. Athanassiades, K. Tarassi, K. Ampelakiotou, S. Pomoni, E. Synodinou, D. Siampani, **A. Tsirogianni**;*
Immunology-Histocompatibility Dept. "Evaggelismos" General Hospital, Athens, Greece.

Introduction: Celiac Disease (CD) is an autoimmune disease caused by genetically induced intolerance to gluten protein that leads to small bowel enteropathy. It affects 1-2% of Caucasoids however is more common in family members (FMs) of CD patients (pts).
The aim of this study was the assessment of HLA typing and autoantibodies screening in the determination of familiar CD prevalence, in a Greek cohort.
Subjects-Methods: The study included 29 recently diagnosed CD pts and 101 asymptomatic first-degree FMs. HLA-DQA1*/DQB1* typing by high resolution PCR-SSP techniques, anti-tissue transglutaminase (tTG) by ELISA and anti-endomysial (EMA) autoantibodies (Aabs) by IIF, were performed.
Results: At least one CD predisposing HLA allele was typed in 28/29 (96.5%) pts and 77/101 (76.2%) FMs. Among them 86 (66.1%) were DQ2, 12 (9.2%) DQ8 and 7 (5.3%) DQ2/8 double positive. All pts and 21 FMs were positive in at least one of the tested Aabs (100% tTG and 96% EMA) and all of them but one pt carried a high risk HLA allele. The study revealed 21 new CD cases (4 parents, 10 offsprings,7 siblings) according to ESPGHAN diagnostic criteria, all possessing both genetic and serological CD markers.
Conclusions: In our cohort the prevalence of CD among first-degree relatives appears higher (20.8%) than in the general population. The fact that these pts remain undiagnosed may lead to severe complications. Therefore, a screening strategy with HLA genotyping as well as tTG and EMA Aabs serological testing, could be strongly recommended in FMs of CD pts.

P.C2.03.17

ANCA-associated Vasculitis: Therapy is the lesser evil

***G. Van Hulst**, L. C. Van Eyndhoven, J. Potjewijd, J. P. Aendekerk, P. van Paassen, J. Damoiseaux, N. de Wit, J. Vanderlocht;*
Maastricht University Medical Centre, Maastricht, Netherlands.

Introduction: The currently applied one-size-fits-all therapeutic approach causes variable levels of immunosuppression between patients due to individual pharmacodynamics and pharmacokinetics. Althoughimmunosuppressive regimens improved overall survival and mortality rates in ANCA-associated vasculitis (AAV), it requires close monitoring of the patients to manage toxicity and prevent life-threatening complications. A paradigm shift to personalized protocols is needed to prevent complications in the future. Therefore, we aim to establish a readout for the level of immunosuppression and secondary risk of complications.
Methods: We compared immune status differences of AAV patients treated with rituximab or azathioprine, during active disease, and age matched healthy controls. Lymphocyte subsets were quantified using standardized 8-color flow cytometry conform the Euroflow consortium. Proliferative capacity of T cells was estimated by flow cytometric analysis of CFSE dilution after polyclonal stimulation. Cytokine secretion profiles will be measured by flow cytometric bead array performed on the culture supernatants.
Results: Our preliminary data indicate that naïve helper T cells and B cells were reduced in rituximab and azathioprine patients compared to age-related controls. Additionally, cytotoxic T cells were decreased by azathioprine whereas relatively unaffected by rituximab.
Discussion: Although underlying mechanisms of both therapies are dissimilar, the similarity of the effect on naïve helper T cells and B cells may motivate the effectiveness of both therapies in the treatment AAV. Interestingly, the dissimilarity of both therapies on cytotoxic T cells could indicate a lesser role for cytotoxic T cells in disease activity of AAV.

Anti-TNFá therapeutics differentially affect *Leishmania* infection of human macrophages

*K. Arens, C. Filippis, H. Kleinfelder, A. Goetzee, G. Reichmann, P. Crauwels, Z. Waibler, **K. Bagola**, G. van Zandbergen;*
Paul-Ehrlich-Institut, Langen, Germany.

Tumor necrosis factor α (TNFα) drives the pathophysiology of human autoimmune diseases and consequently, neutralizing antibodies (Abs) or Ab-derived molecules directed against TNFα are essential therapeutics. As treatment with several TNFα blockers has been reported to entail a higher risk of infectious diseases such as leishmaniasis, we established an *in vitro* model based on *Leishmania*-infected human macrophages, co-cultured with autologous T-cells, for the analysis and comparison of anti-TNFα therapeutics. We demonstrate that neutralization of soluble TNFα (sTNFα) by the anti-TNFα Abs Humira®, Remicade® and its biosimilar Remsima® negatively affects infection as treatment with these agents significantly reduces *Leishmania*-induced T-cell proliferation and increases the number of infected macrophages. In contrast, we show that blockade of sTNFα by Cimzia® does not affect T-cell proliferation and infection rates. Moreover, compared to Remicade®, treatment with Cimzia® does not impair the expression of cytolytic effector proteins in proliferating T-cells. Our data demonstrate that Cimzia® supports parasite control through its conjugated polyethylene glycol (PEG) moiety as PEGylation of Remicade® improves the clearance of intracellular *Leishmania*. This effect can be linked to complement activation, with levels of complement component C5a being increased upon treatment with Cimzia® or a PEGylated form of Remicade®. Taken together, we provide an *in vitro* model of human leishmaniasis that allows direct comparison of different anti-TNFα agents. Our results enhance the understanding of the efficacy and adverse effects of TNFα blockers and they contribute to evaluate anti-TNFα therapy for patients living in countries with a high prevalence of leishmaniasis.

P.C2.04.02
Role of GSK-3 in the IL-10 production of marginal zone B cells

***B. Barátki**[1], D. Kövesdi[2];*
[1]Department of Immunology, Eötvös Loránd University, Budapest, Hungary, [2]MTA TKI, Budapest, Hungary.

Glycogen synthase kinase 3 (GSK-3) is a constitutively active serine/threonine kinase. In macrophages signalling through the IFN-γ receptor antagonizes Akt/PKB activation thus blocks the TLR-induced IL-10 production on a GSK-3-dependent manner. It is unclear however, how GSK-3 is involved in the IL-10 expression of B lymphocytes. We showed previously that marginal zone (MZ) B cells, unlike follicular (FO) B cells, produced a high amount of IL-10 under inflammatory conditions. Therefore, in our recent work we aimed to investigate the involvement of GSK-3 in the BCR, TLR9 and IFN-γ receptors induced IL-10 production of MZ B cells.Throughout our experiments we used MZ and FO B cells isolated from the spleens of DBA/1 mice and stimulated simultaneously with anti-IgM, CpG and IFN-γ in the presence or the absence of a GSK-3 inhibitor. The effects of GSK-3 and its inhibitor on IL-10 production were analysed by Western blot, flow cytometry, real-time RT-PCR and IL-10 specific ELISA.
Our results showed that simultaneous signals through the BCR, TLR9 and IFN-γ receptors had a synergistic effect on IL-10 expression. Using the GSK-3 inhibitor we proved the impact of GSK-3 on the IL-10 production of MZ B cells and demonstrated its prolonged versus transient phosphorylation/inactivation in MZ and FO B cells, respectively.
We assume that the transient inactivation of GSK-3 is needed for the proper induction of IL-10 production and for the regulatory differentiation of MZ B cells under inflammatory condition.

The mechanism of RNA-binding protein HuR regulating Th17 cell differentiation

***J. Chen**, S. Yu;*
Thomas Jefferson University, Philadephia, United States.

T helper 17 (Th17) cells play critical pathogenic roles in several autoimmune and inflammatory diseases including multiple sclerosis and experimental autoimmune encephalomyelitis (EAE). It is well-known that IL-6 in the presence of TGF-b promotes Th17 cell differentiation. Although cytokine-mediated transcriptional regulation of Th17 cell differentiation and proliferation is fully investigated, it remains unknown about post-transcriptional regulation of Th17 cell differentiation and proliferation by RNA-binding proteins (RBPs). We previously demonstrated that the RBP HuR (ELAVL1) post-transcriptionally modulates expressions of IL-17, GM-CSF and CCR6 in Th17 cells. Here we provided new data that demonstrated that HuR upregulates phosphorylation of Stat3 and RoRrt expression to promote Th17 cell differentiation and proliferation using the HuR conditional knockout (KO) mice. Mechanically, HuR protein stabilizes IL-6R mRNAs leading to increased its mRNA half-life and protein level, therefore, enhanced IL-6/IL-6R signaling and phosphorylation of Jak1 and Stat3, ultimately, increased RoRrt expression. Taken together, these results suggested that HuR positively orchestrates Th17 cell differentiation and proliferation. Accordingly, HuR might be a novel therapeutic target for treatment of Th17 cell-mediated autoimmune diseases. (Supported by NIH R01 AI119135)

Heterozygous mutations in the soluble complement regulator factor H (FH) are commonly associated with severe complement-related diseases such as atypical hemolytic uremic syndrome (aHUS) and age-related macular degeneration. We have discovered an anti-FH monoclonal antibody (mAb) that enhances FH function which could be important for clinical use. In ELISA, by measuring C3 deposition on LPS-coated surfaces, the potentiating anti-FH mAb could inhibit alternative pathway-mediated complement activation. Importantly, the mAb neither affects FH cofactor activity in fluid phase, nor causes inhibition by consumption of circulating C3. Addition of the potentiating mAb prevents complement-mediated hemolysis of sheep erythrocytes induced by aHUS patient sera. Moreover, C3b deposition on human endothelial cells (HUVEC) incubated with patient sera is prevented by enhancing FH function with the mAb. In both ELISA and surface plasmon resonance (SPR), binding of the mAb to FH increased the affinity of FH for C3b. And the degeneration of the alternative pathway convertase (C3bBb) by FH is increased. Studying recombinant FH with aHUS mutations shows that the mAb also potentiates FH function of these mutated FH. In contrast to Eculizumab, a well-known complement inhibitor used in the clinic, our mAb did not affect the bactericidal activity of normal human serum against *Escherichia coli* or *Neisseria meningitidis* and might therefore be a safer alternative to treat complement mediated diseases. In conclusion, our unique potentiating anti-FH mAb might serve as an alternative therapeutic for complement-mediated diseases to inhibit unwarranted complement activation on human endothelial cells while maintaining complement-mediated clearance of bacteria.

P.C2.04.05
Understanding the importance of B lymphocytes in the development of Type 1 Diabetes

***L. Egia-Mendikute**[1], B. Arpa[1], E. Rosell-Mases[1], M. Corral-Pujol[1], C. Vived[1], A. Panosa[1], C. Mora[1], J. Carrascal[1], T. Stratmann[2], D. Serreze[3];*
[1]University of Lleida & IRBLleida, Lleida, Spain, [2]University of Barcelona, Barcelona, Spain, [3]The Jackson Laboratory, Bar Habor, Maine, United States.

Introduction: To analyze through which mechanisms B lymphocytes participate in Type 1 Diabetes (T1D) development, we have generated two B lymphocyte transgenic mice, the 116C-NOD and the NOD-PerIg. In 116C-NOD mice, which wears immunoglobulins reactive to a non yet defined ß-cell autoantigen, late disease onset and a decrease of disease incidence is found in both genders compared to the wild-type NOD mice. In contrast, the NOD-PerIg mouse, in which the Immunoglobulins have specificity for peripherin, an acceleration of T1D onset and an increase of disease incidence are observed in both genders.
Materials Methods: Phenotypic flow cytometry analysis, proliferation and cytokine release assays were performed on B and T lymphocytes from mechanically disrupted spleens and pancreatic islets of prediabetic NOD, 116C-NOD and NOD-PerIg mice.
Results: Significant functional and phenotypic differences were observed between both transgenic mouse models. Islet-infiltrating B-lymphocytes (IIBLs) from 116C-NOD displayed lower expression of FAS, CD86, H-$2K^d$ and H-$2IA^{g7}$ compared to NOD mouse, whereas increased expression of the same molecules was detected in IIBLs from NOD-*PerIg*. Moreover, the number of IIBLs expressing BAFF, BAFF-R, and TACI molecular markers was also higher in 116C-NOD compared to NOD and NOD-*PerIg* mice. Moreover, proliferation assays have showed high capacity of NOD-*PerIg* mice B cells to produce large amounts of cytokines and to induce T cell activation, compared to the other models.
Conclusions: In NOD-*PerIg* mice, B-lymphocytes have an activated phenotype and support accelerated T1D development. In 116C-NOD mice, B lymphocytes display an anergic like phenotype, delaying T1D onset and decreasing disease incidence.

P.C2.04.06

Signaling induced by PRL in immature B cells from systemic lupus erythematosus mice

R. Flores[1], *F. Blanco*[1], *E. Fuentes*[2], *A. Pizaña*[3], *P. Gorocica*[3], *L. Chavez*[1], *K. Chavez*[1];
[1]*IMSS, Mexico, Mexico,* [2]*Hospital Infantil de Mexico, Mexico, Mexico,* [3]*Instituto Nacional de Nutricion, Mexico, Mexico.*

Introduction. The ontogeny of the B lymphocyte begins in bone marrow, where the precursor cells pass through different stages of maturation until they become immature B lymphocyte. In this stage, the auto-reactive clones are eliminated by mechanisms of central tolerance, such as the editing of the receptor or death by apoptosis. The PRL receptor has been shown to be expressed on immature B lymphocytes from systemic lupus erythematosus mice and WEHI-231 cells (the WEHI-231 cell line, it has been widely used as a model for the study of tolerance). When these cells incubated with this hormone, a decrease in the apoptosis was found. Prolactin (PRL) is a globular protein composed of 199 amino acids. The PRL receptor belongs to the type I cytokine receptor family. The binding of PRL with its receptor activates the JAK-STAT, MAPK and PI3K-AKT signaling pathways. Objective. Determine the signaling pathways induces by PRL in immature B cells from systemic lupus erythematosus mice. Methodology. Immature B cells from mice and WEHI-231 cells were incubated with PRL for 30 minutes. Then the cells were labelled with anti-STAT-1, STAT-3, STAT-5, AKT, and ERK1/2 phosphorylated antibodies, and IMF was determined by flow cytometry. Results. Immature B cells from systemic lupus erythematosus incubated with PRL increased the activation only of STAT-3, and WEHI-231 cells increased the activation of STAT-3 and AKT. Conclusions. The binding of PRL to its receptor activates only STAT-3 in immature B cells from lupus mice, and activates STAT-3 and AKT in WEHI-231 cells.

Interest of anti-aquaporine 4 in the etiological diagnosis of central nervous system inflammatory diseases

S. Mejdoub[1], *S. Feki*[1], *M. Dammak*[2], *N. Farhat*[2], ***H. Hachicha***[1], *C. Mhiri*[2], *H. Masmoudi*[1];
[1]*Immunology Laboratory, Habib Bourguiba Hospital, Sfax, Tunisia,* [2]*Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia.*

Neuromyelitis optica (NMO) is an inflammatory demyelinating disease of the central nervous system (CNS) with a predilection for optic nerves and spinal cord. Anti-aquaporine 4 antibodies (anti-AQP4) represent a specific biomarker of NMO and its borderline forms known as NMO spectrum disorders (NMOSD). The aim of our study was to evaluate the seroprevalence and the clinical interest of this marker in case of CNS inflammatory disorder in Tunisian patients.
In our study, anti-AQP4 was screened in the serum of 126 patients with CNS inflammatory disorder using indirect immunofluorescence on transfected cells (Euroimmun®, Germany).
Our results showed that anti-AQP4 seroprevalence was 3,9%. The 5 seropositive patients were women and had a mean age of 40 years (26-56). Three patients had an optico-spinal impairment and two had an isolated myelitis. It was the first clinical episod for 3 patients/5. In one case of optico-spinal impairment, seropositivity was detected in a second sample performed one year after an initial seronegativity. The diagnosis of NMOSD was made for the 5 cases.
In conclusion, it seems that anti-AQP4 has a low seroprevalence in our country. However, this marker appears to be clinically relevant for NMOSD diagnosis, especially in case of incomplete and atypical presentation. We also demonstrate the interest of repeating anti-AQP4 screening after an initial seronegativity in front of highly suggestive clinico-radiological features.

P.C2.04.08

NIK-IKK complex controls NF-êB-dependent inflammatory activation of the endothelium in response to LTâR ligation

P. Kucharzewska[1], *C. X. Maracle*[2], ***K. C. M. Jeucken***[2], *J. van Hamburg*[2], *S. W. Tas*[2], *H. Olsson*[1];
[1]*AstraZeneca R&D, Gothenburg, Sweden,* [2]*AMC Amsterdam, Amsterdam, Netherlands.*

Background: Endothelial cells (EC) are important contributors to inflammation via expression of inflammatory mediators, including chemokines and adhesion molecules. Production of inflammatory mediators can be induced via lymphotoxin-β receptor (LTβR)-ligation, resulting in activation of canonical and NF-κB-Inducing Kinase (NIK)-dependent noncanonical NF-κB signaling. However, the relative contribution of the individual NF-κB pathways to inflammatory activation of EC is largely elusive.
Objective: To identify the molecular pathways by which LTβR-ligation drives inflammatory activation of EC.
Methods: EC were stimulated with LTβ or LIGHT to activate LTβR, followed by analysis of downstream NF-κB signaling pathways and expression of inflammatory mediators. To repress canonical NF-κB signaling an IKKβ-inhibitor was used, and noncanonical NF-κB signaling was repressed using siRNAs targeting NFκB2. The role of NIK in LTβR signaling was investigated using inhibitors and siRNAs targeting NIK and overexpression of NIK.
Results: LTβR-ligation resulted in activation of canonical and noncanonical NF-κB signaling, and subsequent expression of inflammatory mediators. IKKβ inhibition repressed LTβR-induced inflammatory activation of EC, indicating that this process was mediated through canonical NF-κB signaling. Interestingly, NIK targeting also decreased LTβR-induced expression of inflammatory mediators, while targeting NFκB2 had no effect. Further analyses, including silencing and overexpression of NIK, demonstrated a clear role for NIK in activation of canonical NF-κB signaling by amplifying IKK complex activity.
Conclusions: These findings suggest that NIK can serve as an amplifier of canonical NF-κB signaling and associated inflammatory responses in EC, which may play an important role in the inflammatory process. Consequently, NIK may be an attractive therapeutic target.

Humanized anti-FH monoclonal antibodies as a new and robust standard and control for anti-FH ELISA

K. A. Gelderman[1], ***A. M. Kamp***[2], *M. C. Brouwer*[2], *L. A. Trouw*[3], *R. B. Pouw*[2], *D. Wouters*[2];
[1]*Sanquin Diagnostic Services, Amsterdam, The Netherlands, Amsterdam, Netherlands,* [2]*Sanquin Research, Dept of Immunopathology, Amsterdam, The Netherlands and landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands, Amsterdam, Netherlands,* [3]*Dept of Rheumato;ogy, Leiden Univercity Medical Center, Leiden, The Netherlands, Amsterdam, Netherlands.*

Genetic variants of regulator alternative pathway regulator Factor H (FH) are strongly associated with renal diseases like atypical HUS (aHUS) and C3-glomerulonephritis (C3GN). Next to these genetic variants, anti-factor H (FH) auto-antibodies are detected in 10% to 50% of these patients. In aHUS these auto-antibodies are associated with extra-renal features and their presence mostly coincides with a deletion of the *CFHR1/3* genes. In C3G, in contrast, the anti-FH antibodies target different epitopes and the presence of anti-FH is not associated with a deletion of the *CFHR1/3* genes. To detect anti-FH an ELISA is widely performed using full-length FH as antigen. Anti-FH detection is performed either for diagnostic purposes or for follow-up. To compare samples and to quality control individual tests, each test requires a reliable and reproducible standard line and controls. Positive patient material is commonly used, but availability is limited and patient-to-patient variation significant. To solve this, we humanized two FH mouse monoclonal antibodies, to produce stable and comparable human anti-FH antibodies that can serve as standard and/or assay control. Two monoclonals were chosen that recognize domain 20 of FH, being representative for patient auto-antibodies that often are directed against this domain. These humanized antibodies recognized FH and the dilution curves were parallel to those of antibody-positive patient samples and to a internationally used plasmaferesis material standard. In conclusion; we made two humanized anti-FH clones that produce antibodies to use as standard and control in an anti-FH ELISA. This allows international standardization and comparability of the anti-FH test.

P.C2.04.10

Neutrophils display features of necroptosis in granulomatosis with polyangiitis

T. Stallbaum, ***A. Kerstein****, G. Riemekasten, A. Müller, P. Lamprecht;*
Department of Rheumatology and Clinical Immunology, Luebeck, Germany.

Introduction Dysregulation of cell death plays a crucial role in the initiation of chronic inflammation and autoimmunity. Cardinal pathological features of granulomatosis with polyangiitis (GPA) are necrotizing granulomatous inflammation and necrotizing autoimmune vasculitis. Here we provide evidence, that necroptosis, *i.e.* a regulated form of inflammation-inducing necrosis, is involved in the pathophysiology of GPA.
Methods Polymorphonuclear leukocytes (PMN) were isolated from peripheral blood of GPA patients and healthy controls (HC) (n = 10, each). mRNA and proteins were extracted. Gene and protein expression of markers of apoptosis (caspase 8) and necroptosis [receptor interacting serine/threonine kinase 1 (RIP1); RIP3; cellular inhibitor of apoptosis protein-1/2 (cIAP1/2); X-linked inhibitor of apoptosis protein (XIAP); mixed lineage kinase domain like pseudokinase (MLKL)] were determined by qPCR and western blot.
Results All markers of cell death, including necroptosis, were expressed by PMN of both GPA and HC in terms of mRNA and protein. There were no significant differences between GPA and HC regarding gene expression. However, there was a decreased protein expression of cleaved caspase 8 as well as an increased expression of apoptosis inhibitors cIAP2 and XIAP, demonstrating blocked apoptosis in GPA PMN. In contrast, necroptosis executers RIP3 and MLKL showed an increased expression in GPA PMN.
Conclusion Our results reveal necroptosis as a relevant form of cell death by PMN in GPA. Given the impact of dying neutrophils for the induction of chronic inflammation and autoimmunity, regulated necroptosis could represent a potential therapeutic target in GPA.

P.C2.04.11

CXCL4 in Tunisian patients with systemic sclerosis

L. Laadhar[1], *I. Nammouchi*[1], *I. Ben Ghorbel*[2], *I. Ayadi*[1], *H. Lahmar*[1], *M. H. Houman*[2], *M. Kallel-Sellami*[1];
[1]*Immunology Department, la Rabta hospital, Tunis, Tunisia,* [2]*Internal Medicine department, la Rabta hospital, Tunis, Tunisia.*

Introduction: We aimed, first to assess the CXCL4 level in Tunisian patients with systemic sclerosis (SSc) comparing to healthy controls and to patients presenting other clinical conditions; and second to search correlations between the level of CXCL4 and the clinical manifestations of the disease. Methods: We enrolled 50 patients with SSc and with no other connective tissue diseases associated. All patients met the 2013 ACR/EULAR classification criteria. We also recruited 30 age- and sex-matched healthy controls, 36 patients with systemic lupus erythematosus (SLE), 30 patients with rheumatoid arthritis (RA) and 27 patients with Sjögren's syndrome (SS). Levels of CXCL4 were determined using ELISA (R&D Systems®). Results: Patients were 47 women and 3 men with a mean age of 50.1 years. The mean level of CXCL4 in patients with SSc was 47.80 ± 18.27ng / ml. It was significantly higher than that in healthy controls (38.34 ± 15.83ng / ml), in patients with SLE (25.46 ± 16.09 ng / ml) and patients with RA (39.28 ± 11.91ng / ml) ($p = 0.021$, <0.001 and $=0.026$ respectively). There was no significant difference between the mean level of CXCL4 in patients with SSc and in patients with SS. There was no statistically significant correlation between CXCL4 levels and the various clinical manifestations of the disease. Conclusion: CXCL4 appears as a potential biomarker for SSc, however it is not correlated to the clinical phenotype of the disease in our cohort.

P.C2.04.12

Bruton's Tyrosine Kinase (BTK) regulates the NLRP3 inflammasome directly through NLRP3 tyrosine phosphorylation

X. Liu*;*
Department of Immunology, Tübingen, Germany.

The NLRP3 inflammasome is an inflammatory machinery participating in the pathogenesis of many inflammatory diseases. Its activation involves NLRP3 recruiting the adaptor ASC, caspase-1 binding and auto-proteolytic activation and finally IL-1β and IL-18 maturation. However, the regulatory mechanisms of this vital inflammatory process are poorly understood. In previous studies, we identified BTK as a novel regulator of the NLRP3 inflammasome. Pharmacological and genetic BTK ablation attenuated caspase-1 activation and IL-1β maturation. BTK directly interacted with NLRP3 and ASC.
In the current study, we further found that tyrosine phosphorylation of NLRP3 was significantly enhanced by the presence of BTK in co-transfected HEK293T cells, and this phosphorylation was diminished by BTK inhibitors, but not the NLRP3 inhibitor MCC950.
Furthermore, a time-course pattern of increased tyrosine phosphorylation of endogenous NLRP3 was observed in human and mouse primary cells in response of Nigericin. However, NLRP3 phosphorylation was reduced in immune cells from genetically deficient human XLA patients and *Btk* knockout mice. Using truncated and tyrosine-mutated NLRP3 constructs, we hope to identify the exact phosphorylation site of NLRP3 that BTK targets and work out how NLRP3 tyrosine phosphorylation by BTK regulates inflammasome activity. Overall, our data contribute to a better understanding of the BTK regulation mechanism of NLRP3 activation. Given the clinical availability of FDA-approved BTK inhibitors this may pave the way for new treatment strategies in NLRP3 inflammasome-linked inflammation.

Down-modulation of autoreactive B-cells by protein-engineered chimeric molecules in mouse model of Type 1 Diabetes

I. Manoylov[1], *G. Boneva*[1], *N. Mihaylova*[1], *I. Doytchinova*[2], *A. Tchorbanov*[1,3];
[1]*The Stephan Angeloff Institute of Microbiology, Sofia, Bulgaria,* [2]*Faculty of Pharmacy, Medical University of Sofia, Sofia, Bulgaria,* [3]*National Institute of Immunology, Sofia, Bulgaria.*

Introduction: Type 1 diabetes (T1D) is characterized by autoimmune attack against the insulin-producing beta-cells of the pancreas. One of the main beta-cells' autoantigens in T1D is glutamic acid decarboxylase (GAD65) - a membrane-bound enzyme catalyzing the formation of gamma-aminobutyric acid. Autoreactive B lymphocytes play major role in the pathogenesis of the disease. They produce autoantibodies against several autoantigens. B cells can activate T cells and can modulate the immune response via cytokine production. Thus, eliminating autoreactive B lymphocytes may serve as a potential treatment against T1D. Downregulation of murine B cells is accomplished via the activation of the negative receptor Fc-gammaRIIB. Logically, this receptor could be a potential target for suppression of autoreactive B lymphocytes.
Materials and methods: We constructed chimeric protein molecules, containing a monoclonal antibody specific for the mouse inhibitory receptor Fc-gammaRIIB, coupled to peptide epitopes derived from GAD65 protein. The ability of these molecules to modulate the immune response was tested in an induced murine model of T1D. The parameters of this interaction were characterized by FACS analysis, ELISpot and proliferation assays.
Results: The chimeric molecules, presented in this study, bind GAD65 - specific B-lymphocytes and suppress selectively their proliferation by co-crosslinking of the inhibitory Fc-gammaRIIB and the BCR.
Conclusions: The aim of our study was to construct chimeric molecules, using antibody against Fc-gammaRIIB conjugated to GAD65 epitopes. The chimeric molecules were expected to suppress specifically autoreactive B-cells in a mouse model of T1D. This treatment presents a novel specific therapy for autoimmune diabetes.

In multiple sclerosis (MS), B cells survive peripheral tolerance checkpoints to mediate local inflammation, but the underlying molecular mechanisms are underexplored. In mice, the macrophage migration inhibitory factor (MIF) pathway controls B-cell development and the induction of experimental autoimmune encephalomyelitis. How the MIF pathway is controlled in human B cells and contributes to disease onset in MS patients remains highly elusive.
Here, we found that MIF receptor CD74 was downregulated, whereas MIF receptor CXCR4 was upregulated in B cells of clinically isolated syndrome (CIS) patients who rapidly develop MS (n=16) as well as clinically definite MS patients (n=15). Transitional and naive mature B cells displayed the highest CXCR4/CD74 expression ratios compared to class-switched and non–class-switched memory subsets in these patients, implying that this $CXCR4^{high}CD74^{low}$ phenotype reflects a more immature state of B cells. Interestingly, B cells were identified as the main immune subset in blood expressing MIF, which was downregulated in early MS patients. Blockade of MIF/CD74 signaling triggered CXCR4 expression, while blockade of MIF/CXCR4 signaling upregulated CD74 on activated B cells. Moreover, CD74-blocked B cells were less able to proliferate and to express pro-inflammatory genes *NFKB1, IL6* and *TNF*. On the contrary, CXCR4-blocked B cells showed increased sensitivity to Fas-mediated apoptosis.
This study points to the existence of a functionally relevant regulation loop between MIF, CD74 and CXCR4 in human B cells. The disturbance of this loop during MS onset provides new insights into how pathogenic B cells survive peripheral tolerance checkpoints in autoimmune diseases such as MS.

Evaluation of MAPK3 in the context of CD25 expression on natural Tregs for the immune tolerance development in patients with recurrent pregnancy loss

R. Susurkova[1], *A. Velichkov*[1], *M. Muhtarova*[2], *M. Guenova*[2], *I. Antonova*[3], *G. Nikolov*[3], *A. Mihova*[4], *V. Terzieva*[1];
[1]*Institute of Biology and Immunology of Reproduction "Acad. Kiril Bratanov", Sofiya, Bulgaria,* [2]*National Specialised Hospital for Active Treatment of Haematological Diseases, Sofiya, Bulgaria,* [3]*Center for Reproductive Biology and Medicine "Reprobiomed", Sofiya, Bulgaria,* [4]*University Hospital Lozenetz, Sofiya, Bulgaria.*

Introduction: The establishment of an immune tolerant milieu is a *conditio sine qua non* for the development of pregnancy. Among multiple factors involved, the population of regulatory T cells (Tregs) is of critical importance. A particular subset of Tregs, natural Tregs (nTregs), is shown to be impaired in women with recurrent pregnancy loss (RPL). The present study is aimed at evaluating the impact of MAPK3 signaling molecule in this process. Materials and Methods: PBMCs from 10 patients with RPL (24-37yrs) and 10 age-matched controls (HC) with history of successful pregnancy were stained with anti-CD3/CD4/CD45RA/CD25/FoxP3/MAPK3 antibodies either non-stimulated or stimulated via IL-2 or anti-CD3/CD28. MAPK3 was assessed by flowcytometry/PrimeFlow™ and confocal microscopy. FACS and statistical analyses were done by FlowJoV10 and GraphPad7 software. Results: The proportion of nTregs in patients was found decreased in comparison to HC ($p<0.05$). In controls, but not in patients, the majority of cells were CD25+ ($p<0.05$). The evaluation of MAPK3 in study groups showed differences between CD25+ and CD25- subsets expressed mainly in anti-CD3/CD28 stimulated cells that were further evidenced by the confocal microscopy. Conclusions: Our results indicate variations in MAPK3 expression that might be associated with the expression of CD25 on nTregs. Further experiments are envisaged to precisely analyze their impact on nTregs for the immune tolerance establishment. Balancing JAK/STAT-signalling with tofacitinib in monocytes of healthy controls and IBD patients

*F. Cordes[1], T. Weinhage[2], E. Lenker[2], D. Bettenworth[1], C. Kessel[2], D. Föll[2], **G. Varga**[2];*
[1]Department of Medicine B, University Hospital Muenster, Germany, [2]Department of Pediatric Rheumatology and Immunology, University Hospital Muenster, Germany.

Background. JAK/STAT-blockade by tofacitinib, an oral JAK1/JAK3 inhibitor, promises new treatment options in inflammatory bowel disease (IBD). Monocytes are key players in inflammatory responses and bridge natural and acquired immunity. However, the impact of tofacitinib on monocytes of IBD patients has not been investigated so far. **Aims**: In this study, inhibition of the JAK/STAT-pathway by tofacitinib was investigated in monocytes of IBD patients and healthy controls. **Methods** Primary monocytes from healthy human controls and IBD patients with active disease were analyzed for cytokine expression and phenotype after stimulation with GM-CSF/IFNg and tofacitinib pre-treatment with non-toxic dosages of 1-1000 nM. Furthermore, dose-dependent inhibition of JAK/STAT-phosphorylation in monocytes and their capacity to induce Foxp3$^+$-regulatory T-cells in co-cultures with autologous naïve T-cells was analyzed. **Results** In control monocytes, tofacitinib at concentrations of 10-100 nM did not inhibit JAK2/STAT5-signalling but blocked JAK1/STAT1-pathway. In a pro-inflammatory setting induced by GM-CSF/IFNγ co-stimulation, tofacitinib had the most beneficial effect on control monocytes at 100 nM leading to blockade of pro-inflammatory cytokines TNFα and IL-6, while simultaneously increasing Tregs in co-cultures. In IBD monocytes with GM-CSF/IFNγ co-stimulation, tofacitinib 1000 nM was most anti-inflammatory including inhibition of TNFα and IL-6 with simultaneous restoration of IL-10. Regulation by tofacitinib was significantly stronger in UC than in CD monocytes. **Conclusion**. Tofacitinib dose-dependently facilitates reprogramming of monocytes to a more regulatory phenotype in control and IBD monocytes. The beneficial effect seemingly is selective JAK/STAT blockade with inhibition of pro-inflammatory responses while regulatory pathways stay intact by adequate tofacitinib dosage. <!--EndFragment-->

P.C2.04.17

Selective depletion of MOG-reactive B lymphocytes by modular T cell targeting

***C. S. Weiss**[1], K. Akgün[1], S. Albert[2], M. P. Bachmann[3], T. Ziemssen[4];*
[1]Center of Clinical Neuroscience, Department of Neurology, University Hospital, 'Carl Gustav Carus' Technische Universität Dresden, Dresden, Germany, [2]University Cancer Center, Dresden, Tumor Immunology, Carl Gustav Carus Universitätsklinikum Dresden, Dresden, Germany, [3]Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Tumor Immunology, UniversityCancerCenter (UCC), 'Carl Gustav Carus' Technische Universit€at Dresden, Cellex Patient Treatment GmbH, Dresden, Germany, [4]MS Center Dresden, Center of Clinical Neuroscience, Department of Neurology, University Hospital Carl Gustav Carus, Dresden University of Technology, Dresden, Germany.

Multiple sclerosis (MS) is defined as primarily T-cell-mediated disease and initial treatment strategies focused on pathogenic T-cell modulation. Nevertheless, auto-reactive B-cells play a relevant role in MS pathogenesis reflected by myelin-specific auto-antibody production, antigen presentation and pro-inflammatory cytokine release. Novel MS treatment regimens target B-cells using general (CD20) but not antigen-specific antibody-mediated depletion. For depletion of auto-reactive pathogenic B-cells we used a system originally established for tumor-cell-targeting. To circumvent severe side effects that occurred in earlier trials, a novel platform was developed where T-cells are equipped with a universal chimeric antigen receptor (UniCAR).
Instead of binding directly to a certain structure on the target cell surface, UniCAR T-cells can be switched on and off by administering a targeting module (TM) consisting of a peptide epitope recognized by the UniCAR T-cell and a binding moiety directed against a distinct structure on the target cell surface. We determined the extracellular domain of the myelin oligodendrocyte glycoprotein (MOG) antigen as TM for specific depletion of B-cells carrying anti-MOG antibodies. We transduced a human B-cell line with an artificial antibody (scFv MOG) to achieve a constant availability of anti-MOG antibody for *in vitro* studies. We could demonstrate efficient redirection of UniCAR T-cells against scFv MOG-positive B-cells in a strictly target-dependent and target-specific manner. Binding capability of the TM was assessed by flow cytometry. We demonstrate that the UniCAR system is not restricted to cancer therapies and that antigen-specific depletion of auto-reactive B-cells is possible and considered to be used in autoimmune diseases, too.

The culture dish surface influences the phenotype and cytokine production of immunogenic and tolerogenic monocyte-derived dendritic cells

*A. Sauter[1], **D. H. Yi**[2], S. Roersma[2], Y. Li[2], S. Appel[2];*
[1]Department of Biomedicine, Bergen, Norway, [2]Broegelmann Research Laboratory, Bergen, Norway.

Monocyte-derived dendritic cells (moDC) are an important scientific and clinical source of functional dendritic cells (DC). However, the optimization of the generation process has to date mainly been limited to the variation of soluble factors. In this study, we investigated the impact of the cell culture surface on the DC phenotype and cytokine profile. We compared a standard cell culture dish to a non-adherent culture dish for two immunogenic maturation conditions, two tolerogenic conditions and an unstimulated control. Phenotype and cytokine profile were determined after a 3-day culture. Light microscopy revealed an increase in homotypic cluster formation correlated with the use of non-adherent surfaces which could be reduced by using blocking antibodies against CD18. All surface markers analyzed showed moderate to strong differences depending on the surface. Significant differences in the secretion of many cytokines were observed, especially for cells stimulated with LPS. These results provide evidence that the DC phenotype crucially depends on the surface used during moDC generation. This might have an important application in the optimization of DC-based immunotherapy development and underlines that the local surrounding can interfere with the final DC population beyond the soluble factors.

Cytokine productionin peripheral blood cells of patients with Diabetes mellitus type 1

***S. Zivancevic-Simonovic**[1], O. Mihaljevic[1], S. Markovic[1,2], S. Popovic[1], I. Majstorovic[3], O. Milosevic-Djordjevic[1];*
[1]Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia, [2]Clinical Center Kragujevac, Kragujevac, Serbia, [3]Military Medical Academy, Institute for Medical Research, Belgrade, Serbia.

Introduction. Type 1 diabetes mellitus (T1DM) is a T cell-mediated autoimmune disease in which the immune system attacks the insulin producing β cells. The role of cytokines in the pathogenesis of T1DM is still insufficiently clarified. The aim of this study was to analyze cytokine profile in patients with T1DM and to compare it with those in healthy subjects. Materials and Methods**.** The study group included 12 patients with DM type 1 and 20 healthy controls. Cytokine levels were determined in supernatants obtained from unstimulated and phytohemagglutinin (PHA)-stimulated whole blood cultures *in vitro*. The concentrations of selected cytokines: interferon gamma (IFN-γ), interleukin 2 (IL-2), interleukin 4 (IL-4), interleukin 5 (IL-5), interleukin 6 (IL-6), interleukin 10 (IL-10), interleukin 12 (IL-12p70), interleukin 13 (IL-13), interleukin 17A (IL-17A) and tumor necrosis factor alpha (TNF-α) were measured using multiplex cytokine detection systems for Human Th1/Th2/Thl7/Th22. Results. Unstimulated blood cell of T1DM patients produced more IL-6 (1056±752 vs 108±49 pg/mL, p=0.045), IL-10 (168±159 vs 0 pg/mL, p=0.014), IL-17A (142±134 vs 0 pg/mL, p=0.029) and TNF-α (105±41 pg/mL vs 33±37 pg/mL, p=0.029) than controls. The mean production of IL-10 and TNF-α in PHA-stimulated blood cells of T1DM patients tended to be higher than in controls, but statistically significant difference was obtained only for IL-6 (4295±2744 vs 1367±1313 pg/mL, p=0.040). Conclusions: The unstimulated peripheral blood cells of T1DM patients produce more pro-inflammatory cytokines IL-6, IL-17A and TNF-α, and anti-inflammatory cytokine IL-10 than controls. *In yitro* stimulated PBC of T1DM patients produce more proinflammatory cytokine IL-6 than controls.

P.C2.05.01

Influence of autologous apoptotic cell cultures on the parameters of early apoptosis of T-lymphocytes from healthy individuals and patients with rheumatoid arthritis

*T. Y. Abramova[1], V. A. Tsura[2], **E. A. Blinova**[1], A. E. Sizikov[1], V. A. Kozlov[1];*
[1]Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation, [2]Novosibirsk State Medical University, Novosibirsk, Russian Federation.

It is accumulated data about the lesion in apoptosis of peripheral blood mononuclear cells in patients with rheumatoid arthritis (RA). On this basis, we investigated the response of native T-cells (recipient-culture) in vitro under the transferring of the autologous apoptotic cultures (unstimulated, anti-CD3- (1mkg/ml) and dexamethasone- (1×10-4 M) stimulated donor-cultures under conditions of crowding and depleted medium).
The subject of the study were blood samples from patients with RA and healthy women, matched by age. Primary-induced apoptotic cultures (CFSE-) cultivated during 3 days, then their cellular and humoral components separately transferred to recipient-cultures, pre-stained with CFSE. After 4 days we obtained secondary-induced apoptotic cultures.
In norm, it was established the possibility to induce early apoptosis of T-cells by transferring the cellular and humoral components of the autologous apoptotic cultures. It was determined that under the equal conditions, transfer of stimulated by anti-CD3 antibodies cells significantly increased the sensitivity of T-cells to apoptosis, whereas stimulation by dexamethasone had a modulating effect.
In RA, it was demonstrated a marked level of early apoptosis of T-lymphocytes in primary-induced donor-culture, stimulated with anti-CD3 antibodies (CFSE-), and secondary-induced culture (CFSE+), compared both to the initial level of apoptosis and under transferring of unstimulated cells. Transfer of supernatants from autologous apoptotic anti-CD3- and dexamethasone-stimulated cultures obviously increased the levels of early apoptosis of T-cells in secondary-induced CFSE+ culture.
The obtained results indicated the features of induced early stage of apoptosis of T-cells by transferring of autologous apoptotic cultures in vitro in norm and in rheumatoid arthritis.

P.C2.05.02

Effects of homeostatic factors on the CD127 and CD215 expression by $CD4^+$ and $CD8^+$ T-cells in norm and rheumatoid arthritis

E. A. Blinova[1], *E. A. Pashkina*[1], *V. E. Balyasnikov*[2], *O. A. Chumasova*[1], *A. E. Sizikov*[1], *V. A. Kozlov*[1];
[1]*Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation,* [2]*Novosibirsk State Medical University, Novosibirsk, Russian Federation.*

It was formed assumption that homeostatic proliferation makes a contribution to the development and maintaining of autoimmune diseases, including rheumatoid arthritis (RA). In this study we investigated expression of α-chain of IL-7R and IL-15R on T-cells before and after culturing with homeostatic factors in norm and RA.
The study included 6 patients with RA and 6 healthy volunteers (average 61±4,5 and 59±4,8 years respectively). After isolation PBMCs were cultivated with or without IL-7 (50ng/ml), IL-15 (50ng/ml) and simultaneously IL-7+IL-15 during 7days. Activation with anti-CD3 antibodies (1mkg/ml) and IL-2 (100ME/ml) used as a positive control. Analysis of CD127 and CD215 expression was performed by flow cytometry.
$CD4^+$ and $CD8^+$ cells from RA patients demonstrated significantly low CD127 expression than donors' cells. There was no difference in CD215 expression and density of receptors to IL-7 and IL-15. Cultivation of PBMCs with or without stimulation led to a decreasing of CD127 expression. However, in patients' group it was observed the high density of CD127 on both T-cell populations under anti-CD3+IL-2 stimulation. Also it was an increasing in $CD4^+127^+$ cells under stimulation with IL-15 and $CD8^+127^+$ under stimulation with IL-7+15 compared to donors' values. There was a decreasing in a number of $CD4^+215^+$/$CD8^+215^+$ cells under stimulation with IL-15 and $CD8^+215^+$ cells – with IL-7 in RA compared to norm. aCD3 stimulation led to a high density of IL15R on $CD4^+$ cells from RA patients versus donors' values.
Obtained data indicated the changes in T-cell homeostasis and in responsiveness of T-cell subsets to homeostatic cytokines.

P.C2.05.03

Protein-engineered molecules carrying GAD65 epitopes and targeting CR1 selectively down-modulate disease-associated human B lymphocytes

I. Manoylov[1], ***G. Boneva***[1], *I. Doytchinova*[2], *N. Mihaylova*[1], *A. Tchorbanov*[1,3];
[1]*Laboratory of Experimental Immunology, Institute of Microbiology, Sofia, Bulgaria,* [2]*Faculty of Pharmacy, Medical University of Sofia, Sofia, Bulgaria,* [3]*National Institute of Immunology, Sofia, Bulgaria.*

Introduction: Type 1 diabetes mellitus is an autoimmune metabolic disorder characterized by chronic hyperglycemia, a presence of autoreactive T- and B-cells and autoantibodies against self-antigens. A membrane bound enzyme on the pancreatic beta-cells, GAD 65, is the main autoantigen in type 1 diabetes. Autoantibodies against GAD65 lead to beta-cells destruction and decline of pancreatic functions. The human complement receptor type 1 (CR1) on B- and T-lymphocytes has a suppressive activity on these cells. We hypothesized that it may be possible to eliminate GAD65-specific B cells from type 1 diabetes patients by using chimeric molecules, containing an anti-CR1 antibody, coupled to peptides resembling GAD65 B/T epitopes. These molecules are expected to bind selectively the anti-GAD65 specific B-cells by the co-crosslinking of the immunoglobulin receptor and CR1 and to deliver a suppressive signal. Materials and Methods: Two synthetic peptide epitopes derived from GAD65 protein, and anti-CD35 monoclonal antibody were used for the construction of two chimeras.
The immunomodulatory activity of the engineered antibodies was tested *in vitro* using PBMCs from diabetes patients. Results: A reduction in the number of anti-GAD65 IgG antibody-secreting plasma cells and increased percentage of apoptotic B-lymphocytes was observed after treatment of PBMCs from patients with type 1 diabetes with engineered antibodies. Conclusions: The constructed chimeric molecules are able to modulate selectively the activity of GAD65-specific B-lymphocytes and the production of anti-GAD65 IgG auto-antibodies by co-crosslinking of the inhibitory CR1 and the BCR. This treatment presents a possible way to alter the autoimmune nature of these cells.

P.C2.05.04

Interleukin-30 suppresses T cell activation in murine primary biliary cholangitis

H. Chen*, Y. Chuang;*
Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, Taipei, Taiwan.

Primary biliary cholangitis (PBC) is a chronic liver autoimmune disease. Our previous study found that PBC mice administered with adeno-associated virus-expressing IFN-γ (AAV-IFN-γ) showed a severe disease performance in early phase but subsequently leads to downregulation of chronic inflammation with an increase of Interleukin-30 (IL-30). IL-30, also called IL-27p28, has been shown to attenuate liver injury and fibrosis. In this study, we investigated whether IL-30 had an immunosuppressive function in PBC by administering mouse IL-30 expressing AAV (AAV-mIL-30) to 2-OA-OVA immunized PBC mice. At first, we defined the immunosuppressive function of AAV-mIL-30 in vivo by a well-known conA-induced hepatitis mouse model. The results showed that serum levels of IFN-γ and IL-12 were decreased in AAV-mIL-30 receiving conA induced hepatitis mice. In addition, the activation marker (CD25) of NKT cells and $CD4^+$ T cells in liver of AAV-mIL-30 receiving mice were also decreased. In PBC, the expression of CD25 and IFN-γ secretion in $CD4^+$ T cells were decreased in mice administered with AAV-mIL-30 three weeks post 2-OA-OVA immunization. Moreover, the frequency of $CD4^+CD25^{hi+}$ regulatory T cells was increased. These results suggested that IL-30 could suppress the activation and IFN-γ production of T cells and induce Tregs. Hence, IL-30 could be a novel therapeutic cytokine in PBC.

P.C2.05.05

PTPN22 negatively regulates immune complex-induced T cell proliferation by modulating dendritic cell antigen presentation and conjugate formation

F. Clarke*, H. Purvis, C. Sanchez-Blanco, E. Gutierrez Martinez, G. Cornish, P. Guermonprez, A. Cope;*
King's College London, London, United Kingdom.

The C1858T single nucleotide polymorphism in the hematopoietic tyrosine phosphatase *PTPN22* confers an enhanced susceptibility to multiple autoimmune diseases including rheumatoid arthritis and type 1 diabetes. Many of the associated autoimmune diseases have an autoantibody component to their pathology. Fc receptors (FcRs) recognise autoantibodies when they bind to autoantigens and form immune complexes. After immune complex binding and receptor crosslinking, FcRs signal via Src and Syk family kinases, leading to antigen uptake, presentation and cytokine secretion. PTPN22 negatively regulates Src and Syk family kinases proximal to immunoreceptor signalling cascades. We therefore hypothesised that PTPN22 regulates immune complex induced FcR responses in dendritic cells (DCs). Bone marrow derived DCs (BMDCs) from wild type and *Ptpn22*$^{-/-}$ mice were pulsed with ovalbumin:anti-ovalbumin immune complexes (ova ICs). Co-culture with WT $CD4^+$ OT-II T cells revealed that ova IC pulsed *Ptpn22*$^{-/-}$ BMDCs have an enhanced capability to induce T cell proliferation. This was associated with an increased capability of *Ptpn22*$^{-/-}$ BMDCs to present immune complex derived antigens and to form ova IC dependent DC-T cell conjugates. These findings highlight PTPN22 as a regulator of FcR mediated responses and provide a link between the association of $PTPN22^{R620W}$ with autoantibody associated autoimmune diseases.

P.C2.05.06

Circulating dendritic cells of patients with multiple sclerosis show inflammation-dependent gene expression changes following transmigration across an in vitro blood-brain barrier

M. De Laere[1], *S. Van Laere*[1], *J. Derdelinckx*[1], *B. Willekens*[2], *Z. Berneman*[1,2], ***N. Cools***[1];
[1]*University of Antwerp, Wilrijk, Belgium,* [2]*Antwerp University Hospital, Edegem, Belgium.*

Control of lymphocyte entry and migration into the brain is vital to regulate protective and pathological responses. Of interest is the finding that increased numbers of dendritic cells (DC) are present in the brain during neuroinflammation. Moreover, this has been associated with the regulation of local disease processes. But what prompts cells to enter the brain? In current study, we aim to delineate genetic differences between migrating and non-migrating DC using an in vitro model for the blood-brain barrier (BBB) and transcriptome profiling. Our findings demonstrate that circulating DC of patients with relapsing-remitting multiple sclerosis (RR-MS) and chronic progressive MS (CP-MS) show an increased expression of chemokine receptors CCR5 and CCR7. This finding is paralleled by augmented chemotaxis towards the respective chemokine ligands by DC from MS patients as compared to DC from healthy controls (HC). By means of an in vitro BBB model, 2 different subtypes of DC are isolated, namely migrating and non-migrating cells, of patients with MS and age- and gender matched HC. RNA sequencing and bioinformatics analyses show that gene expression of the 500 most variable genes differed between migratory and non-migratory cells when comparing RR-MS and CP-MS patients and HC. Using KEGG pathway analysis, the top gene pathways that were changed in migratory cells involved pathways associated with inflammatory processes, such as the Toll-like receptor and NOD-like receptor signaling pathway, and the Jak-STAT signaling pathway. Altogether, our observations contribute to current knowledge on the underlying pathological mechanisms and can provide interesting targets for therapeutic intervention.

P.C2.05.07

Mechanism of GP130 activation and regulation of its downstream signalling

F. Dehkhoda[1], *N. Durisic*[2], *Y. Chhabra*[1], *A. Brooks*[1];
[1]*The University of Queensland, Diamantina Institute, woolloongabba, Australia,* [2]*The University of Queensland, Queensland Brain Institute, St Lucia, Australia.*

GP130 is an archetypal member of the tall cytokine receptors and serves as a signal transducing subunit for IL-6, IL-11, IL-27, LIFR, and others. Physiologically, cytokines signalling via GP130 are involved in autoimmune and inflammatory diseases, including rheumatoid arthritis, inflammatory bowel diseases, and allergic asthma. Although numerous structural studies have elucidated dynamics of GP130 receptor complex, little is known about its activation and regulation of signal transduction. For this purpose, super resolution microscopy aided single particle tracking (PALM) of GP130 molecules was performed on non-stimulated and stimulated HEK293 cells to analyse diffusion properties of the receptors on the cell membrane. To analyse the signal transducing orientation of GP130, the extracellular domain of receptor was swapped with the leucine zipper dimerisation domain of c-jun transcription factor to generate GP130 dimers on the cell surface of pro-B cell line, Ba/F3.

The effect of length, charge, and rotation of the GP130 extracellular juxtamembrane region was investigated resulting in identification of active and inactive receptor configurations. Variable rotations of the GP130 transmembrane and intracellular domains induced by alanine insertions mimicking cytokine induced activation led to differential activation of JAK/STAT and MAPK signalling pathways and generated distinct proliferative responses in Ba/F3 cells. These models with FRET reporters fused after the JAK binding Box1-2 region were generated and movements of the intracellular domains of GP130 with associated JAK kinases were assessed. This is the first study aimed at determining the precise movements in GP130 receptor and will allow for a targeted drug design in near future.

P.C2.05.08

Up-regulation of EP2 and EP3 receptors in human tolerogenic dendritic cells boost the immunosuppressive activity of PGE_2.

G. Flórez-Grau[1]*, R. Cabezón*[2]*, K. E. Borgman*[3]*, C. España*[4]*, J. J. Lozano*[5]*, M. F. García-Parajo*[6]*, D. Benítez-Ribas*[4]*;*
[1]Department of Tumor Immunology, Radboud Institute for Molecular Life Sciences, Radboudumc, Nijmegen, Netherlands, [2]Institut d'investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, [3]Institut Ciencies fotoniques (ICFO), Castelldefels, Barcelona, Spain, [4]Dept of Immunology, Hospital Clinic de Barcelona,, Barcelona, Spain, [5]Centro de Investigación Biomédica en Red, Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain, [6]nsititució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.

Dendritic cells (DCs) are essential in regulating both immunogenic and tolerogenic immune responses. PGE2, which is a lipid mediator produced during inflammation, has a key role i the of DCs maturation and, therefore, is vital in controlling the immune responses. The large variety of biologic functions governed by PGE2 are mediated by its signaling through 4 distinct E-type prostanoid (EP) receptors. Immunogenic DCs express EP2 and EP4, which mediate the PGE2 signaling. However, the presence and functionality of EP receptors in human tolerogenic DCs (tol-DCs), which have a suppressive phenotype, have been not assessed yet. To clarify the role of EP receptors in tol-DCs, we examined the expression of different EP receptors and their effect using selective agonists in human DCs. Our results shown that EP2 and EP3 expression are up-regulated in *in vitro*-generated tol-DCs compared with mature DCs (mDCs). Activation of EP2-EP4 has a direct effect on the surface expression of costimulatory molecules and maturation receptors, such as CD80, CD83, CD86, MHCII and CCR7 in tol-DCs, the latter being exclusively modulated by PGE2-EP4 signaling. Importantly, we find that EP2 and EP3 receptors are involved in tolerance induction through IL-10 production by tol-DCs. These results are in sharp contrast with the inflammatory role of EP4. Additionally, we observed that DCs generated in the presence of agonists for EP receptors, induce naive T cell differentiation toward polarized Th1/Th17 cells. Given the differential effects of EP receptors observed, EP receptor agonist/antagonists might become relevant novel drug templates to modulate immune response.

Interleukin-2 is essential in long-term efficacy of regulatory T cells in type 1 diabetes

M. Gliwiński*, D. Iwaszkiewicz-Grzes, J. Sakowska, P. Trzonkowski;*
Department of Clinical Immunology and Transplantology, Gdansk, Poland.

Introduction: Type 1 diabetes (T1D) is a immunological disease which mainly affects children. Disease develops under the influence of autoreactive lymphocytes T that destroy insulin-producing β-cells. Transfer of autologous regulatory T cells (Tregs) delays the progression of the T1D. We decided to check the influence of interleukin-2 on Tregs therapy in clinical settings.
Materials and Methods: Regulatory T cells were isolated from the patients' peripheral blood with a GMP-compliant FACS-sorter. The expansion was performed under GMP conditions. Tregs were cultured for 8 days after the release of products to the clinic. Tregs and Teffs were cultured separately or co-cultured in a 1:1 ratio in the different concentrations of IL2. Survival of the cells was measured using 7-aminoactinomycin D staining. The levels of IL2 were also measured in sera of T1D patients treated with Tregs.
Results: We observed a rapid decrease in Treg cell survival without supplementation of IL2 in vitro. However, even low concentrations of IL2 were enough to limit cells death. Comparable concentrations of IL2 were found in vivo in the sera of T1D patients. In addition, simple co-culture of Tregs with Teffs without exogenous IL2 significantly improved the viability as Teffs consist a good source of endogenous IL2.
Conclusions: IL2 should be present in the culture constantly to keep Tregs viable. The levels of IL2 in vivo in T1D patients seem to be sufficient to protect Tregs transferred adoptively from cell death.

Exopolysaccharides produced by *Cyanobacterium aponinum* from the Blue Lagoon inhibit SYK and CLEC7a expression by dendritic cells and keratinocytes and dampen the function of T-cells

A. B. Gudmundsdottir[1,2]*, A. Brynjolfsdottir*[3]*, E. S. Olafsdottir*[4]*, I. Hardardottir*[1,2]*, J. Freysdottir*[1,2]*;*
[1]Landspitali - The National University Hospital of Iceland, Reykjavík, Iceland, [2]Faculty of Medicine, Biomedical Center, University of Iceland, Reykjavik, Iceland, [3]Blue Lagoon, Grindavik, Iceland, [4]Faculty of Pharmaceutical Sciences, University of Iceland, Reykjavík, Iceland.

Introduction: Regular bathing in the Blue Lagoon has beneficial effects on psoriasis. We have shown that exopolysaccharides (EPS-Ca) from one of the lagoon's dominating microbes, *Cyanobacterium aponinum*, increased dendritic cell (DC) secretion of IL-10 and DC induction of Tregs at the cost of the inflammatory Th17 cells. The objective of this study was to determine how EPS-Ca affects DCs and to determine its effects on stimulated T-cells and keratinocytes. Materials and methods: Human monocyte-derived DCs, $CD4^+$ T-cells and adult primary keratinocytes were stimulated with IL-1β, TNF-α and LPS; antibodies against CD3 and CD28; or TNF-α and either IFN-γ or IL-17, respectively, in the presence or absence of EPS-Ca. Cytokine secretion was measured by ELISA, expression of mRNA by rt-PCR and expression of surface molecules by flow cytometry. Results: EPS-Ca-treated DCs expressed more CD141 (linked to regulatory DCs) than DCs stimulated without EPS-Ca, and $CD141^+$ DCs secreted more IL-10 than $CD141^-$ DCs. EPS-Ca treatment decreased DC expression of Dectin-1 and transcription of key genes in the SYK-signaling pathway (CLEC7a and SYK). T-cells stimulated in the presence of EPS-Ca secreted less IL-10, IL-13 and IL-17 and expressed less CD69 than T-cells stimulated without EPS-Ca. EPS-Ca decreased keratinocyte secretion of CCL20 and CXCL10 and their transcription of SYK, CLEC7a, and psoriasis autoantigen CAMP (LL37). Conclusions: These results demonstrate inhibitory effects of EPS-Ca on important signaling pathways in DCs, T-cells and keratinocytes, all cells implicated in the pathogenesis of psoriasis, demonstrating the potential of EPS-Ca as a drug lead for the treatment of psoriasis.

P.C2.05.11

Interferon signature in patients with STAT1 gain-of-function mutation is epigenetically determined

E. Kaleviste[1]*, M. Saare*[1]*, R. Leahy*[2]*, W. Ip*[3]*, G. E. Davies*[3]*, P. Peterson*[1]*, K. Kisand*[1]*;*
[1]University of Tartu, Tartu, Estonia, [2]Our Ladys Childrens Hospital, Dublin, Ireland, [3]UCL Great Ormond Street Institute of Child Health, London, United Kingdom.

STAT1 is a transcription factor that mediates signals from interferons (IFNs). While STAT1 loss-of-function mutations confer susceptibility for viral and mycobacterial diseases the gain-of-function (GOF) variants of STAT1 lead to defective Th17 cell development and chronic mucocutaneous candidiasis (CMC). In addition, these patients develop autoimmune disorders: thyroid disease, cytopenias, type 1 diabetes, SLE, vitiligo, alopecia. STAT1 GOF mutation results in hyperphosporylation and delayed dephosphorylation of STAT1. However, the precise molecular mechanisms how this does affect intracellular signal transduction from cytokine receptors remains unknown.
We confirmed that after IFN-α stimulation the patients responded with exaggerated and prolonged upregulation of pSTAT1. However, there was no persistent induction of pSTAT1 ex vivo in spite of significantly upregulated IFN stimulated gene (ISG) expression in circulating blood cells in STAT1 GOF. Chromatin immunoprecipitation (ChIP) experiments showed that active chromatin mark H3K4me3 was significantly enriched in areas associated with ISGs and that STAT1 binding was enhanced in STAT1 GOF cells in comparison to normal cells. We found that STAT3 phosphorylation was not affected by STAT1 GOF after IL-21 stimulation but the balance of pSTAT3/pSTAT1 was significantly impaired.
In conclusion, autoimmunity in patients with STAT1 GOF mutation may be fostered by excessive effect of type I IFNs which is potentiated by epigenetic modifications. Impaired balance of pSTAT3/pSTAT1 after cell stimulation with STAT3-dependent cytokines may be responsible for defective Th17 cell development.

P.C2.05.12

The treatment outcomes in IgG4-related disease

F. Karim*, R. Bansie, S. Rombach, M. van Hagen, J. van Laar;*
Erasmus MC Rotterdam, Netherlands and Groene Hart ziekenhuis Gouda, Netherlands, Rotterdam, Netherlands.

Introduction: IgG4-related disease (IgG4-RD) is an emerging systemic inflammatory disease involving nearly all organs eventually leading to fibrosis. Prompt and adequate treatment to prevent irreversible organ damage is therefore pivotal. To evaluate the treatment outcomes, we studied a well-defined cohort of patients with IgG4-RD. **Method:** 32 patients with histologically confirmed IgG4-RD diagnosed between 1999 and April 2017 were included and reviewed for demographic and clinical characteristics. The response to treatment with glucocorticoids, disease modifying antirheumatic drugs, rituximab and other therapeutic interventions were evaluated. **Results:** Glucocorticoids as well as rituximab appeared successful therapeutic drugs leading to clinical remission (complete or partial remission) in all patients. Recurrences however, were frequently (62% versus 100%, respectively) seen. Diseases modifying antirheumatic drugs (DMARD's), including azathioprine, methotrexate and mycophenolate mofetil were effective in less than half of the cases. A minority of patients was treated with alternative treatments including hydroxychloroquine, thalidomide and infliximab which all appeared effective. Surgical intervention and radiotherapy in local disease seemed to induce clinical remission and were associated with low recurrence rates. **Conclusion:** Glucocorticoids and rituximab induce substantial responses as well as primary surgical intervention and radiotherapy, while the efficacy of DMARD's is limited. Based on the few data available, hydroxychloroquine, infliximab and thalidomide may be promising treatment options for second or third line strategies.

P.C2.05.13
OCA-B in the pathogenesis of Type 1 Diabetes

***H. Kim**, A. Shakya, C. German, D. Tantin;*
The University of Utah, Salt Lake City, United States.

Introduction: Type 1 diabetes (T1D) is an autoimmune disease caused by the destruction of insulin-producing beta cells in the pancreas. The mechanisms of T1D pathogenesis remain incompletely understood. Oct1 is a sequence-specific DNA binding transcription factor that in T cells potently regulates target gene expression with a co-factor, OCA-B. Both proteins control CD4+ T cell memory. Importantly, pathogenic CD8+ memory T cell frequency correlates with severity of insulitis in the non-obese-diabetic (NOD) mouse. The strongest OCA-B expression is found in pancreas-infiltrating-islet-reactive CD4+ T cells. Moreover, GWAS studies associate SNPs at multiple Oct1/OCA-B binding sites with T1D.
Materials and Methods: To study OCA-B effects on CD8+ T cell memory, WT or OCA-B KO naïve CD8+ T cells were cultured with a-CD3/28 for 2days. Subsequently, the cells were rested for 8 days without stimulus, and were re-stimulated for a recall response. To investigate impacts of OCA-B in the pathogenesis of T1D, NOD mice were injected with newly developed OCA-B inhibitor peptides or control.
Results: OCA-B loss in CD8+ T cells failed to induce recall responses in vitro. Strikingly, the inhibitor peptides reversed the elevated blood glucose in NOD mice. T cell infiltration and cytokine production in the pancreas was reduced compared to NOD mice treated with control peptide.
Conclusions: OCA-B regulates both CD4+ and CD8+ T cell memory and plays a role in T1D pathogenesis. To elucidate the mechanisms more deeply, OCA-B germline KO and T cell-specific OCA-B deleted NOD mice have been generated.

P.C2.05.14
Ethyl pyruvate treatment enhances regulatory T cell proliferation and function in type 1 diabetes

***I. Koprivica**, M. Vujičić, T. Saksida, D. Gajić, I. Stojanović;*
Institute for Biological Research "Siniša Stanković", Belgrade, Serbia.

Type 1 diabetes (T1D) is an autoimmune disease in which a strong inflammatory response causes insulin-producing pancreatic β-cell death. Ethyl pyruvate (EP), a stable pyruvate derivate, has exerted antioxidant and anti-inflammatory properties in several disease models. To test its therapeutic potential in T1D, EP was administered intraperitoneally to C57BL/6 mice with multiple low-dose streptozotocin (STZ)-induced T1D. EP treatment decreased T1D incidence and reduced the infiltration of cells into the pancreatic islets. *Ex vivo* analysis by flow cytometry showed that the EP treatment didn't change the number of immune cells in the spleen, pancreatic lymph nodes (PLN) or pancreatic mononuclear infiltrates (PMNI), nor the relative percentages of Th1, Th17 and Th2 cells. However, EP treatment increased the levels of regulatory T cells (Treg) in PLN and PMNI. After the EP treatment, all PLN Treg were $GITR^+CD127^-$, and an increase was noted in the percentage of $CD101^+$Treg, indicating a stronger suppressive activity. That was confirmed by an *in vitro* suppression assay, in which Treg from EP treated mice showed a higher capacity to supress effector T cell proliferation.
The number of $CXCR3^+$Treg and the presence of CD11a and CD62L per cell increased, which might imply an increase in Treg migration into the pancreas. However, a rise in the presence of $Ki67^+$Treg suggested that EP treatment also promotes Treg proliferation. These results show that EP treatment reduces T1D incidence in C57BL/6 mice by enhancing Treg proliferation, suppressive capacity, and recruitment into the pancreas. *This research is supported by MESTD, Republic of Serbia (#173013)*

P.C2.05.15
The role of IL-23TH17 pathway in Inflammatory bowel disease

***Y. Lakhoua Gorgi**[1], M. Majdoubi[1], J. Abdellatif[1], M. Jellouli[1], T. Dhaouadi[1], L. Mouelhi[2], T. Ben Abdallah[1], I. Sfar[1];*
[1]Research Laboratory in Immunology of Renal Transplantation and Immunopathology (LR03SP01), Tunis, Tunisia, [2]Department of Gastroenterology Charles Nicolle hospital, Tunis, Tunisia.

AIMS: Investigate a possible association between the functional polymorphisms: IL-17RC rs708567, IL-17F rs2397084 and IL-23R rs11209026 and the susceptibility to IBD and define the impact of these genetic variants on the IBD clinical forms **METHODS**: A cross-sectional case-control study involving 178 patients with IBD (108 CD and 70 UC) and 100 healthy control subjects was made. The molecular analysis was performed by PCR-RFLP. An ELISA tests were used to process to the quantitative determination of serum IL-17F and IL-23 cytokines.
RESULATS: Quantitatively, the mean level of IL-17F was significantly higher in patients than in controls (p = 0.003) and in CD patients with stricturing complications compared to other clinical forms (p = 0.006). The serum IL-23 levels were similar in patients and controls. The genotype G/G of IL-17RC polymorphism and the A/G genotype of IL-17-F SNP's seem to be associated to a higher occurrence of IBD and to the positivity of the ANCA antibodies in RCH patients in Tunisians (p = 0.049 and p = 0.008). For the R381Q IL-23R polymorphism, the frequency of the A allele was significantly higher in controls than in IBD patients (p <**0,0001)** suggesting a protective role of this SNP. **CONCLUSION:** The results of our study highlight the key role of IL-23Th17 pathway in the pathophysiological mechanisms of IBD. The prognostic interest of these markers deserved to be confirmed by further prospective studies on a larger cohort and by a functional analysis of IL-17F and IL-23mRNA expression

P.C2.05.16
Sulforaphane inhibits inflammatory responses of primary human T-cells by increasing ROS and depleting glutathione

***J. Liang**[1], B. Jahraus[1], E. Balta[1], J. Ziegler[1], K. Hübner[1], N. Blank[2], B. Niesler[3], G. Wabnitz[1], Y. Samstag[1];*
[1]Institute of Immunology, Heidelberg, Germany, [2]Department of Rheumatology, Heidelberg, Germany, [3]Department of Human Molecular Genetics, Heidelberg, Germany.

Sulforaphane (SFN), a compound in plants of the brassicaceae family, was reported to suppress cancer cell growth. Information about the relevance of SFN for human T-cells is limited. This is surprising as T-cells play a critical role in tumor control. We, therefore, investigated the effects of SFN on human untransformed peripheral blood T-cells. While SFN did not show cytotoxic effects and did not interfere with early T-cell activation, i.e. the formation of a mature immune synapse, it affected later activation events as upregulation of CD69 and CD25. The inhibitory effects of SFN could be rescued by thiol-containing antioxidants. In line with that finding, SFN led to an increase of intracellular reactive oxygen species (ROS) and a marked decrease of glutathione. Consistently, increased global cysteine sulfenylation was detected. Importantly, a major target for SFN-mediated protein oxidation was STAT-3, a transcription factor involved in the regulation of TH17-related genes. Moreover, costimulation-induced STAT-3 phosphorylation was significantly inhibited by SFN. In an unbiased gene expression signature analysis, we indeed found that TH17-related genes were predominantly inhibited by SFN. Since IL-17 and ROS regulation may be attractive targets for treating rheumatoid arthritis (RA), we tested the effect of SFN on whole blood from RA patients and found an increase in intracellular ROS levels in T-cells. Moreover, costimulation-induced expression of IL-17 was markedly decreased in SFN-treated T-cells from RA patients. Taken together, our study shows that SFN may act as a promising substance for therapeutic immune suppression via regulating the redox balance in human T-cells.

P.C2.05.17
Novel biomarkers of disease combined with ligand-directed targeted therapy for the control of autoimmune arthritis

*S. H. Venkatesha[1,2], S. Dudics[1,2], R. R. Meka[1,2], **K. D. Moudgil**[1,2];*
[1]University of Maryland School of Medicine, Baltimore, Baltimore, United States, [2]Baltimore Veterans Affairs Medical Center, Baltimore, United States.

Introduction: Rheumatoid arthritis (RA) affects millions of people worldwide. A key event here is the breakdown of self-tolerance leading to anti-self reactivity and tissue dysfunction/damage in the synovial joints. Current biomarkers for the diagnosis and prognosis of RA have inherent limitations. Similarly, the presently used drugs against RA are potent but their prolonged use is associated with severe adverse effects. Thus, there is a need for new biomarkers of disease and novel approaches to improve the therapeutic index of anti-arthritic drugs.
Materials and Methods: We addressed both these issues using the adjuvant-induced arthritis (AA) model of RA. We examined the micro-RNA (miRNA) expression profiles of the peripheral lymphoid cells of untreated/ treated arthritic and control rats, using miRNA-microarray. The data was subjected to statistical and bioinformatics analyses.
Results: We identified 8 specific miRNAs that were upregulated upon arthritis development. Collectively, these miRNAs targeted T cell response, angiogenesis, and bone remodeling pathways, but
individual miRNA specifically affecting Th17/Treg differentiation was also identified. Six of above 8 miRNAs were inhibited following arthritis treatment. For RA therapy, we employed a novel peptide
ligand that preferentially homes to inflamed joints after systemic administration, to direct drug-entrapping liposomes into the joints. Arthritic rats treated with these liposomes showed markedly
reduced severity of arthritis and decreased systemic toxicity compared to rats treated with free drug.
Conclusion: Our study has unraveled novel biomarkers of disease development and therapeutic response as well as an improved targeted therapy for autoimmune arthritis.

miR-130a dysregulation contributes to CD1c$^+$ dendritic cell activation in Sjogren's Syndrome

A. P. Pinheiro Lopes[1,2], *J. A. van Roon*[1,2], *S. L. Blokland*[1,2], *M. Wang*[3], *E. Chouri*[1,2], *A. A. Kruize*[1], *B. M. Burgering*[3], *M. Rossato*[1,2], *T. R. Radstake*[1,2], *M. R. Hillen*[1,2];
[1]*Department of Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands,* [2]*Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands,* [3]*Center for Molecular Medicine, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands.*

Introduction. Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands and mucosal dryness. As dysregulation of CD1c-expressing dendritic cells (cDCs) might play a role in pSS pathogenesis, we investigated miRNA expression in isolated cDCs from pSS patients. ***Methods.*** cDCs were isolated from peripheral blood of two independent cohorts of patients and healthy controls (HC): a discovery cohort (15 pSS, 6 HC) and a validation cohort (14 pSS, 11 HC). qPCR-based profiling of 758 miRNAs was performed in the discovery cohort. A selection of 18 differentially expressed miRNAs was measured in the validation cohort using a custom array. To study miR-130a regulation, isolated cDCs from HC were stimulated with different TLR ligands. To discover novel targets of miR-130a, HEK-293T cells were transfected with a miR-130a mimic and protein synthesis was analysed using pulsed stable isotope labelling by amino acids in cell culture (pSILAC). ***Results.*** 36 miRNAs were downregulated in pSS patients versus HC in the discovery cohort. Of the 18 selected miRNAs for replication, the decreased expression of miR-130a and miR-708 was validated. cDC activation through TLR3 and TLR7/8 downregulated miR-130a. Transfecting HEK-293T cells with miR-130a identified downregulation of proteins involved in NF-kB signalling. ***Conclusions.*** We here show that miR-130a and miR-708 are decreased in pSS cDCs, which is induced by TLR-induced cell activation. In addition, we provide evidence showing that miR-130a targets mediators involved in NF-kB signalling and cDC activation at the protein level.

Type 1 diabetes and related autoantibodies by the age of 13 years are not associated with probiotics administration in infancy

E. Savilahti[1], *M. Knip*[1], ***E. M. Savilahti***[1], *A. K. Kukkonen*[2], *M. Kuitunen*[1];
[1]*Children's Hospital, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland,* [2]*Skin and Allergy Hospital, University of Helsinki and Helsinki University Central Hospital, Helsinki,, Helsinki, Finland.*

Intestinal microbiota is thought to play a role in the development of type 1 diabetes (T1D), but prospective evidence on human studies is scarce. We used the data and material of a clinical double-blind randomized placebo-controlled trial on primary allergy prevention (n=1223) to investigate whether administration of a mix of pro- and prebiotics during late pregnancy and first 6 months of life was associated with prevalence of T1D during 13-year follow-up. Fourteen children had been diagnosed with T1D by November 2017, when the youngest participant was 13 years old. All those who developed T1D had complied to the intervention. Of them, 7 had received the active probiotic preparation. Factors known to have an effect on intestinal microbiota were similar among those developing diabetes and the remaining participants. In the 649 blood samples taken at the age 5, we analyzed GADA (96-585), IA-2A, IAA, ZnT8A 6.2 antibodies. Islet cell antibodies were measured only among those with positivity in any of the afore mentioned measurements. Levels above normal were found in altogether 25 children; 7 of them having increase in two or more measurements. Among these children, 12/25 with positive autoantibodies and 3/7 with ≥ 2 positive autoantibodies had received probiotic treatment during infancy. Probiotic or placebo treatment was thus not associated with positive autoantibodies at the age of 5 years. In conclusion, we found no effect of probiotic treatment in infancy on the development of T1D until the age of 13 years or on islet cell autoimmunity at age 5 years.

P.C2.05.20

Systemic level of IL-12p40 and its genetics polymorphisms in relapsing remitting multiple sclerosis

L. D. Miteva[1], *A. G. Trenova*[2], ***S. A. Stanilova***[3];
[1]*Trakia University, Medical Faculty, Stara Zagora, Bulgaria,* [2]*Medical University, Medical Faculty, Plovdiv, Bulgaria,* [3]*Trakia University, Medical faculty, Stara Zagora, Bulgaria.*

Introduction: Cytokines are tightly involved in the pathogenesis of multiple sclerosis as an inflammatory demyelinating disease. IL-12p70 and IL-23 share an IL-12p40 subunit. Two functional polymorphisms are identified within the IL12B gene encoding IL-12p40, rs17860508 and rs3212227. We aimed to determine the systemic IL-12p40 level among patients with relapsing-remitting multiple sclerosis (RRMS) and to explore the significance of both IL12B polymorphisms for RRMS risk. Materials and Methods: The genotyping was performed among 156 patients and 370 controls by PCR-based methods. Serum IL-12p40 concentrations were measured during remission of the disease by ELISA. Results: IL-12p40 serum levels were significantly higher in RRMS patients than in controls (184.66pg/ml; IQR:125-278.33 vs. 55.45pg/ml; IQR:40.95-72.3;p<0.0001). There was no statistically significant difference in serum IL-12p40 between patients without (EDSS≤1.5) or with mild/moderate (EDSS:2÷3.5) disability (p=0.821). The IL-12p40 levels decreased into the following order of genotypes of rs3212227: AA>AC>CC. Significantly lower IL-12p40 in patients carriers of CC-genotype (118.5pg/ml; IQR:85-161.67) compared to AA-genotype (198.14 pg/ml; IQR:156.67-298.6; p=0.0014) and AC-genotype (178.33pg/ml; IQR:125-278.33; p=0.024) was observed.
With regard to rs17860508, the genotype-22 and heterozygous-12 showed similar IL-12p40 quantities, slightly higher than genotype-11. There was a tendency for a higher frequency of AC/CC genotypes (48% vs. 43%; OR=1.227;95%CI:0.818-1.840) and combined AC/CC+12/22 (28% vs. 23%; OR=1.629;95%CI:0.720-3.719) in RRMS patients than controls, without reaching statistical significance. Conclusion: The significantly increased systemic IL-12p40 suggests the pivotal role of the IL-12 cytokine family in the pathogenesis of RRMS. Moreover, the functional effect of rs3212227 polymorphism was confirmed, although there is no association with RRMS risk.

P.C2.06.01

Therapeutic efficacy of systemic administration of orexin A in established experimental autoimmune encephalomyelitis

L. Becquet[1], *C. Abad*[1], *M. Leclercq*[1], *C. Miel*[1], *L. Jean*[1], *G. Riou*[1], *A. Couvineau*[2], *O. Boyer*[1,3], *Y. Tan*[1];
[1]*Normandie Univ, UNIROUEN, INSERM, U1234, PANTHER, Rouen, France,* [2]*Paris-Diderot University, INSERM U1149, Inflammation Research Center (CRI), DHU UNITY, Paris, France,* [3]*Normandie Univ, UNIROUEN, INSERM, U1234, Rouen University Hospital, Department of Immunology and Biotherapy, Rouen, France.*

Orexins (hypocretins, *Hcrt*) A and B are GPCR-binding hypothalamic neuropeptides known to regulate sleep/wake states and feeding behavior. A few studies have shown that orexin A exhibits anti-inflammatory and neuroprotective properties, suggesting that it might provide therapeutic effects in inflammatory and neurodegenerative diseases like multiple sclerosis (MS). MS is a highly prevalent autoimmune disease where encephalitogenic Th1 and Th17 cells trigger an inflammatory response in the CNS destroying the myelin sheath. Here, we investigated the effects of peripheral orexin A administration to mice with experimental autoimmune encephalomyelitis (EAE), a model of MS.
EAE was induced by active immunization of C57BL/6 mice with myelin oligodendrocyte glycoprotein $(MOG)_{35-55}$ peptide. Orexin A was peripherally administered and the efficacy was assessed clinically, as well as by histopathology and cytokine and chemokine mRNA expression analysis in the CNS. Peripheral responses to MOG_{35-55} were studied by *ex vivo* antigen-recall assays.
Orexin A strongly ameliorated ongoing EAE, limiting the infiltration of immune cells and diminishing inflammation responses in the CNS. Moreover, orexin A treatment was neuroprotective by modulating glial cells and astrocytes. Despite its strong therapeutic effects, orexin A did not impair draining lymph node cell proliferation and Th1/Th17 cytokine production in response to MOG_{35-55} *in vitro*.
These results suggest that orexins may represent new therapeutic candidates that should be further investigated for MS treatment.
This work was supported in part by Inserm Transfert, and co-supported by European Union and Région Normandie. Europe gets involved in Normandie with European Regional Development Fund (ERDF).

Targeting of tolerogenic dendritic cells towards heat-shock proteins: a novel therapeutic strategy for autoimmune diseases?

M. Jansen[1], *R. Spiering*[2], *P. van Kooten*[1], *I. Ludwig*[1], *W. van Eden*[1], *C. Hilkens*[2], ***F. Broere***[1];
[1]*Utrecht University, Utrecht, Netherlands,* [2]*Newcastle University, Newcastle upon Tyne, United Kingdom.*

Rheumatoid arthritis (RA) is an autoimmune disease caused by faulty regulation of the inflammatory process. A promising strategy to specifically target the pathogenic T cell response, while leaving other, protective T cell responses intact, is the use of tolerogenic dendritic cells (tolDCs). Since the self-antigen for RA is unknown and HSP70 has the potential to induce antigen specific Tregs, we investigate HSP70 as surrogate antigen. TolDCs were induced by dexamethasone and 1,25-dihydroxyvitaminD3 treatment of murine bone marrow derived dendritic cells (BMDCs). Subsequently, DCs were loaded with HSP70 peptide (B29) and co-cultured with mB29b TCR-Tg CD4 T cells. Furthermore, the effects of tolDCs on CD4$^+$ T cells *in vitro* and *in vivo* were investigated and tolDCs were injected in a proteoglycan induced arthritis mouse model. TolDCs exhibited a semi-mature phenotype and changed the phenotype of CD4$^+$ T cells to an immunomodulatory state, both *in vitro* and *in vivo*, when compared to mature BMDCs. T cells stimulated by tolDCs showed decreased proliferation and produced more IL-10. Interestingly, only mature tolDC significantly reduced arthritic symptoms, suggesting that a maturation stimulus is necessary to exert their function *in vivo*. These results indicate that cultured tolDCs are able to modulate the CD4$^+$ T cell response towards an anti-inflammatory state. Since the mice that were injected with matured tolDCs show reduced arthritis, we believe this mechanism might contribute to the efficacy of the tolDCs. Studying the immune modulatory capacity of tolDCs is essential for the further development of tolDCs for RA therapy.

P.C2.06.03

The immunomodulatory properties of the hookworm protein*Na*-AIP-1

***G. Buitrago**, S. Ryan, L. Jones, D. Pickering, P. Giacomin, A. Loukas;*
Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Australia.

Introduction: Inflammatory bowel disease (IBD) is an umbrella term for a group of immune-mediated conditions, which are characterised by idiopathic chronic inflammation of the gastrointestinal tract. Current treatment protocols for IBD are often poorly tolerated or ineffective. Multiple studies have described the potential efficacy of live parasitic helminth infection in alleviating symptoms of intestinal inflammation, in both human and animal models of disease. Consequently, there is interest in identifying potential immunomodulatory proteins secreted by helminths, which could be produced as a safer and more acceptable alternative to live worm therapy. Materials and Methods: We have identified, isolated and recombinantly expressed a novel candidate molecule from the secretions of the anthropophilic hookworm *Necator americanus* (*Na*-AIP-1). Results: Recombinant *Na*-AIP-1 was cloned and expressed using *Pichia pastoris* and purified via immobilised metal ion affinity chromatography. Intra-peritoneal treatment of mice with recombinant *Na*-AIP-1 ameliorated clinical, immunological and histological features of disease in two distinct murine models of colitis (TNBS and T cell transfer-induced colitis). Protection against colitis required the presence of CD11c+ dendritic cells and was associated with expansion of $CD4^+$ $Foxp3^+$ cells within mucosal tissue sites. Conclusions: Thus, *Na*-AIP-1 may represent an excellent candidate for further development as a novel treatment of autoimmune or inflammatory diseases of the intestine.

P.C2.06.04

IFN-alpha-treatment has different effects on NK cell populations in relapsing and monophasic rat experimental autoimmune uveitis

***M. Diedrichs-Möhring**[1], X. Liu[1,2], G. Wildner[1];*
[1]Section of Immunobiology, Dept. of Ophthalmology, University Hospital, LMU, Munich, Germany, [2]Present address: Ophthalmic Center of the Second Hospital, Jilin University, Changchun, China.

Interferon alpha (IFN-a) is a successful therapy of ocular Behçet's disease, but the underlying immune mechanisms are not yet fully understood. To further elucidate the therapeutic mechanisms we investigated the effect of IFN-a on leukocyte populations in two experimental rat models of relapsing and monophasic uveitis (EAU).
Uveitis was induced by immunization with either retinal S-Ag peptide PDSAg (monophasic/chronic EAU) or IRBP-peptide R14 (relapsing EAU). Recombinant human IFN-alpha was subcutaneously injected every day or every other day at different doses (1000 or 5000 IU) starting from different time points. Uveitis was graded clinically and histologically. Peritoneal exudate cells (PEC), lymph node (LN) cells and peripheral blood lymphocytes (PBL) were investigated for surface markers and cytokine expression by FACS-analysis. Preventive treatment with IFN-alpha starting with immunization significantly decreased the primary inflammation as well as relapses of R14-induced EAU, while PDSAg-induced, monophasic disease was deteriorated. Lymph node cells of PDSAg-immunized, IFN-a-treated rats revealed more TCR+ cells expressing IFN-γ, IL-17 or both, and less TCR+ cells producing IL-10 compared to the PBS-treated control group. IFN-a treatment decreased cell populations expressing CD161 in PDSAg-immunized Lewis rats, whereas in R14-induced EAU an increase in CD161+ cells.
IFN-a-treatment had different effects on relapsing and monophasic rat uveitis models. The deterioration of PDSAg-induced EAU by IFN-a-treatment might be due to an increase in leukocyte populations expressing inflammatory cytokines, and cells expressing CD161 might have a regulatory effect in R14-induced EAU.

Immune modulating effects of low level laser therapy in oral lichen planus patients

***M. N. Draganova-Filipova**[1,2], M. Z. Mutafchieva[3], S. Y. Bachurska[4], G. T. Tomov[5], P. I. Zagorchev[6];*
[1]1. Department of Medical Biology, Faculty of Medicine, Medical University-Plovdiv, Plovdiv, Bulgaria, Plovdiv, Bulgaria, [2]Technological Center of Emergency Medicine, Plovdiv, Bulgaria, [3]2. Department of Periodontology and Oral diseases, Faculty of Dental Medicine, Medical University-Plovdiv,, Plovdiv, Bulgaria, [4]3. Department of of General and Clinical Pathology, Faculty of Medicine, Medical University-Plovdiv, Plovdiv, Bulgaria, Plovdiv, Bulgaria, [5]2. Department of Periodontology and Oral diseases, Faculty of Dental Medicine, Medical University-Plovdiv, Plovdiv, Bulgaria, Plovdiv, Bulgaria, [6]4. Department of Medical Physics and Biophysics, Faculty of Pharmacy, Medical University-Plovdiv, Plovdiv, Bulgaria, Plovdiv, Bulgaria.

Introduction: Oral lichen planus (OLP) is an autoinflammatory disease, result of activation of T-lymphocytes against unknown antigen. Therefore, destruction of the basal epithelial cells occurs and painful wounds are formed. The low-level laser therapy (LLLT) is considered as promising and harmless opportunity for OLP patients. The aim of this study was to compare the expression of pro- and anti-apoptotic markers in patient's biopsies and the salivary levels of Th-1, Th-2, Th-17-cytokines and SIgA before and after LLLT. Material and methods: 20 OLP patients and 20 healthy donors underwent LLLT with a diode laser (810nm), 3 times weekly for a month. The biopsies were taken before and after therapy and were analyzed immunohistochemically for the p53, p63, and bcl-2-expression. The reaction intensity was measured using a semiquantitative scale. The levels of IL1-β, IL-6, IL-17, and SIgA were measured by ELISA in unstimulated whole saliva.
Results: The results from immunohistochemistry showed that p53 and p63 expression was not changed ($p=0.69$ and $p=0.42$), but bcl-2-levels were increased ($p<0.02$) after therapy. In OLP patients cytokine levels of IL1-β (81±28pg/ml), IL-6 (26,9±10,3pg/ml) and IL-17 (19,0±9,7pg/ml) were higher compared to controls (21,2±3,7pg/ml; 14.1±6,2pg/ml and 11,9±5,1pg/ml) and decreased after therapy (66,2±31,7; 18.6±6,5pg/ml and 16,5±8,5pg/ml). SIgA in controls was 74,7±14,0μg/ml and respectively 88,1±26,0μg/ml and 92,2±23,7μg/ml before and after LLLT. Conclusions: LLLT is useful and harmless treatment modality for OLP patients, capable to balance the immune response. Keywords: immune regulation and therapy, inflammation, autoimmunity Acknowledgements: The investigation is sponsored by Grant HO-03/2014/MU-Plovdiv and partially by National *Science Fund*-Bulgaria-ДН-11/15/18.12.2017

P.C2.06.06

Critical role play by galectin-1 in the T cell mediated regulation of experimental colitis

***R. Fernandez**, O. Aberquilla, R. Sánchez, J. A. Bueren, M. Garin;*
Ciemat/IIS Fundación Jiménez Díaz/Ciberer, Madrid, Spain.

Foxp3-expressing regulatory T cells (Treg) are vital for maintaining balance among tolerance, adequate immune responses, and autoimmunity. In recent years, regulatory T cells are being developed as a cellular therapy with the potential to modulated unwanted immune responses. While their homeostasis has been extensively studied, their mechanisms of immunoregulation still remain to be fully clarified. We previously found that galectin-1 (GAL1), a β-galactoside-binding lectin, is expressed by human and mouse regulatory T cells and contributes to their immunosuppressive function *in vitro*. In this study, we examined the prophylactic and therapeutic effects of GAL1-deficient $CD4^+CD25^+Foxp3^+$ regulatory T cells (GAL1 KO-Tregs) on a T cell transfer *in vivo* model of inflammatory bowel disease (IBD). Our findings demonstrate that GAL1 KO-Tregs retained their capacity to modulate intestinal inflammation induced by $FOXP3^-$ $CD45Rb^+CD4^+$ naïve T cells into Rag-1 mice. However, the immunomodulation achieved was less efficient with respect to wild-type Tregs, as shown by the increase number of GAL1 KO-Tregs required for effective protection against IBD. In addition to this, the long term survival of the mice treated with GAL1 KO-Tregs was compromised when compared to those mice treated with wild-type Tregs. We conclude that galectin-1 plays a critical role in the T cell mediated regulation of experimental colitis and that an adequate expression of galectin-1 should be taken into consideration in future cell therapy protocols with regulatory T cells.

Genetic microglia depletion ameliorates neuroinflammation in experimental autoimmune encephalomyelitis

***J. Han**, H. Lund, K. Zhu, M. Pieber, R. A. Harris, X. Zhang;*
Karolinska Institutet, Stockholm, Sweden.

Microglia are the principal resident immune cells in the central nervous system (CNS) and are believed to be versatile players in both inflammatory and physiological contexts. Although the dysfunction of microglia and microglia-induced neuroinflammation are implicated in the occurrence and progression of many neurological diseases, what remains largely enigmatic is the relative importance of microglia during different disease stages. We immunized $CX3CR1^{CreER}Rosa26^{DTA}$ (DTA) mice with myelin oligodendrocyte glycoprotein (MOG) to induce experimental autoimmune encephalomyelitis (EAE). Microglia depletion in DTA mice was initiated by injecting tamoxifen (TAM) for three consecutive days, resulting in almost complete loss of microglia after another 7 days. Depletion was initiated at day 5 of post-immunization during the period of disease initiation and early progression. The efficiency of microglia depletion was confirmed by using both microglia-specific P2ry12 immunohistochemistry and $CD11b^+CD45^+Ly6C^-Ly6G^-CX3CR1^+$ flow cytometry. The severity of EAE was evaluated using a clinical scoring system. At day 15 post-immunization, the peak of sickness, the mice were sacrificed and the tissues of brain and spinal cord were assessed by flow cytometry. Our preliminary results indicate that microglia depleted mice had less severe neuroinflammation as assessed by both the clinical scores and the data from flow cytometric analyses. Our results demonstrate that microglia are involved in the initiation and early progression of MOG-EAE. The tamoxifen-inducible $CX3CR1^{CreER}$ mice can be viewed as effective microglia-specific genetic tool to study the role of microglia in neurological diseases *in vivo*.

P.C2.06.08

Adipose-derived mesenchymal stem cells alter the Th17/Tregs axis in patients with rheumatoid arthritis yet not in patients with systemic sclerosis - preliminary data

***E. K. Kurteva**, G. Vassilev, M. Ivanova, E. Ivanova-Todorova, K. Tumangelova-Yuzeir, V. Boyadzhieva, N. Stoilov, R. Stoilov, D. Kyurkchiev;*
Medical University of Sofia, Sofia, Bulgaria.

Mesenchymal stem cells (MSCs) are fibroblast-like progenitor cells that possess the capacity to self-renew and can differentiate into several mesenchymal lineages. MSCs suppress the antigen-specific T-cell proliferation and cytotoxicity as well as inducing the generation of T reg cells. Regarding the pivotal role of the Th17/Treg axis in the pathogenesis of systemic sclerosis (SSc) and rheumatoid arthritis (RA), we aimed to study the immunosuppressive effects of adipose tissue-derived MSCs (AT-MSCs) conditioned medium on the percentage of Th17 and Tregs obtained from patients with SSc and RA. We enrolled 5 patients who fulfilled the 2013 ACR/EULAR Criteria for the classification of SSc and 13 patients matching the ACR/EULAR 2010 criteria for RA. AT-MSCs were isolated and cultured according to well established protocols. We used ELISA to quantitate the cytokines produced by AT-MSCs (IL-1, IL-10, IL-4, IFN-γ, IL-6, IL-8, CCL-5, RANTES, IL-17, TGF-β). Peripheral blood mononuclear cells (PBMCs) isolated from SSc and RA patients were cultured in AT-MSCs conditioned media as well as in control media. We performed flow cytometric analysis of the percentage of Th17 and T regs, and TGF-β levels produced by PBMCs were detected by ELISA.Our results demonstrated decreased percentage of Th17 cells (p=0.012) under the influence of AT-MSCs medium in RA yet not in SSc patients. The percentage of Tregs was raised only in RA patients: $CD4^+FoxP3^+$ lymphocytes (p=0,031), $CD4^+FoxP3^+CD25^{neg}$ (p=0.001). Further, in RA patients we found considerable increase in TGF-β levels (p=0.031) produced by PBMCs cultured with AT-MSCs medium as opposed to control PBMCs.

P.C2.06.09

$PD1^{hi}CXCR5^-$ peripheral helper T-cells producing IL21 and IFNγ are increased in systemic lupus erythematosus

***J. Land**, M. Parvaz, M. R. Ehrenstein;*
Centre for Rheumatology, Division of Medicine, University College London, London, United Kingdom.

Introduction: Follicular helper T (Tfh) cells are a specialised CXCR5+ T-cell subset that provide signals to B-cells, which are known to be increased in frequency in systemic lupus erythematosus (SLE) patients. Recently, a distinct circulating subset termed peripheral helper T (Tph) cells was described which are CXCR5- but have similar functional properties to Tfh.
Methods: Flow cytometry was performed on PBMC from 43 SLE patients and 12 healthy controls (HC) to determine the Tfh/Tph phenotype, including expression of PD1 and CXCR5. Production of IL21 and IFNγ was determined in 15 SLE and 5 HC.
Results: The percentage of circulating $CXCR5^+PD1^+$ Tfh cells was increased 1.5-fold in SLE compared to HC. The increase in $CXCR5^-PD1^{hi}$ Tph cell frequency was more pronounced being 4-fold higher in SLE (median 1.8%;range 0.3-9.6%) than in HC (0.4%;0.1-1.2%). SLE patients had an increased proportion of IL-21 producing Tfh and Tph cells. T-cells with high expression of PD1 demonstrated the largest proportion of $IL21^+$ and $IFN\gamma^+$ cells, regardless of CXCR5 expression. Double-positive $IL21^+IFN\gamma^+$ Tfh and Tph cells were also increased in SLE. The percentage of Tfh cells correlated with B-cell frequency in SLE (spearman's *r*=0.5;p=0.001) but not in HC, while Tph cell frequency negatively correlated with C3-levels (*r*=-0.361;p=0.031).
Conclusion: Tph as well as Tfh cells are increased in SLE. The increase in $IL-21^+$ T-cells within these two populations contained a large proportion of IFNγ producing cells. Tfh frequency did not correlate with disease activity, while Tph frequency correlated with C3 levels which are reduced in active disease.

P.C2.06.10

The role of the Tec kinase ITK and the transcription factor NFATc1 in disease pathogenesis of inflammatory bowel disease

***K. Lechner**, S. Mott, M. F. Neurath, B. Weigmann;*
Department of I., Medical Clinic, Erlangen, Germany.

Introduction: ITK, a member of the Tec family kinases, is expressed in T cells and involved in Th2-type mediated immune responses. Colitis patients can be successfully treated with CsA but CD patients not. Therefore, we started to investigate the role of ITK (interleukin-2-inducible T cell kinase) and the linked transcription factor NFATc1 in experimental colitis model.
Methods: Oxazolone colitis was induced in ITK deficient mice, conditional NFATc1-ΔCD4-KO mice and controls. Disease activity was measured by means of body weight, histological and endoscopic score of inflammation activity. Lamina propria mononuclear cells (LPMC) were isolated from these mice. The rate of apoptosis induction after treatment with CsA was assessed via flow cytometric analysis of AnnexinV/7AAD staining. Cytokine concentration was assessed using ELISA.
Results: In the oxazolone induced colitis model, ITK-KO mice are protected against the development of intestinal inflammation compared to control mice. Upon administration of CsA there is an induction of apoptosis in LPMCs from control mice. Conditional NFATc1-ΔCD4-KO mice show no protection against oxazolone induced colitis compared to control mice. Interestingly, administration of CsA could not prevent inflammation in these mice.
Discussion / Conclusion: Our results indicate that in the oxazolone induced colitis model, CsA induces enhanced apoptosis in LPMCs of control- and ITK-KO mice. NFATc1 doesn't seem to play a pivotal role in the development of intestinal inflammation since its knockout doesn't lead to protection against the induced colitis even after administration of CsA. Therefore, we suggest ITK to be a possible target for the therapy of colitis ulcerosa.

P.C2.06.12

Optimization of nanobodies for in vivo targeting of P2X7 ion channel on brain microglia and kidney immune cells.

***C. Pinto-Espinoza**[1], N. Schwarz[1], B. Rissiek[1], M. Junge[1], T. Magnus[1], F. Haag[1], C. Stortelers[2], F. Koch-Nolte[1];*
[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Ablynx NV, Ghent, Belgium.

Nanobodies are the smallest antigen-binding domains derived from heavy chain antibodies, naturally occurring in Camelids.
The P2X7 ion channel is expressed by immune cells and promotes inflammatory responses. We generated nanobodies that effectively antagonize P2X7 and show benefit in animal models of inflammation (1). The clinical efficacy of these biologic antagonists is thought to reflect their excellent *in vivo* tissue penetration. However, little is known about the capacity of nanobodies to penetrate peripheral endothelial barriers or the highly restrictive blood-brain barrier (BBB) (2).
In this study, we reformatted P2X7 antagonistic nanobodies to improve tissue penetration. By genetic fusion, we dimerized them to increase avidity and added an albumin-specific nanobody to extend their *in vivo* half-life. By site-directed mutagenesis, we raised their isoelectric point (pI).
In vivo tissue penetration and efficacy of intravenously injected nanobodies at different doses and various time points were evaluated by determining the degree of P2X7 occupancy and P2X7 blockade using flow cytometry. The results show that very high nanobody doses were required to fully occupy and block P2X7 on microglia whereas a hundred-fold decrease in the dosage achieved the same effect on kidney resident immune cells, suggesting that high doses are required to allow complete translocation of nanobodies through the BBB.

Exploring the immunosuppressive potential of venom-derived molecules

***R. Y. M. Ryan**[1,2,3], V. Lutzky[3], J. Potriquet[1], M. Ikonomopoulou[4], A. Lopez[2], J. J. Miles[1];*
[1]Australian Institute of Tropical Health and Medicine, Cairns, Australia, [2]Griffith University, Brisbane, Australia, [3]QIMR Berghofer, Brisbane, Australia, [4]IMDEA Food Institute, Madrid, Spain.

The unique combinations of potent, specific, and fast-acting molecules within venom act to rapidly disrupt vital biological processes in prey and predators. Ironically, the same characteristics that make venom biologically effective presents an ideal platform for the exploration of novel therapeutics and immunological pathways. This study mapped snake venom components with potent immune modulating abilities for drug development in the field of chronic inflammatory disease, of which many have no cure. Immunosuppressive venoms were fractionated using RP-HPLC and screened for activity against mitogen-induced activation. The effects of venom on human leukocytes were assessed using multiplex bead-based assays, flow cytometry, proliferation assays and cell viability assays. The results showed that specific venom fractions significantly inhibited IFNγ and TNFα release when primary leukocytes were stimulated with either Cell Stimulation Cocktail or CD3/CD28 activation beads. Interestingly, no change was observed in the myeloid compartment in response to lipopolysaccharide activation. Further, venom treatment reduced T-cell secreted cytokines without inhibiting cell proliferation or reducing cell viability, suggesting that these activation pathways are distinct in humans. Collectively, these data reveal novel venom-derived molecules specifically target and deactivate T-cells and could potentially be used to control or fine-tune the function of the human immune system.

Introduction: Immunogenetic studies in Rheumatoid Arthritis (RA) have documented the positive correlation of various gene loci with incidence and/or disease profile. However, the description of gene loci negatively related to the incidence of RA is rarely documented. Even more seldom is the functional, proteomic analysis of such an SNP and of the respective intracellular signaling pathway. **Methodology - Results:** We performed the immunogenetic sequence of the seven exons of the gene TRAF1. 172 patients and 95 controls were genetically assessed. On the position 9:120905076 of exon 7, the registered polymorphism G/A (rs143265058) was described in the controls group. The same polymorphism was not confirmed in any of the patients. Further functional proteomic study of the polymorphism with computing programs (software), revealed that the presence of this polymorphism leads to a differentiation of the quaternary structure of TRAF1 protein. A further three-dimensional configuration of the TRAF-1 associated molecules was performed in order to assess the signaling deviation this SNP may elicit on the TNFα intracellular signaling pathway. **Conclusions:** The present reference is one of the extremely rare genetic studies describing a protective gene locus against rheumatoid arthritis, and a pioneer of its kind in the use of Applied Informatics in the depiction of the quaternary structure of the encoded protein. At the same time, it is one of the few immunogenetic studies describing the functional proteomics of the encoded protein, plotting on a molecular level specific interaction modifications affecting the intracellular signaling pathway of TNFα.

Impact of rituximab therapy on IgG4 levels and B-cell phenotype in rheumatoid arthritis patients

A. Sarantopoulos[1], *E. Farmaki*[2], *M. Mytilinaiou*[3], *A. Gkantaras*[1], *A. Sarantopoulou*[2], *P. Boura*[3], *A. Tsirogianni*[4];
[1]*2nd Department of Internal Medicine, Hippokration General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*First Department of Pediatrics, Hippokration General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [3]*Clinical Immunology Unit, 2nd Department of Internal Medicine, Hippokration General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [4]*Department of Immunology and Histocompatibility, 'Evangelismos' General Hospital, Athens, Greece.*

Introduction: Rituximab is an effective therapeutic option in a variety of diseases. On IgG4-RD, apart from B-cell depletion, rituximab induces remission by reducing IgG4 levels. On RA, no study has inter-associated IgG4 levels and B-cell phenotype following rituximab therapy. We investigated whether B-cell depletion in RA: i) induces selective reduction of IgG4, ii) IgG4 alterations follow specific B-cell immunophenotype imprint. **Patients and Methods**: 31 RA patients, on a standard of care DMARD treatment and rituximab administration every 6 months for 2 years were investigated for alterations on disease activity along with IgG subclasses levels and B-cell immune profile. All parameters were assessed at enrollment (T0), and after 6, 12 and 24 months. On this 2-year period, all patients had been periodically receiving rituximab every 6 months. **Results:** After 2 years of rituximab administration, patients achieved a good response to treatment (EULAR criteria). Igs' levels were not statistically altered, though all of them declined. Furthermore, from IgG subclasses, only IgG4 levels statistically declined. Special features of emerging B-cell subpopulations have been identified in selected patients. **Conclusions:** This is the first time that IgG4 variations and B-cell emerging subpopulations are co-investigated in a non-IgG4RD after rituximab administration. Our results imply that IgG4 may be actively implicated in RA pathophysiology since disease remission is accompanied by only IgG4 level reduction among all classes and subclasses of Igs'. These findings open a new chapter in RA pathophysiology, indicating that this subclass is actively participating in the homeostasis of immune-mediated diseases other than IgG4-RD.

P.C2.06.16

Establishment of a chimeric human-mouse model of rheumatoid arthritis for pre-clinical testing

K. Schinnerling[1], *C. Schäfer*[1], *J. Maggi*[1], *C. Rosas*[2], *L. Soto*[3], *J. C. Aguillón*[1];
[1]*Universidad de Chile, Facultad de Medicina, Instituto de Ciencias Biomédicas, Santiago, Chile,* [2]*Universidad San Sebastián, Departamento de Ciencias Morfológicas, Facultad de Ciencia, Santiago, Chile,* [3]*Hospital Clínico Universidad de Chile, Sección de Reumatología, Santiago, Chile.*

Introduction: Preclinical testing of novel therapeutic approaches for rheumatoid arthritis (RA) requires a mouse model that imitates the human disease. To circumvent limitations due to differences between murine and human immune systems, we intended to establish a humanized mouse model of RA by transferring peripheral blood mononuclear cells (PBMCs) from healthy or RA subjects into immunodeficient mice. Methods: PBMCs were injected intravenously into 5-8-week old female NOD-*scid IL2rg*^{null} (NSG) mice. Human cell engraftment was monitored weekly and reactivity of human cells, recovered from spleens, towards synovial fluid (SF) and polyclonal stimulation, was assessed by flow cytometry. Human immunoglobulins (Ig) were quantified in serum by ELISA. Joint sections were stained with H&E. Results: Engraftment of human cells reached 36±5% in spleen, 77±4% in lymph nodes, 6±2% in bone marrow, and 22±4% in blood of NSG mice at six weeks after PBMC injection, regardless of whether PBMC from healthy or RA donors were used. The human graft consisted predominantly of activated CD4+ T cells which preserved their capacity to express IFN-γ in response to SF or polyclonal stimulation. Engrafted B cells continued producing IgM and IgG. Injection of RA patient-derived PBMC alone failed to generate histological alterations, however, in pilot experiments, additional intraarticular administration of SF, or injection of RA-derived CD4+ T cells together with SF-pulsed dendritic cells, resulted in cellular infiltrates and cartilage degradation. Conclusion: Although requiring further investigation, this chimeric human-mouse model of RA might provide an experimental system for preclinical testing of new therapies. Funded by FONDECYT3150453 and FONDECYT1140553.

Characterization of MALT1 protease resistant CYLD knock-in and HOIL-1 knock-in mice

I. Skordos[1,2], *A. Demeyer*[1,2], *J. Staal*[1,2], *R. Beyaert*[1,2];
[1]*VIB-UGent Center for Inflammation Research, Ghent (zwijnaarde), Belgium,* [2]*Department of Biomedical Molecular Biology, Ghent University, Ghent (zwijnaarde), Belgium.*

Introduction: The paracaspase MALT1 is a key molecule in TCR induced signaling to NF-κB and steers TCR-induced gene expression by two distinct mechanisms: as a protease and as a scaffold protein. MALT1 proteolytic activity fine-tunes inflammatory gene expression and contributes to antigen-induced T cell proliferation as revealed by studies on MALT1 protease deficient (MALT1-PD) mice. Remarkably, MALT1-PD mice suffer from ataxia and lethal multi-organ inflammation, have reduced frequencies of thymic and peripheral regulatory T cells (tTregs and pTregs) and marginal zone (MZ) B cells, but have increased frequencies of effector T cells. Here, we investigated whether preventing the cleavage of an individual MALT1 substrate, CYLD or HOIL-1, leads to a similar phenotype. Materials and Methods: CYLD knock-in (KI) and HOIL-1 KI mice, expressing a non-cleavable form of CYLD or HOIL-1, were monitored for ataxia development and several organs were assessed for inflammation. The T cell activation status, the frequencies of tTregs, pTregs, MZ B cells, Th1, Th2, Th17, Tc1 and the $CD4^+$ T cell proliferation were determined by flow cytometry. Results and conclusions: In contrast to MALT1-PD mice, our KI mice did not develop ataxia or multi-organ inflammation. In addition, frequencies of tTreg, pTreg, MZ B cells, Th1, Th2, Th17 and Tc1 were comparable between KI and wild-type mice as were T cell activation status and $CD4^+$ T cell proliferation. To elucidate the potential function of CYLD and HOIL-1 cleavage by MALT1, we will conduct competitive bone marrow chimera studies and transcriptome analysis of TCR stimulated $CD4^+$ T cells.

Psoriasis (PS), a T-cell mediated autoimmune disease, affects 3% of the population and the search for best immune markers in diagnosis and prognosis of this disease remains an unmet need. We have established a murine model of PS by topical application of Imiquimod (IMQ), and quantified the immune cell populations in both blood and spleen (study approved by the Ethical Committee).
Methods: C57BL/6 mice were constituted in 3 groups: 1) daily topical dose of IMQ (Aldara, Sweden) on the shaved back for 5 consecutive days; 2) control 1-daily topical with vaseline-based cream (Locobase, Netherland); 3) control 2 - no treatment. The progress and severity of inflammation (erythema, desquamation, induration) were scored daily. PASI score was calculated for each day. On the 6th day animals were weighted and euthanized. Spleen weight and bodyweight ratio assessed splenomegaly. Skin samples were histopathological examined. Lymphocytes were evaluated in peripheral blood and in spleen cellular suspension using flow-cytometry methods.
Results: Increase of erythema, scaling, thickening values and PASI score were registered; histology confirmed psoriasiform dermatitis. The main statistically significant changes in peripheral blood were T-CD4+ and B decrease correlated with T-CD8+ and NK increase. In spleen, B and all T cell populations decreased. No differences registered between control 1 and 2 groups.
Conclusions: Data suggest increased cytotoxicity in peripheral blood and decreased splenic cellularity as an expression of post-lesion skin inflammation. Immunophenotyping proves important to highlight the cytotoxic mechanism of disease.

Bone marrow derived mesenchymal stromal cells suppress Th1 and enhance Th17 differentiation of antigen-activated CD4$^+$ T cells in vitro

J. L. Talbot[1], *L. S. Börnsen*[2], *M. R. von Essen*[1], *A. Fischer-Nielsen*[1], *R. S. Oliveri*[1], *M. Blinkenberg*[1], *F. Sellebjerg*[1];
[1]*Danish Multiple Sclerosis Center, København Ø, Denmark,* [2]*Danish Multiple Sclersosi Center, København Ø, Denmark.*

Mesenchymal stromal cells (MSCs) can modulate immune cell proliferation, activation and differentiation. The aim of this study was to assess how MSCs regulate the proliferation and differentiation of healthy immune cell responses to specific antigens known to induce different T helper cell (Th) responses.
Peripheral blood mononuclear cells (PBMCs) from healthy individuals (n=13) were incubated with bone-marrow derived MSCs from 1 MS patient (n=1) and 1 healthy donor (n=1). PBMCs were then stimulated with six different antigens for 7 days and analyzed by flowcytometry. The expression of the chemokine receptors CXCR3 and CCR6 were analyzed on $CFSE_{low}$ CD4$^+$ T-cells as surrogate markers for specific Th responses. Furthermore, we analyzed a panel of intracellular cytokines in CD8$^-$ T cells derived from healthy donors (n=7) after stimulation of PBMCs in coculture with MSCs.
Proliferation of CD4$^+$ T cells was significantly diminished when stimulated with antigens promoting Th1 responses. The expression of Th1- and Th17-associated chemokine receptor in CD4$^+$ T cell responses were significantly suppressed and enhanced, respectively, by mesenchymal stromal cells. Intracellular analysis revealed significantly increased expression of Th17 cytokines and decreased expression of Th1 cytokines on CD8$^-$ T cells cultured with bone marrow stromal cells.
Our results indicate that bone marrow stromal cell-induced suppression of CD4+ T cell proliferation may depend on the type of Th response. Stromal cells can suppress Th1-related responses and enhance Th17-related responses in CD4$^+$ T cells in a dose-response dependent manner.

Anti-inflammatory activity of *Pistacia Lentiscus L*extracts in patients with IBD: an *in vitro* study

I. M. Boutemine[1], ***M. Amri***[1], *K. Layaida*[2], *L. Kecili*[2], *n. Kaddache*[2], *C. Fitting*[3], *J. M. Cavaillon*[3], *Z. C. Amir*[4], *S. Berkane*[2], *C. Touil-Boukoffa*[1];
[1]*University USTHB, Faculty of Biological Sciences, Laboratory of Cellular and Molecular Biology, Algiers, Algeria,* [2]*Gastroenterology department, Mustapha Pacha Hospital, Algiers, Algeria,* [3]*Cytokines & Inflammation, Pasteur Institute, Paris, France,* [4]*Pathology department, Mustapha Pacha Hospital, Algiers, Algeria.*

Introduction: Pistacia lentiscus L. (Anacardiaceae) (PL) is a flowering plant growing in Mediterranean area. It is traditionally used in the treatment of gastrointestinal upsets. Scientific findings also revealed the wide pharmacological activities from various parts of this species, such as antioxidant and anti-inflammatory activities.*Patients and methods:* Intestinal biopsies were performed during colonoscopy in patients with active-phase of inflammatory bowel diseases (IBD) (n = 27). They were cultured in Dulbecco's modified Eagle's medium at 37°C for 24 hours in the presence or absence of the aqueous extract (PLAE) (50 and 100 µg / ml) or fatty oil of PL (PLFO) (0,01% and 0,02% dissolved in 0,1% DMSO). In order to evaluate the effect of PL extracts on inflammation induced during IBD, pro-inflammatory and regulatory cytokines (IL-1β, IL-6, IL-8 and IL-10) as well as nitric oxide (NO) levels were evaluated in the culture supernatants. Moreover, microscopic observation and histological evaluation were performed to evaluate the effect of the PL extract on cell growth.*Results:* Our results demonstrate that the PL extracts significantly decrease the levels of pro-inflammatory cytokines (IL-1β, IL-6, and IL-8) and NO. However, these extracts increase the level of the immunoregulatory cytokine IL-10. Moreover, no cytotoxic effect was observed on the biopsies after cell culture.*Conclusion:* Our results suggest a beneficial effect of the *Pistacia lentiscus* extracts (aqueous extract and fatty oil) by reducing the inflammation induced during IBD. These findings indicate that PLFO and PLAE could constitute a new natural anti-inflammatory tool.

Introduction: Rheumatoid arthritis (RA) is a common chronic inflammatory disease that affects mainly peripheral joints. Sadly here is no cure for RA yet. However, our earlier research found some of the defined epitopes located on Collagen II seem to be associated with protection against arthritis.
Materials and methods: Collagen antibody induced arthritis experiment: Arthritis is induced in 3-4 months old mice by intravenous injection of pathogenic monoclonal antibody (mAb) cocktail. One group received PBS and the others received antibodies to the certain epitopes respectively one day after injection of arthritogenic antibodies. All mice were boosted with 50ug Endotoxin (lipopolysaccharide) by intra-peritoneal injection on day 5. Arthritis was scored every second day until day 21 post immunization.
Results: Antibodies to this particular epitopes could suppress the development of arthritis if injected shortly after injection of arthritogenic antibodies
Conclusion: Antibodies to the certain epitope protects against arthritis in mice.

The role of anticytokine autoantibodies in the pathogenesis of juvenile idiopathic arthritis

Y. Chen[1,2], *Y. Yang*[2], *B. Chiang*[2];
[1]*Department of pediatrics, Taipei City United Hospital, Taipei, Taiwan,* [2]*Department of pediatrics,, National Taiwan University Hospital, Taipei, Taiwan.*

Introduction: anti-cytokine autoantibodies (ACA) have been reported in healthy people and patients with a variety of autoimmune diseases, but their function is still debated. There is little study about ACA in juvenile idiopathic arthritis (JIA). The purpose of study is to examine anti-cytokine antibodies in the patients with juvenile idiopathic arthritis patients. **Material and methods:** Fifty- seven patients in whom oligoarticular, polyarticular and systemic type JIA were diagnosed before 16 years old were recruited on visits to the pediatric rheumatology department (from 2011 to 2015) and twenty healthy control were recruited. The ACA was assayed by indirect ELISA for anti-TNF alpha, anti IL-6 (inflammatory cytokine) antibodies. **Results:**Fifty-seven JIA patients and twenty healthy controls are recruited. Anti TNF alpha IgG and IgM show significantly higher level in oligoarticular and polyarticular subtypes than those of control group($p< 0.05$). Anti IL-6 IgG and IgM level showed significant higher in all subtype JIA group than control group ($P<0.01$). Anti IL-6 IgG showed higher level in active disease (CHAQ>0) than inactive disease(CHAQ=0) in oligoarticular and polyarticular suptypes. The anti IL-6 IgG level showed postivie correlation with WBC, PLT, ESR, CRP in systemic subtype. **Conclusions:**Anti-TNF alpha and anti IL-6 autoantibodies are higher in Juvenile idiopathic arthritis than those of healthy control in some suptypes. Although systemic type JIA is considered as autoinflammatory disease, we found autoantibodies in these patients. These antibodies might play a important role in pathologic mechanism, disease modulation or just reflect the increasing serum level of these cytokines.

Protective effects of mixture of fifteen n-propyl polysulfides on ConA-induced hepatitis mediated by induction of regulatory macrophages

D. Djordjevic[1], *J. Milovanovic*[1], *M. Jurisevic*[1], *B. Stojanovic*[1], *O. Cvetkovic*[2], *M. Pergal*[2], *E. Ristic*[3], *D. Vojvodic*[3], *M. Simic*[4], *D. Manojlovic*[5], *M. Milovanovic*[1], *N. Arsenijevic*[1];
[1]*Faculty of Medical Sciences, Kragujevac, Serbia,* [2]*Institute of Chemistry, Technology and Metallurgy, Belgrade, Serbia,* [3]*Faculty of Medicine, Military Medical Academy, Belgrade, Serbia,* [4]*Center for New Technologies, Belgrade, Serbia,* [5]*Faculty of Chemistry, Belgrade, Serbia.*

Biologically active substances of garlic are different organosulfur compounds that exhibit potent antioxidant, anti-inflammatory, immunomodulatory and antitumor activities. The biological activity of organosulfur compounds is in direct correlation with the number of sulfur atoms. ConA induced hepatitis is acute form of inflammatory liver disease that shares some features of immune mediated liver diseases, including autoimmune hepatitis. In this study, immmunomodulatory and antiinflammatory potential of the mixture of fifteen n-propyl polysulfides was analyzed in ConA-induced hepatitis in mice. Mixture of fifteen n-propyl polysulfides was orally administered to C57BL/6 mice eight hours before intravenous injection of ConA. Disease severity was evaluated by liver enyzme assay, quantitative histology, mononuclear cell infiltration, cytokine production, liver endothelial cell activation and percentage of hepatocellular apoptosis. Mixture of fifteen n-propyl polysulfides almost completely prevented damage of liver tissue, attenuated production of inflammatory cytokines and enhanced infiltration of liver tissue with activated regulatory (CD86+CD206+IL-10+F4/80+) macrophages and regulatory T cells.
In conclusion, mixture of n-propyl polysulfides exerts highly antiinflammatory and immunomodulatory activity. This mixture enhances liver infiltration with regulatory macrophages and thus prevents ConA induced liver damage.

P.C2.07.05

Insufficient interleukin-10 production as a mechanism underlying pathogenesis of systemic juvenile idiopathic arthritis

M. Imbrechts[1], *A. Avau*[1], *J. Vandenhaute*[1], *B. Malengier-Devlies*[1], *K. Put*[1], *T. Mitera*[1], *N. Berghmans*[1], *O. Burton*[2], *A. Liston*[2], *L. de Somer*[3], *C. Wouters*[3], *P. Matthys*[1];
[1]*Rega Institute, KULeuven, Leuven, Belgium,* [2]*VIB-KULeuven, Leuven, Belgium,* [3]*University Hospital Leuven, Leuven, Belgium.*

Objective. Systemic juvenile idiopathic arthritis (sJIA) is a childhood immune-inflammatory disorder with unknown etiology. One of the concepts is that the disease results from an inappropriate control of immune responses to an initially harmless trigger. We investigated whether sJIA may be caused by defects in IL-10, a key cytokine in controlling inflammation.
Methods. IL-10 production was analyzed in a sJIA mouse model, which relies on injection of Complete Freund's Adjuvant (CFA) in IFN-γ deficient mice. Corresponding wild type (WT) mice develop a subtle and transient inflammatory reaction and were used to study the effect of IL10 neutralization. Cytokines and CRP were analyzed in plasma of sJIA patients (active: n=10; inactive: n=8) and healthy controls (n=15). Their PBMCs were used to study cell-specific defects in IL-10.

Results. Diseased IFN-γ deficient mice showed a defective IL-10 production in T_{reg} cells, B cells and NK cells, with B cells as the major source of IL-10. Neutralization of IL-10 in WT mice resulted in a chronic immune-inflammatory disorder clinically and hematologically reminiscent of sJIA. In sJIA patients, IL-10 plasma levels were strikingly low as compared to pro-inflammatory mediators. In addition, B cells from sJIA patients showed a decreased IL-10 production, both *ex vivo* and after stimulation.
Conclusion. Cell-specific IL-10 defects in sJIA mice and patients result in an insufficient IL10 production to counterbalance their pro-inflammatory cytokines. IL-10 neutralization in CFA-challenged WT mice converts a transient inflammatory reaction into a chronic disease and represents a model for sJIA in IFN-γ competent mice.

P.C2.07.06
Exploring the role of genetic variants in gene expression in the context of chronic inflammation

S. Koturan[1,2], *S. Menegatti*[1], *E. Latis*[1,2], *N. Rosine*[1,2], *H. Yahia*[1], *C. Miceli-Richard*[1,3,4], *E. Bianchi*[1,3], *L. Rogge*[1,3];
[1]*Institut Pasteur, Paris, France,* [2]*Université Paris Diderot, Ecole Doctorale BioSPC, Paris, France,* [3]*Immunological Research in Spondyloarthritis (IRIS), Unité Mixte de Recherche, Department of Immunology, Institut Pasteur, Paris, France,* [4]*Service de Rhumatologie, Hôpital Cochin, Paris, France.*

Introduction: Genome-wide association studies have provided detailed information about the genetic variants associated with chronic inflammatory diseases. However, for most genetic variants, the mechanism by which they act and the targeted cell populations are unknown. The general goal of this study is to decipher how SNPs associated with chronic inflammatory disease affect pathogenesis. In particular, we will determine which genetic variants affect cell type-specific gene expression using axial spondyloarthritis (SpA) as a model.
Materials and Methods: Whole blood samples from patients were cultured with a microbial stimulus (LPS) or a T-cell agonist (enterotoxin SEB). $CD14^+$ monocytes were isolated using magnetic bead selection from PBMCs followed by LPS stimulation. $CD4^+$ and $CD8^+$ T cell populations were isolated by cell sorting and stimulated with anti-CD3/CD28. We designed a gene expression panel that allows us to measure the expression of 755 genes that are either associated with chronic inflammatory diseases or the regulation of immune responses. Patients were genotyped using the Illumina Infinium® global screening array.
Results: Of the 755 genes analysed, around 600 genes were expressed in both LPS stimulated and SEB stimulated whole blood samples. For monocytes, we detected expression of 250 genes after stimulation. Our eQTL analysis revealed associations that regulate several immune-modulatory pathway-associated genes. The functional relevance of these findings warrants further study.
Conclusions: Our study demonstrates that the majority of genes genetically linked to chronic inflammation are expressed in whole blood and immune cell populations from SpA patients pointing to new insights in pathogenesis of chronic inflammatory diseases.

P.C2.07.07
Comparative analysis between the *in vivo* biodistribution and therapeutic efficacy of adipose-derived mesenchymal stromal cells administered intranodally in experimental colitis

M. Lopez-Santalla[1], *P. Mancheño-Corvo*[2], *A. Escolano*[3], *R. Menta*[2], *O. Delarosa*[2], *J. Abad*[4], *D. Büscher*[5], *J. M. Redondo*[6], *J. A. Bueren*[1], *W. Dalemans*[7], *E. Lombardo*[2], *M. Garin*[1];

INTRODUCTION: Mesenchymal stem cells (MSCs) have immunomodulatory properties allowing their use for treatment of a wide variety of immunological disorders. The mechanisms that are involved in their therapeutic effects have not been fully determined. Immunomodulatory effect of MSCs takes place both by direct cell-to-cell contact and by soluble factors. A small proportion of infused MSCs can traffic to the draining lymph nodes accompanied with an increase of different types of regulatory immune cells. Intranodal injection of cells is being used in the clinic for treatment of cancer and allergy and can be an alternative route for MSC administration.
METHODS: We analyzed the biodistribution and the efficacy of $Luciferase^+$ adipose-derived MSCs (Luci-eASCs), infused through the inguinal LNs (iLNs), in an experimental mouse model of TNBS-induced colitis.
RESULTS: Luci-eASCs were able to modulate the acute inflammatory response induced by the administration of TNBS. The large majority of Luci-eASCs were found in the iLNs and in the adipose tissue surrounding the injection site. Increase bioluminescence signal was found in the intestine of colitic mice compared to healthy controls. Luci-eASC-infused mice were stratified according to their positive response to the Luci-eASC treatment. A higher accumulation of Luci-eASCs was found in popliteal, parathymic, parathyroid and mesenteric LNs in those mice that had a positive response to Luci-eASCs.
CONCLUSIONS: Acute intestinal inflammatory responses can be modulated by intranodal administration of Luci-eASCs. The accumulation of the eASCs at the inflamed intestine might be beneficial to achieve an optimal modulation of inflammation following intranodal administration.

P.C2.07.08
***In vivo* biodistribution of adipose-derived mesenchymal stromal cells administered intraperitoneally in experimental colitis**

M. Lopez-Santalla[1], *P. Mancheño-Corvo*[2], *A. Escolano*[3], *R. Menta*[2], *O. Delarosa*[2], *J. M. Redondo*[4], *J. A. Bueren*[1], *W. Dalemans*[5], *E. Lombardo*[2], *M. Garin*[1];
[1]*CIEMAT/IIS Fundación Jiménez Díaz/CIBERER, Madrid, Spain,* [2]*Tigenix SAU, Madrid, Spain,* [3]*The Rockefeller University, New York City, United States,* [4]*Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain,* [5]*Tigenix NV, Leuven, Belgium.*

INTRODUCTION: The use of mesenchymal stem cells (MSCs) in the clinical field has gathered tremendous momentum over the last decade due to the varying levels of success in treatment of inflammatory and autoimmune diseases thanks to their immunomodulatory properties. The immunomodulatory effect of MSCs takes place both by direct cell-to-cell contact and by soluble factors. Although the biodistribution of MSCs highly depends on the route of administration, similar efficacy has been described regardless the administration route used. Several studies have shown that a small proportion of the infused MSCs can be found at the site of inflammation. At present, it is unknown whether the migration of the MSCs to the inflamed tissues is a prerequisite to achieve their beneficial effect.
METHODS: We analysed the biodistribution of intraperitoneally (IP) administered luciferase-expressing human expanded adipose derived stem cells (Luci-eASCs), in a mouse model of colitis. Stratification of mouse responses to the Luci-eASC treatment allows us to define whether a correlation between the *in vivo* biodistribution of Luci-eASCs and their therapeutic efficacy exists.
RESULTS: IP administered Luci-eASCs were mainly found in the liver, spleen and intestine. In the intestine of colitic mice, a higher accumulation of Luci-eASCs was found, compared to healthy controls. The bioluminescence signal in the intestine tended to increase at the expense of a decrease in the liver in the `responder´ mice.
CONCLUSIONS: These data thus suggest that the accumulation of the eASCs to the inflamed tissues is beneficial in order to achieve modulation of the inflammatory insult.

P.C2.07.09
Peptide-specificity of the CD4 T-cell response to immunogenic therapeutic antibodies in healthy donors and in patients.

S. Meunier, M. de Bourayne, M. Hamze, ***B. Maillere****;*
CEA, Gif sur Yvette, France.

Immunogenicity of therapeutic antibodies remains an important limitation to their clinical use. Infliximab (Ifx), Rituximab (Rtx), Adalimumab (Adm) and Natalizumab (Ntz) are all known to induce neutralizing anti-drug antibodies (ADA) in many patients. Because CD4 T-cells initiate immune responses, we identified the CD4 T-cell epitopes of these antibodies. With the perspective to anticipate immunogenicity of therapeutic antibodies, the T-cell epitope mapping was carried out using cells collected in healthy donors. CD4 T-cells were expanded by several weekly rounds of antigen-specific stimulation and the T-cell specificity was assessed by ELISPOT using overlapping peptides. Nine epitopes were identified in the VL and VH chains of chimeric Rtx and Ifx and overlapped CDR or FR regions. Nine and eleven T-cell epitopes were found in the humanized and human antibodies Ntz and Adm, respectively. Several peptides were common to multiple donors and their location appeared to rely on their affinity for HLA molecules and their content in mutations with respect human germline sequences. T-cell reactivity of the identified peptides was evaluated in patients having developed (ADA+) or not developed ADA (ADA-). Two third of the T-cell epitopes of Rtx and Ifx identified from the healthy donors stimulated PBMCs from ADA+ patients, while T cell reactivity of Adm T-cell epitopes Is higher in ADA+ patients than in ADA-. T-cell epitopes promote the secretion of a diversity of cytokines either favoring or reducing ADA production. Together our data provide new insights on the origin and mechanisms of immunogenicity of therapeutic antibodies.

P.C2.07.10
A CD4 T cell repertoire specific to immunogenic self therapeutic proteins exists in healthy donors before any injection

S. Meunier, A. Azam, M. de Bourayne, ***B. Maillere****;*
CEA, Gif sur Yvette, France.

Many hormones, cytokines and clotting factors are used as therapeutic molecules but many of them produce anti-drug antibodies (ADA), although their peptide sequence is of human origin. To quantify the rare antigen-specific T-cells from healthy donors, who have never been exposed to the antigen, CD4 T-cells were stimulated by weekly rounds of stimulation by antigen-loaded dendritic cells and their specificity was assessed by IFN-γ ELISpot. The number of specific T-cell lines was used to estimate the frequency of circulating T-cells. Both forms of IFN-β induced ADA in multiple sclerosis patients. We identified a CD4 T-cell repertoire specific to IFN-β and demonstrated the T cell epitopes spread all over the IFN-β sequence, two regions being common to multiple donors. H2-relaxin is a hormone with a insulin-like structure and has been found to induce ADA in scleroderma patients.

A very large repertoire of T cells specific for H2-relaxin was found in the healthy donors. We also identified two major T-cell epitopes hosted in the α and β chains and common to multiple donors. The frequency of FVIII-specific CD4 T cells in healthy donors was very high and similar to that of T cells specific for foreign antigens. We also observed that FVIII-specific T cells originated from both the naïve and central memory cells. Altogether our results showed that endogenous expression of IFN-β FVIII and H2-relaxin is not sufficient to prevent an escape of CD4 T cells from negative thymic selection and to abrogate immunogenicity of the recombinant forms.

P.C2.07.11

IgG and IgM play a main role in the development of demyelinating lesions and axonal damage in patients with multiple sclerosis.

Ú. Muñoz[1], C. Sebal[1], E. Escudero[1], M. M. Esiri[2,3], I. Iturrieta[1], C. Sloan[2], A. Jayo[1], M. C. Sádaba[1];
[1]Facultad de Medicina, Instituto de Medicina Molecular Aplicada (INMA), Universidad San Pablo-CEU, CEU Universities., Madrid, Spain, [2]Nuffield Department of Clinical Neuroscience, University of Oxford, Headington, Oxford, United Kingdom, [3]The Oxford University Hospitals NHS Trust. Headley Way, Headington, Oxford, UK., Oxford, United Kingdom.

Introduction. Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system characterized by demyelination and axonal damage. We have described that IgG and IgM co-localized with complement and macrophages on oligodendrocytes and axons. Oxidative stress is also a hallmark of the lesions. Therefore, we aimed to analyze the role of antibodies and oxidative stress in these patients.
Materials and Methods: Brain samples from patients suffering from MS, neurodegenerative diseases (Alzheimer, Parkinson, Frontotemporal Dementia (FTD), amyotrophic lateral sclerosis (ALS)), and control group. Immunohistochemistry and immunofluorescence techniques were used to detect IgG, IgM, oxidative stress (EO6), axonal damage (amyloid precursor protein, APP). TUNEL assay was used to detect cell damage.
Results. EO6, IgG and IgM were not detected in samples from patients with Alzheimer, Parkinson or control group. In samples from MS patients, IgG and IgM were observed on TUNEL positive oligodendrocytes located in normal appearing white matter and IgM, were observed on APP positive axons in demyelinated lesions. EO6 positive axons were observed in samples from FTD and ALS patients. Lipid oxidation colocalized with APP in this individuals.
Conclusions. IgG and IgM play a main role in the development of demyelinated areas and IgM in axonal damage in MS patients. For the first time, oxidative stress were detected in FTD and ALS patients, which is associated with axonal damage. Our work draw attention in the different pathologic mechanism involved in neurodegenerative diseases.

TNF hampers intestinal tissue repair in colitis by restricting IL-22 bioavailability

***J. Ninnemann**[1], C. Winsauer[1], A. Kühl[2], S. Nedospasov[3], A. Kruglov[1];*
[1]Deutsches Rheuma Forschungszentrum, Berlin, Germany, [2]Charite Medical School, Berlin, Germany, [3]M.V. Lomonosov Moscow State University, Moscow, Russian Federation.

Successful treatment of chronic inflammatory diseases integrates both cessation of inflammation and induction of adequate tissue repair processes. One of the examples of such therapy is Tumor Necrosis Factor (TNF) inhibition in IBD patients. However, molecular mechanisms of intestinal repair upon TNF blockade during IBD remain not understood. Here, by the usage of human TNF Knock-in mice (hTNFKI) in a model of adoptive T cell transfer, we revealed that TNF interferes with tissue repair program via induction of soluble natural antagonist of IL-22 (IL-22Ra2; IL-22BP) in the colon and abrogates IL-22, STAT3-mediated mucosal repair during colitis. Pharmacological T-TNF blockade reduced IL-22BP expression in the colon leading to the increased IL-22 levels, colonic epithelial cell proliferation and restoration of colonic epithelium functions. Thus, our data revealed the mechanism of how anti-TNF therapy induces mucosal healing and provides novel potential targets for IBD treatment in humans. Work was supported by SFB633 and NE1466/2-3 grant from DFG (S.N.), and Russian Science Foundation grant #14-50-00060 (S.N.) and # 17-74-20059 (A.K.).

P.C2.07.13

MCC950 attenuates colonic inflammation in spontaneous colitis mice

***A. P. Perera**, R. Eri;*
Shool of Health Sciences, Launceston, Australia.

MCC950 is a potent, highly specific small molecule inhibitor of both canonical and noncanonical activation of NLRP3 inflammasome and has been evaluated in a diverse array of NLRP3 engaged inflammatory diseases. However, the effect of MCC950 on colitis has not yet been reported. In the present study we investigated the effect of MCC950 in a spontaneous chronic colitis mouse model Winnie, which mimics human ulcerative colitis. Oral administration of 40 mg/kg MCC950 for three weeks at chronic stage of colitis significantly ameliorated colitis with improved body weight gain, colon length, ratio of colon weight to body weight, disease activity index and histopathological scores of MCC950 treated Winnie mice were significantly reduced suggesting not only attenuation of ongoing colitis but also delay of disease onset. MCC950 significantly suppressed IL-1β and IL-18 cytokine expression at both mRNA and protein levels in Winnie colons.
Additionally, MCC950 also effectively suppressed the release of proinflammatory cytokines (IL1-α, IL17, TNF-α and IFNγ) and chemokine (MIP1a) in mucosal explants. Moreover, MCC950 treatment resulted in a significant decrease of IL-1β release and activation of caspase-1 in Winnie explants and *in vitro* macrophage cells isolated from Winnie mice. The treatment of 10μM MCC950 in Winnie mucosal explants shows, for the first time, the contribution of anti-inflammatory effects resulting exclusively from inhibition of canonical and non-canonical NLRP3 inflammasome activation in colitis. Taken together, our results illustrate the efficacy of MCC950 in the treatment of murine ulcerative colitis and provides avenue for a novel therapeutic agent for human inflammatory bowel diseases.

P.C2.07.14

Effect of Tripterygium wilfordii polycoride on inflammation and TLR4 signaling pathway in ulcerative colitis rats model

***D. Qin**[1], Y. Zhou[2], Q. Yang[1], C. Zhang[1], S. Zhang[1], Q. Dai[1], X. Yang[1];*
[1]The First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, China, [2]The First Clinical Medical College of Zhejiang Chinese Medical University, Hangzhou, China.

Tripterygium wilfordii polycoride (TWP) is a water-chloroform extract from a kind of Chinese medicine-*Tripterygium wilfordii* Hook. f. It preserves a good immune regulation effect and has been applied to the treatment of some autoimmune diseases. However, no related studies on its role in ulcerative colitis (UC) were reported till now. In this work, we investigated the effect of TWP on UC inflammation and toll-like receptor 4 (TLR4) signaling pathway in TNBS-alcoholic UC rats model. The study found that TWP can significantly improve the symptoms of UC rats model and has a good inhibitory effect on intestinal inflammation. It not only promotes the healing of mucosal defects, but also inhibits the infiltration of inflammatory cells in mucosal lesions to acquire mucosal healing. Whereas, these effects are dose-dependent. On the research of its mechanism of action, we found that TWP exerts anti-inflammatory effects through inhibiting the protein expression of TLR4/MyD88-dependent and non-dependent signaling pathways, thereby inhibiting the release of downstream inflammatory factors.

P.C2.07.15

Clinical study on the effect of tripterygium wilfordii polyglycoside on intestinal inflammation in inflammatory bowel disease

***D. Qin**[1], Y. Wang[1], G. Ni[1], C. Zhang[1], Y. Mao[1], G. Fang[1], L. Xu[1], X. Hu[1], Q. Qiao[1], S. Zhu[1], Q. Yang[2], G. Cen[2];*
[1]The First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou, China, [2]The First Clinical Medical College of Zhejiang Chinese Medical University, Hangzhou, China.

Objective: To observe the effect of TWP on intestinal inflammation in IBD patients. Method: 32 IBD patients, with steroid hormones resistance or dependence or taking other immunosuppressive agents with intolerable side effects, were selected. We give TWP oral treatment (60mg/d) on the basis of the original aminosalicylic acid treatment (4g/d),after treated for 24 months, we make a before and after treatment comparison analysis for patients, including clinical manifestations, endoscopic mucosal lesions, tissue inflammation, blood changes, mucosal healing, immune response and toxic side effects. Result:(1) TWP improve the symptoms of IBD patients significantly ;(2)The scores of endoscopic MES and SES-CD were significantly decreased after TWP treatment;(3)After treatment, the score of mucosal inflammation injury in IBD patients is decreased; (4) The levels of ESR, CRP, PLT,HGB,ALB are improved;(5)25 patients have a complete response to TWP after treatment, partial response are 7 cases;(6) Hormone dependents included in this study is successfully discontinued after taking TWP 12 weeks and have a complete response to TWP treatment;(7) The major toxic side effects include gonadal suppression,mild bone marrow suppression and mild liver damage in the study, but they will turn back to normal after reducing the dosage of TWP.Conclusion: TWP can relieve the clinical manifestation of IBD, inhibit intestinal inflammatory activity and acquire mucosal healing. Meanwhile, TWP can help the steroid hormone dependent patients to reduce the dosage of hormone smoothly until discontinuation, and to get the response and remission to the treatment.

Immunogenicity assessment of three anti-TNFα blockers (Infliximab, Adalimumab and Etanercept) in 42 chronic inflammatory disease affected patients.

S. Salah[1], *I. Mezghiche*[1], *M. Benidir*[1], *M. Djennane*[2], *D. Fodil*[3], *G. Hamadi*[1], *N. Zaabat*[1], *S. Tefiani-Lefkir*[3], *H. Amroun*[4], *N. Attal*[1];
[1]*Pasteur Institute of Algeria, Algiers, Algeria,* [2]*Tizi Ouzou Hospital, Tizi Ouzou, Algeria,* [3]*Beni Messous Hospital, Algiers, Algeria,* [4]*Parnet Hospital, Algiers, Algeria.*

Introduction: Chronic inflammatory diseases therapy has been revolutionized since the introduction of three main anti-TNFα drugs (Infliximab, Adalimumab and Etanercept). However, as most genetically engineered proteins, they are immunogenic, inducing the production of anti-drug antibodies (ADA) that lead to drug failure. The aim of our study is to assess the immunogenicity of these 3 anti-TNFα therapies. **Materials and methods:** Our study involved 42 patients (19 females and 23 males, mean age 38±13 years, disease duration 10±6 years) with established Rheumatoid arthritis, Crohn disease or ankylosing spondylitis. All patients presented primary or secondary therapeutic failure after anti-TNFα use. Both drug and ADA levels were measured in patient's sera using an enzyme-linked immuno sorbent assay (ELISA) [Promonitor®Progenika Biopharma SA, Spain]. **Results:** 29% of patients produced ADAs (IFX 36%, ADL 32% and ETN 0%). The presence of ADAs is associated with low drug levels below therapeutic range (>80%). Females (58%) and older patients (60%) are most likely to produce ADAs. Moreover, ADAs develop after a fewer number of injections in IFX patients vs. ADL and in females vs. males. However, the association of Methotrexate (MTX) to the anti-TNFα decreases significantly its immunogenicity. ADA frequency varies with the underlying disease but no significant influence of a previous biotherapy switch has been demonstrated in our study. **Conclusion:** Drug failure to anti-TNF-α therapies is due to ADAs production. This immunogenicity is influenced by numerous factors that are either, drug related (drug structure, association to an immunosuppressant agent) or patient related (gender, age and the underlying disease).

P.C2.07.17

TARGET CELLS OF VEDOLIZUMAB IN PERIPHERAL BLOOD AND GUT MUCOSA CELLS FROM IBD PATIENTS

W. T. C. Uniken Venema, *M. D. Voskuil, A. Bangma, B. H. Jansen, G. Dijkstra, R. K. Weersma, E. A. Festen;
University Medical Center Groningen, Groningen, Netherlands.*

Introduction: The biological vedolizumab (anti-α4β7) blocks the migration of leukocytes into the gut. Treatment results in remission in ~30% of Crohn's disease (CD) and ulcerative colitis (UC) patients. In UC, remission is reached faster than in CD. Deeper insight into the immunological effects of vedolizumab is necessary to explain differences in effect of vedolizumab therapy between CD and UC. Aims and Methods: The aim of this study is to determine the binding capacity of vedolizumab to both immune cells in blood and to isolated mucosal cells from the inflamed gut mucosa. We collected blood and intestinal biopsies from patients with CD and UC prior to vedolizumab treatment, and blood from healthy controls. We engineered fluorescent-labeled vedolizumab and assessed the percentage and level of vedolizumab-binding to cell-subtypes, using flow-cytometry. Results: Vedolizumab binds to a variety of peripheral blood immune cells (*i.e.* $CD4^+$T-cells, $CD8^+$-T cells, B-cells, eosinophils, NK-cells and monocytes). It nearly covers all gut mucosa directed $CD4^+CD38^+CD62L^{neg}$ T cells (median 82% [IQR 68-91]), with significantly higher level of binding than T-cells and B-cells (P<0.0001), and eosinophils (median 91% [IQR 83-94]). No significant differences were observed between patients with CD, UC, and healthy controls. Within the intestinal mucosa, vedolizumab mostly binds lamina propria cells, and in particular $CD8^+$T-cells from the terminal ileum (median 64% [IQR 28-94]). Conclusion: Differences in percentages and level of vedolizumab-binding to cell-subtypes does not explain differences in effect of vedolizumab therapy between CD and UC. These results provide baseline data for correlating vedolizumab binding capacities to clinical response in IBD patients.

P.C2.07.18

IMPORTANCE OF THE RECOGNITION OF THE DENSE FINE SPECKLED PATTERN AND ANTI-DFS70 SPECIFICITY CONFIRMATION IN THE AUTOIMMUNITY LABORATORIES

R. VALENCIA PEREIRA, *A. MARTINEZ RODRIGUEZ, M. ESPARRAGO RODILLA, B. SACRISTAN ENCISO, S. CARRETERO CRUZ, S. GORDILLO VAZQUEZ, M. VARGAS PEREZ;
SERVICIO EXTREMEÑO DE SALUD, BADAJOZ, Spain.*

Introduction: The nuclear dense fine speckled (DFS, AC-2) pattern is associated with autoantibodies directed to DFS-70 antigen. This pattern is recognized as a dense fine speckled staining in the nucleus with a strong staining of mitotic chromosomes, it can be difficult to differentiate from similar patterns such as nuclear homogeneous (AC-1). Therefore, it is crucial to confirm the DFS70 specificity.
The aim of this study was to evaluate the frequency of DFS pattern in our population, its association with the DFS70 antigen and its clinical significance.
Material and methods: The Antinuclear Antibodies (ANA) test by IIF on Hep-2000 cells (Inmunoconcept) was requested in 15759 serum samples from 01/04/2016 to 30/06/2017. From the total number of samples tested, those compatible with DFS70 pattern were selected for further confirmatory testing for anti-DFS70 antibodies (QUANTA Flash DFS70, BIO-FLASH, Inova Diagnostics).
Results: Of the 3674 ANA-positive samples, 118 (3.2%) displayed a DFS pattern. The confirmatory DFS70 test was positive in 67 (56.8%) of the samples tested.
None of the patients DFS70(+) was diagnosed with systemic autoimmune rheumatic disease (SARD), except one patient who was diagnosed with lupus nephropathy, without other positive ANA specificities.
Conclusions: Mono-specific anti-DFS70 antibodies are not associated with SARD.
As the recognition of DFS pattern (AC-2) by IIF is not easy, it is important to confirm the DFS70 specificity with other solid phase immunoassay methods.
Testing for anti-DFS70 antibodies can eliminate unnecessary follow-up testing, being more cost-effective and improving the efficiency of diagnosing SARD.

P.C2.07.19

Blood $CD56^{bright}$ $CD16^+$ NK cells predict calprotectin response to anti-TNFα co-medication with azathioprine in pediatric inflammatory bowel disease

M. Wahlbuhl, *F. Knieling, T. Rechenauer, G. Siebenlist, S. Kaspar, C. Ehrsam, A. Rückelt, W. Rascher, A. Hoerning;
Pediatric Gastroenterology and Hepatology, Erlangen, Germany.*

Introduction: Natural killer (NK) cell subsets have recently been found to play an important role in inflammatory bowel diseases (IBD). We studied NK cell subsets before and after initiation of anti-TNFα therapy and co-medication with azathioprine (AZA) in pediatric IBD.
Materials and Methods: The study was approved by the local ethic committee (ethics protocol #347_15B) and written content was obtained from all guardians. A total of n=21 pediatric IBD patients (Crohn's disease, CD/ulcerative colitis, UC) and n=9 healthy controls (HC) were recruited. Blood samples and intestinal biopsies were collected before initiation of the anti-TNFα therapy and during therapy rather at disease exacerbation. Flow Cytometry (CD3, CD8, CD16, CD56, CD62L, CCR9, b7 integrin), immunofluorescence staining (CD16, CD56), and NanoString (NanoString Technologies, Seattle, WA, USA) technique was performed. The data were compared to the clinical data derived from the medical files.
Results: Before initiation of anti-TNFα therapy in patients already receiving AZA, flow cytometry showed low numbers of peripheral $CD56^{bright}CD16^+$ (CD, p=0.002/UC, p<0.0001), $CD56^{dim}CD16^+$ (CD, p=0.049/UC, p=0.027) and γδT-cells (CD, p=0.42/UC=0.024) in patients with IBD compared to HC. CD-patients reaching a calprotectin <50mg/kg after initiation of anti-TNFα/AZA therapy had a significant higher relative increase of peripheral $CD56^{bright}CD16^+$ cells beginning at 6 (1.42±0.67 vs 0.80±0.39, p=0.0478) and 12 months (1.88±0.81 vs 0.73±0.18, p=0.0005). Double positive $CD56^+CD16^+$ cells were reduced in pediatric IBD intestinal biopsies treated with AZA (CD, p=0.0152/UC, p<0.0001).
Conclusions: Peripheral $CD56^{bright}CD16^+$ NK cell subsets predict calprotectin response in pediatric IBD following anti-TNFα/azathioprine therapy.

P.C2.08.01

Pharmacological activation of pyruvate kinase M 2 inhibits T cell activation and suppresses autoimmunity

S. Angiari, *E. M. Palsson-McDermott, M. C. Runtsch, H. Kane, C. E. Sutton, K. H. Mills, L. A. O'Neill;
Trinity College Dublin, Dublin, Ireland.*

BACKGROUND. Pyruvate kinase (PKM) catalyses the conversion of phosphoenolpyruvate to pyruvate during glycolysis, and previous studies suggested that the PKM isoform PKM2 also has moonlighting activities different from its canonical one. However, its role in $CD4^+$ T cell biology has never been investigated so far. The aim of this study was to study the involvement of PKM2 in T cell activation, effector functions and pathogenic activity. RESULTS. We found that PKM2 is strongly up-regulated in $CD4^+$ T cells following CD3/CD28 activation, can be detected in both the cytoplasm and the nucleus of resting and activated T cells, and is present in equilibrium between a monomeric (inactive) and a tetrameric (active) form. Surprisingly, pharmacological activation of PKM2 with TEPP-46, a small molecule that stabilises the tetrameric form, severely impacted T cell functions, reducing activation, proliferation and cytokine production by activating T cells. This effect was due to inhibition of hypoxia-induced factor-1 α (HIF-1α) and alteration of intracellular metabolism. TEPP-46 also induced the expression of forkhead box p3 (Foxp3) and the generation of regulatory T cells (Tregs) during T cell activation *in vitro*. Importantly, treatment with TEPP-46 blocked the development of experimental autoimmune encephalomyelitis (EAE), a mouse model of multiple sclerosis, by reducing T cell activation and inducing Treg cells *in vivo*. CONCLUSIONS. Our results suggest that pharmacological activation of the glycolytic enzyme PKM2 may represent a novel valuable toll for the treatment of inflammatory pathologies, and confirm that modulation of immune cell metabolic profile may have therapeutic utility in inflammation.

P.C2.08.02

Regulatory T cells have a distinct migratory phenotype in relapsing-remitting multiple sclerosis patients

***P. Baeten**, N. Hellings, B. Broux;*
Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium.

Multiple sclerosis (MS) is an autoimmune disorder of the central nervous system (CNS). In healthy donors (HD), autoreactive T cells are suppressed by regulatory T cells (Tregs). In relapsing-remitting (RR)MS patients, blood-circulating Tregs are defective. Little is known about their presence in and migration to the CNS. Here, the migratory phenotype and capacity of Tregs are investigated. Using an *in vitro* model of the human blood brain barrier (BBB), we found that Tregs have a migration frequency of 8% across an inflamed BBB. Analysis of paired blood and cerebrospinal fluid (CSF) samples of untreated RRMS patients shows comparable percentages of Tregs (CSF: 6.8%; blood: 8.4%), indicating their capability of migrating to the CNS. To understand the mechanism of migration, Tregs and BBB endothelial cells (EC) were phenotyped. The percentage of $CD11a^+$ Tregs is significantly decreased in blood of untreated RRMS patients (43.3%) compared to HD (51.2%, p=0.0197). In contrast, the CD11a ligand, ICAM-1, is significantly increased on inflamed BBB-EC. With regard to chemokine receptors, we found that the percentage of $CCR5^+$ Tregs is significantly increased in blood of RRMS patients (39.6%) compared to HD (23.7%, p=0.0075). Interestingly, $CCR5^+$, $CXCR3^+$ and $CCR6^+$ Tregs are enriched in the CSF of untreated RRMS patients. The CXCR3 ligand, CXCL10, is significantly upregulated in inflamed EC. These results suggest that Tregs use a specific set of adhesion molecules and chemokine receptors to migrate to the CNS of MS patients. Further results of ongoing analyses will be presented at the meeting.

P.C2.08.03

Infection risk assessment during immunosuppressant treatment using computer simulations

***K. Beuke**, M. Rehberg, A. Dietrich, T. Klabunde, Ö. Sercan Alp, N. Biesemann, C. Asbrand;*
Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany.

Standard of care biologics for inflammatory diseases, such as rheumatoid arthritis, target cytokines and cell activation / development to break the cycle of chronic inflammation and to interfere with disease progression. However, the relief of pain and other symptoms may come at the cost of an increased infection risk. To better understand the increase in infection risk, we developed a model-platform that describes the innate and adaptive immune response to bacterial and viral infections.
On the cellular level, the platform describes activation of macrophages, development of antigen-presenting cells, induction of the cellular and humoral response in draining lymph nodes of the infected tissue, and recruitment of different T cells and B cells to the site of infection, which was calibrated using tissue cell counts. On the molecular level we used a broad range of in vivo and in vitro data for model calibration to capture secretion of key inflammatory cytokines involved in cell activation, differentiation, maturation and recruitment, as well as antibody production.
This ODE-based dynamic immunology platform allows for exploration of treatment regimens and mode of action of standard immunosuppressants, such as TNF-inhibitors (Adalimumab, Etanercept, Infliximab), IL-6-inhibitors (Sirukumab), IL-6R inhibitors (Sarilumab), and B cell depletors (Rituximab), in their role of reducing the immune systems effectiveness in fighting infections such as dormant tuberculosis.
For Sanofi, the platform is an holistic approach to infer mechanistic understanding from sparse data with a certain predictive power for drug development with orthogonality to current animal models.

[1]The Campbell Family Institute for Breast Cancer Research, Toronto, Canada, [2]LIH, Esch-sur-Alzette, Luxembourg, [3]Tokyo Medical and Dental University, Tokyo, Japan, [4]University of Braunschweig, Braunschweig, Germany, [5]University of Luxembourg, Esch-sur-Alzette, Luxembourg, [6]Australian National University, Canberra, Australia, [7]Yale School of Public Health, New Haven, United States, [8]University of Marburg, Marburg, Germany, [9]Odense University Hospital, Odense, Denmark, [10]University of Düsseldorf, Düsseldorf, Germany, [11]Harvard Medical School, Boston, United States.

Activated T cells produce reactive oxygen species (ROS), which trigger the antioxidative glutathione (GSH) response necessary to buffer rising ROS and prevent cellular damage. We report that GSH is essential for T cell effector functions through its regulation of metabolic activity. Conditional gene targeting of the catalytic subunit of glutamate cysteine ligase (Gclc) blocked GSH production specifically in murine T cells. Gclc-deficient T cells initially underwent normal activation but could not meet their increased energy and biosynthetic requirements. GSH deficiency compromised the activation of mammalian target of rapamycin-1 (mTOR) and expression of NFAT and Myc transcription factors, abrogating the energy utilization and Myc-dependent metabolic reprogramming that allows activated T cells to switch to glycolysis and glutaminolysis. In vivo, T-cell-specific ablation of murine Gclc prevented autoimmune disease but blocked antiviral defense. The antioxidative GSH pathway thus plays an unexpected role in metabolic integration and reprogramming during inflammatory T cell responses.

P.C2.08.05

The diagnostic value of the antiaging protein, Klotho in early and late stages of multiple sclerosis

***M. Emami Aleagha**[1], A. Allameh[1], M. Harirchian[2], S. Rostami[1], S. Lavasani[3], M. Javan[4], M. Pahlevan Kakhki[5];*
[1]Department of Clinical Biochemistry, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, Islamic Republic of, [2]Iranian Center of Neurological Research, Neuroscience Institute, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [3]Department of Biology, Sölvegatan 35, Building C, SE-223 62, Lund, Sweden, [4]Department of Physiology, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, Islamic Republic of, [5]Department of Clinical Neuroscience, Center for Molecular Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Introduction: Expression of an anti-aging protein, i.e Klotho in the CNS, is influenced by inflammatory cytokines such as TNF-α and IFN-γ. On the other hand, in inflammatory diseases Klotho exerts its immunomodulatory effects such as the suppression of TNF-α-induced expression of adhesion molecules and NF-κB activation. The aim of the present study was to investigate the relationship of Klotho expression at protein and mRNA levels with the pathogenesis of MS with emphasize on its diagnostic value.
Methods: Klotho protein level was estimated in cerebrospinal fluid (CSF) from patients with relapsing-remitting MS (RRMS). Changes in klotho was also verified in the brain and spinal cord during distinct stages of experimental autoimuune encephalomyelitis (EAE) development in mice.
Results: The results of the clinical study showed that CSF level of klotho is inversely related to the MS severity in RRMS patients. Accordingly, *Klotho* gene expression in peripheral blood mononuclear cells (PBMCs) was significantly lower in RRMS patients as compared to healthy individuals. The data from EAE mice revealed that *Klotho* gene expression in the brain was dramatically decreased, while there was a significant increase in the expression of *Klotho* gene in spinal cord tissue.
Conclusion: Perhaps, the brain and spinal cord in case of EAE mice exhibited different sensitivities to inflammatory cytokines such as, IFN-γ and IL-17. Hence, it seems that Klotho responds differently to the inflammatory pathways during the MS and EAE pathogenesis. These results may suggest that the Klotho is a potent candidate for diagnosis, monitoring and also treatment of MS.

P.C2.08.06

IMMUNOMODULATORY PROPERTIES OF STROMAL MESENCHYMAL STEM CELLS DERIVED FROM HUMAN AND MURINE FALLOPIAN TUBE IN EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS (EAE)

***C. L. Freitas**[1], C. M. Polonio[1], W. N. Brandão[1], N. G. Zanluqui[1], L. G. Oliveira[1], C. Czeresnia[2], L. P. Evangelista[2], S. Halpern[2], M. G. Nisenbaum[2], M. Maluf[3], P. Perin[3], J. S. Peron[1];*
[1]Institute of Biomedical Sciense, São Paulo, Brazil, [2]Célula Mater, São Paulo, Brazil, [3]Clínica Especializada em Reprodução Humana – CEERH, São Paulo, Brazil.

INTRODUCTION: Multiple sclerosis (MS) is a neurodegenerative autoimmune disease that leads to demyelination of neuronal axons. Fallopian tubes are a source of mesenchymal stromal cells in humans (htMSCs) and mice (meMSCs), wich are undifferentiated multipotent cells that play an important role in autoimmune diseases due its immunomodulatory properties. Since the management of symptoms remains unclear, we propose to evaluate the immunomodulatory effect of htMSCs and meMSCs using the murine model of MS, the Experimental Autoimmune Encephalomyelitis (EAE). **METHODS**: C57BL/6 mice were immunized with MOG_{35-33} and treated or not with htMSCs and meMSCs. At different post-immunization times mice were euthanized, CNS-infiltrating cells were analysed by flow citometry; spinal cords were analyzed by PCR and histology. **RESULTS**: Our data show a significant reduction in EAE scores of htMSC/meMSC treated mice, demonstrating its modulatory effect *in vivo*. We observed fewer infiltrating cells in the CNS in the htMSC/meMSC-treated mice, correlated with reduced number of macrophages, Th1 and Th17 cells. This group also presented less activated microglia with lower levels of MHC II and CD80 expression. The spinal cords showed reduced expression of Ifng and Il17 genes, less infiltrating cells and demyelination compared to control group. Furthermore, analysis *in vitro* showed that the meMSC are able to decrease of proinflammatory cytokines production by $TCD4^+$ cells. **CONCLUSION:** Altogether, our data shows that htMSCs treatment is able reduce neuroinflammation in EAE model. The modulatory effect of *htMSC* and meMSC cells are promising and can lead to a future strategy of treatment of autoimmunity or neurodegenerative diseases.

P.C2.08.07

Combinatorial associative study of IL10, IL18 and TNF-α gene polymorphisms in relapsing-remitting multiple sclerosis

B. Grigorov[1], *A. Trenova*[2], *L. Miteva*[1], *S. Stanilova*[1];
[1]*Medical Faculty, Trakia University, Stara Zagora, Bulgaria,* [2]*Faculty of Medicine, Medical University, Plovdiv, Bulgaria.*

Introduction: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system leading to neurological dysfunctions. The aim of the present study was to investigate the association between the promoter polymorphisms in IL10 (rs1800896), IL18 (rs1946518), TNF-α (rs1800629) and genetic predisposition to relapsing-remitting multiple sclerosis (RRMS) in Bulgarian patients.
Materials and Methods: Our case-control study includes 159 RRMS patients with DMT therapy (114 women and 45 men, 40.08±8.48 years) and 125 women and 44 men (39.27±9.85 years) age-sex-matched healthy volunteers. All included subjects were genotyped by ARMS-PCR and RFLP-PCR methods.
Results: Our results revealed no significant differences of studied polymorphisms between cases and controls: IL10 (χ^2=0.493; p=0.782); IL18 (χ^2 =4.073; p=0.130) and TNF-α (χ^2= 3.153; p=0.207). However, we must note that homozygous for variant allele-A in IL18 polymorphism was not detected in the patient's group in contrast to control. Also, for rs1800629 in TNF-α, it was calculated OR=1,505 for the heterozygous genotype. When we combined both IL10 and IL18 polymorphisms, we detected the lower frequency of AG+GG/CC genotypes compared to the wild genotypes AA/CC (OR=0.481, 95% CI=0.199÷1.157, p=0.073). In the same line were the results when was added the wild genotype of TNF-α polymorphism (GG) to the combination of IL18 and IL10 polymorphisms (GG/AA/CC vs GG/AG+GG/CC, OR=0.446, 95% CI=0.165÷1.189, p=0.073).
Conclusion: Our present results indicate that the carrying of variant allele-G in IL10 (AG+GG genotypes) in combination whit both wild genotypes of IL18, and of TNF-a polymorphisms, might influence the risk of RRMS susceptibility in Bulgarian patients.

Association study of HLA class I antigens with central nervous system inflammatory diseases

S. Mejdoub[1], *A. Charfi*[2], *A. Kamoun*[2], *N. Mahfoudh*[2], *S. Feki*[1], *M. Dammak*[3], ***H. Hachicha***[1], *L. Maalej*[2], *I. Kamoun*[2], *F. Hakim*[2], *L. Gaddour*[2], *B. Mallek*[2], *C. Mhiri*[3], *H. Masmoudi*[1], *H. Makni*[2];
[1]*Immunology Laboratory, Habib Bourguiba Hospital, Sfax, Tunisia,* [2]*Histocompatibility Laboratory, Hedi Chaker Hospital, Sfax, Tunisia,* [3]*Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia.*

Central nervous system (CNS) inflammatory diseases include multiple sclerosis (MS) but also neurological manifestations of systemic diseases such as Behçet disease. As the association of HLA-B51 antigen with Behçet disease is well established, our aim was to evaluate the frequency of this antigen in patients with CNS inflammatory disease suspicion. Patients followed in neurology department for CNS inflammatory disease suspicion (June 2014-May 2016) for whom HLA class I typing was performed (microlymphocytotoxicity complement dependent technique) were included. Our control population included 123 unrelated healthy subjects. Statistics were studied according to Microsoft Excel.
Forty patients (17 men and 23 women) were included. The established diagnosis was MS in 27 cases, clinically isolated syndromes (CIS) in 8 cases, Behçet disease in 2 cases and CNS vascular disease in 3 cases. Among these patients, 10 (7 MS and 3 CIS) expressed HLA-B51 antigen (25% VS 9,76% in controls, *p*=0,01; OR=3,08). Comparing MS patients with controls, HLA-A10 antigen was significantly associated with the disease (25,93% VS 9,76%, *p*=0,04; OR=3,24). All patients expressing HLA-A10 antigen belonged to MS group.
Our study, despite concerning a small number, showed an association of HLA-B51 antigen with CNS inflammatory diseases particularly MS. This can probably be explained by linkage disequilibrium between this antigen and HLA-DR15, reported as a susceptibility marker for MS. Association of HLA-A10 with this disease suggests probably the involvement of another susceptibility region telomeric to HLA-B locus. A bigger patients population size is required to confirm our preliminary results.

P.C2.08.09

Regulatory T cell-driven suppression of experimental autoimmune encephalomyelitis during pregnancy

N. Heckmann[1], *J. B. Engler*[1], *C. Ramien*[1], *S. M. Gold*[1,2], *M. A. Friese*[1];
[1]*Institut für Neuroimmunologie und Multiple Sklerose, Zentrum für Molekulare Neurobiologie Hamburg, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany,* [2]*Charité Universitätsmedizin, Berlin, Germany.*

Pregnancy reduces disease activity of several inflammatory autoimmune diseases including multiple sclerosis (MS), where the relapse rate is reduced by approx. 80% in the third trimester. This protection is mimicked in experimental autoimmune encephalomyelitis (EAE), the animal model of MS. Regulatory T cells (Treg) play a pivotal role in controlling both feto-reactive T cells during pregnancy and auto-reactive T cells in autoimmune diseases, however, it remains unknown how Treg exert their increased suppressive capacity during pregnancy. We have recently reported that Treg increase during pregnancy and that the protective effect on EAE is dependent on regulation via the glucocorticoid receptor in T cells. In the present study, we surveyed energy metabolism, phenotype and T cell receptor (TCR) repertoire of Treg during pregnancy to determine the relative contributions of these factors to pregnancy-induced Treg activity and protection from autoimmunity. We detected no changes in energy metabolism in Treg during pregnancy in mice. Next, we probed the TCR repertoire of Treg and Tcon at different pregnancy stages and under EAE conditions and are currently monitoring the relative distribution of suppressive clones. To understand Treg suppressive capacity and differentiation changes during pregnancy, we extensively phenotyped and functionally analysed Treg from pregnant and non-pregnant EAE mice. Together, our findings give a comprehensive understanding of the pregnancy-induced changes in Treg and how these changes contribute to an amelioration of EAE disease activity.
This work is funded by the DFG KFO 296.

P.C2.08.10

Multiple Sclerosis associated cytotoxic CD4$^+$T cells escape regulatory T cell mediated suppression

C. Hoeks*, M. Vanheusden, L. Peeters, P. Stinissen, B. Broux, N. Hellings;*
Hasselt University, Biomedical Research Institute and Transnationale Universiteit Limburg, Diepenbeek, Belgium.

A terminally differentiated subset of CD4$^+$ T lymphocytes, characterized by loss of the costimulatory molecule CD28 and gain of cytotoxic activity, arises during aging and chronic inflammation. An age-inappropriate expansion of these cells has been found in autoimmune diseases like multiple sclerosis (MS). Our group has recently published that CD4$^+$ cytotoxic T lymphocytes (CTL) contribute to the pathology of MS. We showed that expansion of CD4+ CTL exacerbates experimental autoimmune encephalomyelitis. In addition, we found that presence of peripheral CD4+ CTL is directly linked to MS disease severity and that this holds value as a novel prognostic marker in MS. However, the mechanism behind these findings remains unclear. Here we show that CD4$^+$CD28^{null} T cells are phenotypically distinct from CD4$^+$CD28$^+$T cells, and that CD4$^+$CD28^{null} T cells evade Treg-mediated suppression *in vitro.* CD4$^+$CD28^{null} T cells display enhanced levels of pro-inflammatory molecules such as granzyme B, IFN-gamma, IL-1beta, IL-6, IL-22, and GM-CSF, but decreased levels of IL-10R and GITR. Tregs upregulate IL-10, granzyme B, CTLA-4, and IFN-gamma when exposed to the secretome of CD4$^+$CD28^{null} T cells. An *in vitro* co-culture system has been optimized to further analyze how CD4$^+$CD28^{null} T cells affect Tregs and vice versa. Our results suggest that CD4$^+$CD28^{null} T cells can evade Treg suppression through two distinct mechanisms: 1) by becoming less susceptible to Treg activity and 2) by directly altering the functionality of Tregs. Elucidating these pathways may contribute to the development of novel therapeutic interventions specifically targeting age-inappropriate expansion of CD4$^+$ CTL in autoimmune diseases like MS.

P.C2.08.11

B cell subpopulations in the pathogenesis of multiple sclerosis

R. Holm Hansen*, O. Mcwilliam, H. Højsgaard Chow, F. Sellebjerg, M. R. von Essen;*
Danish Multiple Sclerosis Center, Copenhagen Ø, Denmark.

B cells are important contributors to the pathogenesis of multiple sclerosis (MS), where they regulate the inflammatory immune response and participate in development of lesions in the CNS. Dimethyl fumarate (DMF) is used to treat patients with relapsing-remitting MS (RRMS); however, its impact on B cell subpopulations remains uncertain. In this study we therefore investigated the phenotype of B cell subpopulations in 18 untreated patients with RRMS, 17 healthy controls (HC) and 21 patients treated with DMF for more than 12 months. Using flow cytometry, B cell subpopulations were defined according to their expression of CD27 and CD38. This showed that CD27-CD38- B cells were increased in the blood of untreated patients compared to HC. We also found that CD27-CD38- B cells migrated to the CSF of untreated patients; proposing an association with MS pathogenesis. When patients were treated with DMF we found a treatment-induced reduction in the frequency of CD27-CD38- B cells and CD27+ memory B cells. We also found that the observed reduction in antigen-experienced B cells in DMF-treated patients likely was due to a reduced frequency of follicular helper T (T_{FH}) cells and an increased frequency of follicular regulatory T cells, whose function is to restrain the activity of T_{FH} cells. Studying the impact of fumarate on B cell cytokine production showed that it decreased the frequency of LTα, TNFα, IL-6 and IL-10 producing B cells and increased the frequency of TGF-β producing cells. These data demonstrate an anti-inflammatory role of DMF on the B cell compartment.

Targeting Plasma Cells with Proteasome Inhibitors for Treatment of Myasthenia Gravis

*M. Mané Damas, **M. Losen**, M. Pilar;*
Maastricht University, Maastricht, Netherlands.

Autoantibodies against the muscle AChR are mainly produced by both short- and long-lived plasma cells, which are resistant to standard immunosuppressive drugs (*e.g.* glucocorticoids). A novel therapy to eliminate plasma cells is the proteasome inhibitor bortezomib, which is used to treat patients with multiple myeloma (MM, a plasma cell malignancy). Previously, we demonstrated that bortezomib also reduced autoantibody titers in an animal model of MG (Gomez, A. M. *J. Immunol*. 2011). The thymus of MG patients is frequently enriched in germinal centers and contains plasma cells that produce autoantibodies *in vitro*, even after irradiation (which depletes B and T lymphocytes). We studied the *in vitro* effects of bortezomib in cultured thymus cells from MG patients undergoing therapeutic thymectomy. Treatment with a single dose of bortezomib eliminated plasma cells and thereby blocked the production of IgG, including pathogenic autoantibodies. Ultrastructural signs of apoptosis were detected in plasma cells as early as 8 h after addition of bortezomib; at 24 h, no plasma cells could be detected (Gomez, A. M. *J.Immunol*. 2014). Finally, we are currently testing in vitro and in vivo second-generation proteasome inhibitors efficient in eliminating autoreactive plasma cells with special focus in investigating their side effects such as peripheral neuropathy.

Anti-NF155 chronic inflammatory demyelinating polyradiculoneuropathy strongly associates to HLA-DRB15

***L. Martinez-Martinez**[1], M. Lleixà[2], G. Boera-Carnicero[1], A. Cortese[3], J. Devaux[4], A. Siles[5], Y. Rajabally[6], A. Martinez-Piñeiro[7], A. Carvajal[8], J. Pardo[9], J. Diaz-Manera[5], I. Callegari[3], E. Marchioni[3], D. Franciotta[3], L. Benedetti[10], G. Lauria[11], C. Juárez[1], I. Illa[5], L. Querol[5], Ó. de la Calle-Martin[1];*
[1]Immunology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Neuromuscular Diseases Unit, Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]IRCSS Foundation C. Mondino National Neurological Institute, Pavia, Italy, [4]Centre de Recherche en Neurobiologie et Neurophysiologie, Marseille, France, [5]Neuromuscular Diseases Unit , Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [6]Regional Neuromuscular Clinic, Queen Elizabeth Hospital, Birmingham, United Kingdom, [7]Neurology, Hospital Germans Trias i Pujol, Badalona, Spain, [8]Neurology, Hospital Virgen de las Nieves, Granada, Spain, [9]Neurology, Hospital Clínico de Santiago, Santiago de Compostela, Spain, [10]Neuroscience, University of Genova and IRCCS AOU San Martino-IST, Genova, Italy, [11]Neuroalgology Unit, IRCCS Foundation Carlo Besta Neurological Institute, Milan, Italy.

OBJECTIVE: To study the human leukocyte antigen (HLA) class II allele frequencies in chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) associated with anti-neurofascin 155 (NF155) antibodies. METHODS: Thirteen anti-NF155+ and 35 seronegative CIDP patients were included in a case-control study. The frequencies of the DRB1 HLA allele were analyzed in all patients while DQ frequencies were only studied in patients sharing the DRB1*15 allele. In silico HLA-peptide binding and NF155 antigenicity predictions were performed to analyze overlap between presented peptides and antigenic regions. RESULTS: DRB1*15 alleles (DRB1*15:01 and DRB1*15:02) were present in 10 (out of 13) anti-NF155+CIDP patients and in only 5 (out of 35) seronegative CIDP patients (76.9% vs 14.2%; OR=20, CI=4.035 to 99.13). DRB1*15 alleles appeared also in significantly higher proportions in anti-NF155+CIDP than in normal population (76.9% vs 16.5%; OR=16.9, CI= 4.434 to 57.30). Seven anti-NF155+ CIDP patients (53%) and 5 seronegative CIDP patients had the DRB1*15:01 allele (OR=7, p=0.009), while 3 anti-NF155+ CIDP patients and none of the seronegative CIDP patients had the DRB1*15:02 allele (OR=23.6, p=0.016). In silico analysis of the NF155 peptides binding to DRB1*15 alleles showed significant overlap in the peptides presented by the 15:01 and 15:02 alleles, suggesting functional homology. CONCLUSION: DRB1*15 alleles associate strongly to anti-NF155 antibodies in CIDP and provide additional evidence to support that these patients constitute a differentiated CIDP subset.

P.C2.08.14

Teriflunomide induces in multiple sclerosis a tolerogenic phenotype in innate immune cells resulting in a reduction in terminally differentiated effector lymphocytes.

***S. Medina**[1], N. Villarrubia[1], S. Sainz de la Maza[1], R. Alvarez-Lafuente[2], A. Tejeda-Velarde[1], L. Costa-Frossard[1], E. Rodriguez-Martin[1], R. Arroyo[3], J. C. Álvarez-Cermeño[1], E. Roldán[1], L. Villar[1];*
[1]Ramón y Cajal Hospital, Madrid, Spain, [2]Clínico San Carlos Hospital, Madrid, Spain, [3]Quirónsalud Madrid Hospital, Madrid, Spain.

Introduction: Teriflunomide is a disease modifying treatment approved for multiple sclerosis (MS). This molecule inhibits reversibly dihydro-orotate dehydrogenase, a mitochondrial enzyme involved in de-novo pyrimidine biosynthesis, and down-regulates proliferation of activated lymphocytes. However, there are few data on the impact of this drug on the lymphocyte profiles of MS patients. We further studied this in a cohort of MS patients treated with teriflunomide.
Methods: 55 patients with relapsing-remitting MS who initiated teriflunomide treatment were included in the study. We studied peripheral blood mononuclear cells obtained before and six months after treatment initiation and explored effector, memory and regulatory cells by flow cytometry.
Results: When explored T and B cell subsets, we observed a decrease in the percentages of terminally differentiated CD4+ T cells (p=0.001) and plasmablasts (p<0.0001) after 6 months of treatment. These results were confirmed with the total cell number. When studied regulatory cells, we observed a clear increase of monocytes expressing programmed death-ligand 1 (PDL-1) (p=0.005), which correlated negatively with all effector CD8+ T cell subsets. We also observed an increase in the percentage of CD8+ T cells (p=0.028) and monocytes (p=0.04) producing IL-10.
Conclusions: Teriflunomide induces a specific reduction in effector T and B cells that have shown to play a role in MS course and an increase in regulatory cells. This drug induces the expression of PD-L1, a molecule involved in tolerance to autoantigens, which can contribute to inhibit the abnormal immune response taking place in MS.

P.C2.08.15

Biomarkers for early prediction of dimethyl fumarate associated lymphopenia in multiple sclerosis

***S. Medina**, S. Sainz de la Maza, N. Villarrubia, E. Rodríguez- Martín, L. Costa-Frossard, A. Tejeda Velarde, E. Monreal, J. C. Álvarez-Cermeño, E. Roldán, L. Villar;*
Ramón y Cajal Hospital, Madrid, Spain.

Introduction: Dimethyl fumarate (DMF) is a first line treatment for relapsing remitting multiple sclerosis (MS). Lymphopenia is a major concern in MS patients treated with DMF as increases the risk of serious infectious side effects. Predicting which patients have an increased risk of developing lymphopenia could have important implications for personalized therapy in these patients. The main goal was to identify factors predicting lymphopenia in DMF-treated patients.
Methods: Prospective longitudinal study including 106 patients initiating DMF treatment. They were followed for a mean time of 23.58 months, and monitored every three months. Blood lymphocyte subsets were studied in a representative group of 64 patients by flow cytometry at baseline and 6 months after.
Results: Mean absolute lymphocyte counts (ALCs) decreased by 29% during the first year of DMF-treatment. Patients developing lymphopenia showed a faster decline within the three first months. A reduction of ALCs higher than 36% at this time, accurately predicted subsequent lymphopenia (OR=7.35, 95% CI: 3.0-17.9, p<0.0001).
We classified patients in two groups according to the appearance of lymphopenia. Both showed a significant decrease in effector memory T cells, total and terminally differentiated CD8+ T cells and memory B cells upon DMF therapy. In addition, non-lymphopenic patients experienced a selective increase in naïve CD4+ T cells, not experienced by those developing lymphopenia.
Conclusions: A decline in ALCs below 36% after 3 months of DMF-treatment identifies patients with low probability of developing lymphopenia. This decrease may be associated with retardation in the production of naïve CD4+ T cells.

P.C2.08.16

The inhibition of dopamine receptor D3 signalling in CD4$^+$ T-cells exerts a therapeutic effect attenuating Parkinson's disease development in a mouse model

***R. Pacheco**[1,2], D. Elgueta[1,2], F. Contreras[1], C. Prado[1], A. Montoya[1], M. A. Abellanas[3], M. S. Aymerich[3], R. Franco[4];*
[1]Fundación Ciencia & Vida, Santiago, Chile, [2]Departamento de Ciencias Biológicas, Facultad de Ciencias Biológicas, Universidad Andres Bello, Santiago, Chile, [3]Division of Neurosciences, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona, Spain, [4]Department of Biochemistry and Molecular Biomedicine, University of Barcelona, Barcelona, Spain.

Neuroinflammation constitutes a fundamental process involved in Parkinson's disease (PD). Microglial cells play a central role in the outcome of neuroinflammation and consequent neurodegeneration of dopaminergic neurons in the substantia nigra. Current evidence indicates that CD4$^+$ T-cells infiltrate the brain in PD, where they play a critical role determining the functional phenotype of microglia, thus regulating the progression of the disease. Recently, we demonstrated that mice bearing dopamine receptor D3 (DRD3)-deficient CD4$^+$ T-cells are completely refractory to neuroinflammation and consequent neurodegeneration associated to the intoxication with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). In this study we evaluated the therapeutic potential of targeting DRD3 in CD4$^+$ T-cells by inducing the pharmacologic or the transcriptional inhibition of DRD3-signalling in a mouse model of PD induced by the chronic administration of MPTP and probenecid (MPTPp). We also analysed whether DRD3-signalling was altered in the immune cells of PD patients. The results show that the transference of CD4$^+$ T-cells transduced *ex vivo* with retroviral particles codifying for an shRNA for DRD3 or treated *ex vivo* with the DRD3-selective antagonist PG01037 into MPTPp-mice resulted in a significant reduction of motor impairment and neuroinflammation. *In vitro* analyses showed that the frequency of peripheral blood Th1 cells, a phenotype that is promoted by DRD3-signalling, was significantly increased in PD patients. Nevertheless, DRD3 expression was selectively reduced in CD4$^+$ T-cells obtained from PD patients. Our findings indicate that attenuating DRD3-signalling in CD4$^+$ T-cells exerts a therapeutic effect in parkinsonian animals dampening motor impairments and modifying the pro-inflammatory phenotype of glial cells.

P.C2.08.17

A fusion protein of IL4 and IL10 to resolve inflammatory pain

J. Prado[1], *R. H. Westerink*[2], *J. Popov-Celeketic*[1], *C. Steen-Louws*[1], *A. Pandit*[1], *W. Worp van de*[1], *K. A. Reedquist*[1], *L. Koenderman*[1], *C. E. Hack*[1], *N. Eijkelkamp*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Institute for Risk Assessment Sciences, Utrecht, Netherlands.*

Chronic pain is difficult to treat and new therapeutic approaches to treat it are highly needed. Anti-inflammatory cytokines have potential to resolve chronic pain, but they work most optimal in concert of each other. We developed a novel approach to optimize the potential of anti-inflammatory cytokines to resolve persistent pain by fusing IL4 and IL10 into one molecule. Intrathecal administration of IL4-10 fusion protein (FP) completely resolves inflammatory pain in multiple animal models, in a superior fashion than the combination of individual cytokines. In addition, *in vitro*, IL4-10 FP inhibited TNFα and PGE_2-induced neuronal sensitization of capsaicin-induced calcium fluxes. Importantly, equimolar concentrations of IL4-10 FP more effectively inhibited neuronal sensitization than the combination of individual cytokines. Mechanistically, we show that IL4-10 FP, in contrast to the combination of IL4 and IL10, clusters IL4R and IL10R in sensory neurons as a potential mechanism for the increased effectiveness. *In vivo*, conditional knockdown of IL10R in Nav1.8+ nociceptors and IL4R in sensory neurons using intrathecal antisense oligodeoxynucleotides completely ablated the IL4-10-mediated inhibition of inflammatory pain. Knockdown of IL4R or IL10R only was sufficient to prevent the superior effect of IL4-10-mediated pain inhibition. Finally, intrathecal administration of IL4-10 FP induced a completely different kinome and transcriptome profile in the DRG compared to IL4+IL10 treatment. These data underscore that anti-inflammatory cytokines can be used to target the sensory system to fully resolve persistent pain. Moreover, they show that IL4-10 FP achieved unheralded biological effects that are more than the mere sum of the two cytokines.

P.C2.08.19

Assessment of anti-DFS70 antibodies in the diagnostic approach of Systemic Autoimmune Rheumatic Diseases

A. Tsirogianni[1], *A. Giannakou*[2], *K. Soufleros*[1], *M. Bantadaki*[2], *E. Synodinou*[1], *A. Markantonatou*[2], *E. Pipi*[1], *A. Pavlitou*[2];
[1]*Immunology-Histocompatibility Dept. "Evaggelismos" General Hospital, Athens, Greece,* [2]*Immunology-Histocompatibility Dept. "Papageorgiou" General Hospital, Thessaloniki, Greece.*

Antinuclear antibodies (ANA) are a serological hallmark of systemic autoimmune rheumatic diseases (SARD). However, positive ANA with a dense fine speckled (DFS) pattern (Hep-2), have been reported in other clinical entities. Interestingly, the anti-DFS70 antibodies are not significantly associated with SARD.
Aim: The aim of the study was the investigation whether the use of a protocol that pre-absorbs anti-DFS70 antibodies from the sera, increases the diagnostic efficiency of HEp-2 ANA testing for SARD.
Subjects and methods
Positive ANA-IIF consecutive sera with DFS pattern from 120 patients with SARD and 170 patients with other clinical entities (non-SARD) referred to our Departments for ANA, DNA and extractable nuclear antigen (ENA) antibodies testing, were retrospectively tested using the NOVA Lite® HEp-2 Select* kit for ANA-IIF.
Results: The positive ANA-IIF after anti-DFS70 pre-absorption was 94.1% (113/120) in SARD patients, while in non-SARD patients the positivity dropped to 44.7% (79/170). Among the 7 SARD patients who became negative after anti-DFS70 pre-absorption, 3 were diagnosed with cutaneous lupus (dsDNA and ENA negative), 1 with myositis (SSA and Jo-1 positive), 2 with Raynaud syndrome (ENA negative) and 1 with Rheumatoid Arthritis (anti-CCP positive).Among non-SARD patients, about half of those (76/170) who remained ANA positive (DNA and ENA negative), were diagnosed with an autoimmune/inflammatory disease (e.g. inflammatory bowel disease, autoimmune hepatitis, multiple sclerosis).
Conclusions: Based on our results we recommend that suggest that the anti-DFS70 pre-absorption protocol on ANA-IIF increases ANA-Hep-2 specificity for SARD, but more studies are needed to address whether it decreases the respective sensitivity.

P.C2.08.20

Interaction between the HLA-Shared Epitope (SE) and smoking in anti-CCP positive Greek patients with Rheumatoid Arthritis

K. Tarassi[1], *E. Mole*[2], *V. Kitsiou*[1], *D. Kouniaki*[1], *T. Athanassiades*[1], *K. Soufleros*[1], *E. Synodinou*[1], *A. Petsas*[1], *C. Sfontouris*[2], ***A. Tsirogianni***[1];
[1]*Immunology-Histocompatibility Dept. "Evaggelismos" General Hospital, Athens, Greece,* [2]*Rheumatology Dept. "Evaggelismos" General Hospital, Athens, Greece.*

Genetic and environmental factors involve in etiopathogenesis of Rheumatoid Arthritis(RA). The aim of the study was the assessment of association of HLA-DRB1*-SE in the presence/absence of CCP autoimmunity in Greek patients with RA (smokers and non-smokers). Eighty-three (83) RA patients (41 smokers,42 have never smoked) were typed for HLA-DRB1* alleles by molecular techniques (PCR-SSOP and -SSP). In 62 out of 83 (74.7%) anti-CCP abs were detected by ELISA. In RA patients and in comparison to the controls increased frequency of HLA-DRB1*01:01(28.9%vs6.8%,OR=4.4), *10:01(16.9%vs2.4%,OR=8.4), *04:01(3.6%vs2%,OR=1.8), *04:04(7.2%vs1%,OR=7.6) and *04:05(15.7%vs3.7%,OR=4.8), as well as decreased frequency of *04:02(1.2%vs2%,OR=0.6) and *04:03 (4.8%vs6.8%,OR=0.7) were found. Among RA patients, 77.1 % possess 1SE vs 18.9% in controls (OR=14.4), whereas 10.8 % possess 2SE vs 1% in controls (OR=11.8). In CCP(+) RA patients and in comparison to CCP(-), an increased frequency of HLA-DRB1*01:01(27.4%vs14.3%,OR=2.3) and *10:01(21%vs4.8%,OR=5.3) was observed. Furthermore, 88.7% of CCP(+) carry 1SE vs 42.9% of CCP(-), (OR=10.5). CCP(+) smokers patients and in comparison to CCP(+) non-smokers are presented with an increased frequency of DRB1*01:01 (41.9%vs12.9%,OR=4.9). Among the CCP(+) smokers, 96.8% possess 1SE vs 80.6% of CCP(+) non-smokers (OR=7.2), whereas 12.9% possess 2SE vs 12.9% of CCP(+) non-smokers (OR=1). Conclusions: a) An increased frequency of HLA-DRB1*01:01, *10:01, *04:05 alleles, as well as the protective role of *04:02, *04:03 alleles, in Greek patients with RA were confirmed, b) Presence of any SE, particularly *10:01 allele, strongly influences the production of anti-CCP abs, c) Interaction between smoking and any SE, particularly *01:01 allele, is associated with anti-CCP(+) RA in Greek patients.

P.C2.08.21

Dithiolethione ACDT suppresses neuroinflammation and ameliorates disease severity in experimental autoimmune encephalomyelitis

P. Kuo[1], *D. A. Brown*[2], *B. A. Scofield*[1], *H. C. Paraiso*[1], *I. Yu*[1], ***J. Yen***[1];
[1]*Indiana University School of Medicine, Fort Wayne, United States,* [2]*Manchester University College of Pharmacy, Fort Wayne, United States.*

Introduction: Multiple sclerosis (MS) is an autoimmune disorder characterized by the central nervous system (CNS) infiltration of myelin-specific pathogenic T cells followed by brain inflammation in association with demyelination. Similarly, experimental autoimmune encephalomyelitis (EAE), the animal model of MS, also exhibits increased CNS infiltration of pathogenic T cells, including Th1 and Th17, leading to detrimental effects of neuroinflammation and demyelination. We previously reported that 3H-1,2-dithiole-3-thione (D3T), the structurally-simplest of the sulfur-containing dithiolethiones, exerted a promising therapeutic effect in EAE. In the current study we evaluated the therapeutic effect of 5-Amino-3-thioxo-3H-(1,2)dithiole-4-carboxylic acid ethyl ester (ACDT), a substituted derivative of D3T, in EAE.
Materials and Methods: Chronic C57BL/6 EAE and relapsing-remitting SJL/J EAE were induced and treated with ACDT. The effect of ACDT on pathogenic T cell infiltration, microglia activation, neurotoxic A1 astrocytes, blood-brain barrier (BBB) integrity in the CNS of EAE was assessed.
Results: ACDT, administered post immunization, delayed disease onset and reduced disease severity in chronic C57BL/6 EAE, and ACDT, administered during disease remission, suppressed disease relapse in relapsing-remitting SJL/J EAE. Further analysis of the cellular and molecular mechanisms underlying the protective effects of ACDT in EAE revealed that ACDT inhibited pathogenic T cell infiltration, suppressed microglia activation, repressed neurotoxic A1 astrocyte generation, lessened BBB disruption, and diminished MMP3/9 production in the CNS of EAE.
Conclusions: We demonstrate that ACDT suppresses neuroinflammation and ameliorates disease severity in EAE through multiple cellular mechanisms. Our findings suggest the potential of developing ACDT as a novel therapeutic agent for the treatment of MS/EAE.

P.C2.09.02

The role of *lnc-DC* long non-coding RNA and *SOCS1* in the regulation of *STAT3* in coronary artery disease and type 2 diabetes mellitus

A. Alikhah[1], *M. Pahlevan Kakhki*[2], *M. Behmanesh*[1];
[1]*Department of Molecular Genetic, Tarbiat Modares University, Tehran, Iran, Islamic Republic of,* [2]*Department of Clinical Neuroscience, Center for Molecular Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.*

Introduction: Coronary artery disease (CAD) can be classified as an inflammatory disease, which affected by type 2 diabetes mellitus (T2DM). Elevated levels of many inflammatory molecules were found in the serum of patients with CAD. STAT3 molecule as a transcription factor plays an important role in the cytokines expression. Here, we examined the expression levels of *STAT3* and its important regulatory genes *lnc-DC* and *SOCS1*, in patients with CAD and T2DM. Methods: Blood samples were obtained from 37 CAD+ and 36 CAD- patients. These patients were enrolled in this study based on angiography findings and categorized based on T2DM status. The expression levels of *STAT3*, *lnc-DC*, and *SOCS1* genes were examined with Real-time PCR method. Results: A significant increase was observed in the expression of *STAT3* and *lnc-DC* genes but not *SOCS1* in CAD+ versus CAD- patients. These results replicated partially in some groups categorized based on T2DM and CAD status. However, the severity of CAD had no effect on expressions of these genes. Moreover, we found some significant correlations between expressions of *lnc-DC* with *SOCS1* and *STAT3*, which confirmed by in silico analysis. Conclusion: Our results shed further light on the inflammatory aspects of CAD and T2DM with emphasis to JAK/STAT pathway and the regulatory role of long non-coding RNAs in the physiopathology of these diseases.

P.C2.09.03

Modulation of regulatory T cell stability and functions through the T cell receptor signaling molecules Themis1 and Vav1

M. Benamar[1], *R. Marrocco*[1], *I. Bernard*[1], *J. Argenty*[1], *B. Malissen*[2], *R. Lesourne*[1], *A. Saoudi*[1];
[1]*Cptp, Toulouse Cedex 3 FRANCE, France,* [2]*CIML, Aix-Marseille, France.*

Regulatory T cells (Treg) are of paramount importance for restraining excessive immune responses and their manipulation holds enormous therapeutic potential. Our recent results using a congenic rat model suggested that the integrity of Vav1/Themis1 T-cell receptor signaling hub plays a crucial role in Treg lineage stability and suppressive function. Indeed, Themis1 deficiency in BN, but not in LEW rats, led to the development of inflammatory bowel disease (IBD), linked to high levels of IL-17 and IFNg production by Treg, and defects in their suppressive function. Genetic studies revealed that this phenotype depended on a 117 Kb genomic locus, containing the R63W polymorphism on Vav1 that impacted its expression and functions. To test the importance of the Vav1/Themis1 TCR signaling hub in Treg function, we generated Themis1-$T^{-/-}$ mice expressing conditionally Themis1 in thymocytes, but not in peripheral T cells. In contrast to regular germline Themis1 knockout mice, these mice were not lymphopenic and exhibited normal proportions of CD4+ T cells in the thymus and in peripheral lymphoid organs. Next, Themis1-$T^{-/-}$ mice were crossed with $Vav1^{R63W}$ mice to assess the impact of these combined mutations on Treg suppressive functions. Using in vitro approaches, together with in vivo analyses of IBD or melanoma models, we showed that suppressive activity of Treg was impaired in Themis1-deficient mice harboring the mutated Vav1. Functional studies showed the implication of SHP1 in these functional defects. Together, these data showed that Themis1 and Vav1 cooperate in the same signalosome to regulate the suppressive function of regulatory T cells.

P.C2.09.04

Glucocorticoid hormone treatment enhances the cytokine production of regulatory T cells by upregulation of Foxp3 expression

T. Berki*, L. Prenek, E. Ugor, R. Pap, F. Boldizsár, P. Németh;*
Department of Immunology and Biotechnology, University of Pécs, Pécs, Hungary.

Objective: Despite the fact that glucocorticoids (GC) are important therapeutic tools, their effects on regulatory T cells (Treg) are not well defined. The aim of our work was to investigate how GCs influence in vivo the thymic (tTreg) and peripheral Treg (pTreg) differentiation, survival and cytokine production.
Methods: Tregs were detected with flow cytometry in lymphatic organs of 4-6 weeks old BALB/c mice after repeated (2-4 days), high-dose GC treatment using CD4/CD25 cell surface and Foxp3/IL-10/TGFβ/glucocorticoid receptor (GR) intracellular staining. Cytokine, Foxp3, and GR mRNA levels of sorted $CD4^+CD25^{high}$ T cells were analyzed using RT-PCR. Foxp3 and GR localization in Treg cells was investigated with confocal microscopy and FRET analysis.
Results: GC treatment resulted in increased relative tTreg frequency in the thymus, with unchanged absolute cell count. The pTreg ratio and absolute cell count decreased in secondary lymphatic organs. Elevated intracellular IL-10+ and TGFβ+ tTreg and pTreg ratios were measured in GC-treated animals, accompanied with elevated Foxp3 mRNA expression. GC treatment increased TGFβ and IL-35 mRNA in splenic and elevated IL-10 mRNA in thymic tTregs. GC induced nuclear localization of GR in both tTregs and pTregs, which showed high colocalization (~60%) with Foxp3. These data suggest an interaction of these two transcription factors with further increase due to GC treatment in pTregs.
Conclusion: Our data show selective survival of tTregs and elevated production of immunosuppressive cytokines by Treg cells after GC treatment, which may contribute to the immunosuppressive effects of GCs.

Expression of PD-1 and PD-L1 markers on T-regulatory cells during cytokine- and anti-CD3-induced proliferation in norm and rheumatoid arthritis

E. A. Blinova*, E. A. Pashkina, D. V. Shevyrev, L. V. Grishina, A. E. Sizikov, V. A. Kozlov;*
Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation.

Rheumatoid arthritis (RA) characterized by disruption of tolerance and Treg dysfunction. The aim of our study was to evaluate expression of functional molecules on Tregs under cytokine-induced proliferation in norm and RA.
The study included 6 patients with RA and 7 healthy donors (average 60±4,4 and 60±4,5 years respectively). After isolation PBMCs were cultivated with or without IL-7 (50ng/ml), IL-15 (50ng/ml) and simultaneously IL-7+IL-15, anti-CD3 antibodies (1mkg/ml) and IL-2 (100ME/ml) during 7days. Analysis of PD-1 and PD-L1 expression on $CD4^+25^+127^{low}$ regulatory cells was performed by flow cytometer CantoII(BD).
Groups of donors and patients didn't differ in number of Tregs and PD-1/PD-L1 expression in peripheral blood. Culturing of PBMCs without stimulation led to a decreasing of Tregs in both groups, and conversely - to an increasing of density of CD25 and CD127, perhaps, due to lack of growth factors. Activation by homeostatic factors promotes the increasing of PD-L1 expression on Tregs, but on the lower level than aCD3+IL-2 stimulation. In RA, after stimulation with IL-7 it was demonstrated more PD-1-positive and less PD-L1-positive Tregs than in norm. Under IL-15 and IL-7+15 stimulation, patients had less $PD\text{-}1^+$ Tregs compared to donors. It was an increase in number of $PD\text{-}L1^+$ Tregs after aCD3+IL-2 stimulation in RA compared to norm.
In RA changes in expression of PD-1/PD-L1 on Tregs under the high doses of IL-7 and IL-15 can influenced on capacity of Tregs to control proliferation of auto-reactive T-cell clones.
The reported study was funded by RFBR and Novosibirsk region, the research project No.17-44-540167.

Identification of VIMP as a novel anti-inflammatory gene of CD4+ effector T cells by a correlation network-guided approach

C. M. Capelle[1,2], *N. Zeng*[1,2], *E. Danilecviciute*[1], *M. Ollert*[1,3], *R. Balling*[4], *F. He*[1];
[1]*Department of Infection and Immunity, Luxembourg Institute of Health, Esch-sur-Alzette, Luxembourg,* [2]*University of Luxembourg, Esch-sur-Alzette, Luxembourg,* [3]*Odense Research Center for Anaphylaxis (ORCA), Department of Dermatology and Allergy Center, University of Southern Denmark, Odense, Denmark,* [4]*Luxembourg Center for Systems Biomedicine, University of Luxembourg, Esch-sur-Alzette, Luxembourg.*

Although many key players of the CD4+ T cell inflammatory response have already been identified, many nodes of the underlying network are still missing for a deep understanding of the molecular mechanisms. We previously established a correlation network-guided strategy to identify novel key hub genes and extended the strategy to identify novel genes regulating the inflammatory response of CD4+ effector T cells (Teffs), based on high-resolution time-series data of human Teffs in the first 6 hours following T cell receptor stimulation. We identified VIMP (VCP-interacting protein, also known as SELS, SELENOS), one of the 25 genes encoding the 21st amino acid selenocysteine in humans, as a novel gene involved in Teff function. VIMP is known to be an important component of the endoplasmic reticulum (ER)-associated degradation (ERAD) complex and has functions in cell survival by regulating ER stress. Furthermore, VIMP has been shown to have an anti-inflammatory function in macrophages.
Knocking-down VIMP in Teffs significantly enhanced their proliferation and the expression of different cytokines. By using a computational approach, we predicted the transcription regulatory- and signalling transduction network through which VIMP regulates cytokine expression, based on the dynamic correlation network of Teffs and on transcriptome analysis, and experimentally validated the prediction in a finer scale. Altogether we demonstrate that VIMP inhibits the inflammatory response via both the E2F5 transcription regulatory network and the phosphorylation of NFATC2 through which VIMP regulates the inflammatory response in CD4+ effector T cells.

Background Psoriatic arthritis is a destructive joint disease developing in approximately 30% of psoriasis patients. Both psoriasis and psoriatic arthritis are T-cell mediated diseases, but how T cells migrate from the skin to joint is unclear. Growing evidence suggests that a defective lymphatic system and the lymphatic endothelial cells (LECs) might play a crucial role in the progression of psoriasis to psoriatic arthritis. **Objective** In this study, we aim to elucidate the role of the lymphatic system in psoriasis and psoriatic arthritis. We hypothesize that healthy LECs have immunoregulatory properties that are lost in psoriatic arthritis allowing transmission of pathogenic T cells from skin to the joints. **Methods** Human dermal LECs ($CD31^+$ $podoplanin^+$) and fibroblasts ($CD31^-$ $podoplanin^-$) were isolated from skin from healthy individuals. Human lymph node LECs ($CD31^+$ $podoplanin^+$) were isolated from patients undergoing vascular surgery. Expression of immunoregulatory molecules was analyzed by flow cytometry and RT-qPCR. **Results** Healthy human dermal LECs and healthy human lymph node LECs express immunoregulatory and costimulatory molecules, such as programmed death-ligand 1 (PD-L1), galectin 9, glucocorticoid-induced TNFR-related ligand (GITRL) and OX40 ligand. Furthermore, both LECs from lymph node and skin as well as skin BECs are $HLA\text{-}DR^+$ in contrast to healthy dermal fibroblasts and healthy synovial fibroblasts. **Conclusion** Both dermal and lymph node LECs are HLA-DR+ and express several immunoregulatory and costimulatory molecules indicating an important role for LECs in shaping peripheral T cell responses. Further studies involving dermal, lymph node and synovial LECs from psoriasis and psoriatic arthritis patients are underway.

IL-17A/F contributes to the pathogenesis of experimental Epidermolysis Bullosa Acquisita

F. Deng[1], *I. Prinz*[2], *X. Yu*[3], *F. Petersen*[4], *R. Ludwig*[5], *C. Hölscher*[1];
[1]*Infection Immunology, Research Centre Borstel, Borstel, Germany,* [2]*Institute for Immunology, Hannover Medical School, Hannover, Germany,* [3]*Autoimmunity of the Lung, Research Centre Borstel, Borstel, Germany,* [4]*Biochemical Immunology, Research Centre Borstel, Borstel, Germany,* [5]*Clinical Dermatology, University Hospital Lübeck, Lübeck, Germany.*

Introduction: Epidermolysis bullosa acquisita (EBA) is a chronic autoimmune skin disease caused by autoantibodies against type VII collagen (ColVII). Anti-ColVII antibodies deposit in dermal-epidermal junction to activate complement and mediate neutrophil infiltration, finally triggering skin fragility and blister formation. Interleukin (IL)-17A and IL-17F, mainly produced by Th17, γδT and innate immune cells, are pro-inflammatory cytokines, and have been reported to mediate infectious and autoimmune diseases by promoting the recruitment and activation of neutrophils. However, the contribution of IL-17A and IL-17F in the pathogenesis of EBA is unclear. **Methods:** Rabbit anti-mColVII IgG was transferred to mice to induce passive systemic EBA model. To elucidate the function of IL-17A and IL-17F in EBA, IL-17A/F-/- and IL-17Ra-/- were examined. IL-17A-eGFP and γδTCR-/- mice were used to determine IL-17A-producing cells. Keratinocytes and fibroblasts were selected for in vitro assays to characterize targets cells of IL-17A in EBA. **Results:** After transfer of anti-mColVII IgG, IL-17A/F-/- and IL-17Ra-/- mice showed a milder disease than C57BL/6 wildtype mice, which was accompanied with lower mRNA levels of IL-6 and CCL2 in skin. Flow cytometry analysis of IL-17A-eGFP mice revealed that γδT cells were the main cell type to produce IL-17A during EBA, which was further confirmed by a disease remission in γδTCR-/- mice. In response to IL-17A, keratinocytes and fibroblasts secreted CXCL-1 in vitro to accelerate neutrophil migration. **Conclusion:** Our results demonstrate that IL-17A/F, derived from γδT cells, plays a pivotal role in EBA by the induction of chemokine release in keratinocytes and fibroblasts to promote neutrophil infiltration.

Relationship between body temperature and lifestyle

K. Kimura*, D.Akiyama;*
Department of Health and Sports Management, Japan University of Economics, Dazaifu, Japan.

Introduction: Maintaining a core temperature of 37.0℃ is important for autoimmunity, but reports in recent years show a declining trend in body temperature in Japan. The aim of this study was to investigate the relationship between tympanic temperature and lifestyle.
Materials and Methods: The subjects were 68 healthy females. The subjects measured their tympanic temperature using a thermometer in the evening. We used a questionnaire format to survey the dietary patterns and activity levels of the subjects. The dietary patterns were assessed by examining the average meal content consumed per week over the last 1-2 months and meal consumption, including nutritional content and other factors. The activity levels represented the average duration of physical activity per day and exercise duration per week (4 intensity levels: 3≤ metabolic equivalents (METs) <4, 4≤ METs <6, 6≤ METs <8, 8 ≤ METs ≤15). Correlation coefficient was calculated to determine correlations between tympanic temperature and each item.
Results: There were negative correlations between tympanic temperature and consumption of fat, saturated fatty acid and monounsaturated fatty acid. 36 subjects had tympanic temperature of 36.5℃ or more (normal temperature, N), and 32 subjects had temperatures of less than 36.5℃ (low temperature, L). We compared each item on either side of 36.5℃, the total caloric intake, consumption of saturated fatty acid and monounsaturated fatty acid were significantly lower for N.
Conclusions: This study showed that there was a significant correlation between tympanic temperature and consumption of fat, saturated fatty acid and monounsaturated fatty acid.

Treg specific constitutive Nrf2 activation precipitates an inflammatory state

P. Klemm[1], *B. Denecke*[2], *A. Schippers*[1], *N. Wagner*[1], *K. Tenbrock*[1], *K. Ohl*[1];
[1]*Department of Pediatrics, University hospital RWTH Aachen, Germany,* [2]*Interdisciplinary Centre for Clinical Research (IZKF), University hospital RWTH Aachen, Germany.*

Immune cells are constantly confronted with intracellular and extracellular radical oxygen species (ROS) under steady-state and even more under inflammatory and pathogenic conditions. To investigate the effects of oxidative stress and ROS molecules in regulatory T cells (T_{regs}), we deciphered the role of Nuclear factor (erythroid-derived 2)-like 2 (Nrf2) in this context. T_{regs} were already found to be more resistant to ROS than effector T cells and activated T_{reg} cells show higher expression of genes, which belong to the Nrf2-mediated oxidative stress response compared to activated effector T cells. Here we report a previously unrecognized negative role of Nrf2 in T_{regs}. While mice bearing a constitutive activation of Nrf2 in all immune cells ($Vav^{cre}Keap^{fl/fl}$) accumulate high percentages of Foxp3-positive T_{regs} in the spleen, lymph nodes and thymus, their suppressive capacity seems to be defective. Interestingly, a T_{reg} specific activation of Nrf2 ($Foxp3^{cre}Keap^{fl/fl}$) results in an auto-inflammatory phenotype with immune cell infiltrates in the lung, enhanced effector T cell activation and high percentages of IFN-γ producing effector T cells. Moreover, the constitutive Nrf2 activation in T_{regs} increases their *in-vitro* proliferation, glucose uptake and mTOR activity, while the differentiation and Foxp3 expression in T_{regs} declines. We demonstrate for the first time that constitutive Nrf2 activation specific to T_{regs} affects T_{reg} lineage stability and metabolism and might thereby induce an auto-inflammatory phenotype. Thus, our results may have implications for diseases associated with oxidative stress and dysregulated T_{reg} responses.

P.C2.09.11

The role of $CD8^+$ T lymphocytes in experimental nephrotoxic serum nephritis

A. A. Mooslechner*, A. H. Kirsch, K. Artinger, I. Aringer, F. Moschovaki-Filippidou, C. Schabhüttl, K. Schweighofer, A. R. Rosenkranz, K. Eller;*
Clinical Division of Nephrology, Graz, Austria.

Nephrotoxic serum nephritis (NTS) is known as a $CD4^+$ T cell-dependent murine model of anti-glomerular basement membrane disease. Although the presence of $CD8^+$ T cells in disease progression is known, their role in its pathology is not clear. Recent controversial findings challenge our knowledge of $CD8^+$ T cells and their function solely as effector T cells by suggesting the existence of a regulatory subset, characterized by the marker CD122. We here aim to understand the role of $CD8^+$ T cells and its subset of CD8CD122 double positives in progression of NTS.
Male C57Bl/6J mice, 8 weeks of age, were either treated with an anti-CD8α and/or anti-CD122 depleting antibody, or respective isotype control, one day before induction of NTS and were followed for 5 or 21 days. Renal endpoints such as albuminuria, blood urea nitrogen (BUN), inflammatory cell infiltration and glomerulosclerosis were assessed.
Successful depletion of $CD8^+$ and $CD122^+$ lymphocytes was observed by flow cytometry and confirmed by immunohistochemistry. At disease onset, mice treated with anti-CD8α scored lower levels of BUN. Mice treated with anti-CD122 or both antibodies showed no changes in renal endpoints. After 21 days of disease progression, the group treated with both antibodies scored significantly higher levels of BUN as well as albuminuria/creatinine ratio.
Our data support the hypothesis that $CD8^+$ T lymphocytes play a crucial role in immune regulation of NTS. However, our findings suggest a more complex picture with distinct roles for subpopulations of these lymphocytes, which were formerly thought to be effector T cells only.

P.C2.09.12

PUTRID: a marker that identifies pure and stable regulatory T cells

R. Opstelten[1], *E. Cuadrado*[1], *S. de Kivit*[2], *M. C. Slot*[1], *M. van den Biggelaar*[1], *A. M. Scott*[3], *J. Borst*[2], *D. Amsen*[1];
[1]*Sanquin Research, Amsterdam, Netherlands,* [2]*Netherlands Cancer Institute, Amsterdam, Netherlands,* [3]*Olivia Newton-John Cancer Research Institute, Melbourne, Australia.*

Regulatory T-cells (Tregs) can alleviate autoimmune and organ transplant-related diseases through adoptive cellular therapy. There are two different sources of Tregs. Thymic-derived Tregs are stably committed to the Treg lineage. Tregs that are induced to differentiate from conventional T-cells can, however, lose their suppressive capacity and start producing effector cytokines, thereby forming a potential danger when given to a patient. Discrimination between these lineages is currently not possible. Here, we report the identification of the immunoglobulin superfamily member PUTRID as a surface marker that identifies stable human Tregs. When freshly isolated, $PUTRID^{high}$ Tregs express the key Treg transcription factors FoxP3 and Helios and are unable to produce effector cytokines upon stimulation. Their $FoxP3^+Helios^+PUTRID^{high}$ phenotype is maintained in culture, whereas their $PUTRID^{low}$ counterparts do not stably express these critical molecules. $PUTRID^{high}$ Tregs are suppressive, have a fully demethylated FoxP3 promotor and remain unresponsive to cytokine-inducing stimuli after expansion. High expression of PUTRID is found on both naïve and effector Tregs. In this latter population, $PUTRID^{high}$ cells are the only subset capable of proliferation. Our findings thus reveal previously unrecognized functional heterogeneity among human Tregs. Importantly, our results demonstrate a strategy to isolate Tregs for safer and more efficacious adoptive cellular therapy.

P.C2.09.13

USING CRISPR-CAS9 TO ELUCIDATE THE ROLE OF TNF-RECEPTORS IN TREG FUNCTION

A. M. Pesenacker[1,2,3], *U. Nguyen*[1,2], *J. Gillies*[1,2], *M. K. Levings*[1,2];
[1]*BC Children's Hospital Research Institute, Vancouver, Canada,* [2]*University of British Columbia, Vancouver, Canada,* [3]*Institute of Immunity and Transplantation, UCL Royal Free Hospital, London, United Kingdom.*

FOXP3+ regulatory T cells (Tregs) are crucial to maintain immune tolerance and prevent autoimmune diseases such as Juvenile idiopathic arthritis (JIA) and type 1 diabetes (T1D). Treg function, however, can be influenced by the environment of inflammation. For example, Tumour necrosis factor alpha (TNF-), which is abundant in inflamed JIA joints, can have positive or negative effects on Treg function. TNF- has two receptors, CD120a and CD120b, with CD120a linked to cell death and CD120b to survival. We found skewed CD120a to CD120b expression on Tregs in the inflamed JIA joints, with increased CD120a and decreased CD120b levels. We hypothesized that this altered CD120a:CD120b expression ratios would affect TNF--driven changes in Treg function. To elucidate the functional relevance of the TNF-receptors in primary human Tregs, CRISPR-Cas9 methodology was used to knockout (KO) CD120b, or CD120a or CD120b were over-expressed using lentiviral transduction. CD120bKO or CD120a-overexpressing Tregs possessed a normal Treg phenotype, with expression of FOXP3 and demethylated TSDR, but had higher levels of apoptosis, expression of exhaustion markers (PD-1, Lag3), and decreased suppressive capacity. Upon TCR plus TNF- stimulation only CD120b-expressing Tregs had increased expression of FOXP3, activation markers and proliferation compared to TCR stimulus alone. Understanding how Treg function is controlled by TNF- may reveal mechanisms which lead to the failure of immune tolerance in the joint, provide insight into uncharacterized effects of TNF- blockade on Tregs and ultimately to new therapeutic approaches to restore immune regulation in autoimmunity.

P.C2.09.14

CXCR3+ CD45RA- T cells as downstream effectors of tissue inflammation in psoriatic arthritis

F. Casciano[1], *M. Diani*[2], *L. Marongiu*[3], *M. Longhi*[2], *A. Altomare*[2], *P. Secchiero*[4], *R. Gambari*[5], *F. Granucci*[3], ***E. Reali***[2,5];

Little is known about the link between T cell responses arising in the skin and systemic and joint inflammation in patients with Psoriatic arthritis (PsA). The aim of this study is to explore the T cell recirculating subsets as possible pathogenic elements in systemic and joint manifestations of PsA.
We performed an extensive analysis of the phenotype and cytokine expression in circulating $CD4^+$ and $CD8^+$ T cells in a cohort 69 subjects including 15 patients with psoriatic arthritis (PsA), 28 patients with cutaneous psoriasis and 26 healthy subjects. For each subset correlation was calculated with the serum level of C-reactive protein. In selected patients with PsA we also performed a parallel analysis by comparing T cells in blood and synovial fluid.
In the circulation of PsA patients, we found a marked decrease in the percentage of $CXCR3^+CD45RA^-$ memory T cells, both in the $CD4^+$ and $CD8^+$ compartments. Consistently, there was a lower level of IFNγ-producing $CD4^+$ $CD45RA^-$ T cells in the blood of patients with PsA.
By contrast in the synovial fluid, we found a strong enhancement of $CXCR3^+$ and IFNγ-producing $CD4^+$ and $CD8^+$ T cells.
In the circulation of PsA patients IL-17-producing $CD4^+$ and $CD8^+CD45RA^-$ T cells were significantly more abundant and $CCR6^+CD4^+$ T effector memory cells positively correlated with the extent of systemic inflammation.
The results enlighten the role of $CXCR3^+$ IFNγ-producing effector cell recruitment from the blood stream to the inflamed tissue as a downstream mechanism in the pathogenesis of PsA.
Grant from Fondazione Natalino Corazza Onlus.

P.C2.09.15

The role of cMAF and IKZF3 in anti-TNF induced IL-10 expression in CD4+ T cells

M. L. Ridley[1], *V. Fleskens*[1], *C. A. Roberts*[1], *S. Lalanunhlimi*[1], *G. A. Povoleri*[1], *P. Lavender*[2], *L. S. Taams*[1];
[1]*Centre for Inflammation Biology and Cancer Immunology (CIBCI), Dept Inflammation Biology, School of Immunology & Microbial Sciences, King's College London, London, United Kingdom,* [2]*MRC and Asthma UK Centre in Allergic Mechanisms of Asthma, School of Immunology & Microbial Sciences, King's College London, London, United Kingdom.*

We have previously shown that anti-TNF treatment increases the frequency of IL-10 producing CD4+ T cells *in vitro* and *ex vivo*. We investigated whether transcriptional regulation of IL-10 expression following TNF-blockade involved the transcription factors IKZF3 and cMAF.
We examined the expression of IL-10, IKZF3 and cMAF through flow cytometry and quantitative-PCR. We manipulated IKZF3 expression using lentiviral overexpression and pharmacological inhibition.
IL-10 expression increased in CD4+ T cells upon stimulation, but was maintained at higher levels at the mRNA and protein level upon culture with anti-TNF after 3 days. cMAF was expressed by IL-10+ CD4+ T cells but was not significantly changed by anti-TNF. IKZF3 was expressed at higher levels in anti-TNF treated IL-10+ CD4+ T cells compared to other cytokine producing cells. Pharmacological inhibition of IKZF3 using the drug lenalidomide significantly reduced the frequencies of cells expressing IL-10. However, lentiviral over-expression of IKZF3 was not sufficient to induce *IL10* mRNA expression. Luciferase reporter assays using putative regulatory regions of the *IL10* locus are ongoing to investigate the transcriptional regulation of *IL10* by cMAF and IKZF3.
Our findings indicate that the increased frequency of IL-10 producing CD4+ T cells after anti-TNF treatment is not due to altered cMAF expression. Our findings also indicate that although there is an association between IKZF3 and IL-10 expression upon TNF blockade, IKZF3 by itself is not sufficient to drive the expression of *IL10* in CD4+ T cells. Funded by Arthritis Research UK (Ref 21139)

Thymus derived Treg cell development is regulated by C type lectin mediated BIC miRNA155 expression

R. Sanchez Diaz, *R. Blanco Dominguez, B. Linillos Pradillo, M. Relaño, P. Martin Fernandez;*
CNIC, Madrid, Spain.

Normal 0 false false false EN-US X-NONE X-NONE /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Table Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0in 5.4pt 0in 5.4pt; mso-para-margin-top:0in; mso-para-margin-right:0in; mso-para-margin-bottom:8.0pt; mso-para-margin-left:0in; line-height:107%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri",sans-serif; mso-ascii-font-family:Calibri; mso-ascii-theme-font:minor-latin; mso-hansi-font-family:Calibri; mso-hansi-theme-font:minor-latin;} Thymus-derived regulatory T (tTreg) cells are key to preventing autoimmune diseases, but the mechanisms involved in their development remain unsolved. Here, we show that the C-type lectin receptor CD69 controls tTreg cell development and peripheral Treg cell homeostasis through the regulation of BIC microRNA 155 (miR155) and its target, suppressor of cytokine signaling 1 (SOCS1). Using Foxp3 mRFP*cd69_/_* or Foxp3mRFP*cd69_/_* reporter mice and short hairpin RNA (shRNA) mediated silencing and miR155 transfection approaches, we found that CD69 deficiency impaired the signal transducer and activator of transcription 5 (STAT5) pathway in Foxp3 cells. This results in BIC miR155 inhibition, increased SOCS1 expression, and severely impaired tTreg cell development in embryos, adults, and Rag2_/_γ c_/_ hematopoietic chimeras reconstituted with *cd69_/_* stem cells. Accordingly, *mirn155_/_* mice have an impaired development of CD69 tTreg cells and overexpression of the miR155 induced CD69 pathway, suggesting that both molecules might be concomitantly activated in a positive-feedback loop. Moreover, *in vitro*-inducible CD25 Treg (iTreg) cell development is inhibited in *Il2r_/_/cd69_/_* mice. Our data highlight the contribution of CD69 as a nonredundant key regulator of BIC miR155 dependent Treg cell development and homeostasis.

Serum cytokines and biological therapy of psoriasis -Prospects for personalized treatment?

S. M. Solberg[1,2,3], *L. F. Sandvik*[4,5], *M. Eidsheim*[1], *R. Jonsson*[1,3], *Y. T. Bryceson*[1,3,6], *S. Appel*[1,3];
[1]*Broegelmann Research Laboratory, Bergen, Norway,* [2]*Department of Dermatology, Haukeland University Hospital, Bergen, Norway,* [3]*Department of Clinical Science, University of Bergen, Norway,* [4]*Department of Dermatology, Haukeland University Hospital, Bergen, Norway,* [5]*Department of Clinical Medicine, University of Bergen, Bergen, Norway,* [6]*Centre for Hematology and Regenerative Medicine, Department of Medicine, Karolinska Institutet, Sweden.*

Introduction. Psoriasis is an immune mediated disease where the IL-23/Th17 axis and TNF are central. The aim was to compare serum cytokines in psoriasis patients receiving biological therapy, to Psoriasis Area and Severity Index (PASI) and Dermatological Life Quality Index (DLQI).
Methods. Clinical parameters and 25 serum cytokines (determined by Luminex technology) were measured in 40 patients at inclusion and after 3-4 months.
Results. PASI and DLQI decreased by 71.03% and 64.87%, respectively. Logistic regression revealed four times higher risk of severe psoriasis when IL-17A increased by 1pg/mL (OR 4.064, CI: 1.008-16.383, $p < 0$ .049). Significant association between PASI90 and increase of IL-5, IL-10, IL-12, IL-22 and GM-CSF was detected. Fold change of IL-2 correlated positively with PASI and DLQI improvement. BMI correlated with TNF, IL-22 and IL-1RA.
Conclusions. The important role of IL-17A in psoriasis is confirmed by this study. Increase of GM-CSF, IL-5, IL-10, IL-12, IL-22 and IL-2 during follow-up, correlated with treatment effect. Serum cytokines might be useful biomarkers for monitoring disease activity and optimizing therapeutic strategies for psoriasis patients.
Grant: Norwegian association for Dermatology and Venerology sponsored the ProcartaPlex kit. Fundings: Broegelmann Foundation and Western Norwegian Health authorities.

Myeloid-derived suppressor cells in children with severe psoriasis

*D. Gerasimova[1], T. Radygina[1], N. Murashkin[1], **A. Toptygina**[2,3], S. Petrichuk[1];*
[1]Federal State Autonomous Institution "National Medical Research Center of Children's Health", Moscow, Russian Federation, [2]G.N.Gabrichevsky Research Institute for Epidemiology and Microbiology, Moscow, Russian Federation, [3]Lomonosov Moscow State University, Moscow, Russian Federation.

Psoriasis is a chronic immune-mediated inflammatory skin disease. Lately, participation in the pathogenesis of psoriasis of myeloid-derived suppressor cells (MDSCs) and Tregs cells has been studied. The goal was to determine the number of MDSCs in the blood of children with psoriasis. 78 children with psoriasis at the age between 0.5-18 years were examined: 46 primary patients and 32 children on treatment with a TNF-α inhibitor. The severity of psoriasis was assessed by PASI. The control group consisted of 31 children. The number of MDSCs and the indicator of cell mediated immunity (Tregs, act-Th and Th17) were determined on the NovoCyte ACEA flow cytometr. The group of children with psoriasis was characterized by a large spread of the number of MDSCs (6-198 cells/ml) relative to the control group (10-54 cells/ml, F = 4.6, p <0.01). The number of MDSCs is characterized by a phase dependence on the duration of the disease and does not depend on the age of the patients. During the first 5 years of the disease MDSCs amount increases but after 6 years of disease their number decreases by 30%. With an increasing of the disease duration, amount of Th17 cells increase (R=0.4) while amount of the Tregs cells decrease (R= - 0.39). Among children with severe psoriasis of MDSCs increases with increasing of PASI. As the disease progresses, the amount of MDSCs decreases but the amount of Th17 and act-Th increases.

P.C2.10.01

Changes in cytokine profiles of rheumatoid arthritis patients after Adalimumab or Etanercept anti TNFα therapy.

***T. Ahmed**;*
Ulster University, Londonderry, United Kingdom.

Rheumatoid arthritis (RA) affects approximately 1% of the population and without effective treatment can lead to permanent disability. Biological drugs Adalimumab (ADL) and Etanercept (ETN) target tumour necrosis factor α (TNFα), achieving ~70% response rates. These drugs are expensive and therefore it is imperative to stratify patients who will receive clinical benefit. Here we report that whilst both ADL and ETN inhibit TNFα activity; they produce distinct changes in blood cytokine levels. Anti-TNF naive RA patients were treated with ADL or ETN. Serum samples were collected at baseline (T0) and 6 months post therapy (T6). Serum cytokines IFNγ, IL-10, IL-12 p70, IL-13, IL-4, IL-6, IL-8 and TNFα were measured by MesoScale assay. Cytokine concentrations are reported in pg/mL and statistical significance was determined using Wilcoxon matched pairs signed rank test. After 6 months of therapy; ADL treated patients had significantly lower concentration of IL-6 (T0=3.03 vs T6=0.74), IL-8 (T0=14.18 vs 11.35) and TNFα (1.96 vs 1.704) compared to baseline. ETN treated patients had a significantly higher concentration of IL-10 (T0=0.35 vs 0.60) and TNFα (T0=1.64 vs 52.23). We report that ADL and ETN have differing effects upon blood cytokines. ADL reduced IL-6, IL-8 and TNFα. ETN elevated IL-10 and TNFα. From 11 ETN treated patients; 9 were good responders, 1 was moderate responder and 1 was non-responder according to EULAR classification. TNFα-ETN complexes may have increased blood half-life & reduced clearance, thus explaining why TNFα is elevated in these patients; the majority of whom are responding to treatment.

P.C2.10.02

Sex-based differences in association between circulating T cell subsets and disease activity in untreated early rheumatoid arthritis patients

***J. Aldridge**[1], J. M. Pandya[1], L. Meurs[1], K. Andersson[1], I. Nordström[1], E. Theander[2], A. Lundell[1], A. H. Rudin[1];*
[1]Dept of Rheumatology and Inflammation Research, Institute of Medicine, Gothenburg, Sweden, [2]Dept of Rheumatology, Lund University, Skåne, Lund, Sweden.

Introduction: It is not known if sex-based disparities in immunological factors contribute to the disease process in rheumatoid arthritis (RA). We examined whether circulating T cell subset proportions and their association with disease activity differed in male and female patients with untreated early rheumatoid arthritis (ueRA). **Methods**: Proportions of T cell subsets were analyzed in peripheral blood from 70 ueRA DMARD- and corticosteroid-naïve patients (50 females and 20 males) and in 31 healthy age- and sex-matched controls. Broad analysis of helper and regulatory $CD4^+$ T cell subsets was done using flow cytometry. Disease activity in patients was assessed using DAS28, CDAI, swollen joint counts, tender joint counts, CRP and ESR. **Results**: In male, but not female, ueRA patients Th2 cells showed a positive association with disease activity and correlated significantly with DAS28-ESR, CDAI and tender joint counts. Likewise, proportions of non-regulatory $CTLA\text{-}4^+$ T cells associated positively with disease activity in male patients only, and correlated with DAS28-ESR. In contrast, there was a negative relation between Th1Th17 subset proportions and disease activity in males only. Proportions of Th1 and Th17 cells showed no relation to disease activity in either males or females. There were no significant differences in proportions of T cell subsets between the sexes in patients with ueRA. **Conclusion**: Our findings show sex-based differences in the association between T cell subsets and disease activity in ueRA patients Moreover, Th2 helper T cells may have a role in regulating disease activity in male patients.

Sucrose octasulphate inhibits the differentiation of monocytes to TNF-α synthesising macrophages through inhibition of the PKC pathway: explanation for its anti-rheumatic activity

***P. Bajwa**[1], N. Garrido-Mesa[1], M. P. Seed[2], S. S. Ayoub[2];*
[1]Medicines Research Group, School of Health Sport and Bioscience, University of East London, Stratford, United Kingdom, [2]Clinical Research Group, School of Health Sport and Bioscience, University of East London, Stratford, United Kingdom.

Rheumatoid arthritis, is, driven by an array of cytokines such as tumour necrosis factor-α (TNF-α) synthesised by T-cells and macrophages. Sulphated disaccharides (SDS) are released by heparanase during inflammation to inhibit T-cell function. These, including the synthetic analogue sucrose octasulphate (SOS) inhibit rodent models of arthritis and reduce T-cell function. We have shown SOS inhibits monocyte-to-macrophage (Mϕ) differentiation. The current study was conducted to explore possible mechanisms.
Human monocytes U937 were pre-treated with SOS (10^{-11} to 10^{-4} M) 2h prior to the induction of differentiation by 8nM phorbol 12-myristate 13-acetate (PMA). The cells were then washed and re-suspended in fresh medium for 24h followed by 1μg/ml LPS for 6h to induce TNF-α synthesis. The action of SOS on monocyte differentiation, expression of Mϕ cell surface markers, TNF-α synthesis, intracellular calcium mobilisation (marker for PKC activation) and activation of ERK1/2, p38MAPKinases were investigated.
SOS inhibited differentiation (cell adhesion), down-regulated CD14, CD11a, CD11b and CD68 expression by PMA stimulated U937 cells and reduced LPS induced TNF-α synthesis by the residual macrophages. The inhibitory action of SOS on monocyte differentiation was associated with the down-regulation of intracellular calcium mobilisation and phosphorylation of the ERK1/2, and p38MAPK cell signalling pathways indicative of inhibition of PKC cell signalling.
SOS may mediate its anti-rheumatic actions through the inhibition of pathways downstream of PKC. SDS are released from tissue heparans during inflammation, and we hypothesise that synthetic SDS analogues may have potential as a new basis for treating chronic inflammatory disease such as rheumatoid arthritis.

Dynamics of circulating TNF during adalimumab treatment of rheumatoid arthritis using a novel drug-tolerant TNF assay

***L. C. Berkhout**[1], M. J. l'Ami[2], J. Ruwaard[2], M. H. Hart[1], P. Ooijevaar-de Heer[1], K. Bloem[1], M. T. Nurmohamed[2,3], R. F. van Vollenhoven[2,3,4], M. Boers[3,5], C. H. Smith[6], G. Wolbink[1], T. Rispens[1];*
[1]Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands, [2]Amsterdam Rheumatology and immunology Center | Reade, Amsterdam, Netherlands, [3]Amsterdam Rheumatology and immunology Center | VU University Medical Center, Amsterdam, Netherlands, [4]Amsterdam Rheumatology and immunology Center | Academic Medical Center, Amsterdam, Netherlands, [5]Department of Epidemiology & Biostatistics, VU University Medical Center, Amsterdam, Netherlands, [6]St. John's Institute of Dermatology, Division of Genetics and Molecular Medicine, Kings College London, London, United Kingdom.

Rheumatoid arthritis (RA) patients can be successfully treated with tumor necrosis factor- (TNF) inhibitors, including adalimumab, which binds TNF to form inactive complexes. Once in remission, a proportion of patients can successfully discontinue adalimumab treatment, indicating that blocking TNF is no longer required for disease control. We developed a novel competition assay that can quantify TNF in the presence of large amounts of TNF-inhibitor, i.e. a 'drug-tolerant' assay. This assay was used to quantify TNF levels on initiation and during 2 years of adalimumab treatment in 193 consecutive RA patients. We investigated, for the first time, the relationship between TNF levels and clinical response.
Circulating TNF levels were close to the detection limit at baseline, increased on average >50-fold upon adalimumab treatment, and reached a stable level in time in the majority of patients, regardless of disease activity. During treatment, TNF was in complex with adalimumab, and recovered as inactive 3:1 adalimumab:TNF complexes. Remarkably, low TNF levels at week four were associated with a significantly higher frequency of anti-drug antibodies at subsequent time points, significantly less methotrexate use at baseline, and less frequent remission after 52 weeks.
In conclusion, longitudinal TNF levels are mostly stable in time during adalimumab treatment, and may therefore not predict successful dose-interval prolongation or treatment discontinuation. However, low TNF levels in the early phase of treatment (week 4) are strongly associated with anti-drug antibody formation and may be used as timely predictor of non-response towards adalimumab treatment.

P.C2.10.05

Effects of the medications anakinra and tocilizumab on CD8+iTregs differentiation and function

*M. L. Kristensen[1], **U. Bjarnadóttir**[2];*
[1]Department of Immunology, Landspitali - University Hospital, Reykjavik, Iceland, [2]Department of Immunology, Landspitali - University Hospital. Reykjavík, Iceland, Reykjavik, Iceland.

Introduction: Regulatory CD8$^+$ T-cells (CD8$^+$iTregs) may play an important role in preventing autoimmune processes in the body by their suppressive function. Anakinra (anti-IL-1β mAb) and tocilizumab (anti-IL-6 receptor mAb) are used for the treatment of autoimmune diseases such as RA.
Aim: The aim of this study was to evaluate the role of IL-6 and IL-1β on the differentiation and function of CD8$^+$ iTregs.
Material and methods: Naïve human CD8$^+$CD45RA$^+$ T cells were stimulated with αCD3/αCD28 in the presence of IL-2/TGF-β1, with/without αIL-6 (0.1/10/1000μg/mL) and αIL-1β (0.5/5/500μg/mL) for 120 hrs. Three subpopulations were defined as CD8$^+$/CD127$^-$/CD25$^+$/FoxP3$^{int/hi}$, CD25$^+$FoxP3$^-$ and CD25$^-$FoxP3^{int} and their cytokine pattern observed (IL-17, IFNγ, IL-6, IL-9 and PD1).
Results: CD8$^+$ iTregs were significantly induced and defined as CD8$^+$/CD127$^-$/CD25$^+$/FoxP3$^{int/hi}$. Both αIL-6 (p=0.002) and αIL-1β (p=0.016) inhibited their induction. Anti-IL-6 treatment reduced both PD1 and IL-9 cellular CD8$^+$iTregs expression. The induction of iTregs in the presence of IL-2 and TGF-β1 resulted in an increased secretion of IL-21**, IL-22**, IL-9**, IL-18* and IL-13**. However, anti-IL-6 treatment inhibited the secretion of IL-6**, IL-21** and IL-22**, whereas, only IL-6* and IL-1β** were found to be reduced following anti-IL-1β treatment during the induction of CD8$^+$ iTregs.
Conclusion: CD8$^+$ iTregs induction is dependent on IL-6 and is possibly driven through an IL-9 and PD1 dependent intracellular mechanism. However, the role of IL-1β on CD8+iTregs may be driven through IL-6 induction. Both IL-21 and IL-22 secretion are reduced following tocilizumab treatment during in vitro stimulation of CD8$^+$ T-cells, suggesting a therapeutic role in a B-cell driven autoimmunity.

P.C2.10.08

Different patterns of circulating anti-ENA specific antibody secreting cells and/or ENA-specific B-lymphocytes are detected in SLE patients

***R. de la Varga Martínez**[1,2], B. Rodríguez Bayona[3], G. A. Áñez Sturchio[4], F. Medina Varo[4], C. Rodríguez[5];*
[1]Servicio de Inmunología. UGC de Laboratorios Clínicos. Hospital Universitario Virgen del Rocío, Sevilla, Spain, [2]Unidad de Investigación y Servicio de Inmunología. Hospital Universitario Puerta del Mar, Cádiz, Spain, [3]Área de Inmunología. UGC de Análisis Clínicos. Hospital Juan Ramón Jiménez, Huelva, Spain, [4]Unidad de Reumatología, UGC de Cirugía Ortopédica, Traumatología y Reumatología. Hospital Universitario Puerta del Mar, Cádiz, Spain, [5]Servicio de Inmunología, UGC de Hematología, Inmunología y Genética. Hospital Universitario Puerta del Mar, Cádiz, Spain.

Introduction: Autoantibody (Ab) secretion can be maintained by long-lived Ab-secreting cells (ASC) and by differentiation of auto-reactive B-Lymphocytes (ABL). However, their relative contribution to serum Ab production in SLE is not completely known. Objective: To detect ENA-specific ABL (ENA-ABL) and ASC producing anti-ENA Ab (ENA-ASC) and to analyse their relationship to anti-ENA Ab levels in serum in SLE patients. Material and methods: Blood samples from 20 SLE patients with serum anti-ENA Ab were studied. ENA-ABL were purified by immunoselection with ENA-bearing immunobeads (QUANTA-Flash®-ENA7, Werfen). ENA-ABL were stimulated in culture with anti-CD40 mAb plus IL-21 and BAFF and anti-ENA Ab secretion into the supernatants was measured. ENA-ASC were identified as cells capable to produce anti-ENA Ab spontaneously in culture. In serum and cultures, anti-ENA Ab and IgG were determined by chemiluminescence and ELISA, respectively. Results: ENA-ABL and ENA-ASC were detected in 15 and 10 patients, respectively. Four different profiles were observed. A majority of patients (8/20) showed a predominant ABL profile. A main ASC response was seen in 3 patients. A mixed profile, with both ABL and ASC, was detected in 3 patients. Finally, a negative profile characterised by non-appreciable ABL and/or ASC was seen in 6 patients. Conclusions: ENA-specific ABL and ASC could be responsible for serum anti-ENA Ab levels. Diverse profiles of ABL and/or ASC predominance were observed. Tracking auto-reactive ASC and ABL can represent a biomarker for using therapies blocking B-cells or ASC and a new tool for monitoring minimal residual autoimmune disease in SLE patients.

P.C2.10.09

Toll-like receptor 9 influences inflammatory arthritis and osteoclastogenesis

***A. Fischer**[1], S. Abdollahi-Rodsaz[2], A. Yau[3], E. Lönnblom[3], R. Holmdahl[3], G. Steiner[1];*
[1]Department of Rheumatology, Medical University of Vienna, Vienna, Austria, [2]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Medical Inflammation Research, Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.

Introduction. Release and insufficient removal of endogenous nucleic acids may trigger autoimmune reactions implicated in initiating systemic autoimmune diseases including rheumatoid arthritis (RA). The DNA sensing Toll-like receptor (TLR) 9 has been linked to pathogenic autoimmunity but its role in RA is unclear. Therefore, we investigated the role of TLR9 in in rats with pristane-induced arthritis (PIA) and in mice with streptococcal cell wall (SCW) induced arthritis. **Methods**. Rats were prophylactically treated with a TLR9 antagonist while SCW arthritis was induced in TLR9$^{-/-}$ mice. Arthritis was scored using established scoring systems, inflammation and bone erosions were quantified by histomorphometry. Serum levels of α-1-acid-glycoprotein (AGP), rheumatoid factor (RF) and IL-6 were analyzed by ELISA. Furthermore, the role of TLR9 in osteoclast differentiation was investigated *in vitro*. **Results**. In PIA, the treatment with the TLR9 antagonist led to significantly reduced inflammation, bone erosion and cartilage degradation accompanied by a reduction of AGP, IL-6 and RF. Moreover, the T cell-dependent phase of SCW arthritis was significantly suppressed in TLR9$^{-/-}$ mice. Remarkably, TLR7 and TLR9 mRNA levels differed in the course of *in vitro* osteoclastogenesis. Whereas TLR7 expression remained constant throughout osteoclastogenesis, expression of TLR9 was higher in precursor cells than in mature osteoclasts and stimulation with a TLR9 agonist (CpG) completely inhibited osteoclastogenesis. **Conclusions**. Taken together, the results suggest a role for TLR9 in the T cell-dependent phases of PIA and SCW arthritis and thus an important involvement of TLR9 in the initiation of autoimmune arthritis and during osteoclastogenesis.

Osteoclast progenitors expressing CCR2 are expanded in collagen-induced arthritis and may be involved in bone resorption intensity

***D. Flegar**[1,2], A. Sucur[1,2], A. Markotic[1,2], N. Lukac[3,2], N. Kovacic[3,2], T. Kelava[1,2], V. Katavic[3,2], K. Zrinski Petrovic[3,2], D. Grcevic[1,2];*
[1]Department of Physiology and Immunology, University of Zagreb School of Medicine, Zagreb, Croatia, [2]Laboratory for Molecular Immunology, Croatian Institute for Brain Research, Zagreb, Croatia, [3]Department of Anatomy, University of Zagreb School of Medicine, Zagreb, Croatia.

Introduction: Osteoclast progenitors (OCP) originate from myeloid lineage and mature to osteoclasts, specialized bone resorbing cells. Osteoclast mediated bone and joint destruction is characteristic for rheumatoid arthritis (RA). We investigated frequencies of different OCP subsets and their osteoclastogenic potential in mice with collagen-induced arthritis (CIA), a mouse RA model.
Methods: After receiving Ethical approval, C57BL/6 and DBA mice were immunized with chicken type II collagen to induce CIA, which was confirmed by micro-CT, histology and serum CTX levels. Distal tibia bone marrow (BM) cells were immunophenotyped for hematopoietic markers and chemokine receptor expression. Sorted OCP subsets were assessed for proliferative response by CFSE and TRAP+ osteoclasts number by culturing with M-CSF/RANKL. Mice developing CIA (day 15-23 after immunization) were treated *in vivo* with methotrexate (2mg/kg) and CCR2 receptor antagonist (CRA) (4mg/kg) to assess effect on OCP frequency.
Results: Arthritic mice showed histological presence of BM osteitis and bone destruction assessed by micro-CT and CTX levels. Frequency of CD45+B220-CD3-NK1.1-Ly6G-CD11b−/loCD115+ OCPs was significantly increased in CIA (54% vs. 26% in control), with specific expansion of CCR2+ subset. Regarding the CCR2 expression level, CCR2lo subset underwent through more divisions and generated multinucleated TRAP+ osteoclasts more efficiently, whereas CCR2hi subset generated osteoclasts only when cultured at high density. Our preliminary results indicate that combined methotrexate/CRA treatment may affect frequency of OCPs.
Conclusion: OCP subset expressing CCR2 may contribute to bone resorption in arthritis. Therefore, inhibition of CCL2/CCR2 signaling presents a new therapeutic approach to reduce osteoclast activity.

HISTONE DEACETYLASE 1 (HDAC1): A Novel therapetic target in patients with rheumatoid arthritis (RA)

***L. Göschl**[1], L. Müller[1], V. Saferding[1], S. Knapp[2], J. Backlund[3], P. Mathias[4], C. Scheinecker[1], J. Smolen[1], G. Steiner[1], W. Ellmeier[5], M. Bonelli[1];*
[1]Department of Rheumatology, MUW, Vienna, Austria, [2]Research Center for Molecular Medicine (CeMM), Austrian Academy of Sciences, Vienna, Austria, [3]Department of Medical Biochemistry and Biophysics, Medical Inflammation Research, Karolinska Institutet, Stockholm, Sweden, [4]Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland, [5]Division of Immunobiology, Institute of Immunology, Vienna, Austria.

Objectives: Certain CD4$^+$Tcells have been shown to be major drivers in RA. The expression of their key transcription factors is controlled by histone modifications which are mediated by histone deacetylases (HDAC). Indeed, pan HDAC inhibitors have been shown to be a potential therapeutic strategy. However, major side effects limit the clinical use and underline the need for more specific HDAC inhibitors. We therefore addressed the role of HDAC1 in the development of collagen-induced arthritis (CIA).
Methods: Mice with a Tcell specific deletion of HDAC1 (HDAC1cKO) were generated by using the CD4Cre/LoxP system. CIA was induced at week 8. Paraffin sections of the joints were analysed. Anti-CII antibody levels were determined by ELISA. Sera were analysed by multiplex assays. CCR6 expression in CD4$^+$Tcells was analysed by flow cytometry.

Results: Surprisingly *HDAC1cKO* mice were protected from arthritis. Anti-CII antibodies were detected in *HDAC1cKO* and *WT* mice. IL-17 was significantly decreased in the sera of *HDAC1cKO* mice when compared to *WT* mice, suggesting a role of HDAC1 in the development of Th17 cells. To see whether HDAC1 is involved in the regulation of the chemokine receptor 6 (CCR6), we stimulated $CD4^+$Tcells with IL-6. Significantly diminished levels of CCR6 were detected in $CD4^+$Tcells lacking HDAC1. This data supports the role of HDAC1 in the regulation of CCR6, which is indispensable for the migration of pathogenic Th17 cells and therefore for the development of arthritis.
Conclusion: Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of arthritis.

P.C2.10.12
Identification and analysis of anti-citrullinated protein antibodies in rheumatoid arthritis

*C. Ge[1], B. Xu[1], B. Liang[1,2], **Y. He**[1];*
[1]Section for Medical Inflammation Research, Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden, [2]Department of Pathophysiology, Key Lab for Shock and Microcirculation Research of Guangdong, Southern Medical University, Guangzhou, China.

Background This project aims to investigate the anti-citrullinated protein antibodies (ACPAs) isolated from patients with rheumatoid arthritis (RA). Such antibodies have a high diagnostic value owing to their high specificity in RA. However, it is still uncertain whether these ACPAs are pathogenic or regulatory. In this project, a series of antibodies isolated from RA patients will be studied in detail both regarding specificity and function. **Method** Four antibodies (entitled as E4, F3, L2 and L4) were expressed as chimeric monoclonal antibodies with murine Fc fragment and their specificity were tested using different peptides. Functional studies of E4 and F3 were performed in mouse collagen-antibody induced arthritis (CAIA) model. The crystal structures of the antigen binding fragment (Fab) of E4 in complex with different citrullinated peptides were solved using X-ray crystallography. **Preliminary results** All four ACPAs were identically reactive with citrullinated collagen II peptides whereas they might bind to different epitopes. Most importantly, E4 antibody exhibited a strong protective effect against arthritis and bound mainly to CD11b/c+ cells. Structural studies revealed that citrulline is a critical residue and additionally interacted with the neighbouring peptide backbone. **Future plan** We have demonstrated that some ACPAs could actually be regulatory in RA in terms of our preliminary functional and structural study, the next investigation will focus on the Fab-glycosylation, the interaction between ACPAs and FcR, the targets of ACPAs and the impact of ACPAs on antigen-presenting cells and T cell in the downstream.

La Paz University Hospital, Madrid, Spain.

Introduction: TNF inhibitors(TNFi) are widely used for the treatment of rheumatoid arthritis (RA). This study aims to analyse the profile of peripheral blood mononuclear cells (PBMC) after 6 months(m) of treatment with TNFi in order to find cellular biomarkers of response.
Methods: This was a prospective bi-center pilot study including 50 RA patients under TNFi therapy. PBMC were isolated from patients at baseline and 6m of treatment, and flow-cytometry analysed. Clinical activity at baseline and 6m of TNFi treatment was assessed by DAS28. Clinical remission (DAS28≤2.6) after 6m of treatment was considered as optimal response. The association between clinical remission and the percentage of change (Δ, 6m-0m) within each PBMC subset was analysed through multivariate log-regression model (odds ratio; 95% CI). All the analyses were adjusted by sex, age, concomitant-methotrexate, rheumatoid-factor and baseline-DAS28.
Results: Increased percentage of CD4+ T cells (ΔCD4+) was found after 6m of TNFi treatment in optimal responders; while suboptimal responders showed decreased percentage of this cell population (OR: 1.08; 95% CI: 1.01-1.16; p: 0.017). In addition, the percentage of B cells after 6m of TNFi treatment (ΔCD19+) decreased in optimal responders (OR: 0.7; 95% IC: 0.54-0.96; p: 0.024). This effect was essentially promoted by naïve B cells (OR: 0.7; 95% IC: 0.47-0.93; p: 0.017). The other PBMC subsets (monocytes, NK and CD8+ T cells) did not show statistical differences.
Conclusion: Our results demonstrate that CD4+ T and B cells may be useful as cellular biomarkers of response to TNFi in RA patients.
Funding: ISCIII (PI16/00474; PI16/01092)

Autoreactive B cells against citrullinated protein antigens in rheumatoid arthritis: pathogenic roles and prospects for targeted therapy

***H. Kristyanto**[1], L. P. Lelieveldt[2], E. I. van der Voort[1], D. L. Baeten[3], H. Spits[4], K. M. Bonger[2], H. U. Scherer[1], R. E. Toes[1];*
[1]Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands, [2]Department of Biomolecular Chemistry, Institute for Molecules and Materials, Radboud University, Nijmegen, Netherlands, [3]Department of Clinical Immunology and Rheumatology, Academic Medical Centre, Amsterdam, Netherlands, [4]Department of Cell Biology and Histology, Academic Medical Centre and AIMM Therapeutics, Amsterdam, Netherlands.

Introduction: Rheumatoid arthritis (RA) is characterized by the presence of disease-specific anti-citrullinated protein antibodies (ACPA) and remarkably responsive to the depletion of CD20+ B cells. This suggests that this B cell subset, and in particular ACPA-expressing B cells, play a central role in disease pathogenesis and could be relevant targets for therapeutic intervention.
Methods: We characterized ACPA-expressing B cells by flow cytometry in blood and synovial fluid (SF) of RA patients using streptavidin-tetramer technology and developed a dual-targeting prodrug strategy to eliminate these cells.
Results: The majority of ACPA-expressing B cells in RA blood displayed a memory phenotype (Bmem). In contrast to tetanus toxoid (TT)-specific Bmem, ACPA-expressing Bmem expressed Ki-67 and enhanced levels of CD19, CD20, CD27, HLA-DR, CD80 and CD86. In SF, ACPA-expressing B cells displayed a plasmablast/-cell phenotype and produced pro-inflammatory cytokines spontaneously. Using a cyclic citrullinated peptide (CCP) conjugated to Saporin, we could induce specific death of ACPA-expressing memory B cell clones *in-vitro*. To avoid neutralization of the antigen-drug conjugate by circulating ACPA, a carboxy-nitro-*p*-benzyl (CNBz) moiety was added to CCP-Saporin which diminished CCP recognition by ACPA. The CCP (CNBz)-Saporin prodrug could subsequently be activated in the vicinity of B cells by nitroreductase (NTR). Accordingly, NTR-treated CCP(CNBz)-Saporin induced ACPA-expressing B cell death as potently as CCP-Saporin.
Conclusion: We provide evidence that ACPA-expressing memory B cells express features by which these cells can drive inflammatory processes in RA pathogenesis. In addition, we developed an antigen-specific targeting approach for the directed elimination of this pathogenic B cell subset.

Intranodal administration of adipose mesenchymal stem cells reduces the severity of collagen-induced experimental arthritis

*P. Mancheño-Corvo[1], **M. Lopez-Santalla**[2], R. Menta[1], O. Delarosa[1], F. Mulero[3], B. Del Rio[1], C. Ramirez[1], D. Büscher[4], J. A. Bueren[2], J. Lopez-Belmonte[5], W. Dalemans[6], M. I. Garin[2], E. Lombardo[1];*
[1]Tigenix SAU, Madrid, Spain, [2]CIEMAT/IIS Fundación Jiménez Díaz/CIBERER, Madrid, Spain, [3]Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain, [4]Grifols, Barcelona, Spain, [5]Farma-Cros, Albacete, Spain, [6]Tigenix NV, Leuven, Belgium.

INTRODUCTION: Mesenchymal stem cells (MSCs) are multipotent stromal cells that contribute to tissue regeneration, among other effects, by modulating inflammation. In recent years, novel stem cell therapy protocols for the treatment of immune-mediated disorders such as rheumatoid arthritis have been proposed. It has been demonstrated that MSCs administered systemically migrate to the draining lymph nodes suggesting that homing of MSCs to the lymphatic system plays an important role in the mechanism of action of MSCs. In this study, we proposed that direct intranodal administration of MSCs could be an alternative route of administration for MSC-based therapy.
METHODS: We analyzed the efficacy of human expanded adipose-derived mesenchymal stem cells (eASCs) to modulate established experimental collagen-induced arthritis in mice (CIA).
RESULTS: Intranodal administration of eASCs was able to modulate established experimental arthritis with a concomitant reduction in bone destruction and reduced levels of anti-chicken collagen-II IgG. We also observed an increase in the levels of regulatory T cells ($CD25^+Foxp3^+CD4^+$ cells) and Tr1 cells ($IL10^+CD4^+$), in spleen and draining lymph nodes ultimately leading to a decline in the inflammatory/regulatory balance in the tissues. CONCLUSION: Intranodal administration of eASCs may represent an alternative treatment modality for cell therapy with eASCs since it is very effective in modulating established collagen-induced arthritis.

P.C2.10.17

How do glycans affect immune cells in Rheumatoid Arthritis?

A. Molhoek[1], *L. Hafkenscheid*[2], *R. Toes*[2], *S. van Vliet*[1], *Y. van Kooyk*[1];
[1]*VUmc, Amsterdam, Netherlands,* [2]*LUMC, Leiden, Netherlands.*

The fragment antigen-binding (Fab) domain of Anti-Citrullinated Protein Antibodies (ACPAs) was recently shown to be extensively glycosylated. Glycans play a key role in controlling innate and adaptive immunity and therefore we hypothesized that the glycans on ACPA may interact with glycan binding receptors to modulate immune responses in Rheumatoid Arthritis (RA). A whole blood flow assay was used to study glycan interactions with leukocytes. Leukocytes were isolated from blood and cells were incubated for 2 hours with known immunomodulatory glycoconjugates. Glycan binding and identification of cell subsets was assessed by flow cytometry. Increased sialic acid binding to B cells, monocytes and neutrophils was observed after neuraminidase treatment to free sialic acid-binding receptors on these cells. Our preliminary data indicates that ACPA binds to B cells, NK cells and neutrophils. In addition, this assay revealed high binding of mannose specifically to B cells and monocytes. Interestingly, to date no mannose binding has been observed on peripheral B cells. In conclusion, B cells appear to be superior in their interaction capacity with a variety of glycans, including the Fab glycan on APCA. This is an important finding because B cells play a key role in the pathogenesis of RA.

Pre-treatment leukocyte subsets as biomarkers for early identification of optimal responders to TNF inhibitors in rheumatoid arthritis

I. Nieto-Gañán[1], *B. Hernández-Breijo*[2], *C. Sobrino-Grande*[3], *C. García-Hoz Jiménez*[1], *V. Navarro-Compán*[2], *A. Martínez-Feito*[2], *J. Bachiller-Corral*[3], *G. Bonilla-Hernán*[2], *D. Pascual-Salcedo*[2], *G. Roy-Ariño*[1], *M. Vázquez-Díaz*[3], *A. Balsa*[2], *L. M. Villar-Guimerans*[1], *C. Plasencia-Rodríguez*[2], *E. Rodríguez-Martín*[1];
[1]*Immunology Department Hospital Universitario Ramón y Cajal and IRYCIS, Madrid, Spain,* [2]*Immuno-Rheumatology Research Group, IdiPaz. Hospital La Paz, Madrid, Spain,* [3]*Rheumatology Department Hospital Universitario Ramón y Cajal and IRYCIS, Madrid, Spain.*

Introduction: TNF inhibitors (TNFi) are the most common biological agents used as disease-modifying treatment in rheumatoid arthritis (RA). Although these drugs have contributed to change the natural history of RA, approximately 30-50% of patients do not respond to this therapy. Early identification of optimal responders is crucial in the clinical setting. We aimed to study if baseline percentages of different leukocyte subsets in peripheral blood(PBMCs) can contribute to identify RA patients who will respond to TNFi.
Material and methods: This was a prospective bi-center pilot study including 50 RA patients under TNFi therapy. Clinical activity was assessed at baseline and 6 months of treatment by disease activity score 28 (DAS28), considering optimal responders if they reached remission at 6 months (DAS28≤2.6). PBMCs were obtained before treatment and different leukocyte subsets were evaluated by flow cytometry in a FACSCantoII instrument. All the analyses were adjusted by sex, age, concomitant methotrexate, baseline DAS28 and rheumatoid factor through a multivariate log-regression model (odds ratio; 95% CI).
Results: Optimal responders showed higher percentage of B cells (OR=1.28; 95%; CI:1.06-1.54;p=0.011) and naive B cells (Bn; OR=1.50; 95%; CI:1.11-2.04;p=0.009) at baseline. We established cut-off values by ROC curves and analyzed the ability of both variables in predicting clinical response. Best results were obtained with Bn. Showing more than 2.55% of these cells associated with optimal response.
Conclusions: Although our data should be validated in larger cohorts, our results suggest that basal Bn percentages may contribute to identify optimal responders to TNFi in RA.

Anti-citrullinated protein antibodies (ACPA) hallmark the most disease-specific autoimmune response in Rheumatoid Arthritis (RA). ACPA-IgG are heavily *N*-glycosylated in the variable domain. The aim of the current study is to determine the frequency, origin and localisation of N-glycosylation sites in ACPA variable domains to understand the molecular basis for the remarkable glycosylation. ACPA-expressing B cells were isolated from blood of RA patients. Full-length immunoglobulin (Ig) transcripts of variable regions were obtained and analysed for the degree of somatic hypermutation (SHM) and the presence of *N*-glycosylation sites. Sequences of healthy donors (HD) served as control. 82% of ACPA-IgG, 67% of ACPA-Igκ and 47% of ACPA-Igλ contained ≥1 *N*-glycosylation sites. Despite extensive SHM, no correlation was observed between the SHM and the number of *N*-glycosylation sites. Distribution patterns and structural models indicated that *N*-glycosylation sites were predominantly located at the exterior of the molecule, away from the antigen-binding site. *N*-glycosylation sites in ACPA frequently required multiple somatic hypermutations. Computational modelling of a germinal center (CLONE algorithm), using germline counterparts of ACPA-IgG sequences, generated a pattern of *N*-glycosylation sites comparable to HD-IgG but different from ACPA-IgG. Our analyses revealed an abundance of *N*-glycosylation sites in ACPA clones. These sites frequently required multiple mutations and predominated at specific positions. This indicates that the introduction of such sites in ACPA variable regions might be a selective process that could be advantageous for the survival of ACPA-expressing B cells. Hence, variable domain *N*-glycosylation could facilitate the escape of autoreactive B cells from tolerance control mechanisms.

P.C2.10.20

Synovial tissue profiling in autoantibody positive at risk individuals reveals gene signatures associated with later development of rheumatoid arthritis

L. G. M. van Baarsen[1], *M. J. de Hair*[1], *J. F. Semmelink*[1], *I. Y. Choi*[1], *D. M. Gerlag*[1,2], *P. Tak*[1,3,4];
[1]*Amsterdam Rheumatology and immunology Center, Academic Medical Center|University of Amsterdam, Amsterdam, Netherlands,* [2]*Clinical Unit Cambridge, GlaxoSmithKline, Cambridge, United Kingdom,* [3]*Ghent University, Gent, Belgium,* [4]*University of Cambridge, Cambridge, United Kingdom.*

Objective: To study the molecular changes in synovium during the preclinical phase of rheumatoid arthritis (RA). **Methods:** We included sixty-seven individuals who were autoantibody positive and without any evidence of arthritis. All individuals underwent mini-arthroscopic synovial biopsy sampling of a knee joint at inclusion and were prospectively followed. Synovial biopsies were analyzed by transcriptomics and immunohistochemistry. **Results:** Genome-wide transcriptional profiling in a small test cohort (n=13: 6 developed arthritis) revealed many gene transcripts associated with arthritis development. Gene Set Enrichment Analysis revealed that synovial biopsies of individuals who developed RA after follow up display higher expression of genes involved in several immune response-related pathways (e.g. T cell and B cell receptor pathways, cytokine and chemokine signaling and antigen processing and presentation) compared with biopsies of individuals who did not develop RA. In contrast, lower expression was observed for genes involved in e.g. extracellular matrix receptor interaction, Wnt-mediated signal transduction and lipid metabolism. Subsequently, the expression level of 27 differentially expressed genes was validated by quantitative PCR in 61 RA-risk individuals (16 developed arthritis). Immunohistochemistry (n=54) showed an abundant expression of CXCL12 and CXCR4 already in most RA-risk individuals. Synovial biopsies from RA-risk individuals who developed arthritis were more likely to show a positive gp38 staining and lower lipid staining. **Conclusion:** This study clearly shows molecular changes appearing in synovial tissues before onset of arthritis in the absence of overt synovitis. Preclinical synovial alterations in immune response genes and lipid metabolism were associated with development of arthritis.

P.C2.11.01

T_H17 Cell Plasticity in Renal Autoimmune Disease

M. Zinke, *C. Kilian, B. Steglich, P. Bartsch, A. Borchers, N. Gagliani, U. Panzer, S. Huber, C. Krebs;*
Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.

The discovery of IL-17 producing $CD4^+$ cells as a new T helper subpopulation was a huge breakthrough in the understanding of autoimmunity. T_H17 cells drive inflammatory processes and thus play a pivotal role in autoimmune diseases including crescentic glomerulonephritis (cGN). The ability to transdifferentiate from pathogenic T_H17 cells into Interferon-γ -producing T_H1 cells or into T regulatory cells is strongly limited in cGN while T_H17 cells are highly flexible in other models of autoimmune diseases like EAE and anti-CD3 duodenitis. We aim to understand the factors that contribute to T_H17 cell stability by comparative analysis of mRNA expression profiles and functional *in vivo* testing. In order to do so, we are using T_H17specific reporter mice and autoimmune mediated *in vivo* models for multiple sclerosis (EAE), cGN, intestinal inflammation (Rb^{Hi}-transfer and anti-CD3) as well as S.aureus infection. By bioinformatic comparison of transcriptomes correlated with high vs. reduced T_H17 cell plasticity we were able to identify a number of potentially interesting genes, which may play a role in this regard. Furthermore, we found high abundances of IL-27RA on renal T_H17 cells. As a result of first functional experiments, IL-27 seem to have a protective effect in cGN *in vivo*. Compared to control mice, IL-27 treated cGN mice displayed strongly reduced kidney damage. Further experiments will potentially help to elucidate essential mechanisms for T_H17 cell mediated pathogenic effects in autoimmune kidney disease. The understanding of mechanisms which may push TH17 cells into a regulatory phenotype by modulation of related pathways has a high therapeutic potential.

P.C2.11.02

Liver X receptor agonist restores impaired atherosclerotic lesion regression in rheumatoid arthritis

D. Dragoljevic[1,2]*, W. Shihata*[1,2]*, I. P. Wicks*[3,4]*, A. J. Murphy*[1,2]*;*
[1]*Baker Heart and Diabetes Institute, Melbourne, Australia,* [2]*Monash University, Melbourne, Australia,* [3]*Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,* [4]*Royal Melbourne Hospital, Melbourne, Australia.*

The leading cause of premature mortality in patients with rheumatoid arthritis (RA) is atherosclerotic cardiovascular disease. Recently, we showed that atherosclerotic lesion regression was impaired in a murine model of RA. This was associated with cellular cholesterol efflux defects in bone marrow haematopoietic stem and progenitor cells, which promoted myelopoiesis, monocytosis and impaired atherosclerotic regression. Therefore, we hypothesised that enhanced cholesterol efflux using a Liver X Receptor (LXR) agonist, TO901317, would reduce monocytosis and improve atherosclerotic lesion regression in RA. Low-density lipoprotein receptor deficient mice were fed a western-type diet for 14wks to initiate atherogenesis, after which the mice were switched to chow to induce lesion regression. Mice undergoing regression of induced atherosclerotic lesions were divided into 3 groups; i) controls, ii) mice rendered arthritic using K/BxN serum, or iii) arthritic mice administered TO901317 (25mg/kg) daily for 2wks. TO901317 accelerated atherosclerotic lesion regression in arthritic mice, as evidenced by reduced lesion size, macrophage abundance and lipid content. Furthermore, improved lesion regression was independent to both circulating monocyte and cholesterol levels. TO901317 also reduced foam cell formation by reducing macrophage lipid loading, increasing *Abca1* and *Abcg1* expression, and increased ABCA1 protein in the atherosclerotic lesions of arthritic mice. Moreover, the severity of inflammatory arthritis was attenuated with TO901317. Taken together, we show that LXR agonism rescues impaired atherosclerotic lesion regression in a murine model of RA. This was independent of cholesterol and monocyte levels, and appeared to be due to enhanced cholesterol efflux and reduced foam cell development in atherosclerotic lesions.

P.C2.11.03

Targeting RORγt with antisense oligonucleotides impairs Th17 development in vitro

K. Schirduan, ***A. Uri****, S. Michel, F. Jaschinski;*
Secarna Pharmaceuticals GmbH&Co.KG, Munich, Germany.

RORγt is the master transcription factor of Th17 cells and constitutes an attractive therapeutic target for Th17-mediated diseases, like inflammatory bowel disease or psoriasis. Two factors are hampering the development of RORγt targeting drugs: 1) RORγt is located intracellularly and therefore inaccessible for antibodies. 2) RORγt and the ubiquitously expressed RORγ share the same DNA- and ligand-binding protein domains, impeding the development of RORγt-specific small molecule inhibitors. We here use an innovative antisense oligonucleotide based approach to selectively target RORγt but not RORγ. We designed LNA Gapmer antisense oligonucleotides (ASOs) specifically binding the RORC2 mRNA (encoding for RORγt) but not the RORC1 mRNA (encoding for RORγ) transcript variant. Treatment of a human lymphoma cell line (HDLM2) with our ASOs dose-dependently reduced RORC2 but not RORC1 mRNA expression without the need of transfection reagents. We further were able to suppress RORC2 mRNA expression in primary human $CD4^+$ T cells that were subjected to a Th17 differentiation protocol in presence of RORC2 specific ASOs. Impaired RORγt expression after ASO-treatment of human Th17 cells reduced the secretion of the Th17 effector cytokines IL-21 and IL-17. Production of IL-17 by human $CD4^+$ T cells was equally well supressed by ASOs and the small molecule inhibitors GSK805 and SR1001. Taken together, RORγt-specific ASOs provide a promising experimental therapy to treat Th17-driven diseases. Evaluation of RORγt-specific ASOs in relevant animal models will elucidate their therapeutic potential.

P.C2.11.04

Investigating clonality and function of CD4 T cells in the early phases of a murine model of experimental arthritis

S. Al-Khabouri*, R. A. Benson, C. T. Prendergast, J. M. Brewer, P. Garside;*
Institute of Infection Immunity and Inflammation, Glasgow, United Kingdom.

Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that is characterised by synovial inflammation and joint erosion. $CD4^+$ T cells have been shown to play a key role in disease progression, and their ability to infiltrate joints is associated with perpetuation of local and systemic inflammatory responses. A diverse range of T cell receptor (TCR) usage has been demonstrated in RA patients, however how such diversity arises and is shaped remains unclear. Understanding this will be important for the development and application of antigen-specific therapeutic tolerance regimes. Using an experimental murine model of early arthritis, we find that the initial articular $CD4^+$ T cell response is oligoclonal in nature, with enrichment of several TCRVβ chains in the inflamed joint. The $CD4^+$ T cell response was also determined in the context of antigen and non-specific articular inflammation and the TCRVβ chain bias observed was found to be associated with an antigen driven response. Using next-generation sequencing, CDR3β sequences were analysed to determine how $CD4^+$ clonal diversity develops with disease progression and what the relative contribution of cells specific for joint antigens versus those of irrelevant specificity are to the progression of experimental arthritis. Identifying $CD4^+$ T cell clones and understanding Vβ chain usage in early RA will aid in delineating the events propagating disease. Moreover, understanding the evolution of articular $CD4^+$ T cell responses in the context of antigen specificity will inform future development of regimes to reinstate self-tolerance.

P.C2.11.05

Extracellular vesicles in rheumatoid arthritis synovial fluid contain an immunoregulatory cargo of protein and RNA

A. D. Foers[1,2]*, A. L. Garnham*[1,2]*, S. Chatfield*[1,2,3]*, L. F. Dagley*[1,2]*, A. I. Webb*[1,2]*, G. K. Smyth*[1,4]*, L. Cheng*[5]*, A. F. Hill*[5]*, I. P. Wicks*[1,2,3]*, K. C. Pang*[1,6,7]*;*
[1]*The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia,* [2]*Department of Medical Biology, University of Melbourne, Parkville, Australia,* [3]*Department of Rheumatology, Royal Melbourne Hospital, Parkville, Australia,* [4]*School of Mathematics & Statistics, University of Melbourne, Parkville, Australia,* [5]*Department of Biochemistry and Genetics, La Trobe Institute for Molecular Science, La Trobe University, Bundoora, Australia,* [6]*Department of Paediatrics, University of Melbourne, Parkville, Australia,* [7]*Murdoch Children's Research Institute, Parkville, Australia.*

Introduction In rheumatoid arthritis (RA), extracellular vesicles (EVs) are associated with both the propagation and attenuation of joint inflammation and destruction. However, specific EV content responsible for these processes is largely unknown. Investigations into identifying EV content are confounded by challenges in obtaining high-quality EV preparations from synovial fluid (SF). We recently developed a novel, size exclusion chromatography-based method of EV isolation capable of high-quality enrichments from SF (Foers *et al.*, *J Extracell Vesicles*, 2018). Here, we employed this method to investigate EV protein and RNA in SF obtained from RA and osteoarthritis patients. **Methods** Using our size exclusion chromatography-based approach, SF EVs were purified and subject to proteomics and RNAseq. Differences in protein, mRNA, and small RNA were analysed between RA and osteoarthritis patients, and between RA patients with high- and low-disease activity. **Results** Proteomics revealed RA SF EVs contain proteins associated with promoting inflammation, including tyrosine-protein kinase FER (a positive regulator of NF-κB) and components of the membrane attack complex. Further gene ontology analysis revealed an enrichment for various immunological processes, including cell-adhesion and leukocyte-mediated immunity. Additionally, we observed high-levels of the RA susceptibility gene HLA-DRB1. RNAseq revealed RA patients with high-disease activity are enriched for transcripts associated with both driving (e.g. IL-8) and attenuating (e.g. hsa-miR-27a) inflammation. **Conclusion** Our data suggest that in RA, SF EVs propagate inflammation via a pro-inflammatory protein cargo. The enrichment of HLA-DRB1 warrants further investigations into whether SF EVs present autoantigen via MHC-II. The RNA cargo suggests SF EVs traffic protein-encoding and regulatory transcripts to modulate the inflammatory phenotype of recipient cells.

P.C2.11.07

Regulation of CD20 expression by tetraspanin CD37

P. M. Hagemann[1]*, E. H. Duitmann*[1]*, F. Koch-Nolte*[2]*, F. Haag*[2]*, R. A. Manz*[3]*, Z. Orinska*[1]*;*
[1]*Research Center Borstel, Borstel, Germany,* [2]*Institute for Immunology, UKE, Hamburg, Germany,* [3]*Institute for Systemic Inflammation, Luebeck, Germany.*

B cell depletion therapy with CD20 monoclonal antibodies (mAbs) is used in treatment of lymphomas and autoimmune diseases including rheumatoid arthritis and multiple sclerosis. Among newly developed B cell depleting antibodies, CD37 is a promising candidate already in clinical trial phase II. Here we identified a crosstalk between CD20 and CD37 and indicated CD37 as a negative regulator of CD20 expression. CD37 is highly conserved in mice and humans. This makes the mouse an ideal model system to investigate CD37 induced B cell depletion and to identify potential side effects of CD37 mAb treatment. To explore the possible effects of B cell depletion therapy with CD37-specific antibodies, we generated mAbs against murine CD37 and mapped two different binding epitopes with "back to rat" mutation strategy. We show that in vitro generated plasma blasts had higher CD20 levels when co-stimulated with CD37 mAbs, compared to isotype control. CD37 mAbs alone did not activate splenic B cells, measured by CD69, CD86, MHC class II or CD25 upregulation, but lead to reduced viability (comparable with CD20 mAb control). However, CD37 mAb treatment induced an increase of proliferation in a subset of B cells, indicating activation of pro-survival pathway. In spleen, transitional and marginal zone B cells showed the highest CD37 expression levels as compared to follicular B cells. Interestingly, B cells from *Cd37-/-* mice showed strongly upregulated CD20 expression levels. A better understanding of the CD37 CD20 interaction will improve B cell directed therapies.

P.C2.11.09

L-glutamine attenuates collagen-induced arthritis via inhibition of p38/NF-kB signaling in a MAPK phosphatase (MKP)-1-dependent manner

*S. Jeong, k. Kim, **S. Im**;*
Chonnam National University, Gwangju, Korea, Republic of.

L -Glutamine (Gln), a nonessential amino acid, is abundant in the plasma. Gln has been shown to have anti-inflammatory property. As a result, Gln protects animals from endotoxic shock, and attenuates many inflammatory diseases. Regarding the anti-inflammatory properties of Gln, we have shown that Gln can effectively deactivate both p38 MAPK and cytosolic phospholipase A_2 ($cPLA_2$) by rapid induction of MAPK phosphatase (MKP)-1. In this study, we explore the possibility that Gln can ameliorate collagen-induced arthritis (CIA). Oral Gln intake (0.5 g/kg/day) attenuated not only severity of arthritis based on clinical scores, hind paw thickness, and radiographic and pathologic findings, but also local and systemic levels of proinflammatory cytokines, such as TNF-α, IL-1β, IL-6, and leukotriene B4. Oral Gln inhibited p38 phosphorylation and NF-κB activation in the inflammed tissues. Gln administration resulted in early and enhanced MKP-1 induction. Importantly, MKP-1 small interfering RNA (siRNA), but not control siRNA, significantly abrogated the Gln-mediated 1) induction of MKP-1; 2) attenuation of arthritis; 3) inhibition of p38 phosphorylation, NF-κB activation and tissue levels of proinflammatory cytokines. These data indicated that Gln ameliorated CIA via inhibition of p38/NF-κB signaling in a MKP-1-dependent manner.

P.C2.11.10

Insulin modulation of TLR4 expression in murine macrophages: possible involvement of PI3K/Akt and ERK1/2 signalling pathway

***S. Pal**, S. Maitra;*
Visva-Bharati University, Bolpur, India.

Toll-like receptor (TLR) mediated diet-induced obesity or insulin resistance is involved in the pathogenesis of type 2 diabetes. In obesity, macrophage accumulation in insulin target tissues (visceral adipose tissues) and TLR4 dependent up-regulation of cytokines promotes chronic inflammation, which in its turn leads to diabetic complications including nephropathy, atherosclerosis and retinopathy. Conversely, reducing glucose levels with insulin therapy is associated with decreased inflammation, mortality and incidence of sepsis in critically ill patients. However, importance of insulin signalling in macrophage function and polarization is not well characterized and molecular mechanisms underlying insulin modulation of TLR4 induction in murine macrophages is yet to be determined. In this study participation of insulin-mediated PI3K/Akt and ERK1/2 signalling during high glucose (HG) and/or lipopolysaccharide (LPS)-induced TLR4 expression in murine macrophages has been investigated. Present results show that while expression of insulin receptor (IR) remains unchanged, insulin alone could attenuate HG and/or LPS -induced TLR4 expression in duration-dependent manner, at both mRNA as well as protein level. Further, insulin either alone or in presence of HG and LPS could up-regulate PI3K/Akt and ERK1/2 phosphorylation (activation) *in vitro*. More interestingly, in PI3K as well as ERK1/2 inhibited cells (using wortmannin and U0126 respectively), insulin failed to reverse HG or LPS action on TLR4 induction completely. Collectively, participation of PI3K/Akt and ERK1/2 signalling cascades has pivotal influence in insulin modulation of TLR4 expression induced by glucose or LPS in murine macrophages. This area of research is beneficial for further understanding of the interplay between insulin signalling and host immune system in metabolic diseases.

P.C2.11.11

Are controls in trans the production of medullary thymic epithelial cells expressing Ly6C/Ly6G

***M. Matsumoto**, J. Morimoto, M. Matsumoto, H. Nishijima;*
Institute for Enzyme Research, Tokushima, Japan.

Medullary thymic epithelial cells (mTECs), which express a wide range of tissue-restricted self-antigens (TRAs), contribute to the establishment of self-tolerance by eliminating autoreactive T-cells and/or inducing regulatory T-cells. Aire controls a diverse set of TRAs within Aire-expressing cells by employing various transcriptional pathways. As Aire has a profound effect on transcriptomes of mTECs including TRAs not only at the single-cell but also the population level, we suspected that Aire ($Aire^+$ mTECs) might control the cellular composition of the thymic microenvironment. Here, we confirmed that this is indeed the case by identifying a novel mTEC subset expressing Ly6 family protein whose production was defective in Aire-deficient thymi. Re-aggregated thymic organ culture experiments demonstrated that Aire did not induce the expression of Ly6C/Ly6G molecules from mTECs as Aire-dependent TRAs in a cell-intrinsic manner. Instead, $Aire^+$ mTECs functioned in trans to maintain $Ly6C/Ly6G^+$ mTECs. Thus, Aire not only controls TRA expression transcriptionally within the cell, but also controls the overall composition of mTECs in a cell-extrinsic manner, thereby regulating the transcriptome from mTECs on a global scale.

P.C2.11.12

33°C provides T regulatory cells stability

***K. Piekarska**[1], N. Filipowicz[2], A. Piotrowski[2], M. Gucwa[2], J. Sakowska[3], K. Vogt[4], B. Sawitzki[4], J. Siebiert[5], P. Trzonkowski[3], N. Marek-Trzonkowska[1];*
[1]Laboratory of Immunoregulation and Cellular Therapies, Department of Family Medicine, Medical University of Gdansk, Gdańsk, Poland, [2]Department of Biology and Pharmaceutical Botany, Medical University of Gdańsk, Gdańsk, Poland, [3]Department of Clinical Immunology and Transplantology, Medical University of Gdansk, Gdańsk, Poland, [4]Institute for Medical Immunology, Charité – Universitätsmedizin Berlin, Berlin, Germany, [5]Department of Family Medicine, Medical University of Gdańsk, Gdańsk, Poland.

Introduction – Regulatory T cells (Tregs) play crucial role in self-tolerance and tissue homeostasis. Nowadays, regulatory T-cell therapy is considered safe and effective, for instance in type 1 diabetes treatment. However, Tregs lose their characteristic phenotype and suppressive potential during expansion ex vivo.
Methods – Tregs were freshly isolated from buffy coats obtained from 13 volunteer blood donors. After sorting Tregs were equally divided into 2 separate cultures and expanded at 37°C and 33°C. Each 7th and 14th day of the expansion Tregs were checked for phenotype and function with flow cytometry. In addition, DNA methylation of the Treg-Specific Demethylated Region (TSDR) and RNA-seq were performed for Tregs cultured in both studied culture temperatures, as well as for CD4+ effector T cells (Teffs) derived from the same donors.
Results – 33°C induces robust proliferation of Tregs (4.5-fold higher cell counts as compared with Tregs expanded at 37°C), enhances expression of FoxP3, CD25, Helios, CD39, and CTLA-4 in Tregs and keeps Treg phenotype stable during the culture. Tregs expanded at 33°C were characterized by significantly higher frequency of cells with demethylated TSDR and presented remarkably anti-inflammatory phenotype after culture *in vitro*, as compared with cells at 37°C.
Conclusion – Tregs expanded at 33°C have stronger immunosuppressive potential. Mild hypothermia can preserve Treg phenotype, function and accelerate their proliferation, responding to unanswered question- how to preserve Treg stability in vitro.

Anti-Serotonin antibodies in Fibromyalgia patients

***L. Gimeno**[1], A. Mrowiec[1], P. Martinez[1], G. Salgado-Cecilia[1], E. Novoa- Bolivar[1], J. M. Bolarin[1], O. Montes-Ares[1], A. Bermudez-Torrente[2], A. Martinez-Leon[3], A. Minguela-Puras[1], I. Lozano- Olmos[4], R. Klein[5], A. M. Garcia-Alonso[1];*
[1]Immunology Service-University Clinical Hospital Virgen de la Arrixaca-IMIB, El Palmar, Spain, [2]Rheumatology Service-University Clinical Hospital Virgen de la Arrixaca-IMIB, El Palmar, Spain, [3]Medical Family Health San Andres-Servicio Murciano de Salud, Murcia, Spain, [4]Psychiatry Service-University Clinical Hospital Virgen de la Arrixaca-IMIB, El Palmar, Spain, [5]Laboratory for Immunopathology and HLA, Eberhard Karls University Tübingen, Tübingen, Germany.

Fibromyalgia (FM) is an idiopathic disorder characterized by widespread nonarticular musculoskeletal pain accompanied by fatigue, sleep and memory disorders and mainly affecting women. The etiopathogenesis of FM is still unknown but evidence suggests an inflammatory and autoimmune origin characterized by an autoantibody pattern. Presence of antibodies to serotonin (5-hydroxytrypyamine) has been found in about 70% of German FM patients and appears to be characteristic for this disease. Our aim was to evaluate the presence of antibodies to serotonin in serum of Spanish type I FM patients. The study included 156 clinically defined FM patients and 153 healthy controls. Sera from patients and control subjects were tested by ELISA against Serotonin. Anti-serotonine antibodies were found in 65 % of the patients suffering from FM. Statistically significant difference was found with respect to healthy controls that presented 14% ($Pc<0.05$). Our data corroborate German results, presence of antibodies to serotonine in FM patients.
The diagnostic relevance of these antibodies is supported by the absence of anti-serotonin antibodies in other rheumatic disorders. The association of anti-serotonine antibodies with psychiatric disorders in FM is thought to represent at least partially a dysregulation of the serotonergic neurotransmitter system in the central nervous system. Although these immunological results are still beyond our understanding, they could indicate an autoimmune component of the disease regardless of inflammatory response or alterations of the neuroendrocrine system. Broader studies will be necessary in the future.

P.C2.11.14

Immune gene signature in kidneys of patients diagnosed with antineutrophil cytoplasmic antibody-associated vasculitis

*E. García Moreno[1], R. De la Varga Martínez[2], C. Rodriguez Hernández[1], **A. Sampalo Laínz**[1];*
[1]Immunology Department, Puerta del Mar Hospital, Cádiz, Spain, [2]Immunology Department, Virgen del Rocio Hospital, Sevilla, Spain.

Introduction: Antineutrophil cytoplasmic antibody-associated vasculitis (AAV) are systemic necrotizing small-vessel vasculitis characterized by glomerulonephritis, granulomatous inflammation and pauci-immune necrotizing small-vessel vasculitis. Knowledge regarding the mechanisms involved in AAV has increased. Nevertheless, relapsing renal disease is still a major issue. Our objective was to study the immune-related gene expression in kidneys from patients diagnosed with AAV.

Materials and Method: The .cel data files were uploaded to Gene Expression Omnibus Database (series accession number GSE104948 and GSE104954). We select 46 glomerular and tubular samples from kidney biopsies from 23 patients diagnosed with AAV and, as a control, from 21 transplant living donors. Differential gene expression analysis was performed by using the R/Bioconductor package, *limma.* For biological function analysis, DAVID Bioinformatics Resources were used.
Results: A total of 1783 differentially expressed genes in patients were analysed. The 412 genes with the same pattern of expression (up or down regulated) in both the glomerular and tubular tissues were selected. The functional analysis of the 311 up regulated genes revealed that there was a statistically significant enrichment in pathways involved in chemokine signalling (25 genes), Cytokine-cytokine receptor interaction (25), leukocyte transendothelial migration (14), complement cascade (10), phagocytosis(11), and Natural killer cell mediated cytotoxicity (14).
Conclusions: We have found an immune and inflammatory gene signature in kidneys from AVV patients. Most of up-regulated genes were related to cytokines, chemokines and other factors involved in the activation, growth and movement of immune cells. Therefore, they could be potential targets in renal AAV.

P.C2.11.15
Human DC-SIGN and CD23 do not bind directly to sialylated human IgG

R. Temming[1], *G. Dekkers*[1], *S. van de Bovenkamp*[1], *A. Bentlage*[1], *T. Rispens*[1], *R. Plomp*[2], *M. Wuhrer*[2], *G. Vidarsson*[1];
[1]*Sanquin, Amsterdam, Netherlands,* [2]*LUMC, Leiden, Netherlands.*

The precise mechanism underlying the anti-inflammatory effect of intravenous immunoglobulin (IVIg) therapy remains to be fully elucidated. The potential role of sialylated IgG within IVIg has drawn considerable interest, because this fraction has been found to be more therapeutically active in some mouse models. It has been proposed that upon Fc-sialylation, IgG undergoes a conformational change resulting in closure for conventional FcγRs and simultaneous opening for SIGNR-1 (homologue of human DC-SIGN) and CD23. These latter receptors have been demonstrated to be responsible for the IVIg effect of sialylated human IVIg in mouse models.
However, the precise mechanisms of the interaction between human IgG and DC-SIGN/CD23 are unknown and await confirmation, particularly in the human setting.
This study dissected the binding of human IgG1-glycoforms to DC-SIGN/CD23 in their native configuration. While cells expressing these receptors bound to their native ligands, no binding was observed by FACS regardless of sialylation. More sensitive cellular surface plasmon resonance imaging, to study avidity effects, also did not show binding of any antigen-complexed IgG-glycoform.
In conclusion, these findings indicate that no direct binding between human IgG and DC-SIGN/CD23, regardless of the glycosylation status. This suggests that previously obtained mouse data does not apply for humans.

P.C2.11.16
Immunomodulatory drugs humanization do not avoid immunogenicity

L. Díez Alonso[1,2], *E. Gómez Massa*[1,2], *L. Naranjo Rondán*[1,2], *O. Cabrera Marante*[1,2], *A. Serrano Hernández*[1,2];
[1]*Hospital Universitario 12 de Octubre, Madrid, Spain,* [2]*Instituto de Investigación, Hospital Universitario 12 de Octubre, Madrid, Spain.*

Biological immunomodulatory drugs blocking TNF-α mediated responses are largely used as a treatment for immuno-mediated diseases. Despite its beneficial effects, the treatment may be complicated by the development of unwanted immunogenicity. The development of anti-drug antibodies is associated with important clinical impact in terms of safety and efficacy. The aim of our study was to asses if the origin of the biological drug (murine, humanized or human) affects antibody development.
Blood samples from 484 patients treated with these immunomodulatory drugs at 12 Octubre Hospital were collected during 29 moths between 2016 and 2018. All serum samples were evaluated for drug levels and those that resulted in undetectable drug levels were evaluated for the presence of non-isotype specific anti-drug antibodies using a commercially available bridging format ELISA kit (Promonitor®, Progenika Biopharma S.A., Spain), according to the manufacturer's instructions.
Twenty three out of 257 patients with murine monoclonal antibody infliximab (8.95 %), 21 out of 207 (10.14%) patients with human monoclonal antibody adalimumab and any patient with human recombinant protein etanercept developed anti-drug antibodies. The anti-drug antibodies presence didn't seem to be significantly different between infliximab (murine) and adalimumab (human). Anti-drug antibodies triggers negatively influences to the treatment response so it is important to determine the factors that can promote its development. In this study, we demonstrate that the origin of biological immunomodulatory drugs do not affect the later anti-drug antibody production. Owing to these monoclonal antibodies are produced in the same cell line, post-translational modifications could be the shared immunogenic cause.

P.C3.01.01
The glucocorticoid receptor in recipient cells keeps cytokine secretion in acute graft-versus-host disease at bay

T. K. Baake;
Institute for Cellular and Molecular Immunology, Georg-August-University, University Medical Center, Göttingen, Germany.

Introduction: Acute Graft-versus-host disease (aGvHD) is a life-threatening complication of hematopoietic stem cell transplantation (HSCT) and considered as the main risk factor for transplant-related morbidity and mortality. First-Line therapy of GvHD is usually accomplished by glucocorticoid (GC) application but the mechanisms and target cells of this treatment regimen are not yet fully understood. Objectives: Here we analyzed the role of the glucocorticoid receptor (GR) in recipient myeloid cells and determined how its deletion in mice influences mortality, clinical symptoms, intestinal tissue damage as well as local and systemic cytokine production after allogeneic HSCT. Materials & methods: A total MHC-mismatched model of allogeneic HSCT was used to induce aGvHD in GR^{lysM} mice lacking the GR in myeloid cells. Bone marrow and purified T cells were isolated from wildtype C57BL/6 mice and transferred into irradiated GR^{flox} and GR^{lysM} BALB/c mice. The disease course was followed over a period of 6 weeks, histological and immunological analyses were performed on day 4, 6 and 8 post-transplant. Results: Deletion of the GR in recipient myeloid cells strongly exacerbates aGvHD, an effect which is unrelated to local GC effects in GvHD target organs but rather caused by uncontrolled systemic cytokine release. Conclusion: The regulation of recipient myeloid cells by GC is essential to prevent a lethal cytokine storms after allogeneic HSCT. Selectively targeting this cell type might therefore offer a new strategy to treat aGvHD patients.

P.C3.01.02
Outcome of mesenchymal stromal cell treatment in chronic GvHD predicted by thymic function: A phase II clinical study

E. Boberg[1], *L. von Bahr*[1], *N. Heldring*[2], *G. Afram*[3], *E. Alici*[1], *E. Iacobaeus*[1], *K. Garming Legert*[4], *P. Petzelbauer*[5], *P. Ljungman*[6], *R. Sugars*[4], *N. Kadri*[1], *K. Le Blanc*[1];

Introduction: Treatment options are limited for chronic graft-versus-host-disease (cGvHD) refractory to steroid treatment. Infusion of mesenchymal stromal cells (MSCs) is a promising alternative but the mechanism of action has not been established.
Methods: 11 patients with severe steroid refractory cGvHD were treated with repeated infusions of allogeneic bone marrow MSCs. Clinical response was evaluated using the National Institutes of Health (NIH) criteria. Immunophenotyping and cytokine analysis was conducted on blood samples taken before, and at several time points shortly after each infusion. Skin biopsies were taken before and after treatment.
Results: Nine patients completed the treatment protocol and were evaluated for response. Six patients responded to MSC therapy according to NIH criteria. The responders had significantly higher proportions of naive Th-cells (CD3+CD4+CD45RA+CD27+) and activated naïve B cells (CD19+IgD+CD38low). The proportion of Ki67+ naïve Th-cells was similar in both responders and non-responders, while the percentage of recent thymic emigrants among naïve CD4+ T-cells were higher in responders, suggesting a better thymic function. Several miRNAs increased one hour after MSC infusion in all patients, followed by transient increases in absolute numbers of naïve and regulatory T- and B-cells after 7 days in responders. Long term reductions were seen in the cytokines CXCL2 and CCL2 in responders, while the levels of CXCL9, CXCL10, CXCL12, TNFα and IL-6 increased in non-responders. Skin biopsies showed resolution of epidermal pathology.
Conclusion: Our data highlights the importance of the recipient immune phenotype for response to MSC treatment of cGvHD and suggests a link to thymic function.

P.C3.01.03
In silico analysis of alloantigen landscape in HLA-matched transplantation

N. A. Bykova*, D. B. Malko, G. A. Efimov;*
National Research Center for Hematology, Moscow, Russian Federation.

Minor histocompatibility antigens (MiHAs) are alloantigens in the context of HLA-matched allogeneic hematopoietic stem cells transplantation (allo-HSCT). Due to the crucial role they play in graft versus leukemia effect MiHAs were suggested as possible targets for immunotherapy. However, the restricted number of clinically relevant MiHAs known so far limits their applicability. To make anti-MiHA therapy broadly usable systematic discovery of novel MiHAs is needed. In the current study we performed in silico analysis of the genomic data to describe basic features of MiHA landscape. For this, pairs of samples were arbitrary selected from 1000 Genome project, as donor and recipient. Unique peptides found in the recipient genome that were predicted to bind MHC molecules with high affinity were considered as potential MiHAs.

We further compare the results with known and mass spectrometry (MS) predicted MiHAs. The analysis demonstrated that at the moment our knowledge about MiHAs is largely inconsistent: MS approach to predict new MiHAs poorly reproduces known MiHAs, probably missing significant amount of potentially relevant MiHAs; the ratio of co-dominant/dominant MiHAs is inconsistent between in silico predicted and MS predicted or known MiHAs; MS predicted peptides are biased towards high allele frequency of immunogenic allele, which is suboptimal for usage in immunotherapy. Lower estimations of in silico approach suggest that there are at least several dozen strong MHC-binding SNP-associated peptides in the allele frequency region optimal for off-the-shelf therapeutics, that are still not experimentally tested for immunogenicity. Funding was provided by Russian Science Foundation grant 17-15-01512.

P.C3.01.04

Discovery of HLA class I-restricted minor histocompatibility antigens by a new approach for whole genome association scanning

***K. J. Fuchs**, A. E. Adriaans, M. W. Honders, E. D. van der Meijden, M. J. Pont, R. Monajemi, S. M. Kielbasa, P. A. ,t Hoen, C. A. van Bergen, J. Falkenburg, M. Griffioen;*
Leiden University Medical Center, Leiden, Netherlands.

Minor histocompatibility antigens are polymorphic peptides presented on the cell surface by HLA molecules. After allogeneic stem cell transplantation (SCT) as treatment for hematological malignancies, genetic differences in single nucleotide polymorphisms (SNPs) between patient and donor result in presentation of minor histocompatibility antigens that are recognized by donor T-cells. These T-cells can induce the favourable Graft-versus-Leukemia effect, but also mediate undesired Graft-versus-Host Disease. In our laboratory, whole genome association scanning has been developed to identify minor histocompatibility antigens. In this method, donor T-cells isolated from patients after allogeneic SCT are tested for recognition of a panel of 80 B-lymphoblastoid cell lines, and SNPs that strongly associate with T-cell recognition are subsequently validated to encode the antigens. The number of SNPs that were measured for this panel, however, was limited to one million. Utilizing a new panel of 191 B-cell lines, which are sequenced in the 1000 Genome Project, we now optimized the approach and increased SNP coverage to 12 million. Furthermore, while our previous panel was restricted to few HLAs, the new panel includes six common HLAs. This approach for whole genome association scanning has been successfully applied and various new minor histocompatibility antigens have been found. The aim is to use the optimized method to identify the dominant repertoire of HLA class I-restricted minor histocompatibility antigens, since knowledge about mismatched antigens may allow for a personalized treatment after transplantation as well as a more directed donor selection thereby contributing to a better outcome of patients treated with allogeneic SCT.

P.C3.01.05

The impact of stem cell graft γδT cells on clinical outcome after allogeneic hematopoietic stem cell transplantation

***A. Gaballa**[1], A. Stikvoort[1], B. Önfelt[2,1], J. Mattsson[1], M. Sundin[1], E. Watz[1], M. Uhlin[1,2];*
[1]Karolinska Institutet, Stockholm, Sweden, [2]Royal Institute of Technology, Stockholm, Sweden.

The impact of donor graft composition of T cells on the clinical outcome following allogeneic hematopoietic stem cell transplantation (HSCT) has been thoroughly investigated. However, most of studies have focused on the role of alpha beta ($\alpha\beta^+$) T cells and less attention has been given to the impact of gamma/delta ($\gamma\delta^+$) T cells. Whether $\gamma\delta^+$ T cells are beneficial or not for patient outcome, especially with regards to Graft versus Host Disease (GvHD) is still questionable. In this study, we analysed samples from 105 donor grafts, and the frequencies of $\gamma\delta^+$ T cell subsets were correlated with the clinical outcome. We show for the first time that grafts containing higher proportions of CD8+γδ T cells were associated with increased cumulative incidence of aGvHD II-III. We also found that graft frequency of CD27+γδ T cells was inversely correlated with CMV reactivation and relapse. Our findings illustrate the importance of better understanding of the role played by distinct γδ T cell subsets in allogeneic HSCT.

P.C3.01.07

The CD73/A2A signalling axis impacts graft-versus-host disease in a humanised mouse model

***N. J. Geraghty**, S. R. Adhikary, D. Watson, R. Sluyter;*
University of Wollongong, Wollongong, Australia.

Introduction: Graft-versus-host disease (GVHD) is a major cause of mortality following allogeneic hematopoietic stem cell transplantation. GVHD occurs when T cells in the graft cause inflammatory damage to host tissues. Ecto-5'-nucleotidase (CD73) generates extracellular adenosine, which activates the adenosine 2A (A2A) receptor to limit T cell responses. In allogeneic mouse models of GVHD, CD73 or A2A blockade worsens, whilst A2A activation limits disease. The current study examined the role of the CD73/A2A signalling axis in a humanised mouse model of GVHD. **Material and Methods:** NOD-SCID-IL2γ^{null} (NSG) mice, injected i.p. with $10x10^6$ human (h) peripheral blood mononuclear cells, were subsequently injected i.p. with αβ-methyleneADP (CD73 antagonist) or CGS21680 (A2A agonist) for 6 or 14 days, respectively. GVHD development was assessed by weight loss, clinical parameters, survival and histology. Immune cell markers and cytokines were analysed by flow cytometry. **Results:** Neither CD73 blockade or A2A activation impacted initial human leukocyte engraftment or survival. CD73 blockade worsened GVHD as evidenced by increased weight loss, liver histology and serum hIL-2. Contrary to expectations, A2A activation increased weight loss, decreased human regulatory T cells and increased serum hIL-6. A2A activation however decreased serum hTNF-α and hIL-2, but did not alter histology of target tissues. **Conclusion:** CD73 blockade or A2A activation reduces the health of mice in this humanised model of GVHD. The CD73 blockade effects may be explained by accumulation of proinflammatory ATP rather than reduced adenosine production. The effects of A2A activation may reflect reduced metabolism or food intake rather than GVHD per se.

P.C3.01.08

The fast NKG2C+ NK "memory" expansion in CMV reactivation patients post allogeneic Stem Cell Transplantation

***N. Hassan**[1,2], J. Zuo[1], S. Eldershaw[1], J. Nunnick[3], P. Moss[1,3];*
[1]Institute of Immunology and Immunotherapy, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [2]Institute of Cancer and Genomic Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [3]Birmingham Health Partners, Centre for Clinical Haematology, Queen Elizabeth Hospital, Birmingham, United Kingdom.

Introduction: Human cytomegalovirus (HCMV) reactivation in allogeneic haematopoietic stem cell transplantation (HSCT), regularly leads to HCMV disease and can cause serious morbidity and mortality. The relation between CMV-reactivation and leukaemia recurrence in patients post HCST is highly controversial and there is increasing evidence to show that CMV-reactivation is associated with the decrease rate of Leukaemia relapse post HSCT.
Methods: The phenotype of NK cell in the peripheral blood mononuclear cells (PBMCs) in HSCT patients with HCMV-reactivation was studied using flow cytometry. The HSCT patients without HCMV-reactivation and healthy donors PBMC were used as a control. The markers analysed for NK phenotypes include CD56, CD16, CD94/NKG2C, CD94/NKG2A, KIRs, CD57, KLRG1 and PD-1.
Results: NK cell surface expression markers were compared between HSCT patients with HCMV-reactivation and without HCMV-reactivation. The NK cells from both patient groups have similar composition of $CD56^{dim}/CD16^{bright}$ and $CD56^{bright}/CD16^{neg}$. Strikingly, the percentage of $CD56^{dim}16^{bright}$NKG2C+ population in HCMV-reactivation patients accumulated overtime when compared with no reactivation. Before HSCT, there are 6.4±3.5% (Mean+SEM) NKG2C+ NK cells in HCMV-reactivation group comparing with 2.9±1.4% NKG2C+ NK cells in non-reactivation group. 10 months later, there are significantly higher NKG2C+ NK cells in HCMV reactivation group (35.8±10.4% versus 8.8±2.9%).
Conclusions: This study has shown the fast accumulation of $CD56^{dim}16^{bright}$NKG2C+ NK population in HSCT patients with HCMV-reactivation. We hypothesise that NK population will contribute to the reduction of Leukemia relapse in HSCT patients with HCMV-reactivation. This study will help to guide the future management of HCMV-reactivation and develop strategies to reduce disease relapse.

P.C3.01.09

Exploring immunological mechanisms of human graft-versus-host-disease after hematopoietic stem cell transplantation

***E. Latis**[1,2], C. Leloup[1], D. Michonneau[3], A. Garcia[3], E. Bianchi[1], G. Socié[3], L. Rogge[1];*
[1]Institut Pasteur, Immunoregulation Unit, Department of Immunology, Paris, France, [2]Université Paris Diderot, Paris, France, [3]Service Hematologie Greffe, Hôpital St. Louis, Paris, France.

Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a curative treatment for many hematologic malignancies. However, its success is hindered by graft-versus-host disease (GVHD), a life-threatening complication deriving from alloreactive donor T-cells attacking recipient (host) tissues. Despite the advances in the field of HSCT and GVHD prophylaxis, disease processes in humans remain poorly understood, and the lack of biomarkers for the early diagnosis and prognosis contributes to the high mortality of the disease. In this study we investigated the mechanisms involved in immune reconstitution early after transplantation and in acute GVHD onset. For two independent cohorts of related HLA-identical donor-recipient couples, blood was collected either at GVHD onset, before any treatment, or at day 90 post-HSCT for recipients not developing GVHD. We have performed molecular profiling of cell populations important for GVHD development as well as immuno-phenotyping using spectral flow cytometry. Molecular profiling showed that donor T-cells react to the environment of the host by acquiring an activated phenotype, upregulating genes associated with T-cell activation, co-stimulation, migration and effector functions. Cellular profiling showed an incomplete reconstitution of the T-cell compartment in recipients early after transplantation, and a depletion of naive T-cells associated with an increase of cells with an effector-memory phenotype after HSCT. Finally, we noted an increase of cells with a T memory stem cell-like (TSCM-like) phenotype at GVHD onset. These cells may represent a cellular reservoir for GVHD maintaining the production of alloreactive T cells in the presence of host persistent antigens.

Absence of host macrophages exacerbates acute GVHD

D. Le[1], *M. Ranecky*[1], *A. Jordán Garrote*[1], *K. Ottmüller*[1], *H. Shaikh*[1], *M. Qureischi*[1], *L. Scheller*[1], *T. Steinfatt*[1], *A. Brandl*[1], *Z. Mokhtari*[1], *J. Delgado Tascón*[1], *J. Hartweg*[1], *A. Mottok*[2], *H. Einsele*[1], *E. Vafadarnejad*[3], *A. Saliba*[3], *M. B. Lutz*[4], *A. Beilhack*[1];
[1]*Department of Medicine II, Wuerzburg, Germany,* [2]*Institute of Pathology, Wuerzburg, Germany,* [3]*Helmholtz Institute for RNA-based Infection Research (HIRI), Wuerzburg, Germany,* [4]*Institute for Virology and Immunobiology, Wuerzburg, Germany.*

Allogeneic hematopoietic cell transplantation (allo-HCT) can lead to the severe complication of intestinal acute graft-versus-host disease (aGVHD). Host tissue resident antigen-presenting cells are considered essential in aGVHD initiation. However, in recent years it has become clear that hematopoietic host APCs are not absolutely required to initiate acute GvHD and that non-hematopoietic host APCs are sufficient to effectively activate alloreactive T cells to trigger acute GvHD. Therefore, the role of hematopoietic APCs in GvHD has not yet been clearly def.
Here we report that depletion of host APCs, which highly express CD11c, leads to exacerbation of GvHD as seen from reduced survival and increased clinical score after allo-HCT. Using reporter mice for dendritic cells (Zbtb46-GFP), novel macrophage marker panels for flow cytometry (MHC II, CD11c, F4/80, CD64, CD26) and single cell sequencing we show for the first time that the host intestinal CD11c expressing myeloid cells, which survived after irradiation, are macrophages but not dendritic cells. Moreover, our results indicate, that host macrophages can reduce intestinal aGVHD via PD-L1.
Our data indicate a protective role of host macrophages in aGVHD and suggest that targeting intestinal host macrophages may represent a novel therapeutic strategy for aGvHD.

Acute graft-versus-host disease (aGvHD) is a severe inflammatory complication of hematopoietic cell transplantation. aGVHD is mediated by donor T cells attacking the gastrointestinal tract, liver, and skin. Efficient strategies to improve aGvHD-related morbidity and mortality will rely on more precise methods to predict aGvHD and abrogate disease manifestation. Here, we asked whether the combination of surface receptors, particularly chemokine receptors and adhesion molecules, would identify alloreactive donor T cells before the onset of acute GVHD. To this end we employed multiparameter flow cytometry in two independent murine allo-HCT models to address whether defined markers alone or in combination could predict the onset of GvHD. C57Bl/6 (H-2b, Thy1.1+) or B10.D2 (H-2d, Thy1.1+) T cells plus bone marrow cells were transplanted in conditioned (8Gy) miHAg mismatched BALB/B (H-2b, Thy1.2+) and syngeneic C57Bl/6 (9Gy) or BALB/c (H-2d, Thy1.1+) recipients. To identify suitable predictive markers, we compared the expression pattern of allo-HCT recipients to syngeneic HCT recipients and untreated controls. Notably, the chemokine receptor expression (CCR2, CCR4, CCR5, CCR6, CCR7, CCR9) did not differ in the PB of allogenic vs. syngenic transplanted mice. However, we found an upregulation of α4β7 integrin, and E- and P-selectin ligand on allogeneic PB T-cells early after allo-HCT. The combination of these homing markers with the activation markers CD25 and CD69 at later time points and low expression levels of L-selectin allowed to define alloreactive donor T-cells. Based on these data, we propose a potential predictive blood test, which could allow a timely therapeutic intervention before clinical aGvHD manifestation.

P.C3.01.12

Serine protease activated Protein C alters T cell plasticity in GvHD by inducing anergy and metabolic quiescence in Teffector cells

S. Ranjan[1], *D. Gupta*[1], *A. Goihl*[2], *B. Schraven*[2], *B. Isermann*[1];
[1]*Institute of Clinical Chemistry and Pathobiochemistry, Magdeburg, Germany,* [2]*Institute for Molecular and Clinical Immunology, Magdeburg, Germany.*

Introduction: The serine protease activated protein C (aPC) is an anticoagulant protease. The role of aPC in controlling innate immunity through both its anticoagulant and signaling properties is well recognized. We have recently demonstrated a novel function of aPC and its receptors (protease activated receptors) in adaptive immunity and shown that aPC ameliorates GvHD. Here we test the hypothesis that aPC regulates T cell plasticity in GvHD. Material and Methods: In vitro proliferation assays were done by mixed lymphocyte culture of human and mice Teff cells. Teff cell anergy markers were measured by FACS and OCR and ECAR were measured in Teff cells by Seahorse. GvHD was induced in BALB/c mice by transplanting $2x10^6$ T cells with $5x10^6$ bone marrow cells from C57BL/6 mice. Results: *In vitro* we observed induction of iTregs (CD4+CD25+Foxp3) from Teff (CD4+CD25$^-$ Foxp3^{lo}) cells. This change in T cell plasticity is associated with induction of anergy (induced CD73 and A2A receptor expression, reduced proliferation and IL2 secretion) and metabolic quiescence (reduced glycolysis and mitochondrial respiration) in Teff cells after 24h of stimulation. *In vitro* aPC also reduced phosphorylation of Akt, mTORC1 and p70S6 kinase in human Teff cells. *In vivo* aPC improves GvHD in mice by inducing anergy and altering T cell plasticity. This effect is associated with improved survival, lower clinical scores, and lesser tissue damage and apoptosis in the gut. Conclusions: This data demonstrate that aPC induces anergy and metabolic quiescence and aPC ameliorates experimental GvHD in mice by altering T cell plasticity.

P.C3.01.13

In vitro-generated Th9 cells mediate anti-tumor cytotoxicity against B cell lymphomas in the absence of graft-versus-host disease (GVHD)

T. Reisser[1], *I. Knape*[1], *J. Scheurer*[1], *F. Leithäuser*[2], *K. Debatin*[1], *G. Strauss*[1];
[1]*University Medical Center Ulm, Department of Pediatrics and Adolescent Medicine, Ulm, Germany,* [2]*Institute of Pathology, University of Ulm, Ulm, Germany.*

Introduction: T helper 9 cells (Th9) are characterized by the massive production of IL-9 and contribute to immunopathologies in autoimmunity, but mediate immune responses against helminth infections and solid tumors. GVHD is the most frequent and severe complication after allogeneic bone marrow transplantation (BMT) induced by mature donor-derived T cells destroying recipient target organs.
Methods: We explored in different MHC-mismatched BMT models, whether in vitro-generated Th9 cells influence GVHD development and whether they exhibit a graft-versus-tumor (GVT) effect. Therefore, allogeneic in vitro-generated Th9 cells were co-transplanted with bone marrow cells and different hematological tumor cell lines.
Results: 5 days of Th9 differentiation from naïve CD4 T cells with TGF-ß, IL-4, anti-IFN-γ and TL1A achieves >60 % IL-9$^+$ TNF-α$^-$ IFN-γ$^-$ cells distinguishable by their cytokine profile from other Th-subsets. In different BMT models, in vitro-generated Th9 cells did not induce clinical and histological GVHD or systemically increase the GVHD-associated cytokines TNF-α and IFN-γ. Th9 cells migrated to but did not attack GVHD target organs, but changed their phenotype into IL-9$^-$ TNF-α$^+$ IFN-γ$^+$ producing cells. Regarding the GVT effect, Th9 cells could efficiently prevent tumor development of B cell lymphomas but did not exhibit anti-tumorigenicity against mastocytomas or thymomas.
Conclusion: Adaptively transferred Th9 cells elicit efficient anti-tumorigenicity against different B cell lymphomas while other tumor entities are not recognized. Th9 cells might therefore have the potential to serve as therapy in BMTs to eliminate residual tumor cells. Future experiments will elucidate the molecular mechanism of Th9 selectivity towards B cell malignancies.

P.C3.01.14

Minor histocompatibility antigens as cell therapy target and GvHD predictor after allogeneic hematopoietic stem cell transplantation

D. Romaniuk, *A. Postovskaya, A. Khmelevskaya, N. Bykova, D. Malko, G. Efimov;*
National Research Centre for Hematology, Moscow, Russian Federation.

Use of fully HLA-matched donor for HSCT does not completely prevent development of graft versus host disease (GvHD), which could be driven by minor histocompatibility antigens (MiHA). MiHAs are polymorphic peptides, presented in context of HLA. When MiHA coding gene expression is restricted to the hematopoietic lineage a mismatch could lead to selective graft-versus-leukemia (GvL) reactivity, lowering the risk of relapse. MiHA genotyping of donor-patient pairs is a promising approach to predict severe side effects and to select targets for immunotherapy. We designed multiplex qPCR MiHA genotyping method, and genotyped 25 pairs (10 siblings) for 20 antigens presented in HLA-A*02:01. Related and unrelated pairs have 1-5 (median 2) and 2-7 (median 4) mismatches (MM) respectively. Using expression data from Human Protein Atlas we separated MiHA-coding genes to predominantly hematopoietic and ubiquitous and assigned GvHD/GvL prediction scores to patients. Patients with grade III acute GvHD got up to 7 MM, grade II - 4 and grade I - 3. We analyzed CD8+ T cell response specific to HA-1 and HA-2 using MHC tetramers in six mismatched pairs. We were able to detect antigen-specific response to both HA-1 and HA-2 by cell culture assays only in one patient, who developed grade III aGvHD. Sequencing of TCR-beta repertoires demonstrated the polyclonal nature of both responses. Overall the data suggests that MiHA genotyping of donor-patient pairs represent a valid strategy for GvHD studies, and could be used to search therapy targets. This work has been supported by Russian Foundation for Basic Research grant 17-04-02186.

P.C3.01.15

Long term complete remission after haploidentical allogeneic hematopoietic stem cell transplantation in a 62-year-old man with donor cell myeloid leukaemia and multiple myeloma after allogeneic hematopoietic stem cell transplantation for the treatment of chronic myeloid leukemia

***S. Sánchez Alonso**, A. Alcaraz, J. L. Steegman, Á. Figuera, A. Alegre, C. Muñoz;*
Hospital Universitario de La Princesa, Madrid, Spain.

Second malignancies are a well-defined late complication after hematopoietic stem cell transplantation (HSCT) which includes myelodysplastic syndrome (MDS) and acute myeloid leukemia developed de novo in engrafted cells of donor origin. These donor cell-derived myelodysplastic syndrome (DCM) and donor cell-derived leukemia (DCL) are intriguing phenomena which are considered to carry an extremely poor prognosis, consistent with other secondary leukemias. Intuitively, a different mismatched donor would seem the best therapeutic option since significant graft-versus-leukemia effect would not be anticipated in the total absence of HLA disparity between donor T cells and the leukemic clone.
This case report describes a 62 years old man diagnosed of Philadelphia chromosome positive chronic myeloid leukaemia in chronic phase which relapsed after 20 years from receiving an allogenic HLA-identical sibling HSCT transplantation while maintaining a complete donor chimerism. The patient developed a DCM and a donor-cell monoclonal gammopathy of undetermined significance (MGUS), which finally progress to a myeloid DCL and a smoldering multiple myeloma, respectively. Interestingly, in the meantime his donor also developed a MDS and an MGUS with the same paraprotein isotype as the recipient, which support the existence of a primary inherited gene defect constituting one of the very first hits in the pathogenesis of blood cancers.
The patient was successfully treated with HSCT from his son and remains in complete remission to the date after 33 months, which supports the hypothesis that a haploidentical HSCT is the more logical consolidation strategy in donor cell-derived haematological malignancies.

P.C3.01.16

Rapamycin increases myeloid-derived suppressor cell (MDSC) activation and immunosuppressive function in protecting against graft-versus-host disease (GVHD) in a murine allogeneic bone marrow transplantation (BMT) model

***J. Scheurer**[1], T. Reisser[1], I. Knape[1], F. Leithäuser[2], K. Holzmann[3], K. Debatin[1], G. Strauss[1];*
[1]Department of Pediatrics and Adolescent Medicine, 89075 Ulm, Germany, [2]Institute of Pathology, 89075 Ulm, Germany, [3]Genomic-Core Facility, 89075 Ulm, Germany.

Introduction and Objectives: MDSCs are a heterogeneous population of myeloid progenitors, which suppress T-cell functions and expand during inflammation. GVHD also induces MDSCs, which however don´t protect from GVHD-induced death. Rapamycin is a macrolide immunosuppressant with protective effects against GVHD. The effect of Rapamycin on MDSC in GVHD regulation isn´t well defined. We explored the effect of Rapamycin (1) in GVHD prevention, (2) on MDSC-induction, activation and immunosuppressive function and (3) on changes in T-cell function, polarization and exhaustion.
Methods: Allogeneic bone marrow transplanted mice were treated with Rapamycin or PBS every 2nd day. MDSCs were isolated from spleens and GVHD target organs for defining transcriptional changes and their immunosuppressive capacity. Allogeneic T-cells were analyzed for changes in the expression of cytokines, cytotoxic molecules and exhaustion markers.
Results: Rapamycin treatment effectively prevented clinical and histological GVHD and increased survival. Rapamycin increased splenic MDSC numbers and enhanced their suppressive potential towards alloreactive T-cells. Rapamycin-activated MDSCs significantly up-regulated iNOS expression, while immunosuppressive factors arginase-1, HO-I, COX-2 and IDO were unchanged. Transcriptome analysis revealed distinct transcriptional changes in Rapamycin-activated MDSCs, most evident for genes involved in innate and inflammatory responses, and in the regulation of secretion. Despite Rapamycin induced MDSC-activation, no alterations in T-cell exhaustion, Th1/Th2 polarization or expression of cytotoxic molecules were detectable.
Conclusion: Rapamycin is an effective adjuvant for GVHD prevention, which induces and activates highly immunosuppressive MDSCs. Further experiments will clarify, whether Rapamycin treatment maintains the graft-versus-tumor effect, a major goal in allogeneic BMT therapy.

P.C3.01.17

Non-hematopoietic Antigen Presenting cells in Lymphoid organs

***H. Shaikh**[1,2], M. Qureischi[1,2], K. Ottmüller[1,2], M. Otto[1], D. Le[1,2], A. Beilhack[1,2];*
[1]Department of Internal Medicine II, University Hospital Würzburg, Würzburg, Germany, [2]Graduate School of Life Sciences, Julius-Maximilians University Würzburg, 97078 Würzburg, Germany.

Hematopoietic stem cell transplantation is a curable therapy for hematopoietic malignancies. Allogeneic T-cells residing within the graft have potential to eliminate remaining malignant cells by Graft versus leukemia effect. Nevertheless, in 30–60% of HSCT cases allogeneic T-cells become alloreactive and attack host tissues resulting in acute Graft versus host disease. Dendritic cells are professional antigen presenting cells (APCs) and have thought to be the prime candidate for presenting self-antigens to allogeneic T-cells. However, recent findings claim that even in absence of DCs and other hematopoietic APCs GvHD cannot be prevented, suggesting role of non-hematopoietic APCs in the activation of allogeneic T-cells.
In this project, we investigate role of lymph node stromal cells (LNSCs) in initiation phase of aGvHD and their potential role as non-hematopoietic APCs.
We show that T-cells are activated in lymphoid organs and not in GvHD target organs. In MHC-II deficient bone marrow chimeras bearing MHC-II$^+$ non-hematopoietic APCs, allogenic T-cells still get activated but to a lesser extent. Furthermore, LNSCs upregulates co-stimulatory receptors early after conditioning suggesting their contribution as active antigen presentation cells in initiation phase of aGvHD. However, LNSCs significantly downregulate MHC-II on their surface as LNSCs have been shown to acquire MHC-II from hematopoietic APCs. In line with this, we observed that post irradiation DCs depletion results in loss of MHC-II on LNSCs.
Conclusively, we show that alloreactive T-cells are activated within SLOs even in absence of professional hematopoietic APCs, but still it remains elusive, which non-hematopoietic cell initiates alloreactive T-cell response.

P.C3.01.18

Unraveling the minor histocompatibility antigen immunogenicity through naive CD8 T cell frequencies estimation

***S. Sheetikov**[1], A. Kuchmiy[2], D. Romaniuk[1], G. Efimov[1];*
[1]National Research Center for Hematology, Moscow, Russian Federation, [2]Ghent University, Ghent, Belgium.

Allogeneic bone marrow transplantation is the potentially curative treatment for malignant hematopoietic disease. The therapeutic effect depends on the immune response of donor lymphocytes to residual tumor cells (graft-versus-leukemia effect). At the meantime broader immune response of transplant towards recipient could be detrimental (graft-versus-host disease). In HLA-matched transplantation donor's lymphocytes recognize the differences in peptides repertoires displayed within MHC as foreign antigens (minor histocompatibility antigens). The magnitude of immune responses determines the development of graft-versus-host disease or graft-versus-leukemia reactivity. Different minor histocompatibility antigens differ in their immunogenicity in vivo. Our hypothesis is that this can be explained by the unequal frequency of naive antigen-specific T cells in the donor repertoire. In the current study we examined the size of the naive T cell pool specific for antigens HA-1, HA-2, ACC-1Y, LB-ADIR-1F and LB-NDC80-1P. Donors were genotyped for minor antigens and HLA, and selected on the basis of having restricting HLA allele and lacking allele encoding the minor antigen of interest. By culturing naive CD8 T cell with dendritic cells loaded with minor antigen peptides we expanded and detected rare antigen-specific clones and estimated their frequencies with limiting dilution approach. Our results show that the incidence of naive precursors specific for the LB-ADIR-1F($f_{LB\text{-}ADIR\text{-}1F} \approx 3.5*10^{-6}$), HA-1($f_{HA\text{-}1} \approx 5*10^{-6}$) and HA-2 antigens($f_{HA\text{-}2} \approx 5*10^{-6}$) is significantly higher, than for LB-NDC80-1P($f \approx 2*10^{-7}$) and ACC-1Y($f \approx 2*10^{-7}$) antigens, which corresponds to their immunogenicity in vivo. This data can be useful for selection of the donor and immunosuppressive regimen and for the graft design. Funding was provided by Russian Science Foundation grant 17-15-01512.

P.C3.01.19

Expression of CD38 is elevated on peripheral blood lymphocytes of patients that do not develop chronic GvHD after HSCT

***D. Tomaz**[1], R. Ellis[2], N. Petrov[2], S. Heck[2], G. J. Mufti[1,3], V. Mehra[3], S. Kordasti[1], V. Potter[3], L. D. Barber[1];*
[1]School of Cancer and Pharmaceutical Sciences, King's College London, London, United Kingdom, [2]National Institute of Health Research Biomedical Research Centre, Guy's Hospital, London, United Kingdom, [3]Department of Haematological Medicine, King's College Hospital, London, United Kingdom.

Chronic graft-versus-host disease (cGvHD) is a significant cause of morbidity and mortality following allogeneic haematopoietic stem cell transplantation (allo-HSCT). CD38 is associated with immunosuppressive activity, but its potential role in the context of cGvHD is unknown. In this study, we performed a comprehensive deep-immunophenotyping mass cytometry analysis of peripheral blood lymphocytes from nine patients with cGvHD and eight patients without cGvHD after allo-HSCT using alemtuzumab for lympho-depletion, and eight healthy volunteers. PhenoGraph clustering tools were used for data analysis. Patients with cGvHD were found to have a paradoxically higher frequency of CD4+ Treg cells compared to those without cGvHD (p=0.018). cGvHD patients had a higher frequency of exhausted phenotype (FoxP3low, CD45RAnegative) CD4+ Treg cells compared to patients without cGvHD (p=0.028), who had a higher frequency of activated phenotype (FoxP3high, CD45RAnegative) CD4+ Treg cells (p=0.032). Notably, we observed that the frequency of CD38+ Treg cells and expression levels of this marker were significantly elevated in patients without cGvHD compared to those with active cGvHD. Moreover, expression of CD38 was also significantly elevated in CD4+ T cells, CD8+ T cells and NK cells in patients without cGvHD. In conclusion, the activated CD4+ Treg phenotype and comparatively higher expression of CD38 on lymphocytes in allo-HSCT patients without cGvHD suggests an increased ability to modulate allo-immune responses.

P.C3.01.20

Antigen experienced subtypes of cytomegalovirus specific T-cells substantially differ in clonality

***M. Vagida**, N. Bykova, G. Efimov;*
National Research Center for Hematology, Moscow, Russian Federation.

Cytomegalovirus infection is a serious complication after allogeneic hematopoietic stem cell transplantation. One of the promising therapeutic strategies is adoptive transfer of virus specific T-lymphocytes. Central memory cells have more proliferative potential than other memory subtypes and might be more applicable for therapy. In this work, we sorted three populations of CD8+ lymphocytes, specific for HLA-A02 immunodominant cytomegalovirus epitope - NLV: effector memory, terminal effectors and central memory. RNA was extracted and used as template for T-cell receptor library amplification with unique barcode adapters attached to each cDNA molecule. DNA library was sequenced on the Illumina platform.Studied T-cell subpopulations drastically vary in the diversity of T-cell receptors. The ratio of unique clonotypes to total cells was much higher for central memory T cells 0.349 than 0.127 and 0.022 for effector memory and terminal effectors respectively. Terminal effector repertoire is extremely contracted, compared with repertoires from two other subpopulations. This effect could be a result of proliferation only of small numbers of clones during differentiation to terminal effector T cells. The high number of unique clonotypes in central memory fraction may be the result of a smaller niche and the absence of expansion in the process of differentiation from naive cells. The difference in diversity of T-cell receptor repertoires of CD8+ virus specific T-cell subsets may result in differed therapeutic potential of these cells.This work was supported by the Russian Foundation for Basic Research grant 17-04-02088.

Use of a chimeric antigen receptor-like HLA molecule in T cells for the elimination of anti-HLA alloantibody producing B cells

***S. Betriu Méndez**[1], J. Rovira[1], B. Marzal[1], E. Banon-Maneus[1], A. Mulder[2], F. Claas[2], M. Juan[1], F. Diekmann[1], E. Palou[1];*
[1]Fundació Clínic, Hospital Clínic de Barcelona, Barcelona, Spain, [2]Academic Hospital Leiden, Leiden, Netherlands.

Introduction: Chimeric antigen receptor (CAR) T cell therapy has emerged as a very promising approach to combating cancer with excellent results in anti-leukemic clinical trials, and in a broader appraisal, promising immunotherapeutic results. A major problem in solid organ transplantation is the presence and the generation *de novo* in the recipient of donor specific antibodies which preclude the success of the transplant due to the associated high risk of antibody-mediated rejection. B cells contribute in the acute and chronic allograft rejection processes with the production of anti-donor HLA antibodies. We hypothesize that a CAR (chimeric antigen receptor)-like molecule with a particular HLA molecule as the CAR extracellular domain will engineer T cells to kill alloimmune B cells with anti-HLA antibodies as BcR, completely eliminating alloantibodies in a specific manner.
Methodology and Results: First step, we cloned the extracellular region of HLA-A*02:01 from A*02:01 positive donor cDNA by PCR. We constructed CARs with this extracellular domain and 4-1BB /CD3ζ intracellular signalling domains and delivered into human T cells by lentiviral transduction. Next, to evaluate the specificity and functionality of CAR T cells, we performed a cytotoxicity assay by co-culturing them with anti-HLAA2 alloantibodies producing EBV-transformed B cells.
Conclusion: HLA CAR-like receptor has been constructed in our laboratory and used to generate specific T cells directed to kill anti-HLA alloantibody producing B cells. This technology could open new ways of treatment and prevention of antibody-mediated rejection in solid organ transplantation.

P.C3.02.02

Reconstituted allogenic immune cells direct resistance to tumors in mice

***N. Dang**, Y. Lin, O. Rutgeerts, A. D. Billiau, M. Waer, B. Sprangers;*
KU Leuven, Leuven, Belgium.

Abstract: Acute graft-*versus*-host disease (aGVHD) is an often-lethal syndrome resulting from immune reconstitution and cytotoxic T cells (CTLs) response to allogenic bone marrow transplantation (BMT). Regulatory T cell (Treg) mediated-tolerance is a defense strategy against aGVHD that has a direct positive impact on resistance to tumor - graft-*versus*-tumor (GVT) effect. Here, we demonstrate that induction of Treg cells in response to tumor milieu is critical to establish tolerance to aGVHD after T cell-replete BMT. The protective effect of donor-derived Treg cells is exerted via a mechanism that counters Teff/Treg ratio, and in doing so, M2 polarization as a result of relatively limited tumor-associated macrophages (TAMs). This is required to prevent the development of aGVHD that otherwise promotes resistance to tumor. The reduction of Treg cells establishes the GVT effect therapeutically after T cell-depleted (TCD) BMT. In conclusion, the GVT effect of TCD-BMT relies on a crosstalk between host tumor milieu and *de novo* CTLs response, required to expand TAMs compatible with M1 polarization. **Significance:** Tumor-driven host Treg cells promotes graft acceptance and expansion of donor TAMs that induce *de novo* CTLs after TCD-BMT, rather than donor-derived Treg cells after T cell-replete BMT, an immune reconstituted effect that confers either GVT effect or host tolerance to aGVHD, respectively.

P.C3.02.03

Preservation with portable ex vivo lung perfusion (EVLP) reduces significantly ischemia/reperfusion injury in lung recipients by promoting cytokine antagonists

***C. S. Falk**[1], B. Wiegmann[2], R. Bellmàs Sanz[1], C. Neudörfl[1], C. Kühn[2], I. Tudorache[2], M. Avsar[2], A. Haverich[2], G. Warnecke[2];*
[1]MHH Institute of Transplant Immunology, Hannover, Germany, [2]MHH Department of Cardiothoracic, Transplantation and Vascular Surgery, Hannover, Germany.

Objectives: The INSPIRE trial revealed significant reduction of PGD grade 3 using the Organ Care System (OCS) compared to the standard of care (SOC) for lung preservation. In order to investigate immunological mechanisms during these preservations, immune mediators were measured with the hypothesis that OCS preservation supports an anti-inflammatory milieu leading to reduced ischemia/reperfusion injury (IRI). Methods: Plasma, perfusates from 33 patients with OCS- vs. 26 with SOC-preserved lungs were analysed for 95 immune mediators using multiplex assays. Recipient demographics, cold ischemic times (CIT), PGD scores at T0, T24 were assessed. Results: Clinical evaluation (OCS/SOC) revealed equal distributions of recipient age and diagnoses. Cold ischemic time (549 vs. 258min) was significantly shorter in OCS group ($p<0.0001$). Improved PGD score was observed in OCS recipients ($p=0.035$). IL-6, CXCL8-10, plasma levels were reduced in OCS patients at T0 ($p<0.01$). IL-6 plasma levels of SOC recipients correlated with CIT, PaO2/FiO2 ratio and PGD >2 (all $p<0.01$). However, higher levels were observed in OCS vs. SOC perfusates ($p<0.001$). We proposed suppression of IRI by induction of antagonists. IL-1RA was significantly higher in OCS perfusates ($p<0.05$) and IL-31 correlated with IFN-g ($p=0.001$) only in OCS perfusates. Conclusion: Recipients of OCS-preserved lungs show significantly reduced IRI by reduced levels of pro-inflammatory immune mediators. Strong correlation of IL-6 with CIT and PGD in SOC but not OCS patients argues for its impact on IRI and early lung function. Thus, EVLP may have the potential to ameliorate IRI and improve clinical outcome by induction of cytokine antagonists.

P.C3.02.04

Silencing MHC expression on the organ's endothelium decreases its immunogenicity and prevents a pro-inflammatory cytokine response

***C. Figueiredo**[1], M. Carvalho-Oliveira[1], C. Chen-Wacker[1], Y. Yuzefovych[1], K. Hoeffler[2], O. Pogozhykh[1], Z. Jin[1], A. Haverich[2], G. Warnecke[2], R. Blasczyk[1];*
[1]Institute for Transfusion Medicine, Hannover Medical School, Germany, Hannover, Germany, [2]Department of Cardiac-, Thoracic-, Transplantation- and Vascular Surgery, Hannover Medical School, Hannover, Germany, Hannover, Germany.

Introduction: HLA mismatches are the main cause of graft rejection and failure. Methods: SLA class I and II expression was silenced on the lung endothelium using short hairpin RNAs-encoding lentiviral vectors. The effect of silencing MHC expression was evaluated in a porcine lung transplantation model by monitoring the cytokine response during 12 weeks. Immunosuppression was stopped 4 weeks after transplantation. SLA expression was silenced during normothermic ex vivo perfusion. Nanoluciferase was used as a reporter gene. Levels of SLA were quantified by RT-PCR and flow cytometry. Cytokines were monitored every second day after Tx and weekly after the post-operative day (POD) 7 using multiplex technology. Results: SLA downregulation on lung endothelial cells reached a level of 70%. Already 1h after Tx the serum levels of IL-1beta, IL-6 and IL-8 increased significantly in all animals by up to 0.263, 1.370 and 0.497 pg/ml, respectively.
On POD 1, the cytokine secretion in the SLA silenced group decreased to pre-transplant levels whereas those of the control group remained significantly elevated ($p<0.01$). On POD 14, levels of IL-12 increased significantly by up to 0.286 pg/ml in the control group whereas it remained at pre-transplant levels in the SLA silenced lung recipients. In addition, levels of IL-2, IL-10 and TNF-α increased exclusively in animals with SLA expressing lungs while it was undetectable in animals receiving SLA silenced lungs. Conclusion: These data indicate that MHC-silenced grafts are less immunogenic and may combat the burden of rejection and immunosuppression.

P.C3.02.05

Liver resident mucosal-associated invariant T (MAIT) cells display an active but less proliferative state compared to the peripheral MAIT cells

***W. Huang**, W. He, X. He, Y. GAO;*
The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

The liver is one of the most important immunological organs that remains tolerogenic in homeostasis. The composition of leukocytes in the liver is highly distinct from that of the blood and other lymphoid organs. In particular, the enrichment of innate T cells, i.e. invariant NKT cells (iNKT cells), Mucosal Associated Invariant T cells (MAIT cells).
We performed flow cytometry on MAIT cells in blood and perfusion fluid from 20 patients undergone liver transplantation. Further functional assessments including MAIT cell proliferation, activation, and cytokine-producing capacity.

A much higher percentage of MAIT cells were detected in the perfusion fluid compared with those in the PBMC (8.22% vs. 2.7%, p<0.001). In addition to that, the PBMC peripheral MAIT cells were in a less active state (with lower CD69 expression) compared to their perfusate counterpart. Cytokines productivity post IL-12/IL-18 stimulation by MAIT cells were similar in both peripheral and perfusate as measured by the Luminex analysis. Interestingly, the Liver MAIT cells were found to be less proliferative upon stimulation with anti-CD3/CD28.
In here, we demonstrated that MAIT cells are numerically rich in the liver and functionally distinctive compared to their peripheral counterpart. These observations may be significant in transplantation tolerance in the liver and other liver diseases.

P.C3.02.06
Long-term graft tolerance induction by NFATc pathway inhibition in innate immune cells

L. Gornati[1], *C. Cigni*[1], *F. Mingozzi*[1], *L. Marongiu*[1], *R. Rotem*[1], *M. Colombo*[1], *D. Prosperi*[1], *I. Zanoni*[1,2], *F. Granucci*[1];
[1]*Department of Biotechnology and Bioscience, University of Milano-Bicocca, Piazza della Scienza 2, 20126 Milan, Italy, Milan, Italy,* [2]*Harvard Medical School and Division of Gastroenterology, Boston Children's Hospital, Boston, MA 02115, USA, Boston, United States.*

Introduction: Transplantation is a therapeutic approach for failing organs, whose most feared complication is rejection, mediated by the instauration of alloreactive T cells, supported by the Nuclear Factor of Activated T cells (NFAT). To avoid graft loss, transplanted patients undergo life-long administration of immunosuppressive drugs, completely abrogating the immune response. Since NFAT has recently emerged to be pivotal in sustaining innate immune cells, we aim at evaluating NFAT as a potential specific therapeutic target in these cells to prevent rejection without causing complete immune paralysis.
Methods: By taking advantage of nanoparticles (NPs) delivering a specific NFAT inhibitor peptide to innate immune myeloid cells, we managed to abolish NFAT activation in these cells without affecting T cells, in a model of mismatched skin graft.
Results: The administration of our NPs prevents acute allograft rejection. Accordingly, transplanting NFATc2 KO skin, results in delayed rejection, due to the impaired vessels permeability and thus migration of T cells to the graft as well as of dendritic cells (DCs) to the draining lymph nodes. Moreover, we noticed a strong increase of $CD4^+$ $CD25^+$ $Foxp3^+$ T cells in NPs-treated recipients, suggesting regulatory T cells-mediated tolerance against the graft. Accordingly, anti-NFAT NPs administration can be interrupted without provoking graft rejection. Diversely, if animals are treated with tacrolimus to inhibit rejection, therapy interruption immediately results in graft loss.
Conclusions:
The inhibition of the NFAT signaling pathway in innate immune cells can be considered as a new approach to induce long-term graft acceptance without affecting T cell functions.

P.C3.02.07
Induction and effector phase of human anti-pig T cell responses are differentially affected by the CRISPR/Cas9 induced absence of porcine MHC/SLA class-I molecules

R. Hein, *S. Clever, H. Düvel, B. Trautewig, A. Brinkmann, J. Hundrieser, R. Schwinzer;*
Transplantation Laboratory, Clinic for General, Visceral and Transplantation Surgery, Hannover, Germany.

Introduction: Foreign MHC molecules display the main target for induction of anti-graft responses and rejection processes in the T-cell effector phase. By genetic engineering it is possible to generate porcine cells and tissues lacking MHC expression which might particularly be suited for clinical xenotransplantation. Thus, we asked how the absence of porcine MHC/SLA class-I (SLA, "swine leucocyte antigen") affects the human anti-pig immune response. Therefore, a SLA class-I negative porcine cell line was generated and its stimulatory capacity to activate human T-cells was characterized *in-vitro.*
Methods: SLA class-I deficient B-cell line L23 (porcine APC, $SLA\text{-}I^+$, $SLA\text{-}II^+$) was generated using the Cas9 nuclease and a guide RNA directed against the beta2-microglobulin (b2m) coding gene.
Results: In flow cytometry analyses no b2m or SLA class-I expression was detected in L23-b2m-ko cells; expression of SLA class-II and costimulatory molecules (CD40, CD80/86) was comparable to wildtype (wt) L23 cells. Proliferation of hPBMC triggered by L23-b2m-ko cells was significantly reduced compared to L23-wt stimulation, mainly due to poor reactivity of $hCD8^+$ T-cells. However, ^{51}Cr-release assays showed no protection of SLA class-I negative cells against cell-mediated lysis by human L23-specific cytotoxic T cells (generated in 6-day MLRs between hPBMC and L23-wt cells): L23-b2m-ko cells were lysed with similar intensity as L23-wt cells.
Conclusion: The induction phase of human anti-pig T cell reactivity can be diminished by the elimination of porcine SLA class-I molecules. However, alternative strategies will be required to protect porcine cells from human cytotoxic effector cells.
Supported by the DFG (SFB-TRR 127 "Xenotransplantation").

In vivo and in vitro modulation of mTOR pathway enhances human γδ T cells effector functions

H. Kaminski[1], *V. Pitard*[2], *L. Couzi*[1,3], *P. Merville*[1,3], *A. Tarricone*[4], *C. Larmonier*[4], *I. Pellegrin*[4], *R. Duran*[5], *J. Déchanet-Merville*[1];
[1]*CNRS-UMR 5164 Immunoconcept, Bordeaux University, bordeaux, France,* [2]*CNRS-UMR 5164 Immunoconcept, bordeaux, France,* [3]*renal transplant department, bordeaux university hospital, Bordeaux, France,* [4]*Immunology department, Bordeaux university hospital, bordeaux, France,* [5]*INSERM UMR 1218, Bordeaux University, bordeaux, France.*

Being able to control γδ T cell effector functions is important for the development of γδ T cell-based immunotherapy. mTOR pathway enhances glycolytic metabolism in effector T cells and is crucial for cytotoxicity and IFNγ production. mTOR inhibitors (mTORi) are used in transplantation to prevent rejection but are also paradoxically associated with less CMV infections, the most frequent adverse event of immunosupression. As Vδ2neg γδ T cells are key players against CMV, we wondered if mTORi are able to modulate γδ T cell functions in transplant patients. *In vitro*, Vδneg γδ T cells from CMVpos transplant recipients surprisingly expanded better in the long-term (3 weeks) presence of clinical mTORi doses. They also displayed higher S6 and AKT phosphorylation and higher T bet production, as well as increased IFNγ production when incubated with CMV-infected cells. Our working hypothesis is therefore that mTORi could inhibit mTORC1 while inducing a negative feedback increase of AKT phosphorylation, leading to phosphorylation of S6 and expression of T bet and IFNγ. *In vivo*, faster CMV-induced Vδneg γδ T cell expansion was observed in patients treated with mTORi versus mycophenolate mofetil. Transcriptomic analyses of purified Vδneg γδ T cells from mTORi-treated patients showed higher transcription of the glycolytic enzyme GPI, of IL2Rbeta, CD44, and NFkB, all signs of γδ T cell activation. To conclude, mTORi could increase antiviral functions of γδ T cells in transplant patients and be used in immunotherapy to promote γδ T cell effector functions against tumors or infections.

P.C3.02.09
Modulation of the IL-33-ST2 axis in regulatory T cell therapy

K. Kawai, *M. Uchiyama, J. Hester, F. Issa, K. J. Wood;*
University of Oxford, Oxford, United Kingdom.

Background: Regulatory T cells (Tregs) are crucial mediators of immune homeostasis, with the ability to modulate alloreactive T cell responses and control transplant rejection. Previous work has demonstrated that the modulation of the interleukin-33 (IL-33)/ST2 axis expands a highly suppressive subpopulation of Tregs. Here we present novel data that demonstrate the ability of exogenous IL-33 administration to expand mouse Tregs *in vivo* that can promote the survival of MHC-mismatched skin grafts.
Materials/Methods: Groups of mice received either saline or recombinant IL-33 (1μg/d for 6 days). $CD4^+FoxP3^+$ Tregs from control or IL-33-treated mice were then flow sorted and adoptively transferred together with effector T cells (Teffs) into syngeneic immunodeficient mice. Mice were then transplanted with an allogeneic skin graft where survival was monitored until allograft rejection and their organs were harvested for phenotypic analysis.
Results: Recombinant IL-33 administration expanded $CD4^+FoxP3^+$ Treg populations 10X *in vivo* (p<0.0001). Mice treated with sorted IL-33-expanded Tregs demonstrated an enhanced ability to modulate Teff responses and suppress allograft rejection. While mice treated with Teff only rejected their allografts as expected, with a median survival time (MST) of 14 days, naive and IL-33 Treg administration improved survival to an MST of 64 days and >100 days, respectively. Conclusion: Administration of IL-33 *in vivo* can significantly expand Tregs, which demonstrate an enhanced ability to prolong allogeneic skin grafts *in vivo*. These data highlight an important pathway for the modulation of Treg therapy, which may allow the use of fewer cells in the future.

K. Kotschwarova, *M. Fialova, V. Svachova, L. Curnova, K. Vlasakova, O. Viklicky, I. Striz;*
IKEM, Prague, Czech Republic.

Proinflammatory cytokines induced by ischemia/reperfusion injury upregulate release of chemokines from parenchymal cells to attract immune cells into transplanted kidney. The aim of our study was to evaluate the ability of human renal proximal epithelial cells (RPTEC) to produce multiple chemokines in response to TNF-α and compare the data with chemokine induction in renal adenocarcinoma (RA) and monocyte/macrophage (THP-1) cell lines. Concentrations of CXCL1, CXCL4, CXCL5, CXCL8, CXCL9, CXCL10, CXCL11, CXCL16, CCL2, CCL5, CCL18, CCL21 and CX3CL1 were measured in culture supernatants by Luminex. Chemokines attracting neutrophils (CXCL1, CXCL5, CXCL8), were produced preferentially by TNF-α stimulated epithelial cells. RPTEC released more CXCL1 and CXCL8 while RA cells produced preferentially CXCL5. RPTEC and RA are also an important source of CCL2, chemotactic for monocytes and other immune cells. In contrast, TNF-α stimulated THP-1 cells produced more CCL5 (specific for monocytes, eosinophils and Th cells).

Chemokines attracting Tc and NK cells (CX3CL1, CXCL16) and activated T cells (CXCL10, CXCL11) were preferentially induced by TNF-α in RPTEC. We conclude that chemokines released from human renal epithelial cells in response to TNF-α do not regulate only the influx neutrophils but are involved also in the recruitment of effector cell populations of adaptive immunity. Our data suggest, that primary epithelial cells are more convenient for studying chemokine regulation in kidney than renal adenocarcinoma epithelial cell line. Supported by Ministry of Health of the Czech Republic, grant NR 15-26883A and by MH CZ-DRO (Institute for Clinical and Experimental Medicine - IKEM, IN 00023001).

A novel way to generate human HLA class II monoclonal antibodies for HLA epitope analysis

C. S. M. Kramer[1], *M. E. Franke-van Dijk*[1], *C. C. Zilvold-van den Oever*[2], *R. Rademaker*[2], *P. W. Parren*[1], *D. L. Roelen*[1], *S. Heidt*[1];
[1]*Leiden University Medical Centre, Leiden, Netherlands,* [2]*Genmab, Utrecht, Netherlands.*

Donor-specific antibodies produced upon renal transplantation are triggered by immunogenic epitopes present on mismatched donor HLA. However, not every foreign epitope will lead to antibody formation, which highlights the need to experimentally verify truly immunogenic epitopes. Human HLA-specific monoclonal antibodies (mAbs) have proven to be very useful for identification of HLA class I epitopes. Since currently the number of available HLA class II mAbs is limited, we aimed to produce these mAbs by using HLA class II-specific tetramers and recombinant technology, of which here we show proof of principle. From PBMCs of an individual with HLA-DRB1*07:01-specific serum antibodies, single memory B cells positive for HLA-DRB1*07:01-specific tetramers were sorted (0.0012% of B cells). After expansion, 11/36 of B cell clones produced HLA-DRB1*07:01 antibodies, three also being reactive with HLA-DRB1*09:01. Subsequently, RNA was isolated to obtain the variable heavy and light chains to clone into pcDNA3.3 expression vectors. Analysis of variable domain sequences identified B cells with different combinations of V(D)J segments, suggesting that the isolated B cells originate from different precursors. At time of writing, we recombinantly expressed one HLA-DRB1*07:01-specific mAb and could use this to confirm $25Q_3$ as an immunogenic epitope on HLA-DR7. This study demonstrates that HLA tetramers can be used to isolate HLA class II-specific memory B cells and subsequently can be used as a source to generate recombinant mAbs. With this method a large panel of human HLA class II mAbs can be produced, to verify HLA epitopes and for functional studies on HLA class II antibodies.

Redefining the HLA-DR11 peptide binding motif with new MS data

L. Labeur*, J. A. Collado, Y. Arribas, R. Farriol, D. Jaraquemada, M. Carrascal;*
Institut de Biotecnologia i Biomedicina-Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain.

The HLA-DRB1*1101 (DR11) allele is associated to several diseases, being a protective allele for type 1 diabetes and systemic lupus erythematosus, while in multiple sclerosis it acts as a susceptibility agent. However, the last published data defining the DR11 motif are incomplete because of the low number of analysed peptides. Therefore, our objective is to accurately define this motif using a larger number of peptides eluted from the DR11 allele.
We cultured the human EBV-transformed HLA-DRB1*1101 homozygous cell line BM21 and isolated Class II-peptide complexes by immunoprecipitation with the HLA-DR-specific B8.11.2 antibody. Peptides were eluted and then processed by MALDI and Orbitrap MS. Furthermore, we analysed the peptides previously eluted from thymus and spleen samples from $DR11^+$ donors. We thus observed that the sequences of peptides obtained from human tissue matched the motif obtained from cultured cells *in vitro*. In conclusion, contrary to what is found in the current literature, three anchor positions (P1, P4 and P6) and not four (P1, P4, P6 and P9), were defined. We found that the DR11 motif is broader than previously described, although the main characteristics are maintained. All amino acids in P1 and P4 anchor positions were hydrophobic (F, L, I, V, Y and L, V, I, A, T, F respectively). In contrast, P6 was occupied by basic amino acids (R, K and S), and P9 appeared to be irrelevant. Our data provide new information and add reliability to the current databases.

P.C3.02.13

IL-23IL-17 pathway in kidney allograft rejection

Y. Lakhoua Gorgi[1], *Y. Haouami*[1], *T. Dhaouadi*[1], *M. Jellouli*[1], *J. Abdellatif*[1], *M. Majdoubi*[1], *M. Bacha*[2], *R. Goucha*[2], *R. Bardi*[1], *T. Ben Abdallah*[1], *I. Sfar*[1];
[1]*Research Laboratory in Immunology of Renal Transplantation and Immunopathology (LR03SP01), Tunis, Tunisia,* [2]*Department of Medecine and Nephrology Charles Nicolle hospital, Tunis, Tunisia.*

T helper 17 cell (Th17) subset has been implicated in autoimmune diseases, tumor immunity and transplant rejection. In order to investigate the role of interleukin 17 (IL-17)/ IL-23 pathway in allograft outcome, intragraft expression of IL-17 mRNA and polymorphisms (SNPs) of IL-17A, IL-17F, IL-17RC and IL23R genes were evaluated with a quantification of plasma IL-17A, IL-17F, and IL-23. This study revealed that recipients with acute rejection (AR) had a significant increase in IL-17A mRNA expression levels of after transplantation compared to controls (p=0.037). Moreover, plasma IL-17A levels were significantly higher in AR group; pre-transplantation (Day-1): p=0.00022 and post-transplantation (Day7): p<10E-14. IL-17F and IL-23 plasma levels were significantly higher in AR at Day7 only (47,86 vs. 22.99 pg/ml; and 33.82 vs. 18.811 pg/ml); p=0.015 and p<10E-17, respectively. Using ROC curves, IL-17A and IL-23 plasma levels exhibited excellent sensitivities and specificities for predicting AR. Genetic study revealed no association between IL-17A, IL-17F, IL-17RC and IL23R studied polymorphisms and AR. Nevertheless, plasma IL-17F levels at both Day-1 and Day7 were significantly higher in patients carrying IL-17F-1507*C/T and *T/T genotypes comparatively to those with the wild homozygous genotype *C/C; p=0.015 and p=0.022, respectively. Besides, IL-17A mRNA levels were significantly higher in patients carrying the IL-23R*G/G genotype (1367.845) comparatively to those with *G/A genotype (180.367), p=0.042. Based on these findings, significant increase of IL-17A mRNA and protein levels in AR recipients which are genetically controlled highlights the role of this cytokine that can be a useful clinical biomarker to predict early acute renal allograft rejection

P.C3.02.14

“Off-the-shelf” mesenchymal stromal cell therapy can prolong rejection-free survival of corneal allografts in a high immunological risk transplant model by increasing regulatory cell populations

P. Lohan[1], *N. Murphy*[1], *O. Treacy*[1,2], *K. Lynch*[1,2], *M. Morcos*[1], *A. E. Ryan*[2,1], *M. D. Griffin*[1,3], *T. Ritter*[1,3];
[1]*Regenerative Medicine Institute, National University of Ireland, Galway, Galway, Ireland,* [2]*Discipline of Pharmacology and Therapeutics, National University of Ireland, Galway, Galway, Ireland,* [3]*CURAM Centre for Research in Medical Devices, School of Medicine, College of Medicine, Nursing and Health Sciences, National University of Ireland, Galway, Galway, Ireland.*

Mesenchymal stromal cells (MSC) have been shown to be potently immunomodulatory and capable of prolonging corneal transplant (CT) survival. Patients with pre-existing allo-immunity or receiving a second CT are at higher risk of rejection and represent an unmet clinical need. A high risk CT model was developed in rats by injecting the recipient with donor derived splenocytes 14 days before transplantation. Pre-sensitised CT recipients rejected significantly earlier (day 11.5) than animals which were not pre-sensitised (day 19.3) indicating they had pre-existing allo-immunity. Two pre-transplant intra-venous injections on days -7 and -1 of $1x10^6$ allogeneic (to both donor and recipient) MSC were administered. This strategy significantly prolonged CT survival with 63.6% of MSC treated animals grafts surviving until day 30 compared to 0% in the untreated group. MSC treated animals had higher proportions (13.5%) of the immunomodulatory $CD11b^+B220^+$ monocytic cells in the lungs at the time of transplantation compared to untreated animals (7.6%). At the average time of rejection in untreated animals (day 10), MSC treated animals also had a higher proportion of $CD4^+CD25^+FoxP3^+$ Tregs (7.9%) in their draining lymph node compared to untreated animals (4.4%). Finally, CD11b/c cells isolated from the lungs of naïve rats were shown to generate more Treg *in vitro* after being co-cultured with MSC than those not exposed to MSC. This work sheds light on a potential mechanism of action and underlines the utility of MSC in immunological diseases and particularly in high risk CT.

P.C3.02.15

In vitro TGF-β secretion capacity of stimulated peripheral blood cells correlates with the occurrence of opportunistic infection in liver and kidney transplantation

F. Boix, G. Gonzalez-Martinesz, R. Alfaro, I. Legaz, R. Moya-Quiles, A. Minguela, J. Pons, J. Galian, S. Llorente, ***M. Muro****;*
Immunology Service, Clinical University ´Virgen Arrixaca´ - IMIB. 30120 Murcia, Spain., Murcia, Spain.

Introduction:TGF-β has been known to act as a potent immune-regulatory cytokine, which blocks T-cell activation. It is considered as a potential target for more specific and less toxic immunosuppression and control of alloimmune-responses over the long term in transplantation In this setting, TGF-β main function after SOT remains yet unclear and is important to further characterise its role under different clinical circumstances not only for operational tolerance, but also amongst other comorbidities such as opportunistic-infection(OI).
Objective:The aim of this study was to assess the concentration of TGF-β in the supernatant of stimulated WPB in a cohort of SOT recipients (SOTr) and correlate it with the primary study outcome which was the occurrence of OI. Material and Methods:30 liver(LTr) and 31 kidney(KTr) transplant recipients as well as 15 healthy volunteers (HCs) were recruited and prospective monitored for one year in our Hospital. ELISA was carried out to calculate TGF-β concentration after WPB culture with Concanavalin A for 72 hours.
Results:Prior transplantation, SOTr showed higher TGF-β concentration compare to HCs. The stratification analysis showed that TGF-β was significantly higher in patients with OI within the first six months following transplantation. A TGF-β>363.25ng/ml in LTr and >808.51ng/ml in KTr were shown to be the most accurate cut-off values to stratify SOTr at high risk of OI. The regression model confirmed this biomarker as the main recipient risk factor for developing OI. Discussion:Our data show that the quantification of TGF-β could provide valuable information as to the occurrence of OI in LTr and KTr.

Photoconversion of Alloreactive T Cells in Peyer's Patches: Tracking the Homing of Highly Proliferative Cells *in vivo*

K. J. Ottmüller[1,2], *Z. Mokhtari*[1], *L. Scheller*[1,2], *J. Hartweg*[1,2], *S. Thusek*[1], *D. Le*[1], *M. Ranecky*[1,2], *H. Shaikh*[1,2], *M. Qureischi*[1,2], *K. G. Heinze*[3,2], *A. Beilhack*[1,2,4];
[1]*University Hospital Würzburg, Würzburg, Germany,* [2]*Graduate School of Life Sciences, University of Würzburg, Würzburg, Germany,* [3]*Rudolf Virchow Center, University of Würzburg, Würzburg, Germany,* [4]*Department of Pediatrics, University Hospital, Würzburg, Germany.*

Marking and tracking of T cells is important to study their trafficking, which is an elementary process to all immune reactions. Only with this efficient homing, single immune cell clones can convey protection against intruders or regulate immune responses throughout the whole body. Photoconversion is a superior labeling technique for intravital application because it enables contactless time- and site-specific marking of cells in the tissue without surgically manipulating the microenvironment. However, the converted fluorescent protein may decline quickly in proliferating cells.
We demonstrate the suitability of photoconversion to tracking highly proliferating T cells from the priming site of T cell activation to peripheral target organs. Dendra2$^+$ T cells were photoconverted in the Peyer's patches during the initiation phase of acute graft-versus-host disease (GvHD). We tracked these cells through the mesenteric lymph nodes and the peripheral blood to their effector site, the small intestine, with flow cytometry and intravital two-photon microscopy.
Photoconverted alloreactive T cells preserved the full proliferative capacity and cytotoxicity against tumor cells. We quantified the trafficking cells throughout their homing route and observed that their migration in the intestinal lamina propria was retained after photoconversion.
We conclusively proved that photoconversion of highly proliferative alloreactive T cells in the Peyer's patches is an effective tool to study trafficking of alloreactive T cells under physiologic conditions and to GvHD target tissues. This technique can also be applied to the study of immune cell tracking under inflammatory and non-inflammatory conditions.

P.C3.02.17

Dendritic cells are affected by VEGF depletion leading to corneal graft acceptance

A. Schneider[1], *E. Zinser*[2], *F. Bock*[1];
[1]*Department of Ophthalmology Cologne, Cologne, Germany,* [2]*Department of Immunomodulation, Erlangen, Germany.*

The main risk factor in corneal transplantations is the presence of blood and especially lymphatic vessels in the normally avascular and immune-privileged cornea. In the murine model of high risk corneal transplantation neovascularization is induced by a sterile inflammation caused by intrastromal corneal sutures. VEGF-depletion during this inflammation prevents vessel ingrowth into the cornea, which significantly improves subsequent graft survival. Dendritic cells (DCs) are the main immune cells that are trafficked through lymphatic vessels and are responsible for antigen recognition and subsequent activation of T cell mediated rejection in transplant settings. We demonstrate that VEGF-depletion does not only act on vessel formation, but has an immune modulatory effect on DCs. Treatment of DCs with VEGFR1/R2 Trap affected costimulatory molecule expression, cytokine secretion and impaired the capacity of the cells to stimulate T cells in vitro. VEGF depletion in mice during suture induced neovascularization impairs recruitment of DCs into the cornea and weakens trafficking of DCs. In addition we could show that VEGF depletion acts in an immune modulatory manner on the DCs directly through decreased costimulatory molecule expression and subsequent induction of more potent CD4+CD25+Foxp3+ regulatory T cells.

P.C3.02.18

CD40 ligation on monocyte derived dendritic cells enhances the production of the positive complement regulator properdin

M. F. van Essen*, N. Schlagwein, J. M. Ruben, C. van Kooten, on behalf of the COMBAT Consortium;*
Div. of Nephrology and Transplant Medicine, Dept. of Medicine, Leiden University Medical Center, Leiden, Netherlands.

The important role of local complement production and activation has been demonstrated in experimental transplantation. During APC-T cells interactions, C3a and C5a contribute to T cell proliferation and cytokine production by APCs. Properdin (fP) stabilizes the C3 convertase, thereby enhancing C3a and C5a generation. We investigated the regulation and functional consequence of fP production by monocyte-derived dendritic cells (MoDCs) upon LPS stimulation or the mimic of co-stimulatory signals in T cell-APC interaction CD40L. MoDCs were stimulated for 48h with either LPS, CD40L expressing L-cells or control cells. CD40L induced a dose-dependent increase in fP production (mean 7.5-fold increase, 18 ng/ml, n=10), compared to controls (mean 2.5ng/ml). LPS stimulation increased fP levels as well (mean 15ng/ml, n=10). The combined activation with CD40L and LPS did not result in synergistic fP production, whereas this was observed for IL-10 and IL-12p70.
To explore the functional role of fP, MoDCs were treated with a siRNA-pool against fP at day 5 and additionally cultured for 48 hours with or without stimulation. At day 7, cells were harvested and co-cultured with CFSE-labelled allogeneic T cells. FP knockdown was confirmed by ELISA and exposure of immature MoDCs to allogeneic T cells led to a reduced T cell proliferation, as determined by FACS.
In conclusion, LPS and CD40 activation increases fP production by MoDCs. Since CD40L is specifically expressed on activated T cells, this introduces cognate specificity to this local regulation. This places fP, in addition to C3a and C5a, as a new player regulating APC-T cell activation.

Susceptibility to structural valve deterioration is one of the major drawbacks of bioprosthetic heart valves (BHVs). *N*-glycolylneuraminic acid (Neu5Gc) is an immunogenic dietary-carbohydrate antigen in humans because of inactivation of the gene encoding CMP-*N*-acetylneuraminic acid hydroxylase (*CMAH*), and all humans have circulating anti-Neu5Gc antibodies. We hypothesized that interaction of anti-Neu5Gc antibodies with Neu5Gc on BHVs could lead to immune response resulting in valve deterioration through calcification. We demonstrate Neu5Gc in both native calcified human valves as well as in calcified-BHVs, explanted from human patients, by HPLC and immunohistochemistry. Furthermore, anti-Neu5Gc IgGs were purified from native calcified human valves and explanted calcified-BHVs, further validated by a glycan microarray. In the Neu5Gc-free *Cmah*-KO mouse model, anti-Neu5Gc antibodies promoted calcium deposits in subcutaneous implanted BHV discs, both with passive transfer of affinity-purified human anti-Neu5Gc IgGs, and by active-immunization of *Cmah*-KO mice with Neu5Gc-containing glyco-nanoparticles. Thus, co-existence of Neu5Gc/anti-Neu5Gc likely mediate BHV structural valve deterioration, and in addition they have potential role in native human aortic valve calcification.

High intensity de novo donor specific HLA class II ntibodies associated to renal chronic rejection

R. Alenda[1], *M. Moreno-Hidalgo*[1], *A. Balas*[1], *F. Garcia-Sanchez*[1], *L. Barea*[1], *M. Rodriguez-Ferrero*[2], *F. Anaya*[2], *J. Vicario*[1];
[1]*Centro de transfusion de la comunidad de Madrid, Madrid, Spain,* [2]*Hospital Universitario Gregorio Marañon, Madrid, Spain.*

Introduction: Development of *de novo* donor-specific anti-HLA antibodies (*dn*DSA) is associated with reduction in renal graft survival. High titer (>5000 MFI) of anti-HLA class II antibodies is frequently found in chronic rejection. The aim of the study was to analyze the incidence of dnDSA, their targets/titer, and clinical relevance. **Material and Methods:** The study included 303 renal transplants from 2010 to 2018 at a single center. Sera were tested using Lifecodes Class I and Class II SAB kits (Immucor, USA). **Results:** 44 patients (14.5%) developed *dn*DSA in 144 months as average. 5 patients developed antibodies only against class I (1'6%), 11 patients against class II (3'6%) and 28 patients against both (9'2%). The mean of the high titer reached for anti-HLA class I antibodies was 4833 MFI, anti-HLA class II DRB 11123 MFI, anti-HLA class II DQB1 10258 MFI and anti-HLA class II DQA1 9890 MFI.
Class I antibodies titer is significantly lower than class II. The mean titer of anti-HLA class II DRB4* (15600 MFI) and DQB1*02,03 (11164 MFI) antibodies was calculated, because they are considered as eplets predictors for the development of d*n*DSA. In both cases, the titer is higher than was found for all DRB,DQB1 antigens. **Conclusion:** 14.5% of the patients studied develop *dn*DSA in the follow-up. The percentage of patients with anti-HLA antibodies against class II antigens is higher, and they react with higher maximum titer than anti-HLA class I antibodies. The highest antibody response seems to be directed against immunodominat eplets.

P.C3.03.02

Relationship between adaptive NK cell markers and the incidence of cytomegalovirus infection in kidney transplant recipients

M. Ataya[1], *D. Redondo-Pachón*[1,2], *L. Llinàs*[1], *J. Yélamos*[1,3], *G. Heredia*[4], *L. Soria*[4], *J. Pascual*[1,2], *M. Crespo*[1,2], *M. López-Botet*[1,3,4];
[1]*Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain,* [2]*Nephrology S. Hospital del Mar, Barcelona, Spain,* [3]*Immunology S. Hospital del Mar, Barcelona, Spain,* [4]*Univ. Pompeu Fabra (UPF), Barcelona, Spain.*

Human cytomegalovirus (HCMV) infection has been related with an increased risk for graft loss and reduced host survival in kidney transplant recipients (KTR). HCMV infection may promote the adaptive differentiation and persistent expansion of an NKG2C+ NK cell subset. These adaptive NK cells are functionally mature, efficiently mediate specific antibody-dependent effector functions against HCMV-infected cells and display to a variable extent discrete phenotypic features, reflecting late differentiation events (e.g. CD57 and ILT2 expression; FcεRI γ chain downregulation). In a prospective study of a KTR cohort (N=122), high pre-transplant levels of NKG2C$^+$ NK cells were found associated with a reduced incidence of post-transplant HCMV viremia[1]. We have extended the phenotypic analysis by multiparametric flow cytometry in available cryopreserved pre-transplant PBMC samples from cases of the same KTR cohort. The expression of NKG2A, CD57, ILT2 (LIR-1) and FcεRI-γ was analysed in NK cells and T lymphocytes, including TCRγδ+ subsets (Vδ2+ and Vδ2-). Individually, these markers appeared unrelated with post-transplant HCMV infection. Yet, when their co-expression with NKG2C in NK cells was considered, significantly lower proportions of NKG2C+ NKG2A-, CD57+, CD57-, ILT2+, ILT2-, FcεRI γ- and FcεRI γ+ were detected in KTR developing HCMV infection (Wilcoxon test). These results, together with CMV-free survival analysis (Kaplan-Meier), further support the relationship between NKG2C+ NK cells and the risk of post-transplant HCMV infection.

P.C3.03.03

Ex vivo lung perfusion affects the immunological milieu and regulatory T cells in a porcine lung transplantation model

R. Bellmàs Sanz[1], *J. Salman*[2], *T. Siemeni*[2], *K. Jansson*[2], *A. Knöfel*[2], *F. Ius*[2], *K. Höffler*[2], *A. Haverich*[2], *I. Tudorache*[2], *C. S. Falk*[1], *G. Warnecke*[2];
[1]*Institute of Transplant Immunology, Hannover Medical School, Hannover, Germany,* [2]*Department of Cardiothoracic, Vascular and Transplantation Surgery, Hannover Medical School, Hannover, Germany.*

Introduction: Ex vivo lung perfusion (EVLP) is an alternative to cold static storage for graft preservation in lung transplantation. Here, we investigate mechanisms of improved preservation using the Organ Care System (OCS) as EVLP platform, focusing on immunological changes in a porcine lung transplant model. **Methods**: 12 porcine lungs were explanted from healthy donor pigs: six lungs were preserved for 6h in the OCS (OCS group) and six lungs on ice (standard of care, SOC group). The left lungs were transplanted into allogeneic porcine recipients and all pigs were observed for 6 hours after clamping the contralateral lung. We investigated the presence of cytokines and Treg, Tcon subsets in recipient blood, bronchoalveolar lavage (BAL) fluid and perfusates. **Results**: In BAL of OCS recipients at 6 h, significantly lower levels of IL-6 (p=0.04), IL-1a (p=0.04), IL-1RA (p=0.03), IL-12 (p=0.03), IL-18 (p=0.03) and IFN-g (p=0.04) were observed compared to SOC recipients, which was accompanied to increased expression of CD25 on CD4$^+$ and CD8$^+$ Tcon cells in SOC recipients (p=0.02). In perfusates of OCS lungs, significantly higher pro-inflammatory cytokine levels were detected compared to perfusates of SOC lungs, especially the antagonist IL-1RA. Remarkably, in these OCS perfusates, FoxP3 expression of CD4$^+$CD25$^+$ T cells was maintained but significantly decreased in SOC perfusates (p<0.001). **Conclusions**: Preservation using the OCS has a strong immunological impact towards an anti-inflammatory milieu systemically and maintenance of FoxP3 expression in Tregs in BAL reflecting human data of the INSPIRE trial.

P.C3.03.04

A unique CD56^{dim} NK cell subset, which is also present in lung perfusates, increases in the periphery of lung transplant recipients

R. Bellmàs Sanz[1], *M. Seyda*[1], *B. Wiegmann*[2], *K. Bläsing*[1], *C. Neudörfl*[1], *A. Knöfel*[2], *I. Tudorache*[2], *C. Kühn*[2], *M. Avsar*[2], *A. Haverich*[2], *G. Warnecke*[2], *C. S. Falk*[1];
[1]*Institute of Transplant Immunology, Hannover Medical School, Hannover, Germany,* [2]*Department of Cardiothoracic, Vascular and Transplantation Surgery, Hannover Medical School, Hannover, Germany.*

Purpose: Biomarkers to predict short and long term outcome after lung transplantation are urgently needed. Monitoring of the longitudinal dynamics lymphocyte subsets after lung transplantation represents a feasible strategy for the identification of potential biomarkers for rejection. In this study we defined the phenotype and kinetics of NK and T cell subsets in recipient blood and compared them with their counterparts in perfusates. **Methods**: Perfusion solutions and blood were obtained before (pre Tx), directly after (T0), 24h (T24) and 3 weeks post transplantation from 60 lung transplant recipients. T and NK lymphocyte subsets from peripheral blood and perfusates were analyzed by multicolor flow cytometry. **Results**: At T0, NK cells increased in recipient blood compared to pre Tx values (p=0.01) and declined at T24 (p=0.04), whereas T cells decreased at T0 (p=0.005) and recovered at T24. The phenotype of these NK cells consisted of CD56^{dim} CD16$^+$ CD161$^+$ cells, with high KIR$^+$ NK cell proportions and significantly elevated CD69 and CD25 expression. T cells at T0 were also enriched for CD69$^+$, CD25$^+$ and KIR$^+$ subsets. This was the prevalent T and NK cell phenotype in perfusates, a unique compartment containing T and NK cell subsets significantly different from matched PBMCs. **Conclusion**: After lung transplantation, CD56^{dim} NK cells with a unique phenotype increase in recipient blood, which raises the question whether NK cells are recruited rapidly into the periphery and/or donor cells are migrating out of the transplanted lung. The similarity of these cells with perfusate cells may indicate their donor origin.

P.C3.03.05

Multiplex KIR and HLA class I genotyping using Next Generation Sequencing

L. Closa[1,2], *F. Vidal*[3,2,4], *M. J. Herrero*[1], *J. L. Caro*[1,2];
[1]*Immunogenetics and Histocompatibility Laboratory, Blood and Tissue Bank, Barcelona, Spain,* [2]*Transfusional Medicine Group, Vall d'Hebron Research Institute, Autonomous University of Barcelona (VHIR-UAB), Barcelona, Spain,* [3]*Congenital Coagulopathy Laboratory, Blood and Tissue Bank, Barcelona, Spain,* [4]*CIBER of Cardiovascular Diseases (CIBERCV), Madrid, Spain.*

The killer cell immunoglobulin-like receptors (KIR) are considered the most polymorphic Natural Killer (NK) cell regulators, binding HLA class-I molecules or still unknown ligands. Lately, the interest on KIR genotyping has increased as it has been shown their importance in the identification of the best possible donors for Hematopoietic Stem Cell Transplantation (HSCT) to obtain graft-versus-leukemia effect.
Currently, routine protocols to determine gene content of KIR cluster are exclusively performed by PCR-SSO and PCR-SSP. To improve the study of these genes, we developed a multiplex Long-Range PCR strategy suitable for simultaneous high-resolution HLA class I and KIR genotyping by Next Generation Sequencing (NGS). This protocol allows the amplification of 17 KIR genes and pseudogenes and HLA class I with further sequencing using an Illumina sequencer. The bioinformatics analysis for KIR genotyping was performed using in-house gene-specific virtual probes by CLC Genomics Workbench 11 and the HLA genotyping by GenDx NGSengine software 2.8.0. To validate the method reliability, 96 previously characterized genomic DNA samples were used.
When specific KIR was present, an average of 415 gene-specific virtual probes was detected, meanwhile when it was absent, the average was 6, facilitating the cutoff establishment. Also, the rate of concordance for both KIR and HLA was 100% compared with previous results.
In conclusion, we demonstrated that the multiplex PCR NGS-based strategy could provide a much more efficient and economic method for KIR-ligand genotyping at presence-absence level compared to current techniques. Moreover, reach the allelic level will be possible when specific software becomes available.

P.C3.03.06

Immunosuppressive drug withdrawal late after liver transplantation leads to an improvement of lipid metabolism, a reduction of infections and an increase in gamma-delta Vd1 perforin and granzyme B positive T-cells

A. A. Duizendstra[1], *R. J. de Knegt*[1], *M. G. Betjes*[2], *N. H. Litjens*[2], *J. Kwekkeboom*[1];
[1]*Department of Gastroenterology and Hepatology, Erasmus University Medical Center, Rotterdam, Netherlands,* [2]*Department of Internal Medicine - Division of Nephrology and Transplantation, Erasmus University Medical Center, Rotterdam, Netherlands.*

Background: Liver transplant (LTx) recipients need lifelong treatment with immunosuppressive drugs (IS) to prevent rejection. Long-term use of IS is accompanied by adverse effects. Occasionally LTx recipients can be fully withdrawn from IS and are considered to be tolerant towards their graft. Studies indicate that the Vδ1/Vδ2 ratio of γδT-cells is a useful biomarker to identify tolerant LTx recipients.
Objective: To assess clinical and immunological effects of IS withdrawal late after LTx.
Methods: LTx recipients withdrawn from IS (TOL; n=13), and a control group on IS (CTRL; n=22) matched for time after LTx, age, gender and CMV serostatus were included. Liver and kidney function, lipid profile and infections before and after withdrawal or matching time points were evaluated. PBMCs were characterized by flow-cytometry.
Results: Liver function (bilirubin, AST, ALT) levels significantly improved in TOL after IS withdrawal, whereas kidney function did not. LDL levels and total number of infections significantly decreased in TOL after IS withdrawal, but not in CTRL. No differences were found in Vδ1/Vδ2 ratios between both groups, but Vδ1+GranzymeB+Perforin+ γδT-cells were significantly increased in TOL compared to CTRL.
Conclusion: After IS withdrawal no deterioration of graft function is observed, lipid metabolism improves and total number of infections decrease, but kidney function does not improve. It is likely that kidney damage in LTx recipients is irreversible after long-term IS therapy. Vδ1/Vδ2 ratio is not increased in TOL, which may be due to matched CMV serostatus of CTRL, but in TOL enhanced cytotoxic status of Vδ1 γδT-cells is observed.

P.C3.03.07

Alloantibody can detect a single aminoacid change at position 59 in HLA-B27

N. Egri Córdoba, *M. Digón Doral, A. Manchón Castillo, E. Palou Rivera, J. Martorell Pons;*
Department of Immunology, Hospital Clínic of Barcelona, Spain.

Abstract
Background: HLA antibodies identification by SAB evidences diversity of alloantibody reactivity between alleles with a common first field but different second field (e.g. B*27:03;B*27:05;B*27:08) corresponding to different proteins of the same "serological specificity".
Objectives: Quantify and analyze the differences in reactivity of different HLA-B*27 proteins with common first field but different second field.
Methods: Sera from 1.100 patients on kidney transplant waiting list were analyzed with KIT Lifecodes LSA Immucor. 304 had anti HLA-I. Those positive with at least one B*27 protein were selected. Patterns had been quantified and their rationale was analyzed at the eplet and sequence level.
Results: We found 66 patients with some reactivity with B*27 alleles. Surprisingly, 14/66 (22%) had the pattern (B*27:03-,B*27:05+,B*27:08+) not explained by described eplets. Allele B*27:03 has a single discrepancy with B*27:05&B*27:08 in position 59 Histidine/Tyrosine that should explain this pattern. The rest of the patterns are explained by several eplets as (B*27:03+,B*27:05+,B*27:08+) explained by verified 65QIA, 69AA, 80TLR, 82LR, 131S, 163EW or non verified 66IC, 71KA, 69AT, 76ED, 102DV, 156LA, 170RY, 193PI (37/66); (B*27:03-, B*27:05-,B*27:08+) explained by 76ESN (7/66); (B*27:03+,B*27:05+,B*27:08-) explained by 80TLR, 82LR (7/66). Probably p59H can modify reactivity with eplets 65QIA, 69AA and 163EW that are in a short distance in tridimensional structure.
Conclusion: A single change at position 59 Histidine/Tyrosine can explain differences in alloantibody reactivity in 22% of B*27 reacting patients. This change is not involved in described eplets.

Corneal transplantation is the most common transplantation procedure globally and corneal rejection is still an important complication limiting its success. The aim of this study was to define corneal infiltrating lymphocytes in patients with corneal rejection.
Two patients who needed graft exchange due to corneal rejection were included into the study. Corneal infiltrating lymphocytes were isolated with tumor dissociation kit with gentle MACS Dissociator and were analyzed by flow cytometry. The sample of the first patient was stained with anti-human CD45-FITC/CD14PE, anti-human CD3-FITC/CD19-PE and the second sample was stained with CD45-FITC/CD14-PE, anti-human CD3-FITC/CD4-PE monoclonal antibodies.
The first case was a 36 years-old, male, keratoconus patient who had keratoplasty 8 years ago and the second case was a 23 years-old, male, keratoconus patient who had keratoplasty 3 years ago. Both patients needed rekeratoplasty due to corneal rejection and opacification, which was unresponsive to medical treatment. The flow cytometry analysis revealed that 33% of the infiltrating cells were $CD3^+$ T and 17% were $CD19^+$ B lymphocytes. Among the $CD3^+$ T lymphocytes, expression of CD4 was 19.7%.
This pilot study demonstrated that corneal infiltrating lymphocytes could be isolated from human corneal tissue with kits designed to extract lymphocytes from other solid tissues. Previous animal model work and human aqueous humor studies highlighted role of T cell and B cell cooperation in corneal rejection. This pilot study demonstrated for the first time human corneal infiltration by these cells. Further work on this topic would contribute better understanding of the immunology of human corneal rejection.

P.C3.03.09

PIRCHE-II is related to graft failure after kidney transplantation

K. Geneugelijk[1], *M. Niemann*[2], *J. Drylewicz*[1], *H. G. Otten*[1], *E. Spierings*[1], *on behalf of the PROCARE consortium;*
[1]*Laboratory of Translational Immunology, UMC Utrecht, Utrecht, Netherlands,* [2]*PIRCHE AG, Berlin, Germany.*

Individual HLA mismatches may differentially impact graft survival after kidney transplantation. Therefore, there is a need for a reliable tool to define permissible HLA mismatches in kidney transplantation. We previously demonstrated that donor-derived Predicted Indirectly ReCognizable HLA Epitopes presented by recipient HLA class II (PIRCHE-II) play a role in *de novo* DSA formation after kidney transplantation. In the present Dutch multi-center study we evaluated the possible association between PIRCHE-II and kidney graft failure in 2,918 donor-recipient couples that were transplanted between 1995 and 2005. For these donors-recipients couples, PIRCHE-II numbers were related to graft survival in univariate and multivariable analyses. Adjusted for confounders, the natural logarithm of PIRCHE-II was associated with a higher risk for graft failure (HR:1.13, 95% CI:1.04-1.23, p=0.003). When analyzing a subgroup of patients who had their first transplantation, the hazard ratio of graft failure for ln(PIRCHE-II) was higher compared to the overall cohort (HR:1.22, 95% CI:1.10-1.34, p<0.001). PIRCHE-II demonstrated both early and late effects on graft failure in this subgroup. These data suggest that the PIRCHE-II may impact graft survival after kidney transplantation. Inclusion of PIRCHE-II in donor-selection criteria may eventually lead to an improved kidney graft survival.

P.C3.03.10

Manipulation of macrophage phenotype by genetic, pharmacologic and magnetic interference

M. Kloc[1], *J. Kubiak*[2], *W. Chen*[1], *J. Wosik*[3], *R. M. Ghobrial*[1];
[1]*The Houston Methodist Hospital, Houston, United States,* [2]*Unversity of Rennes, Rennes, France,* [3]*University of Houston, Houston, United States.*

In all eukaryotic cells the cell shapes and the cell functions are reciprocally related. Thus, the genetically, biochemically or mechanically/magnetically enforced change in the cell shape will profoundly reverberate at the cell functions. Cell shape depends on the actin filament cytoskeleton, which is regulated by the small GTPase RhoA and its downstream effector ROCK kinase. We studied how genetic or pharmacologic interference with RhoA pathway changes phenotype, shape and functions of immune cells such as macrophages. We found that RhoA-deletetion or RhoA/ROCK inhibition elongates macrophages and disrupts their actin-dependent organelles and functions such as Golgi complex and receptor recycling pathway. All these changes block macrophage ability to mount post-transplantation immune response in the rodent transplantation model system. We also found that the macrophages exposed to the magnetic field acquire phenotype that mimics the RhoA-interference phenotype. These findings have a potential to be used in development of novel anti-rejection therapies in clinical organ transplantation and anti-cancer and anti-metastatic therapies.

P.C3.03.11

The relationship between the C1q-binding ability and the IgG subclass pattern of anti-HLA antibodies

A. Navas[1], *J. Molina*[2,1], *M. Agüera*[3,1], *A. Jurado*[2,1], *A. Rodríguez-Benot*[3,1], *P. Aljama*[3,1], *C. Alonso*[2,1], *R. Solana*[1];
[1]*Maimonides Biomedical Research Institute of Cordoba (IMIBIC)/ Reina Sofia University Hospital/ University of Cordoba, Cordoba, Spain,* [2]*Department of Allergy and Immunology, Reina Sofia University Hospital, Cordoba, Spain,* [3]*Department of Nephrology, Reina Sofia University Hospital, Cordoba, Spain.*

The presence of antibodies against donor HLA antigens (DSA) is the main barrier prior to transplantation. However, not all DSA seem to involve the same risk for allograft failure. Several modifications of the standardized single antigen bead (SAB) assay have been introduced to identify properties of anti-HLA antibodies which could determine their pathogenic potential. The aim of this study was to ascertain the relationship between the complement-binding ability of anti-HLA antibodies and their IgG subclass profile.
We studied 10 serum samples belonging to highly-sensitized patients awaiting single-kidney transplantation at Reina Sofia University Hospital using the modified SAB-C1q and SAB-subclass assays.
Among the 1,346 Luminex-beads analyzed, 248 (18.4%) were able to bind complement. The presence of IgG1 and/or IgG3 subclasses were found in 274 (25%) non-C1q-binding and 236 (95.2%) C1q-binding anti-HLA antibodies. The correlation per bead between the MFI value by SAB-C1q assay and the MFI value of each subclass was of R_{IgG1}=0.492, R_{IgG2}=0.184, R_{IgG3}=0.376 and R_{IgG4}=0.136. When analyzing the C1q-binding ability according to the IgG subclass pattern, we found that the MFI value in SAB-C1q assay of antibodies comprised of a mixture of subclasses (IgG1+IgG2+IgG3/4) was significantly higher than that of those comprised of isolated IgG1 (p<0.001) and of IgG1+IgG2 (p<0.001).
Both C1q-binding and non-C1q-binding anti-HLA antibodies may be comprised of strong complement-binding subclasses (IgG1/IgG3). IgG1 is the subclass which best correlates with the ability to bind C1q. Antibodies comprised of a mixture of subclasses (IgG1+IgG2+IgG3/4) are more likely be able to bind C1q.

P.C3.03.12

Alternative to CDC Crossmatch in patients candidates to renal transplantation treated with Rituximab

P. Lapuente Suanzes[1], *T. Mateu Albero*[2], ***I. Nieto Gañán***[1], *J. Castañer Alabau*[1];
[1]*Immunology Department Hospital Universitario Ramón y Cajal, Madrid, Spain,* [2]*Immunology Department Hospital Universitario la Princesa, Madrid, Spain.*

Introduction: Rituximab (anti-CD20) can modify the result of crossmatch (XM) in renal transplantation, being necessary to look for complementary studies that allow to interpret the result of XMs only based on the presence or absence of anti-HLA antibodies.
Case presentation: A 62-year-old man with rheumatoid arthritis treated with Rituximab. He required a kidney transplant for thrombosis of the left renal artery and loss of function. Despite the absence of anti-HLA antibodies, both XMs by complement-dependent cytotoxicity (XM-CDC) and by flow cytometry (XM-FC) were positive, the latter being only positive for B cells. An assay was designed to confirm that positivity was due to the presence of Rituximab in serum.

Material and methods: XM-FC was performed by adding anti-CD20 monoclonal antibody (mAb) to the usual protocol and comparing the differences between incubating donor cells with patient's serum before or after labelling with anti-CD20 mAb. BD FACSCanto-II flow cytometer and FACSDiva software were used to acquire and analyse the samples.
Results: XM-FC was negative for B cells pre-incubated with anti-CD20. In addition, the CD20 IMF was higher in comparison with the B cells previously incubated with the patient's serum, being in both cases clearly lower than controls.
Conclusions: This trial allows us to demonstrate that the positivity in XM-FC of these patients is due to the action of Rituximab. Furthermore, knowing the fact that Rituximab does not contraindicate the transplant, the correct interpretation of the XMS made to these patients has a crucial clinical importance since that kidney transplant depends on it.

P.C3.03.13
In search of renal transplantation options for hyperimmunized patients

I. Nieto Gañán[1], *S. Elías Triviño*[2], *S. Jiménez Álvaro*[3], *C. Galeano Álvarez*[2], *A. Collado Alsina*[4], *M. Sacén*[5], *A. Fernández Rodríguez*[2], *J. Castañer Alabau*[1];
[1]Immunology Department Hospital Universitario Ramón y Cajal, Madrid, Spain, [2]Nephrology Department. Hospital Universitario Ramón y Cajal, Madrid, Spain, [3]Nephrology Department Hospital Universitario Ramón y Cajal, Madrid, Spain, [4]Instituto Ramón y Cajal de Investigación Sanitaria, Madrid, Spain, [5]Nephrology Department. Hospital de la Raza, Ciudad de Mexico, Mexico.

Introduction: One essential problem in the waiting lists for kidney transplantation are hyperimmunized patients. The high sensitivity of solid-phase techniques for the study of antibodies and definition of virtual crossmatch make transplant difficult in them. Therefore, it should be considered the possibility of receiving grafts looking for assumable risks depending of fluorescence intensity values of DSAs.
Material and methods: We followed 41 patients with a mean of 47.48 months in waiting list and average panel reactive antibody (PRA) of 52.4% transplanted 2014-2017 with negative CDC-XM and positive virtual-XM (maximun allowed 1 DSA>100.000SFI+1 DSA>40.000 SFI). Correlations were sought between the evolution of the graft based on clinical criteria and immunological studies (anti-HLA antibodies by Luminex and Eplets compatibility by HLA-Matchmaker).
Results: 6 patients lost the graft (PRA≥90%). 3 patients presented humoral rejection, two of them with graft loss (4.9%). A correlation was observed between the number of incompatible donor-recipient eplets and the anti-HLA antibodies titre (R^2=0.37). Patients who received plasma exchange posttransplantation had a decrease in the DSAs titre (except one, with no graft loss).
Conclusions: Currently a large number of patients included in kidney transplant lists are hyperimmunized, being necessary to look for transplant protocols for them with reduced possibility of humoral rejection. Our series seems to indicate that renal transplantation with DSAs imply an assumable risk. However, studies with larger series of patients and with a longer follow-up period are needed to stablish threshold titres of anti-HLA antibodies. Most hyperimmunized patients (PRA>95%) could receive personalized immunosuppressive protocols post-transplant.

P.C3.03.14
Detection of a new HLA-A*30 allele in a donor from the NMDP register

M. Vilches-Moreno, ***M. San Jose-Cascon****, E. Garcia-Moreno, A. Nieto;*
UGC Hematology, Immunology and Genetics, Hospital Universitario Puerta del Mar, Cadiz, Spain.

Introduction: High resolution typing for HLA molecules is a crucial component in donor unrelated stem-cell transplantation. Mismatches between patient and donor may lead to transplantation-related complications resulting in morbidity or mortality. Here we describe the identification of a novel HLA-A*30 null allele in the course of high resolution confirmatory typing that precluded donation from an *a priori* matched unrelated bone marrow donor.
Materials and Methods: HLA alleles were sequenced through exons 2-4 in both directions using reagent kit AlleleSEQR HLA and analysed with Assign SBT software. Primers were designed to separately amplificate and sequence the third exon of HLA-A*30 and HLA-A*01. A PCR-SSP strategy was designed to further confirm the presence of the new allele.
Results: Typing of the sample by registry was A*01:UAUY, A*30:PXPW. The sequence obtained using HLA-A AlleleSeqr kit did not fully match with any allele pairs in the IMGT/HLA and showed two heterozygous mismatches with respect to HLA-A*01:01/*30:01 allele pairs. Specifically, codon 175 showed G/**T** at position 3 and codon 176 showed A/**T** at position 1 (mismatches in bold type). The phase of these changes was ascertained both by sequencing exon 3 of A*01 and A*30 separately from each other and by in house designed PCR-SSP. Both approaches showed that the mismatched TT were in the A*30 allele. The change in codon 176 generates a stop codon (TAG) in the A*30 allele most probably abolishing its surface expression.
Conclusions: We have found a probably null HLA-A*30 allele with sequence variations not described so far.

P.C3.03.15
Prevalence and impact of preformed and de novo anti-HLA donor specific antibodies in liver transplantation

M. Papachristou[1], *A. Fylaktou*[1], *M. Daoudaki*[2], *E. Cholongitas*[3], *T. Karampatakis*[1], *A. Anastasiou*[1], ***A. Sarantopoulos***[4], *G. Chatzika*[1], *L. Vagiotas*[5], *I. Fouzas*[5];
[1]National Peripheral Histocompatibility Center-Immunology Department, Hippokration General Hospital, Thessaloniki, Greece, [2]Biochemistry Laboratory, Aristotle University of Thessaloniki, Medical School, Thessaloniki, Greece, [3]First Department of Internal Medicine, Medical School of National & Kapodistrian University of Athens, Athens, Greece, [4]2nd Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, [5]Solid Organ Transplantation Center, Aristotle University of Thessaloniki Medical School, Hippokration General Hospital, Thessaloniki, Greece.

Introduction: The prevalence and impact of pre-existing and de novo anti-HLA donor-specific antibodies (DSAs) after orthotopic liver transplantation (OLT) is still controversial. We investigated the role of preformed DSAs in the antibody-mediated rejection (AMR) and risk factors implicated in the emergence of DSAs and allograft dysfunction after OLT.
Material: A total of 65 liver transplant patients were tested for anti-HLA antibodies, with single antigen bead technology (SAB), before, 1, 3, 6 and 12 months after transplantation, and thereafter annually, along with other risk factors. **Results:** Sixteen out of 65 patients (24.6%) had circulating pre-existing anti-HLA antibodies and 4 of them (25%) had DSAs. All patients positive for anti-HLA antibodies (100%) presented allograft dysfunction. Fourteen out of 65 patients (21.5%) had circulating de novo DSAs and 12 out of 14 (85.7%) presented allograft dysfunction. The investigated risk factors were: recipient and donor age, time at waiting list, cold ischemia time (CIT), cytomegalovirus (CMV) infection, immunosuppression regimen, de novo DSAs, model for end-stage liver disease (MELD), aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyl transpeptidase (GGT), direct bilirubin (DBIL) and total bilirubin (TBIL) peak post-transplant and alkaline phosphatase (ALP). The multivariate analysis showed that de novo DSAs and time at waiting list were independent risk factors for allograft dysfunction.**Conclusion:** This is one of the few reports where the presence of DSAs is associated with the clinical outcome of an OLT. Further research may confirm the clinical value of these antibodies in developing assessment algorithms of pre-operational candidates and post-operational patients.

P.C3.03.16
Analysis of monocyte derived macrophages from lung transplantation patients

I. Schreurs[1], *B. Meek*[1], *C. van Moorsel*[1], *H. D. Luijk*[2], *J. M. Kwakkel-van Erp*[2], *E. Oudijk*[1,2], *D. van Kessel*[1], *J. C. Grutters*[1,2];
[1]Sint Antonius Hospital, Nieuwegein, Netherlands, [2]UMC Utrecht, Utrecht, Netherlands.

Lung transplantation (LTx) is a last treatment option for patients with an end-stage pulmonary disease. Standard immunosuppressive medication is mainly focussed on the acquired immune system. How this medication affects the monocyte-macrophage lineage is not known. The goal of this study is to determine how monocyte subsets and differentiation towards macrophages is affected in LTx patients. Fresh whole blood samples were analysed and monocyte subsets quantified using flow cytometry. To obtain monocyte-derived macrophages, PBMCs were collected from LTx patients and matched controls. Monocytes were differentiated and macrophage phenotype and cytokine production were analysed. Total peripheral monocyte numbers were decreased in LTx patients compared to healthy controls. The ratio between monocyte subsets showed a shift with increased classical monocytes and decreased non-classical monocytes. Surface marker expression levels of TLR2, CD163 and CD36 were increased and CD86 was decreased. Experiments analysing phenotype and cytokine production in macrophages are currently in progress. The differences found in monocyte count and expression of surface markers are thought to indicate a shift towards an M2 macrophage in LTx patients. In vitro confirmation is ongoing.

P.C3.03.17
The function of external respirationin patients after kidney transplantationin condition of immunosuppressive therapy

O. Shtepa*, O. Kuryata;*
SE "Dnipripetrovsk medical academy of Health Ministry of Ukraine", Dnipro, Ukraine.

The aim of our study was to evaluate the changes of the function of external respiration (FER) in patients after kidney transplantation in condition of immunosuppressive therapy and to assess the relationship between the level of cyclosporin A and tacrolimus with FER indicators. Materials and Methods. The study included 37 patients after kidney transplantation. The first group included 27 patients who under the immunosuppressive therapy regimen received cyclosporine at an average dose of 225 [175-350]mg/day, the second group included 10 patients who received tacrolimus at an average dose of 8.25 [5.0- 9.0]mg/day. Control group - 12 healthy persons. Cyclosporin A and tacrolimus were assayed with electrochemiluminescence immunoassay analyzer in addition to general examination and spirometry.
Results. Our data indicated the presence of significant difference ($p<0.05$) in patients of the first and second groups between the indicators of the VC_{max} (78[71-90]% and 76.5[72-78]%), FVC (93[85-99]% and 95[91-98]%), PEF (82[64-94]% and 80[69-84]%), MEF_{25-75} (75[66-112]% and 82.5[67-90]%) relative to the FER of the control group: VC_{max} (102.5[98-113]%), FVC (107.5[105.5-124]%), PEF (99.5[95-102.5]%), MEF_{25-75} (98.5[97.5-101.5]%).

In both groups, a statistically significant negative correlation was found between the indicators of the VC_{max}, FVC and the level of cyclosporin A (R=-0.69, p<0.0001 and R= -0.4, p<0.037) in the first group and FVC and tacrolimus (R=-0.72, p<0.018) in the second group.
Conclusions. A moderate decrease in the VC_{max} values in patients after kidney transplantation in condition of immunosuppressive therapy requires monitoring FER and conducting such patients by nephrologists together with specialists in the pulmonological profile.

P.C3.03.18
The role of sphingosine-1-phosphate in vascular permeability

G. C. Wilkins[1], *S. Ali*[1], *N. S. Sheerin*[1,2], *J. A. Kirby*[1];
[1]*Newcastle University, Newcastle upon Tyne, United Kingdom,* [2]*Freeman Hospital, Newcastle upon Tyne, United Kingdom.*

Introduction
Organ transplantation is the preferred treatment for end-stage organ failure. However, to meet the ever increasing demand for donor organs, marginal organs are more frequently accepted. Organ quality can be improved by *ex vivo* perfusion, which also allows for the directed delivery of therapeutics. The signalling lipid sphingosine-1-phosphate (S1P) binds G protein coupled receptors (S1PR1-5) to affect the endothelial barrier. This study was designed to determine the potential of perfusion with S1PR agonists/antagonists to enhance the endothelial barrier, thereby reducing organ oedema and leukocyte infiltration.
Materials and Methods
Human microvascular endothelial cells (HMEC-1) were treated with either vascular endothelial growth factor (VEGF) or H_2O_2 and their effects on S1P receptor gene expression measured using qPCR. Concurrently, concentrations of S1P were compared between serum and kidney perfusate using an enzyme-linked immunosorbent assay (ELISA) (n=7). Lastly, HMEC-1 grown on transwells were treated with S1PR agonists and the translocation of Evan's Blue dye used to measure endothelial permeability.
Results
VEGF significantly increased S1PR1 expression ($p \leq 0.05$) and H_2O_2, mimicking reperfusion injury, significantly decreased expression ($p \leq 0.05$). The ELISA showed that concentrations of S1P in serum were significantly higher than in kidney perfusate ($p \leq 0.05$). Treatment with an S1PR1 agonist significantly decreased dye permeability of HMEC-1 ($p \leq 0.05$), whereas treatment with a S1PR3 agonist increased permeability.
Conclusions
This study identifies potential mediators of S1PR gene expression on the endothelium during organ transplantation. As S1P concentrations in perfusate are lower than physiological levels, addition of S1PR1 agonists to the perfusate could enhance the endothelial barrier in transplanted organs.

P.C3.03.19
IMMUNE CROSSMATCH FOR KIDNEY TRANSPLANTATION - IS THERE SPACE FOR METHOD IMPROVEMENT?

M. Zielinski[1], *G. Moszkowska*[1], *H. Zielinska*[1], *A. Dukat-Mazurek*[1], *J. Dębska-Zielkowska*[1], *J. Sakowska*[1], *B. Rutkowski*[2], *A. Dębska-Ślizień*[2], *P. Trzonkowski*[1];
[1]*Department of Clinical Immunology and Transplantology, Medical University of Gdansk, Gdansk, Poland,* [2]*Department of Nephrology, Transplantology and Internal Diseases, Medical University of Gdańsk, Gdansk, Poland.*

There are different laboratory methods for donor-recipient immunological matching before kidney transplantation. Although complement dependent crossmatch is still a gold standard other method have been commonly used like virtual crossmatch (V-XM), and flow cytometry crossmatch (FC-XM). The methods differ in sensitivity and specificity, that may result in dissimilar test results and confusing data interpretation. Recently, cytolytic flow cytometry crossmatch (cytolytic FC-XM) was developed, to detect lytic alloantibodies with a sensitivity of flow cytometry assay. Thus, the aim of this study was to compare the laboratory crossmatch outcome with use of different assays. This was a virtual immunological matching of deceased donors with hypothetical recipients. Serum from 22 sensitized patients was crossmatched with surrogate donors and in all cases V-XM was positive at minimum 5000 MFI cut off. The positive CDC-XM result was noted in 41% of patients, while positive FC-XM in 86% and lytic antibodies (cytolytic FC-XM) were confirmed in 27%. There was a moderate correlation for the CDC reaction and cytolytic FC-XM level, both for total/ B cell enriched lymphocytes pool (CDC-XM) and CD3/CD19 lymphocytes (cytolytic FC-XM). When cut-off value of 7000 MFI of highest DSA was used all the positive CDC-XM cases were identified. Similarly, positive FC-XM was followed by 2500 MFI cut-off value. Our results suggest that donor-recipient immunological matching for kidney transplantation requires different methods to verify the importance of alloantibodies. Thus, there is still space for improvement. This is especially important for immunized patients for successful transplantation.

P.C3.03.20
Lymphocytes B as a potential marker of alloantibodies development after kidney transplantation

M. Zielinski[1], *A. Tarasewicz*[2], *H. Zielinska*[1], *M. Jankowska*[2], *G. Mozkowska*[1], *J. Sakowska*[1], *B. Rutkowski*[2], *A. Dębska-Ślizień*[2], *P. Trzonkowski*[1];
[1]*Department of Clinical Immunology and Transplantology, Medical University of Gdańsk, Gdansk, Poland,* [2]*Department of Nephrology, Transplantology and Internal Diseases, Medical University of Gdańsk, Gdansk, Poland.*

Immune diagnostic after kidney transplant is focused on alloantibodies assessment to confirm humoral rejection episodes. Anti-HLA antibodies development is associated with specific B cells differentiation to long-lived memory cells and molecular signature. Thus, it is interesting whether B cells phenotype can be applied as a marker of humoral immunity activation. This may be beneficial for personalized risk stratification. Low-risk kidney transplant recipients (n=53) were followed-up to 24 months after transplantation for alloantibodies development and signs of organ rejection. Every three months anti-HLA antibodies, naïve/memory B lymphocytes as well as CD5+ B cells phenotype were assessed together with Th1/Th2 and BAFF serum levels. For the 34 recipients, alloantibodies were not present after transplantation, while for 19 others DSA/de novo anti HLA were confirmed. The higher rate was observed 20 months after transplantation. Anti-HLA antibodies development was proceeded by increased in BAFF and INFgamma levels, as well as memory B lymphocytes numbers. It was found, that alloantibodies development was correlated with a number of memory B cells, Rs=0,96 (Spearman rank correlation). Lymphocytes B phenotype monitoring after kidney transplantation is useful for alloantibodies development and may serve as an additional marker of humoral immunity activation. These could be also beneficial for individual risk stratification and tailored immunosuppression protocol development after kidney transplantation. Funding: National Centre for Research and Development, Poland (No. STRATEGMED1/233368/1/NCBR/2014). National Science Centre, Poland (No. NN402420738 and NN402 562440).

P.C3.04 MHC, Stem Cell Transplantation and Regulation

P.C3.04.01
CCR4 and CCR8 chemokine receptor expression on highly suppressive regulatory T cells

G. Adigbli;
Transplantation Research Immunology Group, Oxford, United Kingdom.

Introduction: Human regulatory T cells (Tregs) are a promising therapy for the safe control of transplant rejection. The chemokine receptors CCR4 and CCR8 are expressed by subsets of Tregs with unusually high suppressive activity. However, the mechanisms underlying this enhanced suppressive activity are not fully understood and yet to be explored in transplantation. The aim of this study is to characterise the suppressive abilities of $CCR4^+$ and $CCR8^+$ Treg in transplantation and explore the mechanisms underlying them.
Methods: Peripheral blood human Tregs were sorted by expression of CCR4 and CCR8 surface receptors before being stimulated with anti-CD3/anti-CD28 beads for 14 days and analysed by flow cytometry.
Tregs expanded for 14 days with anti-CD3/anti-CD28 beads were sorted by expression of CCR4 and CCR8 surface receptors and used in an *in vitro* suppression assay. Intracellular interleukin (IL)-10, interferon (IFN)-gamma and IL-17 were also measured.
CCR4 and CCR8 expression in the peripheral blood of recipients of kidney/pancreas transplants with sentinel skin flaps was assessed.
Results: Naïve Tregs upregulate CCR4 and CCR8 expression transiently upon stimulation whereas memory Tregs maintain expression long term.
$CCR4^+$ Tregs are more suppressive than $CCR4^-$ Tregs in a chemotaxis-independent manner and produce greater levels of IL-10 and IFN-gamma.
Treg CCR8 expression is increased in the blood of pancreas/skin transplant recipients undergoing episodes of rejection and may potentially serve as an early marker of rejection.
Conclusion: We hypothesise that CCR4 and CCR8 expression identifies a highly suppressive subset of Treg, which may enhance Treg therapy and monitoring of transplant rejection.

P.C3.04.02
Letrazole and Testosterone Combination Stimulates Bone Marrow Mesenchymal Stem Cell Proliferation Without Altering Their Characteristics

B. Aru*, H. Dagdeviren, T. Simsek, G. Yanikkaya Demirel;*
Yeditepe University, Istanbul, Turkey.

Introduction: Due to their immunomodulatory properties which are proven by in vitro studies and clinical trials, mesenchymal stem cells (MSCs) are considered as the most promising cellular therapy agents. However, since they present a limited population in bone marrow specimens and they undergo senescence and lose characteristic features as the passage number increases; it is an important issue to increase their proliferative capacity before re-infusion to patients.Method: Bone marrow mononuclear cells were isolated from 11 individuals' (healthy n:2 patient: 9) samples by eliminating erythrocytes with ammonium chloride lysis solution. Cells were characterized according to their surface markers ($CD73^+CD90^+CD105^+CD34^{neg}DD45^{neg}$) at the 3rd passage.

Two different doses of testosterone or 17-β estradiol (10 nm and 100 nm) and letrazole (1000 nm) with both doses of testosterone were applied for 72 hours. Proliferation rate was evaluated with MTS assay. DNA content and cell surface markers were analysed with Beckman Coulter FC500 flow cytometry.Results: Both MTS assay and DNA cell cycle analysis showed that testosterone, 17-β estradiol and testosterone combined with letrazole supplements in both doses were stimulating cell proliferation without changing expression levels of CD73, CD90, CD105 and CD34, CD45 markers. Conclusion: In this study, we showed that testosterone stimulates proliferation of BM-MSCs when its' aromatisation is inhibited with letrazole addition without any effect on surface markers. Gene level changes with these treatments will be explored in further studies.

P.C3.04.03

The presence of atopic dermatitis in heart-transplanted pediatric patients is associated with an immune Th2 polarisation

*J. Lopez-Abente[1], M. Camino[2], N. Gil[2], E. Panadero[2], M. Campo[2], M. Pion[1], R. Correa-Rocha[1], **E. Bernaldo de Quiros**[1];*
[1]Instituto de Investigacion Sanitaria Gregorio Marañon, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañon, Madrid, Spain.

Introduction: The incidence of comorbidities, such as atopic dermatitis (AD), has increased in pediatric heart transplantation during the last decades. Their treatment remains a significant challenge in transplantation context. Therefore, understanding the immune mechanisms underlying the disease is important to improve the management of this comorbidity. This study assessed whether potential immune alterations associated with regulatory T cells (Treg) and Th1/Th2 imbalance could be related to AD in heart-transplanted children. Materials and Methods: This single-centre, cross-sectional, observational study included 11 AD and 11 non-AD heart-transplanted aged-matched pediatric patients. Peripheral blood samples were obtained, and immune populations were analysed using flow cytometry. Results: We observed that age at transplant was significantly lower in the AD group. In addition, the development of AD after transplant was associated to a higher frequency of IL-4-secreting CD4+ T cells, a decrease in the ratio of IFN-γ to IL-4-secreting CD4+ T cells, an increase in the frequencies of differentiated Treg and eosinophilia. Non-AD patients presented a negative correlation between Treg and IL-4-secreting CD4+ T-cell frequencies, however, such correlation was lost in AD patients. Conclusion: the loss of the correlation between Treg and IL-4-secreting CD4+ T cells suggested the potential incapacity of Treg to prevent the expansion of Th2 cells, that are crucial players in AD development and thus potential therapeutic targets. Generation of SLA-silenced porcine pancreatic islets to support graft survival after xenogeneic transplantation

***M. Carvalho-Oliveira**[1], E. Valdivia[1], Y. Yuzefovych[1], O. Pogozhykh[1], R. Schwinzer[2], B. Petersen[3], J. Seissler[4], R. Blasczyk[1], C. Figueiredo[1];*

Transplantation Laboratory, Clinin for General, Visceral and Transplantation-surgery, Hannover, Germany, [3]3. Department of Biotechnology, Institute of Farm Animal Genetics, Friedrich-Loeffler-Institute, Federal Research Institute for Animal Health, Hannover, Germany, [4]4. Diabetes Research Group, Medizinische Klinik IV, Medical Center of the University of Munich, Munich, Germany.

Introduction: The prevalence of diabetes increased over the last decades. Xenotransplantation of porcine pancreatic islets may offer an alternative source to circumvent the limitations posed by the lack of donors, but immune rejection remains a major concern. Here, we have investigated the feasibility to silence SLA class I and II expression to decrease xenogeneic immune responses. Methods: Silencing of SLA class I and II was performed using lentiviral vectors for the delivery of specific short hairpin RNAs (shRNA) targeting β2-microglobulin (β2m) or class II transactivator (CIITA), respectively, into islet cell clusters or monolayers. The lentiviral vectors encoded for GFP or Nanoluciferase as reporter genes. SLA transcripts were evaluated by real-time PCR and protein levels by flow cytometry and fluorescence microscopy analyses. The effect of SLA class I silencing was evaluated in human NK cell cytotoxicity assays. Results: Fluorescence microscopy analyses indicated a successful transduction of the islets in its 3D- structure. Expression of NanoLuciferase was detectable already 24h after transduction. Vector activity remained detectable after two weeks. On islet cells, SLA class I expression was silenced by up to 60.3% and class II by up to 30.4%. Interestingly, silencing SLA class I expression showed a protective effect against NK-cell cytotoxicity. A decrease in NK-cell cytotoxic activity of 55.8% was observed when SLA class I silenced islet-derived cells were used in comparison to SLA class I-expressing cells. Conclusion: These data shows the feasibility to silence SLA expression on porcine islets cells, which may contribute to decrease xenogeneic immune responses after transplantation.

Deciphering anti-HCMV HLA-E-restricted unconventional CD8 T-cell responses in seropositive HCMV⁺ hosts

***B. CHARREAU**[1], N. Jouand[2], C. Bressollette-Bodin[3], N. Gérard[1], M. Giral[4], P. Guerif[5], A. Rodallec[6], R. Oger[7], T. Parrot[7], M. Allard[7], A. Cesbron-Gautier[8], N. Gervois[7];*
[1]CRTI UMR1064, Nantes, France, [2]CRTI UMR1064 and CRCINA UMR1232, Nantes, France, [3]CRTI and Service de Virologie, CHU de Nantes, Nantes, France, [4]CRTI and CHU de Nantes, Nantes, France, [5]CHU de Nantes, Nantes, France, [6]Servide de Virolgie, CHU de Nantes, Nantes, France, [7]CRCINA UMR1232, Nantes, France, [8]EFS Pays de la Loire, Nantes, France.

Human cytomegalovirus (HCMV) causes severe illness and poor outcome in immunocompromised hosts such as transplant recipients and HIV-infected patients. Cytotoxic CD8 T cells against HCMV antigens (pp65, IE1) presented by classical HLA class-I molecules are major cellular components of the protective anti-HCMV immunity. HLA-E-restricted CD8 T cells targeting HCMV UL40 leader peptides (Lp) have been recently reported as unconventional T-cell responses also observed in some hosts but they still need clinical and functional characterization. Our study aimed to provide a qualitative and quantitative *ex vivo* analysis of HLA-E_{UL40} CD8 T-cell responses, in a large cohort (n=144) of kidney transplant recipients and healthy volunteers, and to elucidate determining factors. HLA-E_{UL40} CD8 T-cells were detected in >30% of seropositive HCMV⁺ hosts and may represent >30% of total circulating CD8 αβT cells at a time point. We identified host-related genetic factors (HLA-A*02 and HLA-E genotype) and HCMV strain, determining the sequence of UL40Lp, as critical parameters for this response. HLA-E_{UL40} CD8 are effector memory T cells that appear early post-infection as monoclonal/oligoclonal populations and persist for life. Although specifically induced in response to HCMV infection, a key feature of these cells is their potential ability to be also responsive against self and allogeneic HLA resulting from sequence homology between HLA-ILp and UL40Lp. Thus we established that unconventional HLA-E_{UL40} CD8 T cells belong to the common immune arsenal against HCMV. Their functions remain to be defined toward infection as well as their potential side effect in contexts such as autoimmunity and transplantation.

Association of *PTPN22* +788A allele with kidney rejection episode in western Mexican patients with renal failure that had been transplanted

***L. E. CHAVARRIA BUENROSTRO**[1], J. Macias-Barragan[2], M. Arámbula-Navarro[1], J. F. Topete-Reyes[3], J. F. Muñoz-Valle[1], M. G. Ramirez-Dueñas[1], P. E. Sanchez-Hernandez[1], T. Garcia-Iglesias[1], A. L. Pereira-Suarez[1], R. Parra-Michel[3], M. Montoya-Buelna[1];*
[1]UNIVERSIDAD DE GUADALAJARA, GUADALAJARA, Mexico, [2]UNIVERSIDAD DE GUADALAJARA, Ameca, Mexico, [3]INSTITUTO MEXICANO DEL SEGURO SOCIAL, GUADALAJARA, Mexico.

Introduction: kidney transplant allograft rejection episodes have been a major risk factor for adverse transplant outcome, in which regulation of immune cell signaling plays an important role. One of the main proteins involved in immune cell regulation is encoded by *PTPN22* gene. *PTPN22* single nucleotide polymorphisms (SNPs) are associated with autoimmune diseases and transplantation outcome. Studies suggest that rs3399664, +788 G>A *PTPN22* could be related to altered immune response and could be associated with renal graft rejection episode. This study explored the distribution of +788 G>A *PTPN22* polymorphism in Western Mexican general population and examine the association of this SNP with renal graft rejection episode.
Materials and methods: totally 52 patients with renal rejection episodes, 98 renal rejections free episode patients, and 150 healthy subjects were selected. The samples were genotyped for the +788 G>A *PTPN22* gene by PCR-RFLP.
Results: allelic frequencies of +788 G>A *PTPN22* polymorphism for G and A alleles were 98.1%, and 1.9%, respectively; showing a low frequency of A polymorphic allele in a western Mexican population. We found a significant association between patients carrying the heterozygous genotype of +788 G>A *PTPN22* polymorphism and a higher risk for graft rejection episodes as compared to the healthy subjects (p=0.035; OR=4.9, 95% CI=1.26-18.9). The frequency of +788A risk allele was significantly increased in graft rejection episode group patients as compared to the healthy subjects group (p=0.037; OR=4.7, 95% CI=1.24-17.82).
Conclusions: our results show that rs3399664 may confer susceptibility to renal graft rejection episodes development in patients from western Mexico.

P.C3.04.07

***Ex-vivo* expansion of Tregs from Belatacept-Treated Renal Transplant Patients enhances and maintains their suppressive function under inflammatory conditions**

***A. Cortés Hernández**[1], E. Alvarez Salazar[1], J. Alberú Gómez[2], N. Linares Escobar[1], D. Villareal Martínez[1], S. Arteaga Cruz[1], M. Solís Gamboa[3], G. Soldevila Melgarejo[1];*
[1]Instituto de Investigaciones Biomédicas, Mexico, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán,, Mexico, Mexico.

Immunotherapy with Regulatory T cells (Tregs) is a successful therapy to prevent transplant rejection in experimental models. In addition, some studies have addressed the potential effects of immunosuppressive therapy on Tregs from transplanted patients. In this regard, we reported that Tregs from long-term Belatacept-treated kidney transplant patients displayed a significant reduction in their FOXP3 expression and suppressive capacity but remains unknown whether it is feasible *ex vivo* expand their Tregs for use in immunotherapy. In this study, purified Tregs from long-term Belatacept-treated renal transplant patients were *ex vivo* expanded with polyclonal stimulation in the presence of sirolimus and IL-2. Cell yield after *ex-vivo* expansion was similar between Tregs from Belatacept-treated patients and Tregs from healthy controls. Expanded Tregs from patients expressed high levels of FOXP3, CTLA4, Helios and CCR7 similarly to expanded Tregs from healthy controls.
In addition, expanded Tregs from patients exhibited excellent *in vitro* suppressive function comparable to expanded Tregs from controls.

Most importantly, expanded Tregs from patients maintained their phenotype and suppressive function after *in vitro* stimulation in the presence of the pro-inflammatory cytokines IL-6, TNF-α, IL-4 and IFN-ϒ. In conclusion, $CD4^+CD25^{hi}FOXP3^+$ Tregs from long-term Belatacept-treated patients can be *ex vivo* expanded without loss of their phenotype and function. These data demonstrate that despite the reported alterations of Tregs from transplanted patients maintained long-term with immunosuppressive therapy, it is possible to use Tregs as immunotherapy for induction of allograft tolerance.

The application of Next Generation Sequencing (NGS) in histocompatibility laboratories has allowed large-scale high-resolution HLA typing, improving and enlarging genotypic information of donors' registries. The objective of this study was to take advantage of an in-house NGS based strategy for *HLA-A*, *-B*, *-C*, *-DRB1* and *-DQB1* typing, to improve HLA characterization of umbilical cord blood units (CBUs) from Barcelona Cord Blood Bank. Specific primers were designed to amplify exons 2, 3 and 4 for HLA class I genes and exons 2 and 3 for class II genes in a single multiplex PCR per patient, using an in-house previously validated procedure. Concurrent sequencing of 384 samples was carried out in Illumina MiSeq 500-cycle runs and NGSengine software was used to HLA genotyping. With this approach 6.000 CBUs and 3.000 samples from cord blood donors' mothers were typed. An average density of 850 Kclusters/mm^2 and 86% of cluster passing filter was obtained; 83% bases had a Q-score $\geq$ 30 and optimal coverage was achieved for the correct typing of each sample. Improvements were performed during its implementation, such us the design of specific primers to identify null alleles or its automation, that allow the typing of up to 768 samples per week. Additionally, 30 new alleles were identified and more than half were submitted to IPD-IMGT/HLA Database. In conclusion, the implementation of this NGS strategy has allowed a cost-effective high-resolution HLA genotyping of a significant fraction of our CBUs repository, which will rebound in a more accurate selection for hematopoietic cell transplantation.

Background: A 17 year old patient with cystic fibrosis underwent bilateral lung transplantation with immunosuppression (IS) of Tacrolimus, MMF, Prednisone. After 3 months, he developed histology-proven cutaneous GvHD which was successfully controlled by MMF withdrawal but followed by acute rejection of the lung. After treatment by steroid pulse, lung function returned to normal but CMV infection occurred despite valganciclovir prophylaxis. Immunoassays were performed to quantify specific T cell responses as indicator of changes in IS. Methods: Frequencies of HLA-$A32^+$ donor lymphocytes were determined by FACS. ELISpots were performed to detect allospecific and CMV-specific T cells. HLA-A2/NLV-multimer staining was used to detect CMV-specific $CD8^+$ CTL. Results: At the peak of skin GvHD, frequencies of HLA-$A32^+$ donor $CD4^+$,$CD8^+$ T (4%), B (8%) and NK (4%) cells were detected that declined after MMF withdrawal within one week. Simultaneously to improvement of GVHD, acute rejection of the lung developed, accompanied by clonal expansion of A32-allospecific $CD8^+$ CTL, which declined after steroid pulse. HLA-A11-allorestricted, GVHD-mediating CTL were detected at low frequency. With serological detection of CMV, HLA-A2/NLV-specific $CD8^+$ CTL emerged, expanded clonally and persisted for four months. CMV infection disappeared with the appearance of CMV-specific CTL. Conclusions: Using specific immunomonitoring tools, we could follow the clinical course "online" starting with GVHD, followed by rejection and CMV infection. Frequencies of donor lymphocytes, allo- and CMV-specific CTL were indicative for disease stage and adjustment of IS. With full recovery of his lung function, the patient is asymptomatic several months after these complications.

The development of novel multi-parameter flow cytometry panels to identify immune cells in renal transplant recipients undergoing defined exercise program

G. J. Fatania[1,2], *J. E. Pearl*[1], *R. E. Billany*[2,3], *N. C. Bishop*[3], *A. C. Smith*[1,2], *A. M. Cooper*[1];
[1]*Department of Infection, Immunity and Inflammation, Leicester Kidney Lifestyle Team, University of Leicester, Leicester, United Kingdom,* [2]*John Walls Renal Unit, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom,* [3]*School of Sport, Exercise and Health Sciences, Loughborough University, Loughborough, United Kingdom.*

Introduction: Renal transplantation improves renal function but do not reduce cardiovascular risk associated with renal disease. Exercise can reduce both conventional and renal-associated cardiovascular risk; however, exercise can positively and negatively affect immune function depending on the nature of the exercise. It is therefore critical to monitor changes in immune cell populations during exercise. To determine the impact of exercise on circulating immune cells of renal transplant recipients we have developed multi-colour flow cytometry panels covering lymphoid and myeloid populations. Methods: A 10-colour lymphocyte panel and two 6-colour myeloid panels (monocytes and dendritic cells) have been designed to assess changes in the frequency of cells within the peripheral blood of renal transplant recipients undergoing defined exercise programmes. Peripheral blood mononuclear cells were isolated and stained with lymphoid lineage markers: CD3, CD4, CD8a, CD19, CD56, and function associated markers: CD45RA, CD45RO, CD127, CD25, and CD197. Monocyte subsets were identified using HLA-DR, CD14, CD16, and their migratory potential determined using CCR2, CCR5 and CX3CR1. Dendritic cell populations were identified using HLA-DR, CD1c, CD11c, CD141, CD123 and CD14. Results/ conclusion: The panels allow reproducible detection of cell populations in thawed peripheral blood cells from healthy volunteers. These panels are now being used to assess immune cell populations in renal transplant recipients undergoing one of three distinct exercise protocols. Changes in cell populations according to exercise will provide crucial information regarding the impact of exercise on immune function. P.C3.04.11

Human adipose-tissue-derived and bone-marrow-derived mesenchymal stem cell-conditioned medium contain immunoregulatory cytokines and exhibit therapeutic potential in wound repair in vitro

S. Gromolak*, M. Paprocka, H. Kraśkiewicz, A. Klimczak;*
Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wrocław, Poland.

Introduction Conditioned medium from MSC (MSC-CM) contains mixture of growth and immunoregulatory factors and is perceived as a promising tool for regenerative medicine. We investigated MSC-CMs from two sources: human, immortalized adipose-tissue-derived (ATMSC) and bone-marrow-derived mesenchymal stem cells (BMMSC) for their biological activity for secreted factors and their influence on keratinocyte's proliferation, clonogenicity and migration. **Methods** The expression of biologically active factors produced by ATMSC and BMMSC was evaluated by the C-Series Human-Cytokine-Antibody Array. Keratinocyte cell line (HaCaT) was cultured with different concentration: 12%, 25%, 50%, 100% of MSC-CM. Cell proliferation was assessed by MTT assay, a wound healing assay was used to examine migratory properties of HaCaT, and a colony-forming assay was performed to assess their clonogenic potential. **Results** In both ATMSC-CM and BMMSC-CM 70 biologically active factors were detected out of 120 tested. A number of growth, angiogenic and immunoregulatory factors, including IL-6, IL-8, MCP, GRO and eotaxin were identified. Nine factors were secreted exclusively by BMMSC (e.g. GDNF, SCF) and one cytokine only by ATMSC (IL-7). In functional assays both MSC-CMs stimulated HaCaT proliferation, clonogenic potential and in vitro wound closure compared to control. The optimal effect was observed following treatment with 25% of MSC-CM. **Conclusions** The secretion profile of both lines is similar but not identical. The source of MSC does not significantly influence on MSC-CM's bioactivity and therapeutic potential on wound repair. These data suggest that MSC-CM is a good source of immunomodulatory and trophic factors and may promote tissue repair. Grant NCN No. 2012/07/B/NZ4/018

How tissue niche affect mesenchymal stem cells and how important are their biological properties

U. Kozlowska[1], *K. Futoma*[1], *A. Krawczenko*[1], *D. Patrzalek*[2], ***A. Klimczak***[1];
[1]*Hirszfeld Institute of Immunology and Experimental Therapy PAS, Wroclaw, Poland,* [2]*Medical University, Faculty of Health Science, Department of Physiotherapy, Wroclaw, Poland.*

Introduction: Regenerative potential of human organs is permitted by mesenchymal stem cells (MSC) which reside in various tissues of the body. We investigated biological characteristics of MSC from skin (SK), adipose (AT), skeletal muscle (SM) and bone-marrow (BM) tissues, considering their special features for regenerative medicine. **Materials and Methods**: SK-MSC, AT-MSC, SM-MSC and BM-MSC were isolated and long-term cultured in standard conditions. MSC markers for: CD73, CD105, CD90, proangiogenic CD146, PDGFRα, CD31, and multipotency PW1 were examined by flow-cytometry, and immunofluorecence. The osteogeneic, adipogeneic and chondrogeneic potential by culture in dedicated medium, and 7-day cell fusion after PKH26 and PKH67 labelling were assessed. Cytokine secretion with 27-cytokine multiplex-ELISA screening, and pluripotency (Sox2, Oct4), suppressor (p53) and protooncogenic (c-myc) genes expression with qPCR were analyzed. **Results:** MSC from examined tissues had stable CD90+, CD73+ phenotype, but CD105, CD146 and PDGFR-α expression decreased with subsequent passages.

PW1 was present in SK-MSC, AT-MSC and SM-MSC, but not detectable after P3. Examined MSC were able to triple differentiation, except SM-MSC unable to adipogenesis. ELISA revealed secretion of IL-6, IL-8, MCP-1, VEGF in different concentrations, depending on MSC niche. AT-MSC and BM-MSC were able to fuse with SM-MSC population. Sox2 was stable in SM-MSC and AT-MSC, and SK-MSC showed the highest expression in P1. Oct4, p53 and c-myc expression differs between passages. **Conclusions:** Variability in biological properties of MSC from different niche may influence on MSC quality and therapeutic potential. Proper selection of MSC may determine efficacy of action in regenerative medicine.

Introduction: Immune rejection is the main cause of corneal allograft failure with at least 30% of transplanted grafts experiencing an immune complication. In this study, transforming growth factor beta 1 treated (TGFβ) mesenchymal stromal cells (TGFβ-MSC) were administered in a murine model of corneal transplantation and rejection free survival (RFS) of corneal grafts was observed over 30 days.
Results: *In vitro,* TGFβ-MSC derived from BALB/c bone marrow were co-cultured with stimulated lymphocytes. TGFβ-MSC significantly suppressed $CD4^+$ and $CD8^+$ lymphocyte proliferation while increasing the frequency of regulatory T cell (Treg) populations.
In vivo, untreated allogeneic control grafts from C57BL/6 mice were uniformly rejected (RFS 20.5±7.75d, n=12) in BALB/c mice. Untreated MSC were not efficacious in prolonging RFS (RFS 18.28±6.71d, n=14). In contrast, corneal allograft rejection was significantly delayed in 70% of TGFβ-MSC treated allograft recipients (RFS 27.23±4.32d, n=13) with significantly lower mean corneal neovascularization and corneal oedema scores.
ex vivo analysis, draining lymph nodes (DLNs), spleens and lungs of both treated and untreated animals were harvested. Significantly increased populations of Tregs were observed in the lungs of TGFβ-MSC treated animals.
Mechanistic Insights, high concentrations of Prostaglandin E2 (PGE2) were detected in TGFβ-MSC/lymphocyte co-culture supernatants. Co-culturing TGFβ-MSC with stimulated lymphocytes in the presence of a PGE2 receptor 4 (EP4) inhibitor returns frequencies of Tregs to control levels.
Conclusion: TGFβ-MSC had an enhanced ability to prolong RFS when compared to untreated MSC in the absence immunosuppressive therapy. This study points toward the use of MSCs as a therapeutic treatment to improve cellular-based therapies.

TNF-α/IL-1β licensed mesenchymal stromal cells promote corneal allograft survival via antigen presenting cell mediated induction of Foxp3+ regulatory T cells in the lung

N. Murphy, *O. Treacy, P. Lohan, K. Lynch, A. Ryan, M. Marcos, M. Griffin, T. Ritter;*
REMEDI, NUIG, Galway, Ireland.

We have previously demonstrated that allogeneic mesenchymal stromal cells (MSCs) administered intravenously (i.v.) pre-transplantation (day-7, day-1) prolong corneal allograft survival, however, syngeneic (recipient-derived) MSCs administered at these timepoints fail to prolong graft survival. Here, we demonstrate *in-vitro* that pre-activation of syngeneic MSCs with pro-inflammatory cytokines TNF-α/IL-1β ($MSC^{TNF\text{-}\alpha/IL\text{-}1\beta}$) enhances MSC's immunomodulatory properties, potently suppressing syngeneic lymphocyte proliferation (10.26%, p≤0.001) compared to untreated MSCs (MSC^{UTR}) (79.68%). Lymphocyte suppression was mediated primarily by up-regulation of MSC's nitric oxide production (NO). *In-vivo*, when administered post transplantation (day+1, day+7) both MSC^{UTR} (50%, p≤0.05) and $MSC^{TNF\text{-}\alpha/IL\text{-}1\beta}$ (70%, p≤0.001) prolong corneal allograft survival compared to allograft controls (0%). The ability of $MSC^{TNF\text{-}\alpha/IL\text{-}1\beta}$ to prolong graft survival was in part mediated by NO production as shRNA knockdown of NO reduced the graft survival rate of $MSC^{TNF\text{-}\alpha/IL\text{-}1\beta}$ treated animals to 25%. MSC-mediated graft survival was associated with increased proportions of regulatory $CD11b^+B220^+$ macrophages and Foxp3+ regulatory T cells (Tregs) in the lung and spleen at day 9 post transplantation while at the time of rejection (day17-19) increased proportions of Tregs were observed in the lung, spleen and crucially the draining lymph nodes of MSC treated allograft recipients. Finally, ex-vivo, we report a mechanism of MSC-mediated Treg induction where MSCs condition CD11b/c+ sorted lung cells to a regulatory phenotype capable of inducing Tregs from naïve lymphocytes. This study highlights the importance of timing and licensing strategies in enhancing MSC therapy and sheds light on how MSCs exert their immunomodulatory properties in the lung via a $CD11b/c^+$ intermediary cell population.

P.C3.04.15

Finding a needle in the haystack; identifying allopeptides in solid organ transplantation

L. Rowntree[1], *P. Illing*[1], *O. Nguyen*[2], *T. Kotsimbos*[3], *A. Purcell*[1], *N. Mifsud*[1];
[1]*Monash University, Melbourne, Australia,* [2]*University of Melbourne, Melbourne, Australia,* [3]*The Alfred Hospital, Melbourne, Australia.*

Transplantation is currently the best therapy for end-stage organ failure, although associated risks of post-transplant morbidity and mortality remain high due to HLA mismatching and common viral infections. Chronic allograft rejection remains a major barrier to overcome, with some evidence that a specific subset of antiviral T cells, which also recognise different HLA allotypes (i.e. cross-reactive), may contribute to allograft rejection. We have identified a CMV-specific HLA-A*02:01-restricted CD8+ T cell with a unique TCR signature (OTN5) that cross-reacts with a defined hierarchy towards HLA-B27 allomorphs (B*27:07>B*27:09>B*27:05). However, efforts to identify the allopeptide(s) presented by these HLA-B27 allomorphs has remained elusive. Here we utilise a combined immunoproteomics and combinatorial peptide library (CPL) approach for allopeptide discovery. For immunoproteomics, HLA-B27/peptide complexes from transfected C1R cells were captured by immunoaffinity chromatography, fractionated by reversed-phase high-performance liquid chromatography (RP-HPLC) and screened for immunogenicity against a reporter cell line (SKW3) expressing the OTN5 TCR. The composition of the active peptide containing fraction was determined by mass spectrometry and further validated using CPL screening assays to characterise HLA-B27-restricted peptides recognised by the OTN5 T cell. This study demonstrates utility of these two powerful technologies to enhance identification of naturally presented allopeptides.

P.C3.04.16

Stem cell and novel neurotrophic factor therapies to promote functional outcome in limb transplantation

S. K. Salgar, *J. Weiss;*
Madigan Army Medical Center, Tacoma, United States.

Introduction: Currently, sensory/motor function recovery following limb transplantation is suboptimal. We investigated whether adult Mesenchymal Stem Cells(MSCs), Granulocyte-Colony Stimulating Factor(G-CSF), and Dihexa can improve limb functional recovery in a rat sciatic nerve transection/repair model. **Materials and Methods:** Under general anesthesia (Lewis rat) the sciatic nerve was identified, transected, and repaired/approximated using 10-O sutures. MSCs(2 million), G-CSF(50-100μg/kg), (Dihexa 2-4mg/kg) and/or Vehicle were administered locally, i.v./i.p., and to gastrocnemius muscle. Sensory/Motor functions of the limb were assessed. **Results:** MSCs expanded *ex vivo* were CD29+, CD90+, CD34-, CD31-, MHC Class I+, Class II- and multipotent. At two weeks post-nerve repair, total sensory function (peroneal, tibial, saphenous, sural) in all groups was ~1.8 on a scale of Grade 0-3(0=No function; 3= Normal function); however, peroneal nerve function was ~ 2.8(n=6/group). At eight weeks, sensory function was restored to nearly normal ~2.8 in MSC+G-CSF and MSC+Dihexa groups but not in MSC+vehicle control(~2.3). At eight weeks, motor function as determined by walking foot print grades 0-4 (0=no print; 4=heel plus 4-5 toe prints) was 3.2±1, 2.5±1.4, and 1.8±1.2; and at 16 weeks 3.0±0.9, 3.0±0.8, and 2.0±0.6 in MSC+G-CSF, MSC+Dihexa and MSC+vehicle groups, respectively. Motor function improved($P<0.05$) in G-CSF and Dihexa groups. G-CSF or Dihexa administration to gastrocnemius mitigated muscle atrophy and flexion contractures, significantly. In a parallel study with tibial nerve transection, MSC improved($P<0.05$) nerve regeneration and myelination(n≥6). **Conclusions:** MSC with G-CSF or Dihexa therapies appear to be promising to promote limb functional recovery following sciatic nerve injury, and warrants further testing in limb transplant model.

Activated type 3 innate lymphoid cells (ILC3s) are expanded after hematopoietic stem cell-transplantation (HSCT), and have a protective effect against graft-versus-host disease (GVHD). However, the role of various B cell populations in the pathomechanism of GVHD is controversial. We have recently shown that activated ILC3s can help B cell survival, proliferation and the differentiation of immature/transitional B (itB) cells with immune regulatory properties. The impact of the activated ILC3 populations on B cells after HSCT, and their role in the prevention of GVHD have not been investigated thus far. Therefore, we aimed to examine the interrelation of ILC3s and itB cells in acute GVHD. Twenty patients of less than 60 days post-HSCT were included in the study, out of which ten were suffered from acute cutaneous GVHD. Their peripheral blood samples were analyzed before initiation of the treatment. Peripheral blood $Lineage^-CD127^+CD161^+c\text{-}Kit^+$ ILC3s, and their NKp44 and CD69 expression, as well as $CD19^+IgD^+CD24^{high}CD38^{high}$ itB cells and their PD-L1 expression were measured by flow cytometry.

The prevalence of ILC3s was lower in acute GVHD patients compared to HSCT patients without GVHD. Both the absolute numbers and the percentages of ILC3s and itB cells correlated with each other, and the correlation was particularly strong in acute GVHD patients. Our results suggest that activated ILC3s may have a favorable influence on the early post-HSCT period via its itB cell-inducing capacity; and itB cells with regulatory properties may have a protective role against acute GVHD. Clonal tracking of CD45RA-depleted donor T-lymphocytes after infusion in TCR alpha/beta depleted transplantation from unrelated and haploidentical donor

*V. E. Fomchenkova[1], E. A. Komech[2], S. Blagov[3], V. Zhogov[3], Y. B. Lebedev[2], D. M. Chudakov[2], M. A. Maschan[3], **I. V. Zvyagin**[2,3];*
[1]Lomonosov Moscow State University, Moscow, Russian Federation, [2]Shemiakin-Ovchinnikov Institute of Bioorganic Chemistry, RAS, Moscow, Russia, Moscow, Russian Federation, [3]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation.

Low number of T-lymphocytes and extremely low TCR diversity early after alpha-beta T-cell depleted allogenic transplantation holds the risk of death from different pathogens, specifically from persisting and reactivating viruses. Transfer of antigen-experienced T-lymphocytes from donor to recipient early after HSCT can provide the protection from pathogens during the period of immunodeficiency. Fraction of CD45RA-depleted T-cells could potentially serve as the source of the antigen-experienced T-lymphocytes and successful implementation of such selective T-cell depletion was recently shown in the setting of both matched and mismatched HSCT.
Here we report the study of clonal dynamics of CD45RA-depleted donor T-lymphocyte fraction infused in low-dose in children after allogenic HSCT with alpha-beta T-cell depletion. High-throughput sequencing with molecular barcode-based data normalisation was used for TCR beta repertoire profiling of samples of patients' peripheral blood and CD45RA-depleted donor T-cells (DLI) to track the clonal dynamics of donor cells in patients during 1 year after HSCT.
Small number of both CD8+ and CD4+ T cell clonotypes from DLI were observed in peripheral blood of patients early after infusion and persisted during 6 months. Their proportion decreased along with reconstitution of T-cell repertoire diversity and T-cell count. Most expanded clonotypes in recipients' repertoire in the early timepoint, including virus-specific T-cell clonotypes, mostly originated from clonotypes which was low frequent or not detected in DLI.
This study was supported by RFBR grant #16-04-01881-a.

High sodium concentration modulates dendritic cells immune function

***S. AL-HAJJ**[1], A. GOUMARD[1,2], A. HERAUD[1], S. GEORGEAULT[3], J. BURLAUD-GAILLARD[3], C. HOARAU[1,2], P. GATAULT[1,2], M. BUCHLER[1,2], R. LEMOINE[1], C. BARON[1,2], J. HALIMI[1,2];*
[1]EA4245 Dendritic Cells, Immunomodulation & Transplantation, TOURS, France, [2]Nephrology, clinical immunology service, University Hospital Center Bretonneau, Tours, France, [3]Laboratory of cell biology & electronic microscopy, François Rabelais University, Medicine school, TOURS, France.

Introduction: Excessive Na intake is associated with hypertension, increased skin sodium concentration [Na+] (up to 200 mM) and dendritic cells (DCs) recruitment. However, high [Na+] effect on DCs immune function remains unclear. **Methods:** DCs derived from human blood monocytes were stimulated by LPS for 48h at different [Na+]. We studied DCs cytosqueleton modifications by electron and confocal microscopy, analyzed cell viability, expression of CCR7 chemokine receptor ,CD25, CD83, CD86 and CD80 markers, FITC-DEXTRAN endocytosis, reactive oxygen species (ROS) production by flow cytometry. We studied DCs CCL19-driven chemotaxis using transwell, secreted cytokines by ELISA, MAP Kinase and SGK1 expression by western blot. **Results:** At high [Na+] of 200 mM as compared to normal [Na+] 140 mM, DCs viability was maintained (over 84.5±5%). DCs cytosqueleton displayed a more elongated aspect. CCR7, CD25, CD83 CD80 and CD86 expression significantly decreased (-59.3±15.3%, -67.7±32.3%, -60.4±14.5%, -25±20.8%, -13.6±10.3%, respectively, $p<0.0001$). There were less ROS production (-36.1±12.3%, $p<0.005$) and a persistence of endocytosis capacity (+108.3±44.6%, $p<0.005$) with a decreased CCL19-driven chemotaxis (-49.7±25.6%, $p<0.0005$). Cytokines measurement showed a reduced secretion of IL-12p70, IL-6 and IL-23 (-78.5±9%, -66.6±9.2%, -90.4±7.12%, respectively, $p<0.0001$) and an increase of IL-10 and TGF-β (+111±51%, +191.1±110.4%, respectively, $p<0.005$). Higher [Na+] lead to a reduced phosphorylation of p38 (-43.13±25%, $p<0.03$), higher ERK 1⁄2 phosphorylation (+30.57±11.6%, $p<0.007$) and greater SGK1 expression (+35.07±11.5%, $p<0.01$). **Conclusions:** High [Na+] concentration downregulates inflammatory LPS treated DCs immune response, through SGK1 and MAP Kinase related mechanisms. However, the implication of these changes in the development of hypertension remains unknown.

P.C4.01.02

A pro-inflammatory role for CD70 on human regulatory T cells

***R. Arroyo Hornero**, K. Wood, F. Issa, J. Hester;*
University of Oxford, Oxford, United Kingdom.

Introduction: The CD27-CD70 costimulatory receptor-ligand pair belongs to the TNFR superfamily. Ligation of CD27 on T cells with CD70 on APCs promotes T cell survival, controls $CD4^+$ T cell subset differentiation and it is essential for the generation of antigen-specific T cell immunity. CD70 is also expressed by T cells upon activation, although the role of T cell-expressed CD70 is unknown. We have previously shown that CD27 expression on human Tregs correlates closely with suppressive potency. In this study, we hypothesised that the CD27/CD70 axis could be exploited for regulating the balance between pro-inflammatory and regulatory T cell responses.
Materials and Methods: $CD4^+$ Tconv and $CD4^+CD127^{low/-}CD25^+$ Tregs were flow sorted from healthy donors PBMCs and activated for 14 days *in vitro* via αCD3/αCD28 stimulation in the presence of IL-2. Cells were then flow sorted according to CD27 and CD70 and expanded for 14 days prior to analysis.
Results: Human Tregs differentially altered CD27 and CD70 surface expression upon *in vitro* activation, resulting in two distinct subpopulations ($CD27^+CD70^-$ and $CD27^-CD70^+$). Functional *in vivo* and *in vitro* assays revealed that suppressive activity was confined to $CD27^+CD70^-$ Tregs, while $CD27^-CD70^+$ Tregs promoted T cell proliferation and produced higher levels of IL-17A. Stimulation or blockade of CD27 signalling did not affect Treg suppressive activity. In contrast, blocking CD70 on Tregs significantly enhanced their suppressive potency, abolishing the pro-inflammatory effect of $CD70^+$ Tregs.
Conclusions: This study reveals for the first time that $CD70^+$ Tregs provide stimulatory signals by ligating CD70 to CD27 on T cells.

P.C4.01.03

The effects of IFN-gamma on the expansion of suppressive B cells and their action

***P. Bohacova**[1,2], E. Javorkova[1,2], B. Hermankova[1,2], J. Kossl[1,2], A. Zajicova[1], V. Holan[1,2];*
[1]Institute of Experimental medicine, Prague, Czech Republic, [2]Faculty of Science, Prague, Czech Republic.

Introduction: Besides production of antibodies, B cells can also regulate immune response in the antibody-independent manner. Mechanisms of action of suppressive B cells are mainly the production of IL-10 or the expression of surface inhibitory molecules, such as FasL or PD-L1. In this study we have been aiming to characterize modulatory effects of IFN-γ on the development of suppressive action of B cells.
Materials and Methods: $CD19^+$ B cells were prepared using MACS and stimulated with LPS or LPS and IFN-γ for 48 hours. These cells were harvested and cocultivated with peritoneal macrophages for additional 48 hours. Then macrophage expression of costimulatory molecules was determined by flow cytometry and the cytokine production was evaluated by ELISA. Pretreated macrophages were used for the stimulation of CFSE labeled T cells to measure T cell proliferation by flow cytometry.
Results: B cells stimulated with LPS and IFN-γ produced increased concentrations of IL-10 and also expressed higher levels of the genes for FasL and PD-L1. Macrophages, which were cocultivated with B cells stimulated with LPS and IFN-γ, showed decreased expression of costimulatory molecule CD86 and reduced production of IL-6. These macrophages displayed also decreased ability to stimulate proliferation of activated $CD8^+$ T cells.
Conclusions: The results have shown that IFN-γ enhances activation of suppressive functions of B cells which have the ability to inhibit immune response through their effect on macrophages. The possibility to modulate regulatory B cells may have an impact for their use in a clinical setting.

P.C4.01.04

Early Onset Type 1 diabetes and typical juvenile diabetes are distinct clinical and genetic entities

***I. Caramalho**[1], P. Matoso[1], D. Sobral[1], J. Costa[1], D. Ligeiro[2], A. Fitas[3], C. Limbert[3], C. Penha-Goncalves[1], J. Demengeot[1];*
[1]Instituto Gulbenkian de Ciência, Oeiras, Portugal, [2]Centro de Sangue e Transplantação de Lisboa, Instituto Português de Sangue e Transplantação, Lisboa, Portugal, [3]Hospital D. Estefânia, Centro Hospitalar de Lisboa Central, Lisboa, Portugal.

Insulin-dependent Type 1 diabetes (T1D) results from the immune-mediated destruction of insulin-producing pancreatic beta cells, triggered by the interplay between environmental and genetic factors. Susceptibility alleles include Human Leukocyte Antigen (HLA) class II haplotypes and over 100 genetic variants located in more than 50 genetic loci.
In the last decades, an alarming increase in the incidence of T1D affecting preschool children has occurred in Western countries, an unexplained epidemiological concern. We set out to determine whether Early Onset (EO)T1D is clinically and genetically distinct from the typical juvenile T1D.
We established a cohort of 100 EOT1D patients (age of onset ≤5 years) and performed their detailed clinical characterization, including familial history of autoimmune diseases. DNA samples were processed for HLA typing, Single Nucleotide Polymorphisms (SNP) genotyping and Whole Exome Sequencing.

Our clinical analysis evidence that EOT1D patients present with a more severe disease when compared to children with later onset of disease (age of onset >9 years). Moreover, a subset of EOT1D patients presents poly- or multiple- autoimmunity and a familial history of autoimmune aggregation. Our genomic analysis reveals EOT1D differs from typical juvenile T1D, at the HLA and at several of the 118 SNP analyzed. Moreover we identified novel genetic variants likely causal in the aetiology of EOT1D.
Our findings support the notion that EOT1D and juvenile T1D are distinct clinical entities with specific genetic architecture, and should feed the development of predictive diagnostic and the implementation of early preventive measures.

Tolerogenic effects of ethyl pyruvate on dendritic cells

N. Djedovic[1], *M. Mansilla*[2,3], *B. Jevtic*[1], *J. Navarro-Barriuso*[2,3], *S. Stanisavljevic*[1], *E. Martínez-Cáceres*[2,3], *D. Miljkovic*[1];
[1]Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia, [2]Immunology Division, Germans Trias i Pujol University Hospital and Research Institute, Campus Can Ruti, Badalona, Spain, [3]Department of Cellular Biology, Physiology and Immunology, Universitat Autònoma de Barcelona, Cerdanyola del Vallés, Barcelona, Spain.

Introduction: Dendritic cells (DC) are professional antigen presenting cells that have a key role in shaping the immune response. Tolerogenic DC (tolDC) have immuno-regulatory properties and they are a promising prospective therapy for multiple sclerosis (MS). Ethyl pyruvate (EP) is a redox analogue of dimethyl fumarate (Tecfidera), a drug for MS treatment. We have recently shown that EP ameliorates experimental autoimmune encephalomyelitis (EAE), a MS animal model, and that it induces tolerogenicity in mice DC. Here, we expanded our study on human DC.
Methods: Monocyte-derived DC are obtained from MS patients and healthy individuals in the presence of GM-CSF and IL-4 for 6 days. EP is applied to the cultures on days 2 and 4, while maturation stimulus (TNF, IL-1β, PGE_2) is added on day 4 of cultivation.
Results: Phenotypic analysis has shown that DC treated with EP (tEPDC) have significantly reduced levels of molecules required for T cell activation such as CD86, CD83 and HLA-DR whereby CD11c expression and viability of DC were not affected. Further, tEPDC restrained proliferation and modulated cytokine production of allogeneic lymphocytes.
Conclusion: These results demonstrate that ethyl pyruvate has the ability to direct human DC towards tolDC. *In vivo* study on application of tEPDC in EAE and detailed molecular characterisation of these cells are warranted. These steps should complete pre-clinical studies on tEPDC as potential MS therapy. Funding: MPNTR Republic of Serbia, OI173013/ OI173035. Project PI14/01175, PI17/01521, integrated in the Plan Nacional de I+D+I and co-supported by the ISCIII-Subdirección General de Evaluación and the FEDER.

P.C4.01.06

The effect of CD6 targeting in T cell function and Immunopathology

R. F. Freitas[1,2], *S. Almeida*[3,4], *S. Perez*[5], *L. Padron*[5], *K. Leon*[5], *L. Graça*[1,2];
[1]Instituto de Medicina Molecular, Lisboa, Portugal, [2]Instituto Gulbenkian de Ciência, Oeiras, Portugal, [3]Post-Graduate Program in Infectious Diseases, Federal University of Espirito Santo, Vitória, Brazil, [4]Department of Social Medicine, Center of Health Sciences, Federal University of Espírito Santo, Vitória, Brazil, [5]Centro de Inmunologia Molecular, Habana, Cuba.

Introduction: CD6 transmembrane glycoprotein is a cell surface receptor (with three extracellular domains and a long cytoplasmic tail) from the scavenger receptor cysteine rich protein superfamily, expressed in thymocytes, mature T cells, B1a cells and subsets of natural killer cells. One of its three ligands is the activated leukocyte adhesion molecule (ALCAM) that binds to domain 3, thereby affecting T cell activation, proliferation, immune synapse formation and transmigration across the blood brain barrier (BBB). Genome wide association studies identified CD6 as a susceptibility locus for Multiple Sclerosis (MS) and, in clinical trials for psoriasis a humanized anti-CD6 Mab (T1h), has already been tested with promising results. Investigation of CD6-targeting in MS has been hampered by lack of adequate murine reagents. We tested a "murinized" variant of T1h in a mouse model of MS, in order to establish the therapeutic value of CD6-targeting for prevention of autoimmune neuroinflammation. Materials and Methods: Experimental autoimmune encephalomyelitis (EAE) was induced in C57BL/6 mice with subcutaneous injection of MOG_{35-55} emulsified in CFA. Intravenous injection of Pertussis was administered on day of immunization and two days later. The experimental groups received increasing doses of anti-CD6 Mab and they were followed for 30 days. Results/Conclusions: Our data show CD6 targeting led to a delay in the EAE onset, compared to control animals treated with an isotope control. Subsequent studies are required to establish the mechanism leading to the protective effect of CD6-targeting.

P.C4.01.07

Lipidoid-polymer hybrid nanoparticles loaded with anti-TNF siRNA suppress inflammation after intra-articular administration in a murine experimental arthritis model

M. A. A. Jansen[1], *L. H. Klausen*[2], *K. Thanki*[2], *H. Franzyk*[2], *H. Mørck Nielsen*[3], *W. van Eden*[1], *M. Dong*[2], *F. Broere*[1], *C. Foged*[3], *X. Zeng*[3];
[1]Utrecht University, Utrecht, Netherlands, [2]Aarhus University, Aarhus, Denmark, [3]Copenhagen University, Copenhagen, Denmark.

Introduction: Rheumatoid arthritis (RA) is an autoimmune disease which is characterized by chronic inflammation in the joint. RNA interference (RNAi) therapy is a promising way to target gene silencing locally and suppress excessive inflammation. However, efficient delivery of small interfering RNA (siRNA) into a cell is problematic. Therefore, there is a need for new and safe delivery systems. Recently lipid-polymer hybrid nanoparticles (LPNs) for nucleic acid delivery are developed, since these LPNs are less immunogenic compared to other particles.
Methods: We studied the siRNA delivery of the lipidoid-modified poly (DL-lactic-co-glycolic acid) LPNs and stable nucleic acid lipidoid particles (SNALPs) in the murine macrophage cell line RAW 264.7, and investigated their structure-function relationship. Furthermore, we tested the therapeutic capacities of these nanoparticles containing anti-tumor necrosis factor (TNF) siRNA in a murine arthritis model.
Results: Results indicate pathway-specific differences in delivery of siRNA to macrophages between LPNs and SNALPs. Both particles were taken up by micropinocytosis but the SNALP take-up by macrophages also showed signs of clathrin-mediated endocytosis. Next to this, we show that LPNs and SNALPs loaded with anti-TNF siRNA (1 µg) mediate sequence-specific suppression of inflammation in a murine experimental arthritis model upon intra-articular administration.
Conclusion: The results from this study show that functional anti-TNF siRNA encapsulated by LPNs or SNALPs can be delivered both *in vitro* and *in vivo*. The therapeutic effectivity from LPNs and SNALPs containing anti-TNF siRNA indicates that this is a promising therapy for rheumatoid arthritis and possibly other chronic inflammatory diseases.

P.C4.01.08

Tolerogenic potential of dendritic cells obtained from autoimmunity prone and resistant rats

B. Jevtic[1], *N. Djedovic*[1], *S. Stanisavljevic*[1], *G. Timotijevic*[2], *M. Momcilovic*[1], *M. Mostarica Stojkovic*[3], *D. Miljkovic*[1];
[1]Institute for Biological Research, Belgrade, Serbia, [2]Institute of Molecular Genetic and Genetic Engeenering, Belgrade, Serbia, [3]Institute of Microbiology and Immunology, Belgrade, Serbia.

Experimental autoimmune encephalomyelitis (EAE) is a widely used animal model of multiple sclerosis, a chronic, inflammatory and neurodegenerative disease of the central nervous system (CNS). Dendritic cells are essential for the initiation, propagation and for regulation of the autoimmune response against the CNS. One of the main approaches in multiple sclerosis immunotherapy is the application of tolerogenic dendritic cells (tolDC). The aim of this study was to compare the tolerogenic potential of DC obtained from autoimmunity-prone (Dark Agouti, DA) and resistant (Albino Oxford, AO) rats. For this purpose, DC were generated from rat bone marrow of non-immunized and EAE-immunized rats and propagated towards tolDC in the presence of GM-CSF and vitamin D3. tolDC were characterized phenotypically by cytofluorimetry. mRNA expression of various genes was determined by RT-qPCR and cytokines generation by ELISA. Results have shown that AO and DA rat tolDC differ in expression of various mRNA and production of cytokines, emphasizing a stronger tolerogenic potential of tolDC from AO compared to DA rats. Furthermore, tolDC from these strains differed in response to EAE-immunization. The observed differences between tolDC of rats prone and resistant to the CNS autoimmunity call for a similar study in humans. Acknowledgements: This study was supported by grants from the Ministry of Education, Science and Technological Development, Republic of Serbia (173035, 173013, 175038).

Interleukin-10 transfected dendritic cells-induced Treg cells prompt an allogenic tolerance *in vitro* in mice C57BL/6 but not in mice CBA

J. Khantakova, *V. Tereschenko, V. Kurilin, J. Lopatnikova, A. Silkov, N. Knauer, A. Maksyutov, S. Sennikov;*
Federal State Budgetary Institution "Research Institute of Fundamental and Clinical Immunology", Novosibirsk, Russian Federation.

Introduce: Regulatory T-cells (Treg cells) are maintaining the tolerance to self- and foreign antigens. We explored the feasibility of inducing Treg cells by using IL-10 transfected dendritic cells (DCpIL-10). Materials and methods: C57Bl/6 and CBA female mice were obtained from the breeding facility of the Institute of Cytology and Genetics (Novosibirsk, Russia). DCs were generated from the bone marrow monocyte pool with added rmGM-CSF and rmIL-4. The cells were electroporated on days 3 with plasmid pmax-pIL-10 encoding murine IL-10 (pIL-10). Treg cells in splenocyte culture were induced by using DCpIL-10.The phenotypic indicators of the DCs (CD11c, H2, costimulatory molecules) and Treg (CD4, CD25, FoxP3, IL-10) cells were assessed on a FACSVerse flow cytometer. DCpIL-10 effects on allogenic tolerance were investigated by MLR. Results: C57Bl/6 and CBA mice were different in initial percentage of Treg cells and IL-10 production. In C57Bl/6 mice DCpIL-10 guided naïve CD4+ T cells differentiation to Treg cells. This is accompanied by increase IL-10 production and decrease proliferation on allo-splenocytes. In CBA mice DCpIL-10 failed to Treg cells induction, splenocytes proliferation inhibition and IL-10 production.
Conclusion: Initial count of Treg cells and IL-10 production influence to the Treg cells induction. DCpIL-10-induced Treg cells prompt an allogenic tolerance *in vitro* only in C57Bl/6 mice but not CBA mice. The research carried out with the support of the RSF. Agreement №16-15-00086 (11.01.2016).

P.C4.01.10

Interaction of antigen-presenting cells and T cells is modulated by exosomes carrying miRNA-150

K. Nazimek[1,2,3]*, E. Bustos-Morán*[2]*, N. Blas-Rus*[2]*, P. W. Askenase*[3]*, F. Sánchez-Madrid*[2]*, K. Bryniarski*[1]*;*
[1]Department of Immunology, Jagiellonian University Medical College, Krakow, Poland, [2]Department of Immunology, Hospital de la Princesa, Autonomous University of Madrid, Madrid, Spain, [3]Section of Allergy and Clinical Immunology, Yale University School of Medicine, New Haven, United States.

Introduction. Mouse contact hypersensitivity reaction (CHS) is suppressed by T CD8+ cell-derived miRNA-150 carried by exosomes coated with antigen-specific antibody light chains [J Allergy Clin Immunol 2013;132:170-81]. These exosomes target antigen-presenting macrophages that in turn suppress CHS effector cells [Immunology 2015;146:23-32]. Nanovesicle-mediated interactions between cells at the site of antigen presentation were recently examined, showing the passage of CD63-positive exosomes from intact T to B lymphocytes forming the conjugates (immune synapses) [Nat Commun 2011;2:282]. Our current study aimed at investigating the impact of exosomes carrying miRNA-150 on the vesicle-dependent intercellular interactions at the immune synapse.
Methodology. Jurkat T cells and Raji B cells were transfected with CD63-GFP or CD81-GFP plasmids by electroporation and then incubated with miRNA-150-containing exosomes. Superantigen-stimulated formation of conjugates by Jurkat T cells and Raji B cells was then assessed in fluorescence confocal microscopy and intercellular transmission of vesicles as well as T cell activation was analyzed cytometrically.
Results. The polarization of Raji B-cell, CD81-GFP-positive multivesicular bodies towards the site of CD3 accumulation in T cells (immune synapse) was observed. Further, miRNA-150-carrying exosomes induced transfer of CD81-positive, but not CD63-positive, vesicles from Raji B cells to Jurkat T cells. Afterwards, Jurkat T cells were characterized by lower CD69 activation marker expression.
Conclusions. Exosomes carrying miRNA-150 induce the transmission of vesicles from antigen-presenting cells to T cells, impairing their activation at the immune synapse. Supposedly, this mechanism reflects the action of antigen-presenting macrophages on effector T lymphocytes during the suppression of CHS activated by miRNA-150-carrying exosomes.

P.C4.01.11

Role of NK cells in the onset of Rheumatoid Arthritis.

S. Pascual-García*, P. Martínez-Peinado, A. López-Jaén, F. Navarro-Blasco, G. Peiró, J. Sempere-Ortells;*
University of Alicante, Alicante, Spain.

Introduction. Rheumatoid arthritis (RA) is a Th1 systemic autoimmune disease, whose incidence in the Northern Hemisphere countries is from 0.5% to 1%. It is characterised by an inflammation of the synovium leading the destruction of both the cartilage and the bone, diminishing the patients' quality of life. The aim of this study is to determine the prognostic value of the expression of IgG Fc receptors and markers of naïve/effector cells in the different leukocytes subpopulations. Materials and methods. Anticoagulated blood samples from 20 healthy donors and 7 RA *de novo* diagnosed patients were marked with anti-CD16, anti-CD32, anti-CD64, anti-CD45RO and anti-CD45RA monoclonal antibodies (BD and eBioscience). Afterwards, data were analysed using FACSCanto I (BD). Results. A significant increase in the expression of CD64+, CD32+CD64+, and CD16+CD32+CD64+ NK cells from RA patients was observed when compared with healthy donors (p=0.029, p=0.0371 and p=0.0187, respectively). However, percentages of CD16+ granulocytes and CD16+CD64 monocytes from these patients were lower (p=0.0007 and p=0.0046, respectively). On the other hand, we also found a remarkable increase in the percentage of CD45RO+ NK cells from RA patients (p=0.05), as compared with healthy volunteers. Conclusion. NK cells from *de no*vo diagnosed RA patients show a mature phenotype and an increased expression of the IgG Fc receptors. The author has a grant supported by Ministerio de Educación, Cultura y Deporte with reference FPU14/01984.

P.C4.01.12

Generation of human Breg-like phenotype with regulatory function *in vitro* with bacteria-derived oligodeoxynucleotides

J. Gallego-Valle, V. Perez-Fernandez, R. Correa-Rocha, ***M. Pion****;*
Instituto de Investigacion Sanitaria Gregorio Marañon, Madrid, Spain.

Introduction: Regulatory B cells (Breg) participate in the auto-tolerance maintenance and immune homeostasis. Despite their impact on many diseases and due to the difficulty to define them, knowledge about their origin and their physiological inducers are still unclear. The incomplete knowledge about the generation of Breg and their limited numbers in periphery difficult the development of Breg-based therapy. Therefore, identifying factors that promote their development would allow ex-vivo production of large amounts of Bregs in order to create new immunotherapy. **Materials and Methods:** We tested the capacity of several cytokines (IL-1β, GM-CSF and CD40L) and bacteria-derived oligodeoxynucleotides (CpG-ODN), alone or in combination, to generate B cells with regulatory phenotype and function in an *in vitro* model. By flow cytometry we followed Breg-like phenotype in human primary stimulated B cells. Moreover, by co-culture experiments we followed suppressive ability of such cells to suppress PBMC proliferation. **Results:** We have demonstrated that the Breg-associated phenotypes were heterogeneous between one to another stimulation conditions. However, the expression of others markers related to Breg was increased such as IL-10, CD80, CD86, CD71, PD-1 and PD-L1 when cells were stimulated with CpG alone or in combination. Moreover, stimulated B cells presented a suppressive function on autologous activated PBMC proliferation. **Conclusions:** This work demonstrated the feasibility to induce functional Breg-like cells *in vitro* and then open the way to produce Breg-like as a potential future cellular therapy.

P.C4.01.13

Arthritogenic peptides presented by tolerogenic dendritic cells are able to reprogram effector CD4+ T cell responses from rheumatoid arthritis patients

E. C. Rivas Yañez[1]*, J. Maggi*[1]*, O. Aravena*[1]*, K. Schinnerling*[1]*, L. Soto*[2]*, O. Neira*[3]*, D. Catalán*[1]*, J. C. Aguillón*[1]*;*
[1]Laboratorio de Enfermedades Autoinmunes e Inflamatorias, Programa Disciplinario de Inmunología, Santiago, Chile, [2]Unidad de Tratamiento del Dolor, Hospital Clínico, Universidad de Chile, Santiago, Chile, [3]Hospital Del Salvador, Santiago, Chile.

Introduction: Rheumatoid arthritis (RA) is a disabling autoimmune disease generating joint inflammation. A therapeutic approach is the administration of tolerogenic dendritic cells (tolDCs), able to modulate autoreactive T cell responses and re-establish self-tolerance. The selection of appropriate autoantigens to be presented by tolDC is a critical element in the design of tolDC-based therapies. We aimed to identify immunodominant autoantigen peptides and elucidate the mechanisms by which tolDCs challenged with these self-peptides modulate lymphocyte responses. **Methods:** Peripheral blood mononuclear cells (PBMCs) were challenged with 12 autoantigen peptide candidates and reactivity of CD4+ T cells was evaluated based on expression of CD25, CD69, IFN-γ and TNF-α. Peptide-pulsed tolDCs generated from RA patient-derived monocytes were cocultured with autologous CD4+ T cells or peptide-specific T cell lines. Modulation of T cell phenotype and cytokine profile was assessed by flow cytometry. **Results:** From 12 peptide candidates, recently isolated by our group through natural processing of synovial proteins, we identified 6 immunodominant peptides, derived from calreticulin, vimentin, citrullinated vimentin and fibrinogen, which generated inflammatory CD4+ T cell responses in 27-39% of RA patients. While mature DCs, pulsed with these autoantigen peptides, induced CD4+ T cell proliferation and pro-inflammatory cytokine production in cocultures, autoantigen peptide-loaded tolDCs were able to modulate this response, promoting hyporesponsiveness of autoreactive T cells. **Conclusion:** We identified 6 novel immunodominant self-peptides which are recognized by autoreactive T cells from RA patients and are therefore appropriate autoantigens for loading of tolDCs used as cell-based therapy of RA. Inhibitory oligodeoxynucleotides induce an alternative activation state in human plasmacytoid dendritic cells

J. Ruben*, S. van der Kooij, C. van Kooten;*
Div. of Nephrology and Transplant Medicine, Dept. of Medicine, Leiden University Medical Center, Leiden, Netherlands.

Plasmacytoid dendritic cells (pDC) recognize CpG oligodeoxynucleotides (ODN) via TLR9, leading to the production of type I interferons (IFNα) and enhanced antigen presenting cell functions. Mammalian telomeres and commensal bacteria contain sequences which have been described as inhibitory ODN (iODN), since they act as potent antagonists of TLR9 activation. As such, iODN treatment of animal (autoimmune) models was shown to induce immune regulation. Here, we confirm that iODN can dose-dependently inhibit IFNα production by human pDC following TLR9 ligation by either CpG or Cytomegalovirus. In contrast to the IFNα production, TLR9-induced phagocytosis could not be inhibited by iODN. In fact, iODN treatment induced phagocytosis by pDC in the absence of TLR9 agonists, suggestive for the induction of active signaling. Although pDC treatment with iODN did not lead to the production of detectable levels of IFNα, low levels of TNFα and IL-6 could be detected. Interestingly, where CpG-activated pDC increased their capacity to cross-present antigen, iODN-activated pDC strongly enhanced indirect ($CD4^+$) antigen presentation. Moreover, activation of pDC with iODN strongly upregulated the costimulatory molecules CD80 and CD86. Concordantly, iODN-activated pDC were capable of inducing a robust allogeneic T cell proliferation. Despite the strong increase in T cell proliferation, IFNγ levels were >4-fold lower compared to CpG-activated pDC, whereas IL-5 was produced at higher levels. In conclusion, we show that iODN directly impact pDC function and should be classified as a group of novel pDC activating ligands, capable of inducing an alternative activation state as compared to CpG ODN.

Dendritic cells transfected by H-2K epitopes induce functional Tregs and tolerance *in vitro*.

V. Tereshchenko, J. Khantakova, V. Kurilin, A. Silkov, J. Schevchenko, J. Lopatnikova, A. Maksyutov, ***S. Sennikov****;*
Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation.

Introduce: CD4+CD25+Foxp3+Treg cells are necessary component for establishment and maintenance of immune tolerance. We explored the capacity of tolerogenic dendritic cells (tolDCs) transfected by DNA plasmid encoding H-2K epitopes of CBA mice to generate functional Treg cells for tolerance induction.
Materials and methods: DCs were generated from C57Bl/6 mice bone marrow monocyte pool with addition of rmGM-CSF and rmIL-4 without maturation factors. DCs were electroporated by 2 different plasmids: pGVHD encoding H-2K locus epitopes of CBA mice (DCs-pGVHD) and control plasmid (DCs-p5). Electroporated DCs were cultured with autologous splenocytes to generate functional Tregs. The phenotype properties of the DCs (CD11c, H2, CD80, CD86, CD83, and CD40) and Tregs (CD4, CD25, FoxP3, and IL-10) were investigated using flow cytometry. Functional capacity of transfected DCs and Tregs to induce tolerance was investigated by mixed lymphocyte reaction.
Results: DCs-pGVHD represent a tolerogenic phenotype (increase H2-B and decrease CD86, CD80) compared to DCs-p5. DCs-pGVHD induce FoxP3 and IL-10 expression by CD4+CD25hi T-cells in autologous splenocytes cultures. DCs-pGVHD-treated autologous splenocytes cultures showed significantly lower proliferation rate in response to CBA mice splenocytes when compared with control cultures.
Conclusion: DCs electroporated by DNA plasmid encoding H-2K epitopes of CBA mice induce functional Treg cells in splenocytes cultures and guide tolerance *in vitro*.
The research carried out with the support of the RSF. Agreement №16-15-00086 (11.01.2016).

Hemoglobin is preferentially inflammatory, antigenic and immunogenic in lupus

H. Sharma*[1], S. Jain[1], A. Bose[1], B. Bastia[2], R. Sachdeva[1], A. K. Jain[2], R. Pal[1];*
[1]National Institute of Immunology, Delhi, India, [2]National Institute of Pathology, Delhi, India.

Hemolysis-associated anemia is characteristic of diseases such as atherosclerosis, lupus, malaria, and leishmaniasis; the toxic effects of free hemoglobin (Hb) have been extensively described. This study was based on the premise that release of this sequestered, inflammatory molecule can result in deleterious immunological consequences, particularly in the context of pre-existing lupus. PBMCs derived from SLE patients preferentially secreted a variety of inflammatory cytokines in response to Hb, and IgG anti-Hb responses were detected in the sera of lupus patients. Lupus-prone mice exhibited heightened plasma Hb levels, and Hb triggered the preferential release of lupus-associated cytokines from splenocytes derived from aging mice. Additionally, Hb induced the release of IL-17A, IL-12 and IL-8 from plasmacytoid dendritic cells, while also eliciting the release of a spectrum of inflammatory cytokines from purified CD8 T cells, CD4 T cells and B cells derived from such mice. Anti-Hb B cell precursor frequencies were heightened in lupus-prone mice, which exhibited increased titers of anti-Hb antibodies in serum and in kidney eluates. Hb interacted with lupus-associated autoantigens extruded during apoptosis, and co-incubation of Hb and apoptotic blebs had maturation-inducing effects on bone marrow-derived dendritic cells from lupus-prone mice. Immunization of such mice with Hb induced antigen spreading to lupus-associated moieties; increased complement deposition in the kidneys and enhanced-onset glomerulosclerosis were observed. Hb therefore elicits increased inflammatory responses from a variety of cell types, demonstrates both antigenicity and immunogenicity, and triggers specific immuno-pathological effects in a lupus milieu.

P.C4.01.17

Treatment of collagen-induced arthritis mice model with genetically modified tolerogenic dendritic cells

I. Yilmaz*[1], M. Karacay[1], G. Guvenc[2], E. Uz[3], F. Budak[4], F. Ersoy[3], M. Yalcin[5], H. B. Oral[4];*
[1]Department of Medical Immunology, Institute of Health Sciences, Uludag University, Bursa, Turkey, [2]Department of Veterinary Physiology, Institute of Health Sciences, Uludag University, Bursa, Turkey, [3]Department of Molecular Biology & Genetics, Faculty of Arts & Sciences, Uludag University, Bursa, Turkey, [4]Department of Immunology, Faculty of Medicine, Uludag University, Bursa, Turkey, [5]Department of Physiology, Faculty of Veterinary, Uludag University, Bursa, Turkey.

T cells activation has an important role in RA pathogenesis. Activation of T lymphocytes requires the co-stimulatory signals provided by antigen-presenting cells. In this study, to inhibit the activation of T lymphocytes in experimental arthritis, tolerogenic dendritic cells (tolDCs) were aimed to be obtained by the genetic modification of bone marrow-derived dendritic cells (BM-DCs). B7 co-stimulatory molecules expression were down-regulated with a gene construct encoding a modified cytotoxic T lymphocyte antigen 4 molecule (CTLA4-KDEL) which targets to the endoplasmic reticulum (ER). Mouse CTLA4 cDNA mammalian expression plasmid (pCMV/mCTLA4) was commercially provided from Sino Biologicals (China). The mCTLA4 gene was cloned into pCMV/myc/ER (Invitrogen, Life Technologies, USA). Plasmids subcloned into LeGo-iG2 (AddGene, USA) for lentiviral vector production. BM-DCs were non-viral and lentiviral transfected with CTLA4-KDEL and incubated for 48 hours. Flow cytometric analysis was performed using mouse monoclonal antibodies against CD80 and CD86 (Tonbo Biosciences, United Kingdom) and appropriate isotype controls. Furthermore, in vivo studies, tolDCs were transferred intraarticularly 3 weeks after collagen-induced arthritis (CIA) mice model and followed up for 4 weeks. It was observed that CD80/86 expression on the surface of BM-DCs significantly downregulated as tolDCs. Moreover, in vivo studies showed that tolDC treatment group significantly reversed the increase in the joint thickness and number of white blood cells compared with control groups. This study is supported by The Scientific and Technical Research Council of Turkey (TUBITAK-COST Project No: 114S354) under Cost Action BM1404. COST is supported by the EU Framework Programme Horizon 2020.

P.C4.02 Manipulation of tolerance - Part 2

Cross-talk between the maternal endometrial micro-environment and tolerogenic dendritic cells

G. Amodio*[1], P. Panina-Bordignon[2], C. Semino[2], S. Gregori[1];*
[1]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS San Raffaele Scientific Institute, Milan, Italy, [2]Division of Genetics and Cell Biology, IRCCS San Raffaele Scientific Institute, Milan, Italy.

Successful pregnancy involves highly coordinated interactions between decidualized endometrial stromal cells and maternal immune cells to generate a receptive “maternal niche” for embryo implantation. DC-10 are a subset of dendritic cells, expressing HLA-G and secreting IL-10, which modulate T cell responses, promote tolerance, and accumulate in decidua during the first trimester of pregnancy. To assess whether DC-10 are critical components involved in favoring embryo implantation and successful pregnancy, we studied the in vitro crosstalk between endometrial stromal cells and DC-10. Immortalized human endometrial stromal cells (T-HESC) were *in vitro* decidualized with cAMP and medroxyprogesterone acetate for 7 days. During T-HESC decidualization, supernatants were collected at different time points and added during DC differentiation from peripheral blood $CD14^+$ monocytes. As control, DC-10 were differentiated from the same monocytes without T-HESC supernatants. Differentiated DCs were characterized by: i) expression of DC-10-associated markers; ii) cytokine profile; iii) ability to suppress a primary allogeneic response *in vitro*. Results showed that monocytes cultured with T-HESC-conditioned media collected at day 2 post-hormonal stimulation, differentiated into DC-10-like cells as demonstrated by the expression of CD14, CD141 and CD163, and display a cytokine secretion profile similar to that of DC-10. Moreover, DC-10-like cells suppress allogeneic $CD4^+$ T cell responses showing a functional parallel with DC-10 . These results support the hypothesis that the decidual micro-environment of early pregnancy sustains and promotes tolerogenic DC-10 differentiation. We are currently investigating the interactions of DC-10-like cells with the different immune players known to influence pregnancy outcome as NK cells.

P.C4.02.02

Milk protein-specific IgE and IgG4 in pediatric patients with food allergy

C. Kang*, Y. Yang, B. Chiang;*
Department of Pediatrics, Taipei, Taiwan.

Introduction: Food allergy is gaining attentions from the clinicians as it leads the development of atopic march. Milk proteins are the first foreign proteins an infant could encounter in life. We studied the prevalence and manifestation of milk-protein sensitized patients with the milk protein specific IgE and IgG4 levels.
Methods: We retrieved test results of serum allergen-specific tests (Mast and ImmunoCAPs, respectively). Any IgE level of specific food allergen higher then 2+ (range: 0~4+) in MAST IgE level higher than 0.70 kUA/L in ImmunoCAPs (class 2 out of class 0~6) was considered positive. In addition, milk protein-specific IgG4 will be also assessed.
Results: Total 1064 pediatric patients (55.6% of total 1914 patients) had Mast test, while 196 pediatric patients (6.61% of total 2966 patients) received ImmunoCAPs. The percentage positive for food specific IgE were 33.55% (n = 357) and 20.9% (n = 41) respectively for each tests. The age of Milk IgE(+) patients are significantly younger than the general food IgE(+) patients (2.83 ± 1.79 years vs 5.75 ± 3.92 years, p-value 0.005). Most of the milk IgE(+) patients presents with atopic dermatitis clinically, especially patients with higher titers.
Conclusions: The prevalence of milk protein sensitization was lower than what we expected, with the majority among children less than 5 years old. The age of milk IgE(+) patients is significantly younger than patients with other kinds of food IgE. The development of tolerance to milk protein over time might play a role in the reduction of milk protein-specific IgE.

P.C4.02.03

THEEFFECT OF RECOMBINANTPP 65 OF CMV ON FUNCTION AND MATURATION OF MICE DC

M. Karimi[1], *R. Yaghobi*[1], *Y. Nikmanesh*[1,2], *S. Shahmahmoodi*[1,2], *S. Marashi*[1,3];
[1]*Transplant Research Center, shiraz, Iran, Islamic Republic of,* [2]*Tehran University of Medical Sciences, Virology Department, Tehran, Iran, Islamic Republic of,* [3]*Tehran University Of Medical Sciences, Virology Department, Tehran, Iran, Islamic Republic of.*

The aim of the present study was to assess the impact of pp65 on the maturity and function of DCs. DCs were isolated and purified from the spleen of Balb/c mice. The HCMV-derived protein was exposed to isolated DCs. Then, DCs maturation was determined by using CCR7, CD86, CD40 and MHCII. The function of pp65-treated DCs was evaluated using the MLR assay. In addition, we measured transcriptional factors and T cell differentiation factors, including ROR-γ, GATA3, T-bet, and FoxP3, using Real time-PCR method. Cytokines levels INF-γ (Th1), IL4 (Th2), IL35 (Treg) IL17 (Th17), IL-22, TNF-α, and IL-6 were also determined by ELISA and flow cytometry. The phagocytosis rate in the group treated with pp65 was lower than the non-treated group, showing a significant difference. The levels of CD40, CD86 and CCR7 in the treatment group showed a significant increase compared with the non-treated group. The expression of ROR-γ and T-bet gene in the treatment group showed a significant increase compared with the non-treated group.The cytokine levels of IL-12, IL-6, IL-17, IL-22, and TNF-α showed a significant increase in the treated group as compared with the non-treated group, while a significant increase in the IFN-γ cytokine level was observed in pp65-treated groups as compared with the non-treated group. However, IL-4 and IL-35 cytokine levels were not detected in treated groups. Therefore, Such DCs can be used to induce immunity against CMV infection for CMV reactivation inhibition, particularly in immunosuppressed and transplanted individuals.

P.C4.02.04

Opioid analgesics differently modulate immune responses in mice

I. Filipczak-Bryniarska[1], *K. Nazimek*[2], ***M. Kozlowski***[1,2], *M. Wasik*[2], *K. Bryniarski*[2];
[1]*Department of Pain Treatment and Palliative Care, Jagiellonian University Medical College, Krakow, Poland,* [2]*Department of Immunology, Jagiellonian University Medical College, Krakow, Poland.*

Introduction. Immune cells commonly express opioid receptors and thus could be stimulated with opioids exerting immunomodulatory effects. Current research aimed at investigating the influence of various opioid analgesics on immune responses in mice under homeostatic conditions.
Methods. Mice were treated intraperitoneally with respective opioid drug (morphine, fentanyl, methadone, buprenorphine, oxycodone) for a week and, in some instances, skin-sensitized with hapten to induce contact hypersensitivity (CHS). Macrophage-induced humoral immunity was assessed in plaque-forming assay together with measurement of antibody titers in sera of mouse recipients of SRBC-pulsed macrophages from mice treated with different opioids. In addition, the effects of opioids on the production of reactive oxygen intermediates (ROIs), nitric oxide and cytokines by peritoneal macrophages along with expression of surface markers were estimated.
Results. Morphine administration significantly intensified CHS response in actively sensitized mice, while buprenorphine or oxycodone administration exerted the opposite effect. All tested opioids enhanced the release of proinflammatory cytokines, ROIs and nitric oxide by macrophages and altered their expression of antigen phagocytosis and presentation markers. Additionally, the inhibitory effect of morphine, fentanyl and methadone treatment on induction of humoral immunity by macrophages was demonstrated, while buprenorphine significantly increased the production of antibodies by B cells.
Conclusions. Our current studies confirm that macrophages greatly contribute to immunomodulatory effects induced by opioids. Better understanding of mechanisms of immunomodulation by opioids has great importance allowing for evaluation of its beneficial and adverse effects on patient condition.

P.C4.02.05

Immune effects of opioid drugs are modulated by analgesic adjuvants

M. Kozlowski[1,2], *I. Filipczak-Bryniarska*[1], *K. Nazimek*[2], *M. Wasik*[2], *K. Bryniarski*[2];
[1]*Department of Pain Treatment and Palliative Care, Jagiellonian University Medical College, Krakow, Poland,* [2]*Department of Immunology, Jagiellonian University Medical College, Krakow, Poland.*

Introduction. Opioids exert immunomodulatory effects. We have shown that repeated administration of morphine increases cell-mediated allergic response in mice and, as fentanyl, methadone, buprenorphine and oxycodone, enhances the release of proinflammatory cytokines, reactive oxygen intermediates (ROIs) and nitric oxide by macrophages as well as alters their expression of antigen phagocytosis and presentation markers. In contrast to buprenorphine administration, morphine, fentanyl and methadone treatment impairs humoral immunity induced by macrophages. However, little is known about the possible impact of adjuvant drugs on opioid-induced immune effects. Thus, current study aimed at investigating the influence of analgesic adjuvants on morphine-activated immune effects in mice.
Methods. Mice were treated intraperitoneally with morphine, naloxone, amitriptyline, gabapentin and/or venlafaxine for a week. Macrophage-induced humoral immunity was assessed in plaque-forming assay together with measurement of antibody titers in sera of mouse recipients of SRBC-pulsed macrophages from mice treated with different opioids. In addition, macrophage production of ROIs, nitric oxide and cytokines along with expression of surface markers were estimated.
Results. We observed an overall decrease in cytokine, ROIs and nitric oxide production by macrophages from adjuvant-treated mice, with the strongest effect of amitriptyline administration. Further, addition of adjuvants amplified morphine-induced inhibition of humoral immune response activated by macrophages pulsed with SRBC.
Conclusions. Our current results suggest that adjuvants normalize morphine-increased macrophage innate immune activity, which seems to have great importance during sterile inflammation. However, adjuvants additionally impair B cell activation that is reduced by morphine treatment.

P.C4.02.06

Lymph node stromal cells control T follicular helper cells as well as B cell responses directed against a self-antigen

R. Nadafi[1], *E. D. Keuning*[1], *M. N. Erkelens*[1], *A. Bos*[1], *M. van Gool*[1], *A. Breedveld*[1], *R. M. Reijmers*[2], *L. G. M. van Baarsen*[3,4], *R. E Mebius*[1];
[1]*Molecular cell biology and immunology, VU university medical center, Amsterdam, Netherlands,* [2]*Department of hematology, Leiden university medical center, Amsterdam, Netherlands,* [3]*Department of experimental immunology, Academic medical center, University of Amsterdam, Amsterdam, Netherlands,* [4]*Amsterdam Rheumatology & immunology Center (ARC), Academic Medical Center, Amsterdam, Netherlands.*

The hallmark for autoimmunity, such as rheumatoid arthritis, is the production of autoantibodies by B cells against self-antigens. To have an effective germinal center response and antibody production, B cells cooperate with T follicular helper cells (Tfh) to undergo somatic hypermutation and improve the affinity of antigen recognition. Tfh formation and differentiation occurs in the T cell area of the lymph node where a highly organized network of lymph node stromal cells (LNSCs) control and regulate peripheral immunity. Here, we use in-vivo murine lymph node transplantation model and show that LNSCs can clearly repress formation of autoreactive Tfh while maintaining T regulatory cells (Treg) specific for a given self-antigen. Moreover, control of Tfh formation by LNSCs significantly reduced the germinal center B cells response directed against self-antigen. Importantly, inhibition of IL-2 reduced the LNSC-mediated maintenance of Tregs and released the repression of autoreactive Tfh cell formation in-vivo. These findings show that continuous presentation of self-antigens by LNSCs plays a critical role for Treg maintenance while repressing of Tfh and germinal center B cell formation directed against these self-antigens. Ultimately, these findings provide opportunities to modulate humoral immunity at different stages of rheumatoid arthritis.

P.C4.02.07

Intravenous administration of antigen-coupled red blood cells induces suppressor T CD8+ cell recurrent release of exosome-carried miRNA-150 targeting antigen presenting cells in mice

K. Bryniarski[1], ***K. Nazimek***[1], *M. Wasik*[1], *M. Ptak*[1], *W. Ptak*[1], *P. W. Askenase*[2];
[1]*Department of Immunology, Jagiellonian University Medical College, Krakow, Poland,* [2]*Section of Allergy and Clinical Immunology, Yale University School of Medicine, New Haven, United States.*

Introduction. Mouse contact (CHS) and delayed-type hypersensitivity (DTH) responses are suppressed by intravenous administration of syngeneic red blood cells (RBC) coupled with hapten or protein antigen, respectively. Current studies aimed at investigating the mechanism of RBC-induced suppression.
Methodology. CBA/J, C57BL/6 or miRNA-150KO mice were injected intravenously with trinitrophenyl or oxazolone hapten-coupled RBC or with ovalbumin-conjugated RBC and then were either contact sensitized with hapten or intradermally immunized with ovalbumin. In some instances, tolerized mice were either injected intraperitoneally with clodronate liposomes or immunized second time after DTH elicitation. Supernatant of tolerized mouse lymph node and spleen cell culture was filtered and ultracentrifuged (100.000g) and pelleted exosomes were tested for their suppressive activity in adoptively transferred CHS or DTH. In some cases, cells prior to culture were positively or negatively selected according to CD3, CD4 and CD8 expression.
Results. Intravenous injections of hapten or antigen-coupled RBC induced the release of suppressive, miRNA-150-carrying exosomes by T CD8+ cells, that were preliminarily shown to mediate the memory of suppression. Further, suppressive exosomes targeted antigen-presenting macrophages that in turn inhibited CHS or DTH effector T cells, while miRNA-150KO mice failed to produce suppressive exosomes.
Conclusions. Above data showed that antigen-coupled RBC activate suppressor T CD8+ cells, which deliver exosome-carried miRNA-150 that targets antigen-presenting cells to suppress CHS and DTH reaction in mice. Consequently, according to our initial data, we speculate that memory of exosome-mediated suppression develops in mice intravenously administered with RBC. Supported by grant No 2013/11/B/NZ6/02041 from Polish National Scientific Centre (NCN).

P.C4.02.08

Repeated administration of hypotensive drugs and diuretics shifts immunity towards Th2-type in healthy mice

*P. Bryniarski[1], S. Strobel[2], A. Chmielowski[2], M. Michalak[2], K. Bryniarski[1], **K. Nazimek**[1];*
[1]Department of Immunology, Jagiellonian University Medical College, Krakow, Poland, [2]Students' Scientific Society, Department of Immunology, Jagiellonian University Medical College, Krakow, Poland.

Introduction. Nowadays, altered inflammatory reactivity of immune cells, especially those infiltrating perivascular tissues, is associated with pathogenesis of hypertension. However, little is known about possible immunomodulatory effects of clinically relevant hypotensives and diuretics. Therefore, our current studies aimed to investigate the effect of these drugs on immunity in healthy mice.
Methodology. 10-week-old CBA mice were treated intraperitoneally with the following drugs: propranolol, hydrochlorothiazide (10mg/kg), carvedilol, captopril, verapamil, furosemide (5mg/kg), amlodipine (3mg/kg) or olmesartan (1mg/kg) for 7 days. On the third day of drug administration, mice were either sensitized with hapten or intraperitoneally injected with mineral oil. Five days later mice were either challenged with hapten to elicit contact sensitivity (CS), or peritoneal macrophages were collected for assessment of their phenotype, cytokine production or for humoral immunity testing, after pulsing with SRBC.
Results: Amlodipine administration slightly increased generation of oxygen and nitrogen radicals and all drugs' administration caused decreased secretion of pro-inflammatory cytokines and slightly enhanced production of anti-inflammatory cytokines by macrophages, and furosemide increased this effect. SRBC-pulsed macrophages from drug-treated mice more potently activated splenic B cells to release antigen-specific antibodies. Finally, all tested drugs, amlodipine and verapamil especially, at both, the induction and effector phases of CS, suppressed cellular immune response.
Conclusion: Our research findings showed that hypotensives modulate immunity by affecting macrophage function and by polarizing towards Th2-type. Further research should be conducted to examine clinical effect of those observations. Supported by K/DSC/003595 and partly by budget funds for science in 2017-2021 under the "Diamond Grant" program (0168/DIA/2017/46).

Inhibiting squalene synthase increases cellular tolerance to cholesterol-dependent cytolysins

***M. Pospiech**[1], S. Owens[1], D. J. Miller[2], R. K. Allemann[2], I. M. Sheldon[1];*
[1]Swansea University Medical School, Swansea, United Kingdom, [2]Cardiff University School of Chemistry, Cardiff, United Kingdom.

BACKGROUND: During infection bacteria secrete toxins that damage the epithelium of the skin and mucosa. Whilst antibiotics are commonly used to treat infection, another approach is to improve the host tissues to tolerate pathogens. Cholesteroldependent cytolysins are secreted by bacteria and target cholesterol-rich areas of mammalian cell plasma membranes, where they form pores, which leads to cytolysis. The present study aims to inhibit squalene synthase to reduce the biosynthesis of cellular cholesterol and increase cellular tolerance to cholesterol-dependent cytolysins.
METHODS: Novel bisphosphonate compounds were designed to inhibit squalene synthase, and synthesised de novo. The bisphosphonates were screened for their ability to inhibit squalene synthase in a cell-free system using a radiometric assay. Twenty bisphosphonates were then evaluated by treating HeLa cells prior to a challenge with a concentration of the cholesterol-dependent cytolysin, pyolysin, that causes 90% cytolysis. Cytolysis was evaluated using the MTT assay, and pore formation was evaluated by measuring the leakage of cellular potassium ions and LDH protein.
RESULTS: Reference compounds as zaragozic acid and methyl-β-cyclodextrin treatment of cells reduced the cytolysis caused by pyolysin by 95%. Amongst the 20 bisphosphonates, we identified two lead compounds that reduced cytolysis caused by pyolysin in a concentration-dependent manner, with a maximum reduction of cytolysis of 95% and 81%. These lead bisphosphonates also prevented short-term potassium leakage from cells, and reduced longer-term LDH leakage by 92%from cells challenged with pyolysin. In conclusion, inhibition of squalene synthase by bisphosphonates increased the ability of HeLa cells to tolerate a cholesterol dependent cytolysin.

Role of Pbx-regulating-protein 1 (Prep1) in the control of effector and regulatory T cell response in metabolic disorders

***C. Procaccini**[1], D. Faicchia[1], S. Cabaro[2], A. Liotti[2], F. Oriente[3], V. Gigantino[4], F. Blasi[5], P. Formisano[3], F. Beguinot[3], G. Matarese[6];*
[1]Ist. Endocrinologia e Oncologia Sperimentale, Consiglio Nazionale delle Ricerche (IEOS-CNR), Napoli, Italy, [2]URT 'Genomica Funzionale' Istituto di Endocrinologia ed Oncologia Sperimentale, 'G. Salvatore', Consiglio Nazionale delle Ricerche (IEOS-CNR), Napoli, Italy, [3]Dipartimento di Scienze Mediche Traslazionali, Università degli Studi di Napoli, 'Federico II', Napoli, Italy, [4]Unità di Patologia, "Istituto Nazionale Tumori, IRCCS, Fondazione Pascale,", Napoli, Italy, [5]IFOM, FIRC Institute of Molecular Oncology, IFOM-IEO Campus, Milano, Italy, [6]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università di Napoli "Federico II", Napoli, Italy.

Pbx-regulating-protein 1 *(Prep1)* is an homeodomain transcription factor, which plays an important role in organogenesis and in the regulation of energy homeostasis and metabolism. *Prep1* heterozygous mice (*Prep1*$^{i/+}$), expressing 55-57% of protein, display increased sensitivity to insulin and are protected from diabetes. As accumulating evidence has shown that metabolic disorders such as obesity and type 2 diabetes are associated with immune system dysfunction, in this study we characterized the role of *Prep1* in the modulation of immune response, associated with protection from metabolic disorders. *Prep1* deficiency significantly inhibited T cell proliferation, by decreasing their activation and secretion of pro-inflammatory cytokines. These effects were associated with an impaired activation of the mammalian-target of rapamycin (mTOR) pathway, cell growth arrest and an altered bioenergetic profiling of CD4$^+$ T cells. On the contrary, CD4+CD25^{hi}Foxp3$^+$ regulatory T cells (Treg) from *Prep1*$^{i/+}$mice displayed a higher ex vivo proliferative capacity and increased suppressive activity, which determined protection of these mice from metabolic alterations, hepatic inflammation and steatohepatitis, induced by high fat diet (HFD). These data unmask a previously unknown role of *Prep1* in the regulation of T cell functions, suggesting that Prep1 might represent a novel platform for potential therapeutic manipulation of immune system functions to control immune-mediate metabolic disorders.

P.C4.02.11

Identification of immune tolerance-related aberrant epigenetic hubs in T cells from multiple sclerosis patients

*D. Avancini[1], V. Martinelli[2], C. Farina[2], S. Gregori[1], **F. R. Santoni de Sio**[1];*
[1]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), San Raffaele Scientific Institute IRCCS, Milan, Italy, [2]Institute for Experimental neurology (INSPE), San Raffaele Scientific Institute IRCCS, Milan, Italy.

The molecular mechanisms underlying the breakage of immune tolerance triggering multiple sclerosis (MS) autoimmune manifestations remain mainly unclear. Recently, deregulation in epigenetic control has been associated with immune cell alterations and MS-related autoimmunity. We have studied epigenome and transcriptome in CD4+ T cells from peripheral blood of relapsing-remitting MS patients and matched healthy controls (HC) to identify aberrant epigenetic hubs (nodes of aberrantly activated regulatory elements and target genes). We identified by ChiP-seq analysis a number of Differentially Active Regulatory Elements (DARE), most of which active in HC and less/not active in MS cells. We defined DARE-target genes by intersecting the DARE list with public 3C-based datasets. DARE-target genes resulted over-represented among genes up-regulated in the RNA-seq analysis of HC and enriched in autoimmune/inflammatory disease gene ontology classes, confirming the differential activity of identified DARE in MS and HC T cells and suggesting their functional role in MS autoimmune manifestations.
To assess the molecular network controlling the activity of MS-DARE, we in silico mapped transcription factor (TF) binding sites and found some interacting master TF enriched for binding at DARE and DARE-target gene promoters, suggesting that a core of TF might control the activity of MS-DARE. Our data suggest aberrant control of regulatory elements as player in T cell alterations in MS. Current studies aimed at validating chromatin data by ATAC-seq and evaluating the role of identified altered epigenetic hubs in T cell function will assess the pathogenic role of identified alteration in MS and in autoimmune diseases in general.

P.C4.02.12

Regulatory T cell numbers in inflamed skin controlled by ALK3 signaling in dendritic cells

***T. Sconocchia**[1], M. Hochgerner[2], I. Borek[1], E. Schwarzenberger[1], C. Tam-Amersdorfer[1], H. Strobl[1];*
[1]Otto Loewi Research Center, Chair of Immunology and Pathophysiology, Graz, Austria, [2]Institute of Cancer Research, Medical University of Vienna, Vienna, Austria.

Bone morphogenetic protein 7 (BMP7) is expressed at aberrant high levels by keratinocytes during skin inflammation and induces inflammatory-type Langerhans cell (LC) differentiation. Regulatory T cell (Treg) are increased in inflamed epidermis and LCs are known to stimulate Tregs. Thus, we asked whether BMP signaling in LCs may promote Treg generation. Human LCs were generated from CD34$^+$ cells in response to either BMP7 or TGF-β1, to generate LCs resembling inflammatory LCs or steady-state-like LCs, respectively. LCs were cultured with allogeneic CFSE-labeled naïve CD4$^+$ T cells. BMP7-LCs displayed an enhanced T cell stimulatory capacity compared to TGF-β1-LCs. Also, the extent of Treg content utilizing BMP7-LCs, was significantly higher than that induced by TGF-β1-LCs. In addition, Tregs derived from BMP7-LCs were significantly more immunosuppressive than that derived from TGF-β1-LCs. *In vivo* validation was carried out by measuring FoxP3$^+$ cell frequencies in DC-specific ALK3/BMPR1a knockout mice in an imiquimod induced model of skin inflammation. ALK3 deficiency was associated with fewer FoxP3$^+$ cells compared to wild type mice. Subsequently, molecules that interfere with LC-mediated Treg induction were evaluated. An interfering ALK3 fusion protein specifically reduced Treg generation by BMP7-LCs. Vice versa, BMP7 directly promoted Treg differentiation in an APC-free system from naïve T cells *in vitro*. These data demonstrate that BMP/ALK3 signaling in inflamed skin enhances Treg numbers at least partially via modulation of DCs.

Investigation of the molecular mechanisms that affect regulatory T cell function in patients with active systemic lupus erythematosus

*C. Albany[1], Z. Catak[1], D. McCluskey[1], G. Giganti[1], L. Nel[2], G. A. Povoleri[1], M. Catapano[1], M. Robson[1], J. Spencer[1], D. D'Cruz[2], R. I. Lechler[1], G. Lombardi[1], **C. Scotta**[1];*
[1]King's College London, London, United Kingdom, [2]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.

Systemic lupus erythematosus (SLE) is a multisystem, chronic, debilitating and frequently-relapsing condition. Although anti-inflammatory treatments are available, none is curative and relapses remain common. There is a critical requirement for effective therapies that obviate the need for immunosuppression and restore self-tolerance. Regulatory T cells (Tregs) in healthy individuals prevent the development of autoimmune diseases; however, in SLE-patients Tregs are numerically deficient and/or functionally impaired. *Ex vivo* expansion of SLE-Tregs along with the repair of their function to obtain a clinical product for cell-therapy is an attractive and novel option for re-establishing self-tolerance. Functional, phenotypic and genetic data were collected from SLE-Tregs either freshly isolated or cultured in the presence of rapamycin. Results showed that although SLE-Tregs resemble the typical phenotype of healthy-Tregs, their suppressive capacity is impaired during active disease. The analysis of Treg sub-populations revealed differences in cell-distribution during the relapsing and remitting course of the disease that correlate with the breakdown of self-tolerance. However, the *ex vivo* expansion of Tregs from SLE-patients in the presence of rapamycin fully restored their function. The analysis of molecular data from SLE-Tregs identified a list of differentially expressed genes/molecular pathways that describes both the signature of dysfunctional Tregs and the 'repairing effect' of rapamycin. Altogether our data indicate that the functional defect of Tregs in SLE can be corrected along with their expansion in a therapeutic cell-product. Our findings suggest a new approach to use autologous Tregs in a programme of adoptive-cell-therapy for the treatment of SLE.

Immune inhibitory CD200-Receptor potentiates type I immunity during inflammation

***M. Van der Vlist**[1], M. Ramos[1], L. van den Hoogen[2], S. Hiddingh[2], M. van der Kroef[2], R. Lebbink[2], T. Radstake[2], L. Meyaard[1];*
[1]UMC Utrecht; Oncode Institute, Utrecht, Netherlands, [2]UMC Utrecht, Utrecht, Netherlands.

Immune responses are tightly regulated to allow pathogen clearance but prevent autoimmunity. Systemic Lupus Erythematosus (SLE) is an autoimmune disease that predominately affects women (9:1) and arises from dysregulated Toll-like receptor (TLR) 7 signaling and aberrant type I interferon production. The CD200 Receptor 1 (CD200R) is an inhibitory immune receptor that limits TLR7-induced type I interferon responses especially in females. Therefore, we hypothesized that CD200R-mediated inhibition is absent in SLE patients. Surprisingly, we discovered that in PBMC from SLE patients TLR-induced cytokine production was not suppressed by CD200R but was instead potentiated by it. CD200R signaling also potentiated TLR-induced cytokine production in healthy control (HC) PBMCs treated with IFNα. We found that in the absence of inflammation, CD200R inhibited Akt activation through Dok2 and Erk/rpS6 activation through RasGAP, resulting in suppression of cytokine production. In contrast, SLE PBMC or HC PBMC treated with IFNα had decreased RasGAP to levels that were insufficient for CD200R to inhibit Erk/rpS6. Furthermore, CD200R retained its ability to inhibit Akt via Dok2, which normally provides negative feedback on type I cytokines. Thereby CD200R potentiated type I cytokine production. We conclude that IFNα negatively regulates CD200Rs ability to dampen inflammatory response through RasGAP, while leaving intact its ability inhibit Akt. Taken together, we demonstrate that the signal transduction machinery of the immune-inhibitory receptor CD200R is responsive to type I IFNs thereby allowing CD200R to switch from inhibitory to potentiating depending on the inflammatory environment.

P.C4.02.15

Immunomodulatory properties of cellulose nanocrystals depend on their functionalization

***M. Vasiljevic**[1], M. Bekic[2], B. Joksimovic[1], D. Mihajlovic[3], M. Milanovic[3], I. Majstorovic[3], D. Vucevic[3], S. Tomic[2], M. Colic[2,1,3];*
[1]Medical Faculty Foca, University of East Sarajevo, Foca, Bosnia and Herzegovina, [2]Institute for the Application of Nuclear Energy, Belgrade, Serbia, [3]Medical Faculty of the Military Medical Academy, University of Defence, Belgrade, Serbia.

Cellulose nanocrystals (CNC) are attractive nanomaterials with large surface area suitable for development of drug delivery and diagnostic systems. However, the biocompatibility and immunomodulatory properties of CNC have not been studied so far, especially in relation to CNC functionalization. Here we used wood-based native (n)CNC, as precursors for TEMPO-oxidized (o)CNC and phosphonated (p)CNC, to assess their toxicity and immunomodulatory potential on human peripheral blood mononuclear cells (PBMC) and monocyte-derived dendritic cells (MoDC). We found that non-toxic concentrations (<400 μg/ml) of nCNC and oCNC impaired the proliferation and IL-2 production by phytohemaglutinin-stimulated PBMC, whereas pCNC had no significant effects. According to CD14/CD1a expression analysis, oCNC displayed the strongest inhibitory effect on MoDC differentiation, followed by nCNC and pCNC, respectively. These results correlated with the weakest maturation capacity of oCNC-treated MoDC induced by LPS/IFN-γ. Additionally, nCNC- and oCNC-treated MoDC expressed higher levels of PD1-L, TGF-β and ILT-4 compared to control MoDC, whereas pCNC-treated MoDC showed no such property. The capacity of MoDC to produce high levels of IL-12p70, IL-1β, IL-23, and low levels of IL-10, were impaired by nCNC and oCNC, but not by pCNC. In line with this, nCNC- and oCNC-treated MoDC displayed an increased capacity to induce alloreactive Th2 cells and TGF-β-producing CD4+CD25^{hi}FoxP3+ Treg cells, and a decreased capacity to induce IFN-γ-producing Th1 cells in co-culture. Cumulatively, these results suggest that CNC may induce tolerogenic properties in MoDC, whereas phosphonation of CNC prevents such effects, thus restoring the immunogenic potential of MoDC.

P.C4.02.16

Investigation of EZH2 as an epigenetic modulator of FoxP3 expression in regulatory T-cells in the light of immune tolerance impairment

***A. Velichkov**[1], R. Susurkova[1], A. Mihova[2,3], M. Guenova[2], I. Antonova[4], D. Staneva[5], M. Georgieva[5], G. Nikolov[4], G. Miloshev[5], V. Terzieva[1,3];*
[1]Institute of Biology and Immunology of Reproduction, BAS, Sofia, Bulgaria, [2]National Specialised Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria, [3]University Hospital "Lozenetz", Sofia, Bulgaria, [4]Medical Center "Reprobiomed", Sofia, Bulgaria, [5]Laboratory of Molecular Genetics, Institute of Molecular Biology "R. Tsanev", Bulgarian Academy of Sciences, Sofia, Bulgaria.

Introduction: Regulatory T-cells (Tregs) represent the effective arm of immune tolerance. Their function is tightly regulated and its impairment is associated with recurrent pregnancy loss (RPL), autoimmune and allergic reactions. Our aim is to evaluate EZH2, an epigenetic modulator of FoxP3 expression by the model of recurrent pregnancy loss.
Materials and Methods: PBMCs from healthy controls (HCs) with no RPL: women with successful pregnancy (n=24; 23-45 years) and without pregnancy (n=10; 26-38 years) and patients with RPL (n=18; 25-44 years) were stained with anti-CD3/CD4/CD45RA/CD25/FOXP3 antibodies. FoxP3 and EZH2 expression were determined by PrimeFlow™ assay and qRT-PCR in non-stimulated or stimulated with progressively increased progesterone concentrations. The FACS-analysis was done using FlowJo V10 and the Statistical analysis by GraphPad Prism7.
Results: The overall analysis showed lower CD45RA+FOXP3+nTregs percentage in patients compared to the healthy groups ($p<0.05$). The highest proportion of CD25+nTregs was found in the group of women w/o pregnancy ($p<0.05$). Conversely, the proportion of CD45RA+FOXP-CD25-T-cells dominated in the group of patients ($p<0.05$). The percentage of EZH2mRNA+ cells in non-Tregs and Tregs was greater in HCs ($p<0.05$) and showed progesterone-dependent variations.
Conclusion: Our results show that the pregnancy impacts mainly nCD4+ population. Epigenetic modifications facilitated by the hormonal milieu might be associated with variations in FoxP3 expression. Considering that EZH2 and FOXP3 are indispensable for the fate of Treg, further investigations are inline to clarify the precise regulation mechanisms in Tregs.

Genome-wide methylation analysis of regulatory and conventional T cells

***A. Salumets**[1], H. Peterson[1], P. Peterson[2];*
[1]Institute of Computer Science, Tartu, Estonia, [2]Institute of Biomedicine and Translational Medicine, Tartu, Estonia.

Regulatory T cells (Tregs) represent a subpopulation of T cells that are specialised in immune suppression and maintenance of immune tolerance. They have a crucial role in the prevention of autoimmunity and their failure leads to development of autoimmune diseases. We compared the Tregs to their conventional counterparts (Tconvs) that serve an opposing role - activation of immune system. The aim of our study was threefold: (1) to examine differentially methylated positions (DMPs) and regions (DMRs) between Tregs and Tconvs; (2) find DMPs and DMRs between Tregs from healthy controls and Graves' patients; and (3) find which DMPs and DMRs from the previous step are characteristic to Tregs. To meet the objectives, we performed a genome-wide methylation analysis with Infinium Human Methylation EPIC BeadChips. Firstly, we focused on CpG sites that were differentially methylated between Tregs and Tconvs (6 healthy controls). As a result, we found nearly 19,000 DMPs and 630 DMRs (FDR<0.05). Secondly, we investigated differences between Tregs from healthy controls (10 individuals) and Graves' patients (11 individuals) which resulted in 19 DMPs (FDR<0.05). Our analysis indicated no overlap between those two sets of DMPs. However, we observed differences between methylation value distribution of Tconvs and Tregs where Tconvs had more extreme methylation values i.e. they had more CpGs with either low or high methylation level.

P.C4.03.01
Expression of PHD2 regulates regulatory T cell capacity to control Th1-like inflammatory responses

***Y. Ajouaou**, H. Hussein, S. Denanglaire, F. Andris, M. Moser, O. Leo;*
Université Libre de Bruxelles, Gosselies, Belgium.

Inflammation is often associated to a hypoxic state imposing a metabolic constraint on inflammatory cells. The protein HIF1α plays an important role in cells hypoxia adaptation, and its stability is regulated by the oxygen sensor prolyl-hydroxylase 2 (PHD2) in numerous cell types including T lymphocytes. The impact of hypoxia on immune cells, in particular on regulatory T cell (Treg) function, has not been fully elucidated. The purpose of our study is to evaluate the role of the PHD2-HIF1α axis in the regulation of homeostasis and function of Tregs.
We demonstrate in this work that selective ablation of PHD2 expression in Tregs ($PHD2^{\Delta Treg}$ mice) leads to a spontaneous intestinal inflammatory syndrome, as evidenced by the development of a rectal prolapse and elevated expression of IFNγ and IL-10 in the mesenteric lymph nodes and spleen. PHD2 deficiency in Tregs leads to an increased number of activated CD4 and CD8 conventional T cells expressing an effector-like phenotype ($CD44^{hi}CD62L^{low}$). Concomitantly, the expression of innate-type cytokines such as IL1-β, IL-12p40, IL-12p35 and TNF-α is found to be elevated in peripheral (gut) tissues. Finally, $PHD2^{\Delta Treg}$mice display an enhanced sensitivity to DSS-induced colitis and to experimental autoimmune encephalomyelitis (EAE), suggesting that PHD2-deficient Tregs do not efficiently control inflammatory response *in vivo*. The mechanisms whereby PHD2 controls Treg activity is presently under investigation, in particular through the development of *in vitro* models of immune suppression. We hope that our study will contribute to a better understanding of the role of oxygen-sensing pathways in the regulation of inflammatory responses.

P.C4.03.02
Short term cold acclimation enhances human Treg induction

***M. Becker**[1,2], I. Serr[1,2], L. Mengel[3], H. Hauner[3,4], M. H. Tschöp[2,5,6], C. Daniel[1,2];*
[1]Institute of Diabetes Research, Group Immune Tolerance in Diabetes, Helmholtz Diabetes Center at Helmholtz Zentrum München, German Research Center for Environmental Health, Munich, Germany, [2]German Center for Diabetes Research (DZD), Munich, Germany, [3]ZIEL-Institute for Food & Health, Else Kröner-Fresenius Zentrum für Ernährungsmedizin, Technische Universität München, Freising-Weihenstephan, Germany, [4]Institute for Nutritional Medicine, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany, [5]Institute for Diabetes and Obesity, Helmholtz Diabetes Center, Helmholtz Zentrum München, Munich, Germany, [6]Division of Metabolic Diseases, Technical University of Munich, Munich, Germany.

$Foxp3^+$regulatory T-cells (Tregs) function as critical immune regulators, thereby controlling tissue-specific differentiation, homeostasis and local inflammation. We recently found that murine Tregs represent key components of the molecular interface connecting adipose tissue (AT) function with environmental cold or low-dose beta3-adrenergic stimulation. Specifically, by loss- and gain-of-function experiments, including Treg depletion and transfers in vivo, we identified a T-cell-specific Stat6/Pten signaling axis that links cold exposure or beta3-adrenergic stimuli with Treg activity and AT function. However, the translational relevance of these findings for human Treg induction in response to beta3-adrenergic stimulation or cold remains currently unknown. Here, we show that beta3-adrenergic stimulation using Mirabegron (Mira) induces human Tregs in a preclinical setting of humanized NSG mice (human $CD3^+CD4^+CD127^{low}CD25^{high}Foxp3^+$Tregs [% of $CD4^+$T cells]: control: 1.9±0.5 vs. +Mira: 4.9±1.0; p=0.0319) accompanied by increased Treg induction potential from naïve $CD4^+$T cells in vitro. Moreover, human $CD4^+$T cell analyses of subcutaneous AT biopsies after an acute cold stimulus of 2 hours to healthy subjects provide first evidence for an increase in local $CD3^+CD4^+CD127^{low}CD25^{high}Foxp3^+$Tregs (Tregs [% of $CD3^+CD4^+$]; t0=1.54±0.34% vs. t2=2.31±0.98%). Of note, short-term human cold acclimation in vivo also enhanced human Treg induction potential from naïve $CD4^+$T cells in peripheral blood ($CD3^+CD4^+CD127^{low}CD25^{high}Foxp3^+$Tregs [% of t0]; t0=100.0±7.5% vs. t2=137.1±25.9%; p=0.0030). These findings support the concept that cold exposure or beta3-adrenergic stimulation can exert pro-tolerogenic functions on human $CD4^+$T cells. Further mechanistic analyses are required to dissect molecular underpinnings of human $Foxp3^+$Treg induction in response to cold or beta3-adrenergic stimulation in health and metabolic disease.

P.C4.03.03
Salt modulates cellular metabolism of regulatory T cells

***B. F. Côrte-Real**[1], O. Matveeva-Kolm[1], I. Hamad[1], A. Geuzens[1], L. Dubois[2], M. Kleinewietfeld[1];*
[1]VIB Laboratory for Translational Immunomodulation, VIB Center for Inflammation Research (IRC), Hasselt, Belgium, [2]Department of Radiation Oncology (Maastro), GROW - School for Oncology and Developmental Biology, Maastricht, Netherlands.

High salt intake has been associated with shifts in the immune cell balance, mainly by promoting proliferation and activity of pro-inflammatory cells, such as T helper 17 (Th17) and M1 macrophages, and by impairing the functions of anti-inflammatory cells such as regulatory T cells (Tregs) and M2 macrophages. However, the precise molecular mechanisms that lead to this phenotype are still unknown. The role of metabolic regulation in shaping immune responses has gained increasing attention in recent years. Cellular metabolism is a vital process, which is essential for growth, survival and proliferation of every cell type, and can be greatly influenced by environmental factors such as diet. A recent study has shown that high-salt leads to metabolic changes in M2 macrophages by decreasing their mitochondrial oxidative phosphorylation (OXPHOS) and glycolysis necessary for their activation. Therefore, we analyzed the effect of high-salt on human Treg metabolism. Our results on human Tregs show a similar trend induced by high-salt as the ones observed in macrophages. This changes might be linked to the loss of suppressive function of Tregs upon high-salt challenge. M.K. was supported by the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation program (640116), by an SALK grant from the government of Flanders, Belgium, and by an Odysseus grant from the Research Foundation Flanders, Belgium (FWO).

P.C4.03.04
Treg profile associated with long-term immunosuppressed transplanted patients with cancer

***L. Daniel**[1,2], L. Dufour[3], A. Robin[1,3], A. Herbelin[1,2], J. Gombert[1,2,3], A. Thierry[1,3];*
[1]Inserm U1082, Poitiers, France, [2]Université de Poitiers, Poitiers, France, [3]CHU de Poitiers, Poitiers, France.

Background: The long-term immunosuppressive therapy required to maintain host tolerance of a transplanted organ contributes to an increased risk for malignancy in organ transplant recipients. A variety of factors, including the intensity and duration of immunosuppression, can influence the likelihood for the development of cancer in these patients. Here, we focused on the regulatory CD4(+)CD25(+)FoxP3(+) T cells (Treg) as possible targets for the immunosuppressive treatments, and explored their profile associated with cancer.
Methods: We analyzed by flow cytometry blood samples from 60 renal transplant recipients for more than 10 years, without signs of rejection, treated with minimized immunosuppression: azathioprine+steroids or anticalcineurin monotherapy.
Results: We observed an increase in Treg frequency and memory Treg CD45RA(-)FoxP3(hi) frequency in patients with a history of cancer, compared to patients without cancer. We also observed an increase of CTLA4 expression in Treg from anticalcineurin-treated patients with a history of cancer, compared to patients without cancer and healthy controls. Lastly, we observed an increase of CD4(+)FoxP3(+)Helios(+) Treg with a stable immunosuppressive phenotype in patients treated with azathioprine+steroids and a history of cancer, whereas the frequency of these cells decreased in the other groups of patients compared to healthy controls.
Conclusion: The proportion and functional status of Treg appeared to vary according to the type of treatment and background of cancers in renal transplant patients with long-term minimized immunosuppression. Further assays evaluating donor-specific responses of recipient Treg in our cohort would promote a better understanding of the mechanisms underlying operational tolerance in transplantation.

P.C4.03.05
Identification of a tolerogenic Factor V peptide and its potential role in Factor VIII tolerance induction

***A. S. De Groot**[1,2], A. Rosenberg[3], S. Lelias[1], P. Hindocha[1], F. Terry[1], B. Roberts[1], W. Martin[1], E. Guillen[1];*
[1]EpiVax, Inc., Providence, United States, [2]University of Rhode Island, Providence, United States, [3]Center for Drug Evaluation and Research, FDA, White Oak, United States.

Inhibitory Anti-Drug Antibody (ADA) responses interfere with Factor VIII replacement efficacy in 25-30% of Hemophilia A (HA) cases, greatly increasing patient morbidity and treatment costs. As an extension of previous work on tolerance-inducing peptides in IgG (Tregitopes), we investigated whether there were peptides in other ubiquitous serum proteins that could have high homology to peptides found in Factor VIII. We hypothesized that tolerance to cross-conserved peptides in other prevalent proteins might explain why anti-FVIII antibodies fail to develop in some severely FVIII-deficient HA patients. Using advanced computational modeling tools, we discovered in Factor V a potent regulatory peptide (FVP4) with an immunologic profile (HLA and TCR binding) that is homologous to a non-identical peptide in FVIII. We postulated that treatment with a FVP4-peptide containing biologic may be able to invoke tolerance to Factor VIII in patients who have anti-FVIII antibodies. In an ex vivo assay using human PBMC, we found that the CD4 and CD8 effector recall response was strongly inhibited by FVP4. However, other Factor V peptides with similar HLA-binding properties did not suppress the response. The peptide homologue to FVP4 found in Factor VIII shows similar inhibitory activity on activated CD4 T cells. Using this assay, we are determining the evolution of markers on regulatory T cells, Antigen Presenting Cells, and effector T cells as well as the cytokine secretion profile over time in order to identify specific parameters associated with cell populations and soluble factors mediating immune suppression in response to FVP4.

Introduction: Circulating regulatory T cells (Tregs) in anti-neutrophil cytoplasmic antibody associated vasculitis are frequently functionally deficient. The mechanism behind their impaired function is however unknown. Here, we hypothesized that the dysfunctionality of Tregs in AAV is due to altered microRNA (miR) expression in these cells.
Methods/results: Tregs (CD4+CD45RO+CD25+CD127-) of healthy controls (HC) and AAV patients in remission without treatment (AAV-REM) were FACS-sorted, and total RNA was isolated. Samples from 8 HCs and 8 AAV-REMs were subjected to miRNA microarray analysis. Nineteen miRNAs were differently expressed, and in an independent validation cohort, miR-142-3p was confirmed to be significantly upregulated (2-fold, p=0.03) in Tregs of AAV-REM patients (n=23). In vitro transient overexpression of miR-142-3p using a mimic-miR-142-3p, showed that the suppressive capacity of Tregs was significantly inhibited upon overexpression (1.9 fold reduction, p=0.02), and miR-142-3p levels tended to negatively correlate to the suppressive capacity of Tregs (p=0.06, rho=-0.591). A database and literature search identified adenylyl cyclase-9 (AC9) as validated target for miR142-3p. mRNA levels of AC9 (3.8-fold) tended to be lower in AAV-REM Tregs. In addition, cyclic AMP (cAMP) levels in Tregs, partly produced by AC9, were measured after aCD3/CD28 stimulation. After 48h stimulation, cAMP levels were significantly lower in AAV-REM Tregs (1.7 fold, p=0.003). Moreover, overexpression of miR-142-3p also significantly lowered the cAMP production.
Conclusion: Increased expression of miR-142-3p in Tregs of AAV-REM patients may induce their functional impairment by targeting the AC9/cAMP mediated suppression.

In vivo screening of novel fusion proteins targeting CD28 and PD1 pathways inhibiting immune responses and promoting long-term transgene expression in the context of muscle gene therapy

L. Dupaty[1], *M. Demeules*[1], *G. Riou*[1], *L. Jean*[1], *A. Salvetti*[2], *O. Boyer*[1], *S. Adriouch*[1];
[1]*Normandie Univ, UNIROUEN, INSERM, U1234, Physiopathologie, Autoimmunité, maladies Neuromusculaires et THErapies Régénératrices (PANTHER), Rouen, France,* [2]*Cancer Research Center of Lyon (CRCL), INSERM U1052, CNRS UMR5206, Lyon, France.*

In vivo gene transfer mediated by adeno-associated viral (AAV) vectors has become a feasible therapeutic strategy in human. However, immune responses against the therapeutic gene products (TgP) represent a major concern as this method widened to a spectrum of pathologies and individuals. One remaining challenge is to induce immunological tolerance towards the TgP.
For that, we implemented a stringent animal model and evaluated a panel of 12 novel fusion proteins derived from CTLA-4 and/or PDL1 with the aim to manipulate these major immunoregulatory axes and to induce long-term tolerance. To directly screen in vivo the immunoregulatory properties of our selected protein candidates, we used AAV vectors to produce them in vivo and co-injected them together with an AAV vector coding for the strongly immunogenic Ovalbumin TgP. This screening strategy allowed the identification of 2 immunoregulatory candidates, PD-L1^{n1} and PD-L1^{n2}, that significantly inhibit cellular and antibody responses against the TgP and, remarkably, improved Ova persistence *in vivo*. Interestingly, and in contrast to CTLA-4/Fc, these molecules preserve the Treg compartment and are associated with active immunoregulation rather than inhibition of lymphocytes priming.
Finally, based on our results, we implemented sequential strategy relying on a single injection of CTLA-4/Fc, to inhibit the priming of initial immune response, subsequently followed by the injections of our selected PD-L1^{n1} or PD-L1^{n2} immunoregulatory proteins. This strategy may be of interest in gene therapy as well in transplantation where long-term tolerization remains a major challenge.

A novel approach for the isolation of medullary thymic epithelial cells from murine thymi improves purity and cell recovery

R. Engelmann[1], *D. Dohr*[2], *B. Müller-Hilke*[1];
[1]*Institute of Immunology & Core Facility for Cell Sorting and Cell Analysis, Rostock, Germany,* [2]*Institute of Immunology, Rostock, Germany.*

Objective: Medullary thymic epithelial cells (mTEC) play a central role in the removal of T cells specific for tissue-restricted antigens and thus prevent disastrous autoimmunity. Thus methods to efficiently isolate these cells are warranted. **Methods:** Excised murine thymi were digested with a standard dispase/collagenase/DNase mixture. Thereafter, mTEC were magnetically enriched using UEA-1 microbeads and CD45+ thymocytes were subsequently depleted by cell straining. This novel method was compared to the broadly used enrichment by percoll density gradient centrifugation followed by flow cytometry cell sorting. **Results:** The usage of 2µl UEA-1 beads per 1x10^8 cells for magnetic enrichment was superior to the percoll method in terms of the percentage of enriched mTEC (22% versus 1.2% on average) and the number of isolated mTEC per thymus (2x10^5 versus 5x10^4). The viability after both procedures was comparable. Subsequent depletion of CD45+ cells resulted in an mTEC purity of 76% compared to 87% after flow cytometric cell sorting. However, the recovery rate of cells proved to be significantly higher after cell straining as compared to flow cytometric cell sorting. **Conclusions:** The combination of magnetic enrichment of UEA-1+ cells with subsequent depletion of CD45+ cells via cell straining results in increased yields of mTEC as compared to the current gold standard method.

Myeloid derived suppressor cells (MDSC), discovered as one of the major factors driving tumor progression, are also involved in beneficial effects during the course of autoimmune diseases, but their role is not fully understood. The protocols for differentiation of human monocyte-derived MDSC *in vitro* have not been fully established, especially considering the immense role of prostaglandin (PG)-E2 in the induction of MDSC *in vivo*. Here we found that GM-CSF and IL-6 were required for the induction of CD33$^+$HLA-DR^{low}CD14$^+$CD209$^-$ MDSC *in vitro* that failed to up-regulate/express co-stimulators and IL-12p70 upon LPS/IFN-γ stimulus. However, the addition of PG-E2 to GM-CSF/IL-6 cocktail up-regulated additionally CD14 and CCR7, and down-regulated the expression of CD1a, HLA-DR, CD209, CD16, CD11c, CD11b on these cells. PG-E2-induced MDSC expressed higher levels of CD39, PD1L, ILT-3 and ILT-4, and produced higher amounts of TGF-β and IL-27, and lower amounts of IL-1β, IL-10, IL-23 and TNF-α after LPS/IFN-γ stimulation, compared to GM-CSF/IL-6-induced MDSC. Alloreactive T cells co-cultured with PG-E2-induced MDSC contained more IL-4-producing CD4$^+$GATA-3$^+$ T cells, and less IL-17-producing CD4$^+$ RORγt$^+$ T cells, as well as IFN-γ-producing CD8+ T cells, but not CD4+IFN-γ+ T cells. Interestingly, PG-E2-induced MDSC generated a smaller percentage of alloreactive CD4+CD25^{hi}FoxP3+TGF-β Tregs, but increased significantly the percentage of CD4+IL-10+FoxP3-IL-4- Tr-1 and CD8+IL10+ T cells, compared to GM-CSF/IL-6-induced MDSC. Therefore, PG-E2 potentiate the suppressive phenotype and functions of GM-CSF/IL-6-induced MDSC, and change the mechanisms involved in Treg induction, which could be important in development of therapeutic strategies focused on MDSC-related effects in tumors and autoimmune diseases.

P.C4.03.10

Post-translational modified protein antibodies in Rheumatoid arthritis: searching for the eye of the storm

A. S. B. Kampstra, *J. Dekkers, A. M. Dorjee, M. Volkov, L. Hafkenscheid, A. Kempers, M. A. van Delft, T. M. Huizinga, D. van der Woude, R. E. Toes;
Leiden University Medical Center, Leiden, Netherlands.*

Autoantibodies against post-translationally modified proteins (Anti-modified Protein Antibodies or AMPA) are a hallmark of Rheumatoid Arthritis (RA). A variety of AMPAs against different protein modifications, such as citrullinated proteins, carbamylated proteins and acetylated proteins have now been described in RA. Since these antibodies are far less frequently found in health or patients with other auto-immune diseases, a shared 'developmental' basis is suggested. At present, the origin or mutual relationship of AMPAs is poorly understood. Here, we aimed to study the origin of AMPA-responses by postulating that the AMPA-response shares a common "background" that evolves over time into different classes of AMPAs. Immunisation of mice with carbamylated proteins not only induced an antibody response recognizing carbamylated proteins, but also acetylated proteins. Similarly, also immunization with acetylated proteins led to the formation of (autoreactive) AMPAs against other modifications as well. Analysis of antibodies purified with citrullinated antigens (ACPA) from blood of RA-patients antibodies revealed that ACPA, besides citrulline-reactivity, can also display reactivity to acetylated and carbamylated peptides. Similarly, purified anti-carbamylated protein antibodies showed cross-reactivity against all three post-translational modifications. Our data show that different AMPA-responses can evolve from exposure to only one type of modified protein. These findings indicate that the different AMPA-responses originate from a common "precursor" B cell response that diversifies into multiple distinct AMPA-responses over time and explain the presence of multiple AMPAs in RA, one of the hallmarks of disease.

P.C4.03.11

Modulating the production of active TGF-b1 by Tregs with antibodies against GARP/latent TGF-b1 complexes

F. Lambert[1], *B. Van Der Woning*[2], *M. Saunders*[2], *S. Lucas*[1];
[1]*de Duve Institute, Brussels, Belgium,* [2]*arGEN-X BVBA, Gent, Belgium.*

Regulatory T cells (Tregs) exert contact-dependent inhibition of immune cells through the production of active TGF-β1. This immunosuppressive cytokine is secreted by all immune cells as a latent and inactive form, in which the mature cytokine is associated to the Latency Associated Peptide (LAP), that precludes the interaction of the mature cytokine with its receptor. To exercise its activity, mature TGF-β1 must be released from the LAP, a process referred to as « TGF-β1 activation ». Tregs activate latent TGF-β1 via a mechanism that requires a transmembrane protein called GARP, which binds latent TGF-β1 by forming disulfide bonds with LAP. We wish to derive monoclonal antibodies that activate latent TGF-β1 by binding to GARP/latent TGF-β1 complexes, to provide means to stimulate Treg functions *in vivo*. If we succeed, we will attempt to obtain the crystallographic structure of GARP/latent TGF-β1 in complex with our activating antibody. We intend to identify the tri-dimensional changes in GARP/latent TGF-β1 complexes that lead to the release of active TGF-β1 and obtain information on the mode of action of the antibody. We tested 81 monoclonal antibodies directed against GARP, latent TGF-β1 or GARP/latent TGF-β1 complex *in vitro*. Only 7 were capable of activating TGF-β1 from GARP/latent TGF-β1 complexes. All these antibodies bind murine latent Tgf-β1 regardless the presence of Garp. After analysis of binding and activating properties of these anti-mouse latent Tgf-β1 antibodies, we started to confirm their activity *in vitro* on murine cell populations expressing Garp/latent Tgf-β1 complexes such as CD4+ T lymphocytes or platelets.

TOLERance-induction with autologous tolerogenic dendritic cells treated with VITamin D3 and loaded with myelin peptides in Multiple Sclerosis (TOLERVIT-MS trial): The design of a multicenter, dose-escalation phase I clinical trial

M. Mansilla[1], *S. Presas-Rodríguez*[2], *J. Navarro-Barriuso*[1], *A. Teniente-Serra*[1], *B. Quirant-Sánchez*[1], *A. Lopez-Díaz de Cerio*[3], *S. Inogés*[3], *F. Prósper*[3], ***E. Martínez-Cáceres***[1], *C. Ramo-Tello*[2];
[1]*Germans Trias i Pujol Hospital and Research Institute. Campus Can Ruti, Badalona, Spain,* [2]*Germans Trias i Pujol Hospital, Badalona, Spain,* [3]*Cell Therapy Center, Clínica Universidad de Navarra, Pamplona, Spain.*

Tolerogenic dendritic cell (tolDC) therapy is a promising strategy for the attenuation of pathogenic T cells in autoimmune diseases such as multiple sclerosis (MS). Our group has developed an autologous antigen-specific cell therapy based on vitamin D3 (VitD3)-tolDC loaded with myelin peptides. **OBJECTIVE**: To describe the design of a multicenter, open-label, dose-escalation Phase I clinical trial to evaluate feasibility, safety, tolerability and preliminary efficacy of intranodal administration of VitD3-tolDC in active MS patients. **METHODS:** In vitro studies have demonstrated a potent immunoregulatory activity of vitD3-tolDC reducing lymphocyte proliferation and IFN-g production and increasing IL-10 levels, in co-culture experiments. Moreover, in vivo studies in the animal model of MS revealed a beneficial effect of VitD3-tolDC ameliorating the severity of the disease. Considering these pre-clinical results, a clinical trial was designed. **RESULTS**: Active MS patients will be included in a dose-escalation best-of-five design: Cohort 1 (5x10^6 VitD3-tolDC), Cohort 2 (10x10^6), Cohort 3 (15x10^6). A fourth Cohort of patients under IFN-beta treatment receiving the selected dose of VitD3-tolDC will be included. The trial protocol has been approved by the Spanish regulatory authorities (AEMPS) (https://clinicaltrials.gov/ct2/show/NCT02903537). Each cohort will received 6 administrations of tolDC (first 4 every 2 weeks and last 2 every 4 weeks). Clinical, MRI and immunological monitoring of 12 patients will be performed for 24 months. Each patient will be its own pre- and post-intervention control. **CONCLUSIONS:** Positive outcomes of this phase I clinical trial may lead to a phase II trial to investigate the efficacy of this therapy in MS patients

P.C4.03.13

TNFR2 blockade on Treg unleashes anti-tumor immune response after hematopoietic stem cell transplantation

A. Moatti[1,2], *A. Debesset*[1,2], *C. Pilon*[1,3,2], *S. Maury*[1,2,3], *J. Cohen*[1,2,3], *A. Thiolat*[1,2];
[1]*Inserm, U955, Equipe 21, Créteil, France,* [2]*Université Paris-Est, UMR_S955, UPEC, Créteil, France,* [3]*APHP, Hôpital H. Mondor-A. Chenevier, Centre d'Investigation Clinique Biothérapie, Créteil, France.*

Background. Allogeneic hematopoietic stem cell transplantation (alloSCT) was the first immunotherapy developed to treat hematological malignancies. Even if the graft-versus-tumor (GVT) effect of alloSCT relies on effector donor T cells (Teffs), regulatory T cells (Tregs) also present in the graft could minimize GVT. In mouse and human, Tregs highly express the TNFα type 2 receptor (TNFR2) and TNFR2+Tregs display a strong suppressive capacity. Importantly, by blocking the TNF/TNFR2 pathways, we recently revealed a complete TNF dependency for Treg in terms of suppressive capacity in vivo after alloSCT. Here, we hypothesize that the disruption of the TNF/TNFR2 pathway could be use to set off an efficient GVT effect after alloSCT.
Methodology. B6D2F1 irradiated mice were receiving B6 bone marrow cells plus sub-optimal numbers of donor T cells that were not capable to eliminate the murine mastocytoma cell line (P815) administered at time of alloSCT. 500µg of anti-TNFR2 blocking mAb were administered at days 0, 2 and 4. Mice were monitored for clinical and biological tumor emergence.
Results. In the blood of grafted mice receiving a sub-optimal T cell dose, P815 cells were detected and almost all mice died from tumor development. Despite TNFR2 expression on P815 cell surface, anti-TNFR2 treatment did not allow tumor elimination. In contrast, 64% of anti-TNFR2 treated mice were free of P815 attesting of a strong GVT effect.
Conclusion. Targeting TNFR2 can be a promising strategy to impact the Teff/Treg equilibrium in the favor of an improved alloreactivity and a better anti-tumor effect.

P.C4.03.14

Study of autoantibodies in limbic encephalitis and their relationship with paraneoplastic syndromes

I. Olivas Martinez, *L. Gonzalez Garcia, M. Montes Cano, E. Franco Macias, A. Palomino Garcia;*
Hospital Virgen del Rocio, Sevilla, Spain.

This work had as objective to do a retrospective study in patients with a suspected autoimmune encephalitis, analyzed during 2016-2017 period, looking for a possible association with paraneoplastic syndromes, commonly related to this kind of immune disorders. We studied serum and/or cerebrospinal fluid (CSF) from 113 patients, 58 men and 55 women with ages between 3 and 80, for a 2-year period. These samples were analyzed by indirect immunofluorescence to detect autoantibodies against surface neuronal antigens. First, a screening was done using cerebellar and hippocampus tissue, as well as cells transfected with glutamate receptor (NMDAR). Positive samples were subjected to a second study with a biochip containing cells transfected with six different surface neuronal antigens: NMDA-R, AMPAR1/2, CASPR2, DPPX, LGI1 Y GABARB1/2. Finally, clinical data of positive patients were contrasted searching a possible primary tumor that could be indicative of paraneoplastic syndrome. A total of nine patients (8%) showed antibodies for surface neuronal antigens. Six out of these 9 presented antibodies for NMDAR (67%), 1 for CASPR2 (11%), 1 for LGI1 (11%) and the other (11%) didn't show any associated specificity after a positive screening against hippocampus. Three patients (33%) suffered from a primary ovarian or breast cancer in the context of a paraneoplastic syndrome, all of them with anti-NMDAR antibodies (50% of patients with these antibodies). Detection of autoantibodies against surface neuronal antigens can lead to early identification and diagnosis of paraneoplastic syndromes, thus allowing the application of suitable treatments for primary tumors and neurological symptoms of limbic encephalitis.

P.C4.03.15

Functional interaction of Bcl-3 and IkBNS alters Treg cell development

C. Plaza Sirvent[1,2], *A. Matthies*[1,2], *M. Schuster*[1,2], *I. Schmitz*[1,2];
[1]*Otto-von-Guericke-Universität, Magdeburg, Germany,* [2]*Helmholtz Centre for Infection Research, Braunschweig, Germany.*

Regulatory T (Treg) cells are essential to maintain immune homeostasis. NF-κB proteins participate in the regulation of the Treg master transcription factor Foxp3. NF-κB proteins are regulated by nuclear proteins, called atypical IκB proteins, which modulate the transcriptional activity of NF-κB. We have previously demonstrated that IκBNS, an atypical IκB, drives the expression of Foxp3 via the association with the Foxp3 locus. Thymic Treg cells develop from $CD4^+$ $CD8^-$ thymocytes, which upregulate first GITR (Treg pre-precursor) and later CD25 (Treg precursor). Afterwards, Foxp3 is expressed and these cells are considered Treg cells. IκBNS-deficient mice show a blockage in the Treg precursor stage ($CD4^+$ $CD8^-$ $GITR^+$ $CD25^+$ $Foxp3^-$) of the thymic development, resulting in a 50 % reduction in the peripheral Treg population. Strikingly, these mice do not develop any autoimmune disorder. Other investigators have shown that overexpression of Bcl-3, another atypical IκB protein, affects Treg development and function causing spontaneous colitis in mice. In our current work, we demonstrate that the deficiency of the atypical proteins Bcl-3 and IκBζ do not have any impact on Treg development. Interestingly, despite the normal Treg development in Bcl-3-deficient mice, the combined absence of Bcl-3 and IκBNS causes Treg development blockage in an earlier stage compared to the single IκBNS-deficient mice. Moreover, these mice show signs of spontaneous immune activation in young mice suggesting functional impairment of Treg cells in double-deficient mice. Our data suggest that the functional interaction of the different atypical IκB proteins is important for Treg development and function.

P.C4.03.16

Investigating the cellular and molecular basis of bystander suppression in autoimmunity

***N. Richardson**, D. Wraith;*
Institute of Immunology and Immunotherapy, Birmingham, United Kingdom.

Induction of tolerance by peptide immunotherapy towards a single epitope of an antigen dampens the immune response not only of CD4+ T cells specific to tolerised antigen, but also of pathogenic T cells specific for other spatially-related auto-antigens. The tolerisation protocol extends tolerance from a single epitope to multiple disease-relevant epitopes by the mechanism of bystander suppression. Therefore, clinical application of peptide immunotherapy could have therapeutic potential for complex autoimmune diseases characterised by reactivity to multiple antigens.
Damage to the myelin sheath in multiple sclerosis is mediated by T cells targeting a number of myelin proteins. We have found that tolerised MBP-specific CD4+ T cells are able to exert bystander suppression to MOG-specific cells *in vivo*. When Tg4 mice are tolerised to MBP, then challenged with a MBP-MOG hybrid peptide, responses to both peptides are reduced. The coupling of the epitopes with a four amino acid linker domain mimics spatial proximity of disease-mediating antigens.
We are currently exploring the specific phenotype of the induced, regulatory CD4+ T cells, and the roles of TGF-β, IL-10, IL-4 and co-inhibitory receptors in the mechanism of bystander suppression in this model.

P.C4.03.17

Beneficial effect of probiotic *Lactobacillus kefiri* in lipopolysaccharide induced preterm birth in mice

***M. VENTIMIGLIA**;*
Centro de Estudios Farmacologicos y Botanicos-CONICET, Buenos Aires, Argentina.

Preterm birth (PTB) is a recurrent complication of pregnancy affecting 5-18% of all births worldwide and leading to serious consequences for the mother and the progeny. Although aetiology is not fully determinate, it is known that inflammation is a contributing factor to PTB. Probiotics were proved to be able to modulate immune responses promoting anti-inflammatory environments. Hence, they are being used in prevention and treatment of infectious diseases and immunopathologies. The aim of this work was to study the effects of *L.kefiri* on lipopolysaccharide (LPS) induced PTB in mice. C57BL76 females were administered every 48h by oral gavage during a week with probiotic (PB) or vehicle. Afterward, animals were mated with BALB/c males. Day of the vaginal plug detection was considered day 0.5 of pregnancy. Treatment continued every 48h during pregnancy, and females were challenged with LPS on gd 16.5. Births before gd 18.5 were considered PTB. Mice from control group given LPS exhibited 100% of PTB, with a majority delivering dead pups or live pups prematurely. Remarkably, treatment with probiotic completely protected pregnant mice to develop LPS-induced PTB with a majority delivering viable term pups. Additionally, while uterus from PB mice looked healthy, uterus from control mice exhibited haemorrhagic areas and implantations sites were barely recognized. Pups from PB mice were bigger at birth and also gained higher weight during lactation period compared to pups from control mice. Our results demonstrate that *L.kefiri* prevents LPS-induced PTB, opening new avenues to explore its therapeutic use for preventing PTB in humans.

CD4+ Foxp3+ regulatory T cell-mediated immunomodulation by pharmacological inhibition of the acid sphingomyelinase in humans

***T. Wiese**[1], F. Dennstädt[1], C. Hollmann[1], S. Stonawski[2], C. Wurst[2], M. Buttmann[3,4], A. Menke[2], J. Schneider-Schaulies[1], N. Beyersdorf[1];*
[1]University of Würzburg, Institute for Virology and Immunobiology, Versbacher Str. 7, Würzburg, Germany, [2]University Hospital Würzburg, Department of Psychiatry, Psychosomatics and Psychotherapy, Margarete-Höppel-Platz 1, Würzburg, Germany, [3]Caritas Hospital Bad Mergentheim, Department of Neurology, Uhlandstraße 7, Würzburg, Germany, [4]University Hospital Würzburg, Department of Neurology, Josef-Schneider-Str. 11, Würzburg, Germany.

The acid sphingomyelinase (ASM) is a key modulator of cellular signaling pathways in which bioactive sphingolipids play crucial roles by catalyzing the cleavage of sphingomyelin to ceramide and phosphocholine. Recently, we have demonstrated that genetic deficiency for or pharmacological inhibition of the ASM increases the activity and frequency of mouse Foxp3$^+$ regulatory T cells (Treg) among CD4$^+$ T cells. Furthermore, pharmacological inhibition of the ASM had beneficial effects in different mouse models of autoimmune and inflammatory diseases. In the present study, we performed *in vitro* experiments with human T cells using two widely prescribed antidepressants with high (sertraline) or low (citalopram) capacity to inhibit ASM activity. Similar to our findings in mice, ASM inhibition in human PBMC increased the frequency of Treg among human CD4$^+$ T cells. To assess whether these effects on human Treg are transferable *in vivo,* we have been prospectively analyzing the composition of CD4$^+$ T cells in patients treated for major depression. Our preliminary data show that pharmacological inhibition of the ASM is superior to anti-depressants with little or no ASM-inhibitory activity in normalizing effector Treg frequencies among CD4$^+$ T cells in patients treated for depression. In summary, we find that inhibition of the ASM increases the frequency of (effector) Treg among CD4$^+$ T cells in mice and humans suggesting that ASM blockade might beneficially modulate autoimmune diseases and depression-promoting inflammatory reactions. This study was supported by a grant from the DFG (FOR2123 project P02).

P.C4.03.19

The effect of IL-2/anti-IL-2 complex treatment on antigen presenting cells

***M. Wiletel**[1], B. Mahr[1], N. Granofszky[1], M. Muckenhuber[1], T. Wekerle[1], J. Sprent[2], N. Pilat[1];*
[1]Department of Surgery, Medical University of Vienna, Vienna, Austria, [2]Immunology Division, Garvan Institute of Medical Research, Sydney, Australia, Sydney, Australia.

Introduction: The use of Interleukin-2 (IL-2) complexed with a specific antibody against IL-2 (IL-2cplx) has been shown to selectively increase regulatory T cells (Tregs) without significant proliferation of other IL-2 responsive immune cells. Here we focused on the effect of IL-2cplx treatment on antigen presenting cells (APCs) and changes in the expression of markers known to be relevant for immune response activation.
Methods: C57BL/6 mice received IL-2cplx (1µg/5µg), i.p., for 3 consecutive days and were sacrificed on day 5. We used flow-cytometric analysis to investigate the frequency of Tregs and APCs focusing on the expression of relevant markers on APCs for immune response activation, namely CD80, CD86, PDL-1 and MHC class II in samples taken from spleen.
Results: We demonstrate that IL-2cplx led to significant expansion of Tregs (17.88% vs 4.3% p=0.00006; vs naïve) and changes in the frequency of CD11c+ APCs (2.01% vs 0.94% p=0.005; vs naïve). Moreover we demonstrated significantly lower expression of CD80 and CD86 (16.4% vs 22.8% p=0.02 and 29.8% vs 34% p=0.09; vs naïve) and significantly higher expression of MHC class II on CD11c+DCs (82.9 % vs 75.35% p=0.009; vs naïve).
Conclusion: Treatment with IL-2cplx and subsequent expansion of Tregs leads to reduced expression of CD80+ and CD86+ but increased MHC class II expression on APCs which could cause impaired effector T cell function. This may highlight possible ligand-receptor interactions and help to understand important cellular key mechanism mediated by APCs and T cells.

P.C4.03.20

Treatment of collagen-induced arthritis (CIA) in mice model with disease-inducible indoleamine-2,3-dioxygenase (IDO) gene

***I. Yilmaz**[1], G. Guvenc[2], M. Karacay[1], A. O. Barazi[3], F. Ersoy[4], C. Akkoc[5], A. Akkoc[6], A. Yilmaztepe Oral[7], M. Yalcın[8], H. B. Oral[9];*
[1]Department of Medical Immunology, Institute of Health Sciences, Uludag University, Bursa, Turkey, [2]Department of Veterinary Physiology, Institute of Health Sciences, Uludag University, Bursa, Turkey, [3]Department of Immunology, Institute of Health Sciences, Gazi University, Ankara, Turkey, [4]Department of Molecular Biology & Genetics, Faculty of Arts & Sciences, Uludag University, Bursa, Turkey, [5]Department of Histology and Embryology, Faculty of Veterinary, Uludag University, Bursa, Turkey, [6]Department of Pathology, Faculty of Veterinary, Uludag University, Bursa, Turkey, [7]Department of Medical Biochemistry, Faculty of Medicine, Uludag University, Bursa, Turkey, [8]Department of Physiology, Faculty of Veterinary, Uludag University, Bursa, Turkey, [9]Department of Immunology, Faculty of Medicine, Uludag University, Bursa, Turkey.

In RA patients, tryptophan catabolism has an impact on progression and indoleamine-2,3-dioxygenase (IDO) has a crucial role in the induction of immune tolerance. In this study, the treatment responses of disease-inducible IDO gene over expression in CIA mice were investigated. Human IDO cDNA mammalian expression plasmid (pCMV/hIDO) CMV promoter (constantly active) was replaced with pELAM-1 promoter (only active in the presence of inflammatory cytokines) which was taken out from pELAM-1pro/CAT plasmid. HeLa cells were transfected with pELAM-1pro/hIDO and induced with IL-1β for 6 or 24 hours. hIDO levels were determined from the cell lysate. The combination of therapeutic plasmid and controls with liposomes intraarticularly delivered after arthritis developed in mice and followed up for 4 weeks. The therapeutic effects evaluated by considering ankle circumference, clinical and histopathological scoring of mice. Moreover, the difference between CD4+ T cell and CD68+ synovial macrophages amounts, and IDO expression in joints was examined. It was observed that hIDO was significantly increased following 6 and 24 hours stimulation with IL-1β in HeLa cells transfected with pELAM-1pro/hIDO. Ankle circumference, clinical and histological scores decreased in CIA mice which are treated with pELAM-1pro/hIDO. The ratios of CD4$^+$ T cells and CD68$^+$ synovial macrophages decreased and IDO levels increased following pELAM-1pro/hIDO treatment. Thus, conditional targeting IDO can be a new approach for the treatment of RA. This study is supported by The Scientific and Technical Research Council of Turkey (TUBITAK-COST Project No: 113S375) under Cost Action BM1305. COST is supported by the EU Framework Programme Horizon 2020.

Background: Prevention of milk allergy is an urgent problem that has attracted the attention of food scientists. In previous studies we proved that the unloaded apo-form of the lipocalin beta-lactoglobulin (BLG) from milk promoted Th2 cells and inflammation, whereas the holo-form acted immunosuppressive. In this study, we tested in BALB/c mice whether nasal application of holo-BLG can prevent allergy to BLG.
Methods: BALB/c mice were sensitized twice intraperitoneally with BLG adjuvanted with aluminum hydroxide after being nasally treated 3 times in biweekly intervals with the unloaded apo-form of BLG, or holo-BLG loaded with quercetin-iron complexes, or water as sham-treatment. Then mice were intraperitoneally challenged with apo-BLG. Subsequently, body temperature drop was recorded as a sign of a systemic allergic reaction. Specific antibodies in serum as well as cytokines of BLG-stimulated splenocytes were analyzed by ELISA. MHC Class II I-Ad+ and CD86+ expression on CD11c+ dendritic cells from spleens were analyzed by flow cytometry.
Results: Intranasal prophylactic treatment with holo-BLG prevented allergic sensitization to BLG. Mice pretreated with water or apo-BLG had significantly elevated BLG-specific antibodies (IgG1, IgG2a, IgA and IgE), cytokine levels (IL5, IL13 and IL10) and significantly upregulated MHC Class II I-Ad and CD86+ on CD11c+ dendritic cells in the spleens, compared to holo-BLG treated group. Pretreatment with holo-, but not apo-BLG prevented body temperature drop upon allergen-challenge.
Conclusion: Prophylactic treatment with holo-BLG provided specific protection against sensitization to BLG and prevented the onset of allergy.
Grants: FWF, grant SFB F4606-B28, Austria and a grant from Egypt to SMA.

P.C5.01.02
Analysis of IRF4-binding characteristics using a streptavidin-biotin-dependent "bio-ChIP"

S. Dietzen*, T. Bopp;*
University Medical Center of the Johannes Gutenberg-University, Institute for Immunology, Mainz, Germany.

Mast cells as well as IL-9 play a crucial role in the pathogenesis of asthma and recent findings demonstrated that the transcription factor IRF4 regulates the *Il9* gene expression in mast cells. We could demonstrate that IRF4 transactivates the *Il9* promoter and IRF4 deficiency leads to an impaired IL-9 production. The aim of the project is to analyze IRF4-binding characteristics, thus identify the concrete binding sites of IRF4 in the genome and describe physical interaction partners of the transcription factor. To this end, we established a transgenic mouse which allows constitutive *in vivo* biotinlyation of IRF4. We used a mouse expressing the BirA ligase (an enzyme which catalyzes the biotinylation of proteins that are tagged with a specific recognition sequence) and crossed it to a mouse expressing IRF4 fused to the BirA ligase recognition sequence as a transgene. Breeding of this mouse strain allows the generation of a mouse model where IRF4 will be biotinylated *in vivo*. To identify IRF4 binding sites within the *Il9* promoter and also the whole genome, mast cells from the IRF4-transgenic mice shall be used to establish a so called "bio-ChIP" that allows for precipitation of IRF4-bound DNA elements by using streptavidin-coated magnetic beads instead of protein-specific antibodies. Upon NGS-based sequencing, this method can be used for genome-wide analyses of IRF4-bound genes. Moreover, data achieved by purification of IRF4 in combination with co-binding proteins and following analysis via western blot and mass spectrometry will help to enlighten further details of the regulatory network of IRF4.

P.C5.01.03
Helminths protect from basophil- and eosinophil-mediated chronic allergic skin inflammation.

J. U. Eberle*, D. Voehringer;*
Department of Infection Biology, University Hospital Erlangen and Friedrich-Alexander University Erlangen-Nuremberg (FAU), Erlangen, Germany.

Introduction: Basophils are required for IgE-mediated chronic allergic skin inflammation (IgE-CAI) in the mouse and promote the accumulation of eosinophils in tissues. However it is not clear how eosinophils are recruited and if helminth-elicited IgE is protective in this setting.
Material and Methods: Here, we used an antibody-induced model of IgE-CAI in mice. 33µg IgE antibody against TNP was injected intravenously followed by intradermal injection of 10µg TNP-OVA in the ear the next day. We measured changes in ear thickness and recruitment of effector cells into the ear parenchyma and compared helminth infected vs. naïve and several transgenic mouse strains.
Results: The ear swelling was absent in basophil- and eosinophil-deficient mice as well as in mice lacking the high affinity receptor for IgE on basophils. Swelling was decreased in mice infected with *Nippostrongylus brasiliensis* and *Heligmosomoides polygyrus* compared to wildtype mice. Further IL-4/IL-13-deficient mice, as well as Stat6-deficient mice showed slightly decreased ear swelling. Infiltration of basophils, eosinophils, and neutrophils was also impaired.
Conclusion: From our studies we can conclude that in IgE-CAI basophils are activated via the IgE receptor and promote the recruitment of eosinophils which are required for pathology. Saturation of basophils with Helminth-elicited IgE appears to protect from IgE-CAI.

Introduction: IgE-mediated food allergy to fish is a persistent, potentially life-threatening hypersensitivity disease. IgE-sensitization to food allergens is is detectable already at three months of age. Thus a prophylactic strategy for prevention of IgE-sensitization to food allergens in infants is the ultimate goal. This study sought to investigate the effect of feeding of natural carp parvalbumin (nCyp c 1) on the antibody responses and allergic symptoms in a fish allergy mouse model. Materials and methods: BALB/c mice (n=8) were fed with 10mg nCyp c 1 or PBS (day 1). Following feeding mice were immunized twice subcutaneously with 20µg nCyp c 1 adsorbed to aluminum-hydroxide in a 2-week interval. Control groups were sensitized to Cyp c 1 without gavage or received gavage only. Upon intragastric allergen challenge with nCyp c 1 allergic symptoms and body temperature were recorded.
Cyp c 1-specific antibody responses were analyzed in ELISA and rat basophil leukemia assay. Results: Measurement of Cyp c 1-specific antibodies demonstrated that IgE-sensitization was prevented by prophylactic feeding with nCyp c 1. Further, mice fed with nCyp c 1 before sensitizations were protected from symptom-development upon allergen challenge. Conclusions: A high-dose feeding with carp parvalbumin induced tolerance in our mouse model. The induction of clinical tolerance to allergens was investigated in numerous oral immunotherapy trials. However, the application of natural allergens causes severe symptoms in patients and clinical tolerance is often not persistent. We suggest prophylactic tolerance induction as alternative strategy. Background: Eicosanoid lipid mediators play key roles in allergy and asthma. Macrophages represent major cellular sources of these mediators, but their complex and dynamic eicosanoid output during type 2 immune responses is not understood. Objective: We aimed to comprehensively track lipid mediator production in type 2 immune responses. Methods: We established an LC-MS/MS workflow for the quantification of 52 oxylipins to track lipid mediator reprogramming in human monocyte derived macrophages (MDM) during exposure to house dust mite (HDM) or in nematode infection *in vivo*. Eicosanoid enzymes were studied by qPCR and westernblot and cytokine production was assessed by multiplex assays. Results: Differentiation of macrophages with GM-CSF and TGFβ1 resulted in a phenotype ("aMDM") with characteristic features of airway macrophages such as high expression of 5-lipoxygenase (5-LOX), which resisted IL-4-mediated transcriptional repression. Exposure of aMDM to HDM resulted in the suppression of 5-LOX expression and product formation.

In contrast, HDM triggered increased prostanoid production with thromboxane and prostaglandins D_2 and E_2 as major metabolites. HDM also induced pro-inflammatory cytokines and chemokines, resulting in an overall M1-like mediator profile.
Finally, distinct changes in lipid mediator profiles occurred during the type 2 immune response to nematodes *in vivo*. Conclusion: Our findings show that type 2 immune responses are characterized by fundamental reprogramming of the lipid mediator metabolism with macrophages representing particularly plastic responder cells. Targeting mediator reprogramming in airway macrophages may represent an approach to regulate pathogenic lipid mediator profiles in allergy or asthma. Hapten-induced contact hypersensitivity is upregulated in interleukin-19 knockout mice

***Y. Fujimoto**, Y. Azuma;*
Laboratory of Veterinary Pharmacology, Division of Veterinary Science, Graduate School of Life and Environmental Science, Osaka Prefecture University, Izumisano, Osaka, Japan.

Interleukin-19 is a member of the IL-10 family of interleukins and is an immuno-modulatory cytokine produced by the main macrophages. The gastrointestinal tissues of IL-19 knockout mice show exacerbated experimental colitis mediated by the innate immune system and T cells. There is an increasing focus on the interaction and relationship of IL-19 with the function of T cells. Contact hypersensitivity (CHS) is T cell-mediated cutaneous inflammation. Therefore, we asked whether IL-19 causes CHS. We investigated the immunological role of IL-19 in CHS induced by 1-fluoro-2,4-dinitrofluorobenzene as a hapten. IL-19 was highly expressed in skin exposed to the hapten, and ear swelling was increased in IL-19 knockout mice. The exacerbation of the CHS response in IL-19 knockout mice correlated with increased levels of IL-17 and IL-6, but no alterations were noted in the production of IFN-gamma and IL-4 in the T cells of the lymph nodes. In addition to the effect on T cell response, IL-19 knockout mice increased production of inflammatory cytokines. These results show that IL-19 suppressed hapten-dependent skin inflammation in the elicitation phase of CHS.

The impact of glycation on dendritic cell responses to proteins

***S. L. Harris**[1], F. Manodoro[2], A. G. Rust[2], R. Chauhan [2], N. Matthews[2], A. E. Moghaddam[1], Q. J. Sattentau[1];*
[1]The Sir William Dunn School of Pathology, Oxford, United Kingdom, [2]The Institute of Cancer Research, London, United Kingdom.

Introduction: Advanced Glycation End products (AGEs) are a group of protein modifications formed by the non-enzymatic reaction between a reducing sugar and a free amine group. AGEs are formed endogenously and in food, for example during dry roasting of peanuts. AGE-modified proteins, including dry-roasted peanuts, have an enhanced immunogenicity compared to unmodified proteins and induce a Th2 bias. However, dry-roasted peanut and other glycated proteins do not induce conventional activation of dendritic cells (DCs). We hypothesised AGE-modified proteins may instead induce a non-canonical DC activation.
Materials and Methods: murine bone marrow derived DCs were pulsed with either dry-roasted or raw peanut proteins, AGE-modified egg allergens (hen egg lysozyme (HEL) or ovalbumin) or low dose lipopolysaccharide. Supernatants were collected to assess cytokine/chemokine secretion. DCs pulsed with AGE-modified HEL were also used for RNAseq.
Results: The transcriptomic and proteomic analyses demonstrated that modified proteins induced changes which were distinct from those elicited by the classical inflammatory stimulus lipopolysaccharide. There was a significant change in the expression of a small group of gene in response to HEL-Glucose. Pathway analysis using these results implicated a number of pathways, including those involved in the cell cycle and metabolism. Changes in secretion depended on both the modification type and the base protein.
Conclusions: Our results provide initial evidence for an alternative mode of DC activation by AGE-modified proteins. The variable secretory profiles induced by modified proteins indicate that multiple receptors are involved in these responses. Future studies will examine these potential receptors and their signalling pathways.

Complement drives IgE-mediated experimental food allergy through the C5a/C5aR1 axis

***A. Kordowski**[1], A. T. Reinicke[1], D. Wu[2], J. Lee[2], Y. Wang[2], S. P. Hogan[2], J. Köhl[1];*
[1]University of Lübeck, Lübeck, Germany, [2]Cincinnati Childrens's Hospital and University of Cincinnati, College of Medicine, Cincinnati, United States.

Food-induced anaphylaxis is a serious allergic reaction caused by antigen cross-linking of IgE-loaded Fcε-receptors on mast cells (MCs), leading to the release of pro-inflammatory mediators and disease manifestation.The exact mechanisms breaking oral tolerance and the effector pathways driving food allergy remain elusive. As complement activation occurs in food-induced anaphylaxis, we aimed to assess the role of C5a in disease pathogenesis. BALB/c wildtype (wt) and *C5ar1*$^{-/-}$mice were subjected to oral antigen-induced food allergy model. Readouts included diarrhea development, changes in rectal temperature, hematocrit, antigen-specific serum IgE, MCPT-1 and intestinal MC numbers as well as FcεR1-mediated MC functions including C5a receptor 1 (C5aR1) regulation. Further, histamine-mediated hypothermia and regulation of endothelial tight junctions was determined. Repeated oral OVA challenge resulted in diarrhea, hypothermia, increased hematocrit, high OVA-specific serum IgE and MCPT-1 levelsin wt mice. In contrast, male *C5ar1*$^{-/-}$mice were completely whereas female *C5ar1*$^{-/-}$were partially protected from anaphylaxis development. The lower incidence of diarrhea in *C5ar1*$^{-/-}$mice was associated with decreased OVA-specific serum IgE in male and mast cell activation (MCPT-1 levels) in both sexes. Mechanistically, IgE-mediated degranulation and IL-6 production from *C5ar1*$^{-/-}$BMMCs of both sexes were significantly reduced. Importantly, FcεR1 cross-linking strongly upregulated C5aR1 MC expression *in vitro*and *in vivo*. Finally, histamine treatment resulted in a milder temperature drop in *C5ar1*$^{-/-}$males than in wt mice. Our findings identify C5aR1 activation as an important driver of IgE-mediated food allergy. C5aR1 targeting may prove useful to suppress the inflammatory response in food-induced anaphylaxis.

P.C5.01.09
Modulation of C5a receptor 2 expression in experimental allergic asthma

*I. Osman[1], K. M. Quell[1], A. V. Wiese[1], T. Vollbrandt[2], P. König[3], J. Köhl[1], **Y. Laumonnier**[1];*

C5a drives airway constriction and inflammation during the effector phase of allergic asthma, mainly through the activation of C5a receptor 1 (C5aR1). In addition to C5aR1, C5aR2 (C5L2) regulates the allergic asthma phenotype. However its expression pattern on myeloid and lymphoid cells during the allergic effector phase is unknown. Recently, we generated and characterized a novel floxed tandem-dye Tomato fluorescent protein (tdTomato)-C5aR2 knock-in mouse, showing that C5aR2 expression is restricted to myeloid cells in the airways, the lungs and lymphoid organs. Using this reporter strain, we monitored C5aR2 expression during the effector phase of house dust mite-driven allergic asthma. C5aR2 reporter and wildtype mice developed an allergic phenotype with comparable airway resistance, mucus production, eosinophilic/neutrophilic airway inflammation and Th2/Th17 cytokine production. No major changes in C5aR2 expression occurred in myeloid cells during the allergic effector phase, in particular in airway eosinophils and a subset of neutrophils. However, we observed significant down regulation of C5aR2 on pulmonary macrophages. Lymphoid cells remained tdTomato-C5aR2 negative upon allergic inflammation except a small subset of NK cells, suggesting a functional role of C5aR2 in NK cells. In line with this observation, the NK cell marker NKp46 was strongly upregulated in C5aR2$^{-/-}$ NK cells. In summary, we show that C5aR2 expression is not altered in the allergic effector phase on most myeloid cells. In contrast, C5aR2 is downregulated in pulmonary macrophages. Further, it controls NKp46 expression in a subset of NK cells suggesting a novel function of C5aR2 in such cells during allergic inflammation.

P.C5.01.10
A critical role of IL-18 in the maturation of PDL1 expressing pathogenic eosinophils

***A. Mishra**, S. Upparahalli Venkateshaiah, A. Mishra;*
Tulane University School of Medicine, New Orleans, LA, United States.

Eosinophils are multifunctional leukocytes with diverse functions in health and disease. We for the first time demonstrate that IL-18 has a critical role in the development and maturation of eosinophils. Herein, we provide evidence that IL-18 differentiates eosinophils, even in the absence of endogenous *IL-5,* both *ex vivo* and under physiological conditions (*in vivo*). IL-18 and IL-5 differentiated *ex vivo* eosinophils have differences in size, shape, granularity and differentially regulated *CD274 (PDL1)* transcript expression. Most importantly, we provide evidence that IL-18 is critical for transforming homeostatic eosinophils into mature *PDL1* expressing eosinophils. Notably, eosinophils with and without PDL1 expression are present in healthy mouse and human blood. Moreover, the proportion of eosinophils that express PDL1 is markedly increased in allergic mice and humans. Additionally, we report that all eosinophils in the lungs of asthmatic mice and the nasal lavage of asthmatic patients harbor PDL1 expressing pathogenic eosinophils. Analysis of mouse and human eosinophil data in healthy and disease state indicates that *IL-18* and *IL-5* synergistically promote differentiation, maturation and proliferation of *PDL1* expressing pathogenic eosinophils in allergic disease states. Enhanced IL-18 expression is reported in almost all allergic diseases and our data suggest that it has a critical role in eosinophil differentiation and the maturation of PDL1 expressing pathogenic eosinophils. Collectively, we first time identified the role of IL-18 in transforming naive eosinophils to pathogenic *PDL1* expressing eosinophils and this finding may have broad implications regarding non-invasive diagnostic and therapeutic strategies for eosinophil-associated diseases.

P.C5.01.11

A polymorphism rs928413 associated with asthma development and regulation of *IL33* gene expression

A. Muratova[1,2]*, N. Mitkin*[1]*, D. Kuprash*[1,2]*;*
[1]Engelhardt Institute of Molecular Biology Russian Academy of Sciences, Moscow, Russian Federation, [2]Biological Faculty, Lomonosov Moscow State University, Moscow, Russian Federation.

Cytokine IL-33 is secreted by epithelial and endothelial cells during necrosis and stimulates humoral immune response. Elevated IL33 expression in pulmonary epithelium of asthmatic patients correlates with exacerbation of allergen-induced inflammation and disease progression. We hypothesized that individual variations in the *IL33* gene expression may be explained by polymorphisms of non-coding regulatory regions, in particular by SNP rs928413 located in an promoter region in the *IL33* locus and associated with development of asthma.
Activities of the *IL33* promoter variants containing different rs928413 alleles were assessed upon transfection of the corresponding luciferase reporter constructs into NCIH pulmonary epithelial cell line followed by TNFα stimulation. CREB1 binding to DNA was estimated using pull-down assay.
We observed that rs928413 risk allele creates a functional binding site for CREB1, a transcription factor that stimulates expression of a number of inflammatory mediators. *IL33* promoter containing active CREB1-binding site showed significantly elevated activity in stimulated human lung carcinoma cells.
Our data suggest that differential binding of the rs928413 alleles to may underlie the emergence of asthmatic phenotype in response to increased *IL33* gene expression and of systemic inflammation.

Sensitization state to Hymenoptera venom of an asymptomatic healthy beekeeper cohort

A. Navas[1]*, B. Ruíz*[2,1]*, M. Fisichella*[1]*, P. Serrano*[2,1]*, C. Moreno*[2,1]*, A. Jurado*[2,1]*;*
[1]Maimonides Biomedical Research Institute of Cordoba (IMIBIC)/ Reina Sofia University Hospital/ University of Cordoba, Cordoba, Spain, [2]Department of Allergy and Immunology, Reina Sofia University Hospital, Cordoba, Spain.

Allergy to Hymenoptera venom is a potentially mortal disease, being the specific immunotherapy the unique healing treatment. Beekeeping sector is the most vulnerable group to this health problem. There are not useful biomarkers to predict the response to stings or immunotherapy. Basophil activation test (BAT) has been correlated with medium and long-term immunotherapy effectiveness. The aim of this study was to evaluate the allergy immune state of a beekeeper cohort highly exposed to Hymenoptera venom but bee-sting tolerant, regarding a control healthy population using BAT.
We selected a cohort of 17 healthy beekeepers and 17 non-allergic control individuals. BAT was performed using Basotest (BD Biosciences). Total-blood samples were incubated with 0,1 and 1 µg/mL of *Apis mellifera* venom (Pharmalgen). Activated basophils were identified using CD123-PE, DR-PerCP and CD63-FITC monoclonal antibodies.
Interestingly, among 17 recruited healthy beekeepers, BAT was positive in 9 (52.9%) of them, while none of the healthy individuals exhibited a positive result in BAT ($p<0.001$). The average of $CD63^+$ cells degranulated against 1 µg/mL of venom was significantly different between beekeepers and healthy individuals (15.62% vs. 1.06%; $p=0.037$). No significant differences were found between groups when cells were stimulated with 0.1 µg/mL of venom ($p=0.407$).
Despite the fact that all recruited beekeepers were non-responders to Hymenoptera venom stings, more than the half were *in vitro* reactive by BAT. Therefore, the *in vitro* degranulation of basophils was not well associated with the immunological tolerance status observed in this cohort of individuals.

P.C5.01.13

Patients sensitized to the Ole e 7 lipid transfer protein from olive pollen, exhibit positive reactivity against Pru p 3 by basophil activation test

C. Oeo-Santos[1]*, A. Navas*[2]*, B. Ruíz*[2]*, M. Fisichella*[2]*, R. Barderas*[3]*, M. Villalba*[1]*, A. Díaz-Perales*[4]*, C. Moreno*[2]*, A. Jurado*[5]*;*
[1]Complutense University of Madrid, Madrid, Spain, [2]Maimonides Biomedical Research Institute of Córdoba (IMIBIC)/ Reina Sofía University Hospital/ University of Córdoba, Córdoba, Spain, [3]CROSADIS, Carlos III Health Institute, Madrid, Spain, [4]Center of Biotechnology and Genomics of Plants, Polytechnic University, Madrid, Spain, [5]Department of Allergy and Immunology, Reina Sofia University Hospital, Madrid, Spain.

Ole e 7 lipid transfer protein (LTP) from olive pollen is responsible for severe symptoms in the south of Spain. Many Ole e 7 sensitized patients exhibit co-sensitization to the peach LTP Pru p 3, despite there is no evidence of cross-reactivity which explains this co-sensitization to date. Herein, we present the preliminary results from basophil activation test (BAT) to Pru p 3 of sensitized patients to Ole e 7. IgE specific serum level to Ole e 7 and Pru p 3 were measured by ImmunoCAP 250 and ELISA. BAT was performed using Basotest (BD Biosciences). Total-blood samples were separately incubated with 10 µg/mL of Ole e 7 and Pru p 3 purified recombinant allergens. Activated basophiles were identified using CD123-PE, DR-PerCP and CD63-FITC monoclonal antibodies. None of the patients had been treated with immunotherapy for the last 3-years. The all four patients, who only had serum specific IgE against Ole e 7 (40.4±19.8 kU/L), exhibited basophil degranulation using Pru p 3 as stimulus. The average of $CD63^+$ cells after stimulating with Ole e 7 and Pru p 3 were 45% and 32.2%, respectively. Despite the small size of the study-cohort, we observed a double *in vitro* basophil degranulation using Ole e 7 and Pru p 3 as stimulus. However, no specific IgE sensitization to Ole e 7 was detected either by ELISA or ImmunoCAP. Further molecular studies should be performed to support the cross-reactivity observed in the present work.

P.C5.01.14

Naïve human T cells selectively differentiate into Th1 and Th17 cells after costimulation by human keratinocytes

C. Orlik[1]*, D. Deibel*[1]*, E. Balta*[1]*, B. Niesler*[2]*, Y. Samstag*[1]*;*
[1]Institute of Immunology, Heidelberg, Germany, [2]Institute of Human Genetic, Heidelberg, Germany.

Allergic contact dermatitis (ACD) corresponds to a delayed-type hypersensitivity response induced by repeated skin contact with low molecular weight chemicals (haptens). It shows common histological characteristics, e.g. cytopathic effects on keratinocytes and infiltration of T cells, monocytes as well as dendritic cells into the epidermis and dermis. In the pathophysiology of ACD, keratinocytes are critically involved by functioning as the primary barrier of the skin as well as by their ability to secrete pro-inflammatory mediators. However, the potential impact of keratinocytes on skin-infiltrating and skin-homing T cells, remained mainly elusive. Here we investigated the direct interaction of primary human keratinocytes with primary human T cells under ACD-related conditions by using an *in vitro* coculture system. We demonstrated that under pro-inflammatory conditions, keratinocytes may act as non-professional antigen presenting cells (APC) causing T cell activation. A more detailed analysis revealed that even naïve T cells can be activated through keratinocytes. By disrupting interactions between stimulatory coreceptors and their ligands in the *in vitro* coculture, the necessity of CD54 and CD58 for keratinocyte-induced T cell activation was demonstrated. Subsequent gene expression analysis showed a selective upregulation of IFNγ-regulated genes in these keratinocyte-activated naïve T cells. Interestingly, naïve T cells co-stimulated by keratinocytes selectively differentiated into Th1 and Th17. Furthermore, keratinocyte-induced T cell activation initiates the specific upregulation of skin-homing factors on naïve T cells. Thus, local interference with T cell-keratinocyte interactions may open up novel strategies for the treatment of skin-related diseases.

Treatment with toxoplasma gondii tachyzoite lysate reduces allergic mono- and polysensitization and airway inflammation in mice

M. J. Orola[1]*, E. Korb*[1]*, M. Drinić*[1]*, T. Svoboda*[2]*, M. Ehling-Schulz*[2]*, I. Schabussova*[1]*, U. Wiedermann*[1]*;*
[1]Institute of Specific Prophylaxis and Tropical Medicine, Medical University of Vienna, Vienna, Austria, [2]Institute of Microbiology, Department of Pathobiology, University of Veterinary Medicine, Vienna, Austria.

Toxoplasma gondii is an obligatory intracellular protozoan parasite which can infect a range of hosts via ingestion of oocysts. Studies have shown that *T. gondii* infection can influence allergic sensitization and even suppress allergic airway inflammation in mouse models. Our previous work examined the properties and the immunological impact of the tachyzoites lysate antigen (TLA) which is derived from the differentiated state of the parasite.
The aim of this study was to further investigate the effects of TLA immunization through mucosal application upon OVA sensitization and challenge as well as polysensitization and challenge with the recombinant proteins Bet v 1, Phl p 1 and Phl p 5 in BALB/c mice.
In both settings, TLA ameliorated Th2-mediated airway inflammation, as indicated by the general decrease of IL-4 and IL-5 along with a reduction of IL-13 in the lungs. Similarly, eosinophilia was diminished, while expansion of macrophages and neutrophils were observed in the bronchoalveolar lavage. Moreover, FACS analysis from the polysensitization model revealed a significant increase of IL-17 producing $CD4^+$ T-cells in the lungs. TLA not only influences the immune system directly but also appears to alter the gut microbiota in the context of OVA sensitization, as indicated by Fourier transform-infrared spectroscopy. TLA application upon allergen challenge improved airway inflammation, further highlighting the potential benefits in treatment of allergy.

The mechanism of reactive oxygen species-induced apoptosis in mast cells in response to lysosomotropic agents

A. Paivandy[1]*, F. R. Melo*[1]*, G. Pejler*[1,2]*;*
[1]*Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden,* [2]*Department of Anatomy, Physiology and Biochemistry, Swedish University of Agricultural Sciences, Uppsala, Sweden.*

Mast cells are infamous for their detrimental roles in allergic reactions and inflammatory lung diseases, such as asthma. Therefore, efficient strategies to limit their adverse effects in such pathological settings are needed. We have previously reported that lysosomotropic agents, such as mefloquine, induce mast cell apoptosis through granule permeabiliation and enhanced production of reactive oxygen species (ROS). Here we sought to explore the underlying mechanism of ROS-induced apoptosis in mast cells upon mefloquine treatment. Interestingly, we found that the ROS production in response to mefloquine is diminished in mast cells deficient in serglycin proteoglycan, suggesting that mast cell granules (also known as secretory lysosomes) may play a role in the ROS production. Given that previous reports highlighted a role for lysosomal metal ions in ROS production, we next pre-incubated mast cells with chelators of iron (deferoxamine) and/or copper (tetrathiomolybdate), followed by mefloquine treatment and assessment of ROS level. We observed that deferoxamine- or tetrathiomolybdate-treated mast cells generated reduced level of ROS after mefloquine treatment, indicating that iron and copper ions are key component in mefloquine-induced ROS production in mast cells. Another potential source of ROS could be through the action of NADPH oxidase. However, our preliminary data show that inhibition of NADPH oxidase had little inhibitory effect on the ROS production in response to mefloquine, arguing against this possibility. Taken together, our preliminary data suggest that enhanced ROS production upon mefloquine treatment is likely the result of the Fenton reaction to a large extent.

P.C5.01.17

A fragment of extracellular matrix collagen drives epithelial remodelling and airway hyper-responsiveness in allergic airways disease

D. F. Patel[1]*, T. Peiro*[1]*, A. Shoemark*[1]*, S. Akthar*[1]*, S. A. Walker*[1]*, A. Gaggar*[2]*, G. Tavernier*[3]*, L. G. Gregory*[1]*, A. Simpson*[3]*, C. M. Lloyd*[1]*, R. J. Snelgrove*[1]*;*
[1]*Imperial College London, London, United Kingdom,* [2]*University of Alabama, Birmingham, United States,* [3]*University of Manchester, Manchester, United Kingdom.*

The enzyme leukotriene A_4 hydrolase (LTA_4H) is classically recognized for its capacity to generate the potent pro-inflammatory mediator leukotriene B_4 (LTB_4). However, we have previously demonstrated that LTA_4H exhibits a secondary anti-inflammatory activity whereby it degrades the collagen-derived tripeptide and neutrophil chemoattractant Pro-Gly-Pro (PGP). LTB_4 has been implicated in the pathology of many chronic diseases, with a prominent role ascribed to this mediator in driving inflammation and airway hyperresponsiveness (AHR) in asthma. Accordingly, pharmaceutical companies have developed LTA_4H inhibitors to ameliorate LTB_4-driven pathologies, but these have thus far failed to demonstrate efficacy in the clinic - potentially owing to their inadvertent capacity to cause PGP accumulation. In a house dust mite model of allergic airways disease, we show that specific abrogation of LTB_4 signaling ameliorated inflammation and AHR, yet global loss of LTA_4H exacerbated AHR - despite the absence of LTB_4 and a profound reduction in T_H2 inflammation. This exacerbated AHR was attributable to PGP accumulation and a neutrophil-independent capacity of this peptide to promote pathological airway epithelial remodeling and mucus production- a phenotype recapitulated by direct application of PGP to human airway epithelial cells at air-liquid-interface. Subsequently, we show that PGP accumulates preferentially in the sputum of severe asthmatics in two distinct cohorts of patients. In conclusion, we highlight the capacity of a fragment of collagen to directly drive pathological airway remodeling. These studies have implications for our understanding of remodeling phenotypes in asthma, and other chronic diseases and may rationalize the failure of LTA_4H inhibitors in the clinic.

Active transport of iron-flavonoid complexes by the major allergen Bet v 1 leads to enhanced activation of the aryl hydrocarbon receptor

A. Regner[1]*, M. Czernohaus*[1]*, G. Hofstetter*[1]*, K. Kienast*[1]*, Z. Dvorak*[2]*, L. F. Pacios*[3]*, E. Jensen-Jarolim*[1,4]*, F. Roth-Walter*[1]*;*
[1]*Department of Comparative Medicine, Interuniversity Messerli Research Institute, University of Veterinary Medicine Vienna, Medical University Vienna, University of Vienna, Vienna, Austria,* [2]*Department of Cell Biology and Genetics, Faculty of Science, Palacky University, Olomouc, Czech Republic,* [3]*Center for Plant Biotechnology and Genomics and Department of Biotechnology-Vegetal Biology, ETSIAAB, Technical University of Madrid, Madrid, Spain,* [4]*Institute of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Medical University Vienna, Vienna, Austria.*

Introduction: Our *in silico* calculations predicted that the major allergen from birch, Bet v 1, has lipocalin-like function and is able to bind iron via high-affinity-iron-chelators called siderophores. Only when loaded with iron it was *in vivo* able to prevent to the development of IgE and allergic sensitization. Here we analysed *in vitro* the iron-binding capacity of Bet v 1, using flavonoids (catechol-type-siderophores). Furthermore, we determined the bioactive function of these iron-chelators focusing on the aryl-hydrocarbon-receptor (AhR).
Materials and Methods: UV/VIS-spectra of three major flavonoids (Quercetin, Catechin, Epi-Catechin) in the presence or absence of allergens and iron were analyzed. Using the reporter cell line AZ-AhR activation of the AhR-pathway was determined by measuring luciferase activity. Presence of iron was measured with Calcein.
Results: All three tested flavonoids served as ligands for Bet v 1 regardless of the presence or absence of iron. Binding of these flavonoids alone or in complex with iron to Bet v 1 significantly enhanced AhR-activation in a concentration-dependent manner indicating active shuttling of flavonoids into the intracellular compartment. Moreover, iron transport into cells was confirmed by Calcein measurements.
Conclusions: Flavonoids act as siderophores and bind to Bet v 1. Only the loaded form of Bet v 1 significantly stimulated AhR-activation via active transport of these flavonoids and iron into the cell, thereby enabling an immune-suppressive stimulus. The ligands of allergens may thereby be decisive for the subsequent immune response promoting tolerance.
The study was supported by the Austrian Science Fund FWF, grant SFB F4606-B28 to EJJ.

Olaparib, a Poly(ADP-ribose) Polymerase Inhibitor Abates Ovalbumin-induced Airway Inflammation and Remodeling in Murine Model of Chronic Asthma

G. S. Sethi*, A. S. Naura;*
Department of Biochemistry, Panjab University, Chandigarh, India.

Poly(ADP-ribose) polymerase (PARP) has been reported to play a crucial role in the manifestation of allergen-induced airway inflammation, a characteristic feature of acute asthma. However, the role of PARP in airway remodeling (a hallmark of chronic asthma), is not completely known. Accordingly, the present study was designed to evaluate the potential of olaparib (a PARP inhibitor) on airway remodeling traits using an ovalbumin (OVA)-induced murine model of chronic asthma. The results demonstrated that olaparib administration (5 mg/kg b.wt. *via i.p.*), 30 minutes after every OVA challenge for six-weeks attenuates the airway inflammation, mucus production, collagen deposition in airways and the expression of coupled factors such as Th2 cytokines, Muc5ac, Col1α1, MMP-9, and TGF-β in lung tissues. Additionally, the OVA-induced alteration in the level of ROS, MDA, protein carbonyls and GSH/GSSH ratio were restored toward normal upon olaparib treatment. Furthermore, drug suppressed the expression of STAT-6, GATA-3, and vimentin, markedly along-with the partial attenuation of NF-κB activation. Overall, our results suggest the beneficial potential of olaparib in the prevention of airway remodeling associated with OVA-induced chronic asthma in mice.

P.C5.01.20

Allergic sensitization profile of polysensitized asthmatic patients in Southern China using molecule-based IgE technique

H. Hu, ***B. Sun****, W. Luo;*
First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China.

Objective: Most of allergic asthma patients are sensitization to a variety of allergens. This study aimed to analyze the sensitization profiles of polysensitized asthmatic patients in southern China utilizing molecule-based IgE diagnostic technique. **Method:** Serum samples from 63 asthma patients in southern China were tested with ISAC for specific immunoglobulin E (sIgE) against 112 single allergen components. **Results:** In this group of patients, 79.36% showed sIgE positive to more than three allergen components. Polysensitized asthmatic patients in southern China were mainly allergic to rDer f 2 (68.25%), nDer f 1 (66.67%), nDer p 1 (65.08%), rDer p 2 (61.90%), rFel d 1 (26.98%), nCyn d 1 (15.87%), nPhl p 4 (14.29%), rCanf 1 (12.70%), rDer p 10 (11.11%) and rLep d 2 (11.11%). Polysensitized asthma patients complicated with rhinitis showed higher positive rates of the allergen components Phl p 4 (19.05% vs. 0.00%) and nCyn d 1 (26.19% vs. 4.76%) than patients without rhinitis ($P < 0.001$). Among food allergen components, the walnut allergen component nJug r 2 showed the highest positive rate (9.52%). An optimal scaling analysis indicated that a positive test of rDer p 10 was associated with food allergy (Cronbach's Alpha = 92.0%).**Conclusions:** The sensitization profiles of polysensitized asthmatic patients in southern China were different from other countries. Polysensitized asthma patients complicated with rhinitis showed higher positive rates for nPhl p 4 and nCyn d 1 than without. Polysensitized asthmatic patients who positive for rDer p 10 were associated with food allergy.

P.C5.01.21

The value of allergy screening in Chinese adult patients with chronic respiratory diseases

*H. Hu, **B. Sun**, P. Zheng;*
First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China.

Objective: The prevalence of allergen-induced chronic respiratory disease (CRD) is increasing annually. This study aimed to analyze sensitization characteristics of adult Chinese CRD patients and the value of allergy screening. **Methods:** Serum immunoglobulin E (sIgE) was detected with an allergy screening test. Total immunglobulin E (tIgE) levels were measured in 85 asthma patients, 98 chronic obstructive pulmonary disease (COPD) patients, and 69 patients with other CRDs. **Results:** The total positive rate of allergy screening among CRD patients was 36.1%. Asthma had the highest rate (45.9%), followed by COPD (32.7%) and other CRDs (29.0%). The positive rate of allergy screening was significantly higher among urban asthma patients (56.1%) than among rural patients (25.0%, $P < 0.05$), and significantly higher among office staff (68.9%) than among outdoor workers (42.8%, $P < 0.05$).
Patients with COPD (42.9%) and recurrent exacerbation were atopic. Atopy was a risk factor for dyspnea (OR = 1.22; 95% CI, 0.95-1.75, $P < 0.05$).
Optimal scaling analysis revealed a correlation between tIgE levels and smoking index (Cronbach`s alpha = 91.1%). Up to 35.0% of patients who met the Global Initiative for Chronic Obstructive Lung Disease III (GOLD III) IV criteria and had a low Phadiatop level (≤10 kU/L), had a high tIgE level (≥1000 kU/L), compared to GOLD I II patients (5.5%). **Conclusion:** Patients with CRD had high sensitization. Asthma patients who work indoors were more susceptible to allergies. Atopy was associated with COPD pulmonary function. It is necessary to initially screen the sensitization situation of CRD patients.

Maternal IgG impairs the maturation of offspring intrathymic IL-17-producing γδT cells: possible implications for murine and human allergy

*M. G. de-Oliveira[1], A. A. Lira[1], F. R. Sgnotto[1], A. H. Inoue[1], L. S. Santos[1], A. J. Duarte[1], M. Leite-de-Moraes[2], **J. R. Victor**[1,3];*
[1]School of Medicine - USP, Sao Paulo, Brazil, [2]Institut Necker-Enfants Malades (INEM), Paris, France, [3]Laureate International Universities (FMU), São Paulo, Brazil.

Using a well-standardized murine model of offspring allergy inhibition mediated by maternal allergen immunization, we aimed to evaluate the relationship between IL-17-producing γδT cells and allergy inhibition by focusing on the regulation of the intrathymic maturation and γδT cell biology. Female mice were immunized or not, and the allergic response, frequency of γδT cell subsets and cytokine production of the offspring were analysed by flow cytometry. The effects of passive in vivo transfer of thymocytes or purified IgG were investigated in offspring. A translational approach was employed to analyse γδT cells in the thymus and PBMCs from humans. Maternal immunization reduced the frequency of spontaneous IL-17-producing γδT cells in the thymus, spleen and lung of offspring. This effect was mimicked by the in vivo treatment of females with purified IgG. IgG directly interacted with γδT cell membranes. Human infant intrathymic γδT cells showed reduced IL-17 production in response to purified IgG from non-atopic individuals, whereas adult peripheral γδT cells from atopic individuals were prone to produce IL-17 in response to IgG. Together, our results reveal that IgG from atopic mice can influence the thymic γδT cell maturation. Further, IgG is an unprecedented modulatory factor of murine and human γδT cells.

Mango chitinase is a major allergen in Chinese pediatric patients

***L. Xia**[1], H. Cao[1], X. Xu[1], X. Xiao[1], D. Cai[2], Z. Chen[3], P. Yang[1], Z. Liu[1];*
[1]College of Medicine, Shenzhen University, Shenzhen, China, [2]Clinical molecular diagnostic laboratory, Shenzhen Children's Hospital, Shenzhen, China, [3]Department of Pediatrics, Third Affiliated Hospital of Sun Yat-sen University, Shenzhen, China.

Introduction: Allergies to mango are frequently observed in clinical practice. However, only one allergen has been identified from mango until now.Materials and Methods: Protein crude extract of mango flesh was resolved by using 1-D SDS-PAGE. The reactive bands were analyzed by MS/MS mass spectrometry. A band showed significant homology to the mango chitinase (Genbank Accession: ACD69683.1). The cDNA of the chitinase was synthesized and cloned into a plasmid pMAL-C5X and expressed as a recombinant protein. The reactivity of the recombinant protein towards mango allergic patients was assayed by using western blot. The linear IgE epitopes of the chitinase were then analyzed by six peptides spanning the entire protein with putative potential of IgE reactivity. Results: The mango chitinase reacted with IgE of 9 out of 13 sera (69%) of pediatric patients with mango allergies. Only one peptide (8-28) which contains the chitin-binding domain possesses IgE reactivity. Conclusions: The mango chitinase is a major allergen in Chinese pediatric patients.

P.C5.02.01

The skin as a mirror of the functionality of our immune system

L. N. Ahmetaj;
University of Prishtina, Prishtina, Kosovo, Republic of.

Case report

Woman I.M., 1950, Prishtina,with ambulantory diagnosis Dermatitis cruris, Erythema region faciei. The patient showed up to our hospital with multiforme erythematous changes along crural and palmoplantar region, following unsuccessful five-month ambulantory treatment. During physical examination, we observed asymmetrical erythematous changes in both legs and palmoplantar regions, with induration, without pain. Laboratoric data showed high level of erythro-sedimentation 30/66, RBC=5.21, PLT =246,Le=6.4.
Chemical analyses were normal (urea,creatinine, bilirubin, ALT and AST)
Protein C reactive= 2.40(0.6),Rheumatoid factor 12.0(<12) andASTO=400 IU/ml (200 IU/ml)
Normal Rtg pulmis.
In alergologic tests the level of total IgE is normal, eosinophilia (4%), positive skin prick test in D.pteronyssinus and D.farinae (house dust mites). We concluded with erythema multiforme as a diagnosis and started with conservative anti-allergic treatment with corticosteroids and antihistamines and also antibiotics. Etiological treatment continues with subcutaneous specific immunotherapy to house dust mites. After a five-year treatment,we consider that our patient is cured. But, there were some unusual findings in this case: Unusual in this case was that the EM is described as allergic reaction with unknown etiology, type IV (four). Different allergic triggers in this condition are prescribed (viral infections, bacterial, mycotic,etc).Histologically, IgM depositions were found along small blood vessels.
On the other side, we know that specific immunotherapy is an etiological treatment for IgE mediated allergic reactions.

P.C5.02.02

Cyclic-dipeptide isolated from *Hirsutella sinensis*mycelium attenuates ovalbumin-induced asthma in a murine model

***L. B. Antig**[1], C. Lin[1,2], Y. Chen[3], P. Hsieh[3], Y. Ko[4], H. Lai[1,2];*
[1]Department of Medical Biotechnology and Laboratory Science, Chang Gung University, Taoyuan, Taiwan, [2]Microbiota Research Center, Center for Molecular and Clinical Immunology, Chang Gung University, Taoyuan, Taiwan, [3]Graduate Institute of Natural Products, Chang Gung University, Taoyuan, Taiwan, [4]Chang Gung Biotechnology Corporation, Taoyuan, Taiwan.

Background: Asthma is a chronic inflammatory disorder that affects millions of people worldwide. It is characterized by eosinophilic inflammation, airway hyperresponsiveness, and airway remodeling. Traditional Chinese Medicine has been used for centuries for their immunomodulatory and anti-inflammatory effects. *Hirsutella sinensis*, a medicinal mushroom, was found to have anti-asthmatic effects. Water extracts from *Hirsutella sinensis* mycelium reduced ovalbumin-induced asthma and TH2 responsiveness in mice, yet the bioactive compound that promotes this occurrence remains unknown.
Materials and Methods: Bioactivity-graded fractionation such as thin layer chromatography (TLC), high-performance liquid chromatography (HPLC), nuclear magnetic resonance (NMR) and an *in vitro* TH2 cell inhibition screening model was used to isolate and identify the cyclic-dipeptide from *Hirsutella sinensis* mycelium. Ovalbumin-induced asthma model in BALB/c mice were utilized to test the compound *in vivo.*
Results: Cyclic-dipeptide directly inhibited TH2 responsiveness by decreasing production of TH2-associated cytokines such as IL-4, IL-5, and IL-13 *in vitro* and *in vivo.* Further *in vivo* asthma model demonstrates that cyclic-dipeptide from *Hirsutella sinensis* mycelium dose-dependently attenuates ovalbumin-induced asthmatic responses, including airway hyperresponsiveness, immune cells infiltration, TH2 cytokines responses, and ovalbumin-specific humoral responses.
Conclusions: Taken together, we identified a patentable anti-asthmatic and anti-allergic compound isolated from HSM and potentially explore its underlying mechanisms.

P.C5.02.03
Effects of Immunotherapy on different allergic conditions

F. Arooj;
Sir Gangram hospital, lahore, Pakistan.

Background: The study was conducted in Sir Ganga Ram Hospital. 100 patients were randomly selected and their allergy status and the effects of immunotherapy were determined. 36% had bronchial asthma, 32% had allergic rhinitis, 18% had allergic conjunctivitis, 10% had urticaria and 4% had atopic dermatitis.
Methods: Provisional diagnosis of allergic symptoms was confirmed by the skin prick test, before and after immunotherapy, against various pollens (mixed trees, weeds, sunflower [Helianthus annuus], Acacia, bottlebrush [Elymus elymoides]), dust, paper mulberry and dandelion [Taraxacum officinale]. Aqueous mixed allergen preparations were used for immunotherapy. The 1st injection administered was a small dose (0.5 ml), and gradually increased to 1 ml, from a low concentration to a higher concentration, over a period of 3 months. Immunotherapy lasted for 1 year. A placebo control study was also conducted simultaneously on 50 patients selected randomly in the same manner.
Results: The results clearly indicated that immunotherapy was a useful treatment against all allergic diseases, with varying effectiveness. Percentage improvement was highest (73.75%) for allergic rhinitis in the 26-40 years age group and lowest (20.00%) for urticaria in the 10-25 years age group. Therapy was also found to be useful in all other age groups.
Conclusions: The study revealed that the various grass pollens and dust particles gave the highest degree of allergic reaction in the patients.

P.C5.02.04
The quest for bacterial allergens - Serine proteases of *Staphylococcus aureus* are inducers of type 2 airway inflammation

*M. Nordengrün[1], A. Teufelberger[2], S. Michalik[3], S. Stentzel[1,4], F. Schmidt[3], C. Bachert[2], U. Völker[3], O. Krysko[2], **B. M. Bröker**[1];*
[1]Department of Immunology, University Medicine, Greifswald, Germany, [2]Upper Airways Laboratory, Ghent University, Ghent, Belgium, [3]Department of Functional Genomics, University Medicine, Greifswald, Germany, [4]IDT Biologika, Greifswald-Insel Riems, Germany.

Introduction: According to the hygiene hypothesis, childhood infections as well as early exposure to microbial diversity protect from allergy. *Staphylococcus aureus*, in contrast, is associated with allergic reactions, besides its well-known commensal and invasive behavior. In patients suffering from allergic airway inflammation, *S. aureus* colonization is much more frequent than in controls. However, the driving allergens of *S. aureus* remained elusive.
Methods and Results: By immunoproteomics we identified the serine protease-like proteins (Spls) A-F as major IgG4-binding proteins of *S. aureus*. IgG4 served as a surrogate marker for IgE, since production of IgG4 and IgE are both initiated by a similar Th2 cytokine profile. The *S. aureus* Spls A-F are extracellular proteases of so far unknown function. We observed increased Spl-specific serum IgE titers in asthma patients. Following stimulation with Spls, memory T cells of healthy donors secreted Th2 cytokines. In contrast, Th1/Th17 cytokines were of low concentration or absent. In mice, intra-tracheal application of SplD without adjuvant induced allergic lung inflammation, including infiltration of inflammatory cells and generation of SplD-specific serum IgE. This identifies SplD as a triggering allergen of *S. aureus*. To elucidate the underlying mechanism, we blocked the downstream effects of IL-33 by co-administration of sST2, the soluble IL-33 receptor. sST2 treatment counteracted the SplD-mediated allergic lung inflammation, indicating that SplD causes a Th2 response in an IL-33 dependent manner.
Conclusion: We identified Spls as triggering allergens of *S. aureus,* opening prospects for diagnosis and causal therapy of asthma.

P.C5.02.05
Inhibition of basophil activation by an Omalizumab-resistant IgE-Fc glycovariant

*P. Gasser[1], L. Pennington[2], D. Brigger[1], N. Zbären[1], T. Jardetzky[2], **A. Eggel**[1];*
[1]Department for Rheumatology, Immunology and Allergology, 3010 Bern, Switzerland, [2]Department of Structural Biology, Stanford University School of Medicine, Stanford, California 94305, United States.

Background: Allergen-specific IgE plays a major role in immediate hypersensitivity reactions. It binds with high-affinity to its primary receptor FcεRI on basophils and mast cells. Upon allergen stimulation, these cells degranulate and release soluble mediators causing allergic symptoms. The therapeutic anti-IgE antibody Omalizumab is known to prevent binding of IgE to basophils and mast cells. Recently, we have reported that Omalizumab actively desensitizes basophils at high concentrations. Furthermore, we have provided evidence that an IgE-Fc glycovariant, which is resistant to Omalizumab binding, may be used to replace the IgE-repertoire on the surface of primary human basophils when co-applied with Omalizumab. This combination treatment significantly increased inhibition of antigen-mediated basophil activation ex vivo. Here, we provide mechanistic insight into the mode of action of this IgE-Fc glycovariant.
Methods: Human primary basophils were isolated from whole blood donations of grass-pollen allergic individuals and treated with the IgE-Fc glycovariant alone or in combination with Omalizumab. Subsequently, cells were challenged with a grass-pollen allergen mix. Basophil activation was measured by flow cytometry.
Results: Interestingly, the IgE-Fc glycovariant alone diminished basophil activation in a competition-independent manner. Furthermore, it showed dose-dependent inhibition already at low concentrations when used in combination with Omalizumab.
Conclusions: Our data indicate that the IgE-Fc glycovariant induces inhibitory signaling in human primary basophils. The IgE-Fc variant could potentially be used as an efficient add-on treatment to the current Omalizumab therapy.

P.C5.02.06
Modulation of allergen-specific immune response with allergen-laden virus-like nanoparticles (VNP) co-expressing surface-anchored cytokines and growth factors

***S. Hofer**, B. Kratzer, D. Trapin, W. F. Pickl;*
Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria.

The expression in producer cells of structural core proteins of *Moloney* murine leukemia virus (MoMLV) leads to the formation of non-infectious virus-like nanoparticles (VNP), which become enveloped by the lipid-raft containing regions of the plasma membrane through which they are budding. This had allowed to decorate VNP with a collection of immunomodulatory and fluorescent molecules by their fusion to lipid modification sequences or viral structural proteins in the past. Here we examined the immunomodulatory potential of surface-anchored cytokines on VNP co-expressing the major mugwort pollen allergen, Art v 1. The coding sequences of GM-CSF, IFN-γ, IL-10, IL-12 and TGF-β1 were C-terminally fused to the GPI anchor acceptor sequence of CD16b and tested for surface expression on producer cells and VNP. Subsequently, they were evaluated for their potential to modulate effector functions of allergen-specific T cells from humanized mice which are reactive to mugwort pollen allergen. All five GPI-anchored fusion proteins expressed well on producer cells and VNP alike, as confirmed by flow cytometry and biochemical analyses. Notably, the expression of the different cytokines and growth factors co-stimulated the proliferation of allergen-specific $CD4^+$ Teff cells towards the allergen, with the exception of IL-12, which inhibited proliferation by 50 percent when compared to VNP decorated with allergen alone. Notably, IL-12 decorated, allergen-expressing VNP strongly induced IFN-γ expression in $CD4^+$ Teff cells, which, however, elaborated 20-30-fold less Th2 and Th17 cytokines. Cytokine decorated, allergen-specific VNP might help prevent and treat allergies in the future. Supported by Austrian Science Fund (FWF) DK-W 1248, SFB-F4609.

P.C5.02.07
Asthmatic airway inflammation is alleviated by adeno-associated viral vectors carrying CD39 in OVA-sensitized mice model

***Y. Huang**[1], C. Kuo[1], J. Ma[1], M. Kuo[1,2];*
[1]Graduate Institute of Biomedical Sciences, Chang Gung University, Taoyuan City, Taiwan, [2]Department of Microbiology and Immunology, Chang Gung University, Taoyuan City, Taiwan.

Introduction: Asthma is a chronic respiratory disease characterized by recurrently attacks of breathlessness and wheezing. ATP accumulation in bronchoalveolar lavage fluid (BALF) of asthmatic subjects indicates that extracellular ATP (eATP) and downstream responses are involved. The level of eATP is tightly controlled by apyrase (also named as CD39) in healthy tissues and it is downregulated upon inflammatory stimulation. In order to transduce exogenous genes, recombinant adeno-associated virus (rAAV) has been developed and characterized by low toxic and difference tissue tropisms among serotypes.
Materials and Methods: ATP levels in supernatants of stimulated RAW 264.7 cells and BEAS-2B cells were determined. rAAV-CD39 was generated and applied to OVA-mediated asthmatic mice model. The mice were sensitized intraperitoneally and challenged intratracheally with OVA and treated with rAAV-CD39 three days before OVA challenge. At the end of procedure, some asthmatic and inflammatory cardinal features were examined.
Results: Elevated ATP level was determined either in stimulated-culture supernatant and BALF of OVA-sensitized mice. rAAV-CD39 treatment downregulated the level of ATP in BALF with rescued expression of *cd39*. Several asthmatic features, such as eosinophilia, IL-13 production from draining lymph node cells and AHR were decreased in the rAAV-CD39 treated group. The frequency of $CD4^+FoxP3^+$ regulatory T cells was also increased in lymph nodes. However, OVA-specific IgE and IgG1 were not impacted.
Conclusion: The treatment of rAAV carrying CD39 attenuated the asthmatic airway inflammation locally. We consider that extracellular ATP signaling could be a potential target for gene therapy on asthma.

Intranasal inoculation of PM2.5 induces inflammation in both the lung and liver of the mouse via distinct signaling pathway

S. Jeong[1], *S. Park*[1], *I. Park*[2], *P. Kim*[2], *N. Hoon*[3], *Y. Hyun*[1];
[1]*Department of Anatomy and Brain Korea 21 PLUS Project for Medical Science, Seoul, Korea, Republic of,* [2]*Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,* [3]*Department of Pathology, Yonsei University College of Medicine, Seoul, Korea, Republic of.*

Particulate matter (PM2.5) is currently major issue of air pollutants to threat public health related to the exposure through pulmonary pathway. Although many studies have been performed to directly treat mouse model with PM2.5, there were few reports about PM2.5 using two-photon intravital imaging. In this study, we aimed to investigate neutrophil migratory pattern and structural changes in the lung and liver, respectively. To compare the inflammatory response of both organs, we performed two-photon intravital imaging of mice lung and liver, respectively at 24 and 48 hours post to PM2.5 treatment through intratreacheal inoculation. We found that there was no significant difference in the number of neutrophils in both lung and liver of PM2.5-treated mice compared to the control mice. On the other hand, using immunohistochemistry and electron microscopy, we found that lymphocyte number was significantly higher in the lung and liver of PM2.5 treated mice than the control mice. Also, from the microarrays of PM2.5-treated organs of mice, there were distinct upregulations of mRNA in the lung and liver, respectively, in response to PM2.5 treatment. While lung showed the upregulation of mRNAs associated with IL-17 signaling pathway related to the regulation of neutrophil, liver showed high level expression of mRNAs associated with metabolic pathways. Therefore, these results suggest that lung is distinctly regulated from liver under acute PM2.5-induced inflammatory condition. In summary, our data of lung and liver of PM2.5-treated mice uncovered that lung and liver are regulated via distinctive signaling pathway.
