Ki-67 protein was reported as a quantitative indicator of lymphocyte proliferation in PHA stimulated cultures. Its detection was shown to be more sensitive than the DNA content analysis and the measurements of incorporated nucleoside analogues. We used Ki-67 staining in whole blood cultures stimulated with food allergen extracts to evaluate specimens obtained from patients previously diagnosed with delayed type of hypersensitivity to gluten. Allergen extracts were aseptically lyophilized at the bottom of polystyrene tubes with dual position caps. The tubes were intended to the cell culture, antibody staining and cytometry analysis. Whole blood was diluted 1:10 in culture medium and cultivated for 7 days. Various amounts of interleukin 2 were added to the medium to improve the sensitivity of the test. Tetanus vaccine was used as the positive control. Samples were stained with CD3/CD4/Ki-67. The flow cytometry analysis of unstimulated lymphocytes revealed virtually no background. The Ki-67 antibody conjugate to phycoerythrin provided high signal to noise ratio thus the previously described variations in Ki-67 expression were negligible in discrimination between negative and positive cells. All the cultures supplemented with interleukin 2 were found responsive for the respective allergen with clear dose-response curves. The blood stimulations without interleukin 2 were negative in allergen stimulations and sometimes in tetanus stimulations. We conclude that supplementation with interleukin 2 helps to reveal the presence of allergen specific lymphocytes that would otherwise be missed in whole blood allergen specific stimulations.

P.C5.02.10

NK-cell mediated contact hypersensitivity in obese mice

P. Kowalczyk*, D. Biała, A. Strzępa, K. Marcińska, M. Majewska-Szczepanik, M. Szczepanik;*
Department of Medical Biology, Faculty of Health Sciences, Jagiellonian Univeristy Medical College, Krakow, Poland.

Previous experiments showed that liver NK cells can mediate contact hypersensitivity (CHS) reaction in mice. To investigate influence of diet-induced obesity on NK cell-mediated CHS, RAG1-/-B6 mice were maintained on HFD or normal diet (ND). After 8 weeks the animals kept on HFD or ND were split into two groups, one of which was sensitized with DNFB, while the second one was treated with solvent alone. Then, the animals were challenged with DNFB on the ears and tested for the CHS reaction. The subcutaneous fat tissue was collected and weighed and then cells obtained by mechanical dissociation were cultured to determine cytokine production. Additionally, lipid profile in HFD and ND mice was determined. Also, liver mononuclear cells (LMNC) were cultured with DNP-BSA antigen to determine antigen-specific cytokine production. We found that mice fed HFD for 8 weeks developed aggravated CHS reaction determined by ear swelling measurement when compared to animals kept on ND prior to CHS sensitization and challenge. The increased ear swelling in HFD-fed mice was confirmed by increased MPO activity in ear homogenates, higher ear weight and increased vascular permeability. Subcutaneous fat tissue from mice on HFD weighed more and produced more IL-6 but less IL-10 when compared to ND mice. RAG1-/-B6 mice on HFD showed higher concentration of total cholesterol and LDL-cholesterol in serum when compared to ND mice. Finally, LMNC from HFD mice restimulated *in vitro* with DNP-BSA produced more IFN-γ than LMNC from ND mice. Supported by grant from National Science Center 2016/23/N/NZ6/01488 to PK

Overexpression of the AP-1 subunit, Fra2 causes a non-allergic asthma phenotype in mice

L. M. Marsh[1], *A. Gungl*[1,2], *V. Biasin*[1], *J. Wilhelm*[3,4], *G. Kwapiszewska*[1,2];
[1]*Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria,* [2]*Otto Loewi research center, Medical University of Graz, Graz, Austria,* [3]*Department of Internal Medicine, Universities of Giessen and Marburg Lung Center, Giessen, Germany,* [4]*German Center for Lung Research, Justus-Liebig University, Giessen, Germany.*

Introduction: Asthma is a complex chronic inflammatory disease characterised by airway inflammation, remodelling and hyperresponsiveness (AHR). Members of the AP-1 family of transcription factors have been shown to play important roles in the activation of the immune system and the control of cellular responses. Here we have investigated the role of the lesser known AP-1 family member, Fra2 in experimental asthma.
Methods and Results: Gene expression profiling of Fra2 overexpressing (TG) mice revealed a high number of regulated genes associated with airway remodelling, inflammation and mucus production. In line with this finding TG mice exhibited increased airway remodelling, with peribronchial collagen and smooth muscle thickening as well as mucus production. TG mice possessed a strong inflammatory infiltrate in the lung, predominately, eosinophils and T cells and increased expression of Th2 cytokines and eotaxin. Furthermore, TG mice possessed AHR in response to increasing doses of methacholine. Therapeutic intervention via IL-13 blocking antibodies or corticosteroids partially reduced AHR, mucus secretion and eosinophil recruitment. However, only corticosteroid treatment could reduce all aspects of airway remodelling.
Conclusion: Here we describe a novel model of non-allergic asthma, which does not require the application of exogenous allergens. Fra2 represent a key molecule that coordinates several aspects of asthma pathogenesis, including airway inflammation, remodelling and hyperresponsiveness.
This study was funded in part by the Austrian Science Fund (FWF): P27848-B28 and Austrian National Bank grant number 16187.

Quality of life in patients with bronchial asthma during immunotherapy with autologous activated T-lymphocytes

E. Pashkina*, A. Makarova, E. Blinova, V. Nepomnyashchikh, M. Leonova, D. Demina, V. Kozlov;*
Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation.

Today bronchial asthma (BA) is one of the most common chronic diseases associated with immunological disorders. The purpose of this study was to study the effect of immunotherapy with activated autologous T-lymphocytes, including the evaluation of the quality of life in the dynamics of this type of therapy in patients with BA.
The study included 23 patients, (average 38.5 ± 4.3 years) with moderate severity of BA, receiving treatment at the Clinic of Immunopathology of RIFCI, Novosibirsk. The study was approved by the ethical commission of RIFCI. After obtaining Informed Consent to participate in the study, patients were injected subcutaneously with autologous activated T cells according to scheme: 1 injection once a week - 4 times, then 1 injection per month - 6 times. Patients also received basic therapy. A study of quality of life in patients was carried out using the AQLQ(S). The AQLQ(S) has 4 domains: activity limitations, symptoms, emotional function, and exposure to environmental stimuli. After 2 months, it was observed significant improvement in the “activity limitations” domain compared with the values before the beginning of therapy. Also there was a tendency (p=0.08) to increase the indicators in the domain “emotional function”. After 7 months, in the end of immunotherapy, it was shown a statistically significant improvement in all domains of AQLQ(S) compared before treatment. That was indicated the efficacy of the immunotherapy.
Our findings suggest that the therapy with autologous activated T-cells led to an improvement in the quality of life in patients with BA.

Tolerogenic Immune Modifying Nanoparticles as an Antigen-Specific Therapy for the Treatment of Th2-Mediated Food Allergy

J. R. Podojil[1,2]*, C. Smarr*[1]*, T. P. Neef*[1]*, R. M. Pearson*[3,2]*, D. Getts*[2]*, P. J. Bryce*[1]*, L. D. Shea*[3]*, S. D. Miller*[1]*;*
[1]Northwestern University, Chicago, United States, [2]COUR Pharmaceuticals Development Company, Chicago, United States, [3]University of Michigan, Ann Arbor, United States.

Standard allergy treatments fail to target the underlying Th2-mediated cause of disease. Thus, development of safer, more efficient means of inducing antigen-specific tolerance is a major goal of allergic disease research. Previously published data show that i.v. injection of antigen-pulsed splenic antigen-presenting cells (Ag-SP) chemically fixed with ethylene-carbodiimide (ECDI) safely inhibit Th1/Th2/Th17-mediated disease via the induction of antigen-specific tolerance. We hypothesized that Tolerogenic Immune Modifying Nanoparticles (TIMP; poly(lactide-co-glycolide nanoparticles containing an encapsulated disease-associated antigen), which are in clinical trial for treating celiac disease, would also be effective for the induction of immune tolerance in murine models of Th2-mediated food allergy. Importantly, the treatment of WPE/alum primed mice with TIMP-WPE has been shown to be safe when administered via i.v. injection. Additionally, the present data show treatment of mice with TIMP-WPE either prophylactically or therapeutically in WPE-induced food allergy resulted in a decrease in the level of IL-4, IL-5, and IL-13 secreted upon ex vivo recall culture of splenocytes. Thus, we illustrate progression toward the safe and effective inhibition of food allergy without the need for nonspecific immunosuppression in animals with established Th2 sensitization.

P.C5.02.15

The role of atopy in the pathogenesis of bleomycin induced lung fibrosis

L. Pur Ozyigit[1,2]*, E. Cetin Aktas*[3]*, Z. Senbas*[4]*, A. Ozturk*[5]*, E. Ozturk*[6]*, M. Ergonul*[7]*, L. Tabak*[8]*, B. Ferhanoğlu*[9]*, M. Cetiner*[9]*, G. Deniz*[3]*;*
[1]Koç University, School of Medicine, Department of Allergy and Immunology, Istanbul, Turkey, [2]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Immunology Department, Istanbul, Turkey, [3]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Immunology Department, Istanbul, Istanbul, Turkey, [4]Koç University, School of Medicine, Istanbul, Turkey, [5]Koç University Hospital, Department of Allergy and Immunology, Istanbul, Istanbul, Turkey, [6]Koç University Hospital, Department of Haematology, Istanbul, Istanbul, Turkey, [7]Koç University, School of Medicine, Department of Infectious Diseases, Istanbul, Istanbul, Turkey, [8]Koç University, School of Medicine, Department of Respiratory Medicine, Istanbul, Istanbul, Turkey, [9]Koç University, School of Medicine, Department of Haematology, Istanbul, Turkey, Istanbul, Turkey.

Bleomycin pulmonary toxicity (BPT) is a potentially life-threatening consequence of bleomycin usage in patients. An overproduction of epithelium-derived cytokines, habitually linked to allergic inflammation, has been recently revealed in experimental models of BPT. We assessed retrospectively our cohort of patients with Hodgkin Lymphoma treated with bleomycin between 2014-2016 for their demographic, clinical features, including BPT development, atopy status and risk factors for BPT. Then they were invited for allergy testing and blood sample collection. The samples were stimulated with different stimuli (Bleomycin, IL-33, TSLP) for 24 hours *in vitro* cell culture. The culture supernatants were analysed for TGF-β, Galectin3, Arginin, Amphiregulin, Eotaxin, IFN-γ, TNF-α, IL1-β, -4, -5, -6, -10, -13, -17, MIP-1α and bleomycin hydrolase (BLH) levels by ELISA and LUMINEX. The cohort consisted of 51 patients showed that atopy was the only significant risk factor for BPT occurrence (OR: 7.2, p=0.007). Fourteen subjects were included for blood analysis. The analysis of supernatants at the unstimulated condition revealed that BLH and Amphiregulin were significantly lower in patients who had BPT than controls. The BLH cut-off that best identified a history of BPT was 175.31 (sensitivity: 62.5%, specificity: 100%). Following the stimulation, BLH reduced compared to the unstimulated condition and the difference between groups remained significant (p< 0.05). Our study is the first report that low levels of bleomycin hydrolase in allergic individuals might be predisposing to a possible pathway of fibrosis. This work was supported by the Scientific and Technological Research Council of Turkey (TUBITAK), (Grant No: 116S019).

P.C5.02.16

Profile of component-resolved diagnostics allergy by microarray assay in a souther Spanish area

M. San Jose-Cascon*, M. Vilches-Moreno, D. Garcia-Cuesta, A. Sampalo;*
UGC Hematology, Immunology and Genetics, Hospital Universitario Puerta del Mar, Cadiz, Spain.

Identification of sensitization profiles in our geographic area by analysis of component-resolved diagnosis allergy in multiplex support for detection of relevant allergen sources, differentiation between genuine and cross-reactive sensitizations, and analysis of risk and severity of allergic reactions.
160 Patients (72 male/88 female), median aged 31.3 (SD 16.4, range 2-74 years) with suspected allergic symptoms were selected for testing IgE antibodies by microarray assay (ISAC). 74% of the patients showed two or more clinical manifestations at respiratory, digestive and skin levels. 26% of the patients studied showed only one symptom. Unexplained anaphylaxis was present in 62 patients.
ISAC analysis showed sensitization in 131 patients (82%). Sensitization were not found in 29 cases (18%). 87patients (54%) were positive for both, genuine and cross-reactive allergens. Main specific primary sensitization components in respiratory allergy were: ole e 1 (56%), Derp1 (33%), Derp2, Phlp1 (37%), Phlp5 (8%), Alta1 (17%), Salk1 (13%), Artv1 (7%). Primary sensitization components in digestive allergy were nuts: Jugr2 (15%), Jugr1 (11%), Arah1 (4%) and Cora9 (5%) and fruits: Prup1 (5%), Actd1 (6%). Main reactions detected in protein family were: storage protein (49%), nLTPs (47%),lipocalins (21%), Tropomyosins (16%), Profilins (11%), PR10 protein (7%) and polcalcin (3%).
Retrospective analysis of component resolved diagnosis allergy (CRD) by multiplex platform provides useful information about allergenic sources, genuine and secondary sensitization and risk and severity of allergic reaction. A specific map of sensitization in our geographic area will be shown.

P.C5.02.17

IL-33 cooperates with TL1A for potent induction of IL-9-producing ILC2s in allergic airway inflammation

P. Schmitt*, A. Duval, S. Roga, M. Camus, O. Burlet-Schiltz, A. Gonzalez-de-Peredo, C. Cayrol, J. Girard;*
Institut de Pharmacologie et de Biologie Structurale, Toulouse, France.

IL-9 is key driver of chronic and allergic inflammation at mucosal surfaces, with important roles in the activation and survival of mast cells and ILC2s. *IL-9*-reporter mice have established T cells (Th9) and ILC2s as major sources of IL-9 *in vivo*. The discovery that TGF-β and IL-4 cooperate for induction of Th9 cells has been an important breakthrough. However, the signals that induce IL-9+ ILC2s remain incompletely characterized. Here, we show that IL-33, a critical activator of ILC2s, with important roles in type-2 innate immunity and allergic inflammation (Cayrol, Duval and al., Nature Immunology 2018*)* synergizes with TNF-family cytokine TL1A to induce prodigious amounts of IL-9 secretion by ILC2s. Unbiased global proteomic analyses revealed that IL-9 was the most-induced protein in ILC2s treated with IL-33 and TL1A. More than 99 % of ILC2s expressed IL-9 intracellularly after co-stimulation with IL-33 and TL1A. The amounts of IL-9 produced by ILC2s in response to IL-33/TL1A were significantly higher than those that have been reported for Th9 cells cultured with TGF-β and IL-4. ILC2s are known to produce very large amounts of IL-5 and IL-13, but ILC2s producing such high levels of IL-9 have not been described previously. Interestingly, IL-9 production by ILC2s was transient and associated with a phenotypic shift characterized by upregulation of IRF4, pSTAT5 and downregulation of ICOS, KLRG1, and GATA-3. Finally, IL-33 and TL1A expanded IL-9^{high} ILC2s in the lungs and adoptive transfer experiments revealed that IL-9^{high} ILC2s are potent inducers of allergic airway inflammation *in vivo*.

P.C5.02.18

A child with influenza vaccine-associated anaphylaxis without egg allergy

D. Shim*, M. Kim, S. Kim, I. Sol, Y. Kim, K. Kim, J. Lee, M. Sohn;*
Yonsei University College of Medicine, Seoul, Korea, Republic of.

Anaphylaxis associated with influenza vaccines in patients without egg allergy was very unlikely. We reported a pediatric case of influenza vaccine-associated anaphylaxis without egg allergy. A 3 year old girl was admitted to emergency room, showing rash and edema on face, abdominal pain, and hypotension with tachycardia. She was vaccinated with a seasonal quadrivalent influenza vaccine, within 15 hours before onset. She had no history of any allergy, but only had an experience of urticaria after administration of trivalent influenza vaccine last year. Even though she was treated with fluid therapy and epinephrine injection, blood pressure and pulse rates were unstable. She was transferred to PICU for treatment with monitoring. After her vital signs were stable and symptoms were relieved, she could be ward out on the next day. Laboratory findings including allergy test were unremarkable. We collected blood samples on days 1, 3, 7 after anaphylaxis. Specific IgE levels to whole influenza vaccines of different manufacturers and HA proteins measured using ELISA. Compared with age-matched controls, this patient showed elevated specific IgE levels against whole vaccines from egg-based manufacturing process, especially with split virion. And specific IgE levels to influenza vaccines were decreased over time. A child without egg allergy could also have an anaphylactic event to influenza vaccination, caused by elevated specific IgE levels to egg-based and split virion vaccines. In this case, cell-based and subunit vaccine could be safe from unexpected vaccine-associated anaphylaxis.

P.C5.02.19

The PDK1/TBK-1 inhibitor BX-795 is a potent suppressor of Th1 and Th2 cytokines that stimulates IL-2 secretion

P. A. Tauber*, M. R. Candia, D. Trapin, C. Köhler, A. Neunkirchner, S. Jutz, P. Steinberger, U. Smole, W. F. Pickl;*
Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria.

BX-795 is an inhibitor of 3-phosphoinositide-dependent kinase-1 (PDK1) and TANK-binding kinase-1 (TBK1), involved in T cell receptor (TCR) and innate signaling. We investigated the immunomodulatory effects of BX-795 on splenocytes of TCR/DR1 double transgenic mice and hPBMCs. We assessed viability, activation marker expression and transcription factor activity of T cells by flow cytometry and proliferation by methyl-^{3}H-thymidine uptake upon TCR ligation. Cytokine secretion was measured by multiplexing of culture supernatants, RT-qPCR and intracellular cytokine staining. Notably, BX-795 strongly inhibited secreted IFN-γ (72.9±10.0%, p<0.01) at 24 hours and also inhibited IL-4 (88.3±6.5%, p<0.05), IL-13 (75.8±8.7%, p<0.001) and IL-10 (80.8±13.1%, p<0.001) after 48 hours. After 72 hours, BX-795 also reduced secreted IL-5 and TNF-α levels.

Interestingly, Th17 cytokines were not reduced while IL-2 was strongly increased peaking at 72 hours (4.7±1.4-fold, p<0.001) in murine cells. Similar results were obtained with hPBMCs stimulated with bacterial superantigens or anti-CD3/CD28 beads. Upon TCR-specific stimulation of Jurkat T cells, BX-795 increased secreted IL-2 levels (4.0±0.38-fold, p<0.001), NFAT, NFκB and AP-1 reporter activity, and IL-2 mRNA levels while IFN-γ mRNA levels remained unchanged. In summary, BX-795 potently inhibits Th1 and Th2 while maintaining Th17 cytokines and strongly promotes IL-2 synthesis/secretion upon TCR ligation of murine and human T cells *in vitro*. Future experiments will reveal the molecular mechanisms underlying our observations and will clarify the Th2 blocking potency of BX-795 in allergen-specific asthma models *in vivo.*
Supported by the Austrian Science Fund (FWF) projects DK W1248, SFB-F4609 and the Medical University of Vienna.

P.C5.02.20
Transient expression of the major birch pollen allergen Bet v 1 in the tobacco *Nicotiana benthamiana* using *in planta* assembled TMV-based provectors

***Ö. Üzülmez**, V. Mayr, A. Tscheppe, C. Palladino, H. Breiteneder;*
Institute of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria.

Birch is the main pollen-allergen-producing tree in mid- and northern Europe. Its major allergen, Bet v 1, is considered an important inducer of tree pollen and related plant food allergies. Here, we present a platform technology for expressing plant-derived allergens in a plant system.
Agrobacterium tumefaciens, a plant pathogen, contains a Ti plasmid enabling the delivery of T-DNA into plant cells. We used two tobacco mosaic virus (TMV)-based provectors that harbor either T-DNA encoding Bet v 1 on a 3'-module or viral proteins on a 5'-module. A third provector delivered phiC31 integrase for recombining the 5'- and 3'-modules. Plants were infiltrated under vacuum while submerging leaves into a suspension of agrobacteria transformed with the corresponding plasmids. The mRNA synthesis of Bet v 1 was achieved after a successful recombination which brought the subgenomic promoter, polymerase, and allergen sequences together.
Recombinant (r) allergen, including a C-terminal hexa-histidine tag, was extracted from the leaves and isolated using Ni-NTA loaded beads. The purified rBet v 1 was able to bind both the mouse monoclonal anti-Bet v 1 antibody Bip 1 and IgE from birch pollen allergic patients' sera. After optimizing infiltration rates and incubation times of the plants, the highest expression yield of rBet v 1 was 12 mg per kg fresh leaf.
We made use of this *in planta* expression system for the first time to produce a plant-derived allergen. We will apply this system for more complex allergens in the future.
Supported by Austrian Science Fund doctoral program W1248-B30.

P.C5.02.21
CyTOF analysis of nasal tissue cell composition in allergic rhinitis patients following controlled allergen challenge

***A. Voskamp**[1], M. Gerdes[2], E. Duijster[2], K. de Ruiter[1], T. Groot Kormelink[3], S. de Jong[1], M. Yazdanbakhsh[1], E. de Jong[3], R. Gerth van Wijk[2], H. Smits[1];*
[1]LUMC, Leiden, Netherlands, [2]Erasmus MC, Rotterdam, Netherlands, [3]AMC, Amsterdam, Netherlands.

Allergic immune responses are well characterized and typically dominated by T helper 2 cells and allergen-specific IgE. Most knowledge on allergic immune responses is based on peripheral blood cells from allergic patients or from animal models. Information on tissue-specific responses is scarce, however allergen-specific immune responses are initiated locally and this information is crucial for the development of novel therapies. Nasal biopsies provide valuable information regarding the upper airway immune responses, however the number of cells obtained from these biopsies is a limiting factor. A recently developed technique, combining mass-spectrometry and cytometry (CyTOF) overcomes this limitation by measuring up to 42 phenotypic cell markers in one measurement.
In this study nasal biopsies were taken from 15 allergic rhinitis patients and 15 healthy controls, before and after nasal challenge with House Dust Mite allergen. The biopsies were digested and the cellular composition of the resulting single-cell suspensions were measured by CyTOF.
Our analysis shows clear differences in cellular composition between nasal tissue and peripheral blood. Nasal tissue contained mast cells, plasma cells and dendritic cell populations, which were absent or present in low numbers in the blood. In accordance with their atopic status, patients could be distinguished from healthy controls based on increased FcεRI expression levels on dendritic cells, monocytes and mast cells. The results will provide a comprehensive overview of the local cellular responses to allergen challenge in both allergic and healthy individuals.
This study was funded by the Longfonds.

P.C5.02.22
Role of the membrane trafficking regulator Lyst during type 1 allergic responses

***A. Westphal**, F. Niko, K. H. Lee;*
Inflammation Research Group, Institute of Clinical Chemistry, Hannover Medical School, Hannover, Germany.

Mast cells are key effector cells in human allergic disorders and inflammatory disease. The activation of mast cells via antigen-mediated triggering of FcεRI causes immediate degranulation and release of pro-inflammatory mediators in a process that involves poorly characterized vesicle transport and membrane fusion events. LYST is an evolutionary conserved regulator of lysosomal trafficking. Mutations in the LYST gene cause human Chédiak-Higashi syndrome (CHS) and the orthologous phenotype in *beige* (*Bg-J*) mice. A diagnostic feature of this severe immunodeficiency disorder is the accumulation of enlarged lysosome-related granules in a variety of cells, including mast cells. The aim of this study was to characterize role of lysosomal trafficking regulator Lyst for mast cell-mediated anaphylactic reactions.
We here report that in two different FcεRI-mediated animal disease models of passive systemic and passive cutaneous anaphylaxis, Lyst-mutant *Bg-J* mice display substantially enhanced immediate anaphylactic reactions. Subsequent mechanistic *in vitro* studies in bone marrow-derived mast cells (BMMCs) aimed at identifying the underlying mechanism surprisingly revealed normal FcεRI-mediated release of preformed mediators. However, *Bg-J* mice showed exacerbated allergic responses when injected with a mix of mediators from degranulated BMMCs, suggesting a mast cell-independent but rather tissue-dependent mechanism. Interestingly, *Lyst*-mutant BMMCs exhibited impaired *de novo* secretion of inflammatory cytokines, which correlated with impaired recruitment of inflammatory immune cells during the second phase of the anaphylactic response *in vivo*.
In summary, our data demonstrate a negative tissue-dependent regulatory role of Lyst in immediate allergic reactions and indicate a role during *de novo* secretion in mast cells.

A regulatory macrophage phenotype induced by IgG4: implications for allergen immunotherapy-mediated immune tolerance

***R. Bianchini**[1], F. Roth-Walter[1], A. Ohradanova-Repic[2], S. Flicker[3], M. B. Fischer[4,5], H. Stockinger[2], E. Jensen-Jarolim[1,3];*
[1]The Interuniversity Messerli Research Institute, University of Veterinary Medicine Vienna, Medical University of Vienna, Dept. of Comparative Medicine, Vienna, Austria, [2]Institute for Hygiene and Applied Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, [3]Institute of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, [4]Medical University Vienna, Dept. of Blood Group Serology and Transfusion Medicine, Vienna, Austria, [5]Danube University Krems, Dept. of Health Science and Biomedicine, Vienna, Austria.

Background: The presence of pro-allergic M2a macrophages is a characteristic of the immediate type of allergy and probably allergen-specific immunotherapy (AIT) is associated with the occurrence of IgG4 is considered and probably of the immunoregulatory M2b subtype. So far, no clear tolerance function is associated with IgG4. Here, we investigated whether IgG4, has implications in the conversion of the M2a into M2b-like phenotype as a new concept to explain the AIT-mediated immune tolerance. **Methods:** The *in vitro* protocol for alternative macrophage polarization was modified and M2a macrophages were incubated on plates-coated with myeloma IgG1 or IgG4, or with recombinant human anti-Phl p 5 specific-IgG1 or IgG4, to mimic the presence of immune complexes. M2a polarized cellular markers and cytokines were analyzed by flow cytometry, ELISA, and rtPCR. **Results:** Immune complexes with myeloma- and allergen-specific IgG4 pushed M2a cells to alter their phenotype and function. Down-regulation of CD163 and CD206, and a significant increase in IL-10, IL-6, TNFα and CCL1 secretion indicated a shift to an M2b-like phenotype. Fc gamma receptors (FcγRs) analyses revealed that treatment with IgG4 containing ICs resulted in almost exclusive expression of FcγRII and down-modulation of FcγRII in comparison with IgG1 treated cells (p= 0.0335) or untreated cells (p < 0.00001). **Conclusion:** Our findings indicate that the IgG4 subclass can redirect pro-allergic M2a macrophages to an M2b-like immunosuppressive phenotype. This may suggest the involvement of macrophages in tolerance induction in AIT. **Supported by FWF-project SFB F4606-B28 to EJJ.**

Allergenic potencial of aquaculture fish due to the presence of Anisaki sp L3 proteins

M. Carballeda Sangiao[1], *A. Rojas Gomez*[1], *I. Sánchez Alonso*[2], *M. Careche Recacoechea*[3], *S. Cobacho Arcos*[2], *A. Navas Sánchez*[2], *S. Pascual del Hierro*[2], *M. González-Muñoz*[1];
[1]*Foundation for Biomedical Research Hospital La Paz, Paseo de la Castellana, 28046 Madrid, Spain, Madrid, Spain,* [2]*State Agency Superior Council of Scientific Research, CSIC, Madrid, Spain., Madrid, Spain,* [3]*State Agency Superior Council of Scientific Research, CSIC, Madrid, Spain, Madrid, Spain.*

Some feed components can be carried-over into and detected in animal products. The aim of this work was to detect *Anisakis* sp. antigens/allergens in aquaculture fish due to carry-over from fish feed. We have analyzed 4 aquaculture fish (*Scophthalmus maximus*) and 2 fish feed collected in Spanish farm. Protein extracts from fish and feed were prepared and the presence of parasite allergens was assessed by immunoblotting using anti-Ani s 4 antisera and a pool of *Anisakis* allergic patients' sera. Allergens were identified by sequencing analysis and basophil activation test was performed to assess if the allergens were functionally active. Allergens were detected in both fish and feed extracts with anti-Ani s 4 and patient' sera. In addition, both extracts were able to activate basophils. The presence of Ani s 4 was confirmed by immunoblotting inhibition and specific peptides of *Anisakis* sp. haemoglobin, enolase, Ani s 9 were identified by mass spectrophotometry. Aquaculture fish contain *Anisakis sp*. allergens and can pose an unsuspected source of parasite allergens. The presence of allergens of *Anisakis sp*. in feed suggests that these allergens are carried-over from feed.

P.C5.03.03

Regulatory T cells in cord blood of children of allergic and healthy mothers

V. Černý[1], *O. Novotná*[1], *P. Petrásková*[1], *K. Macholdová*[1], *K. Boráková*[2], *L. Prokešová*[1], *J. Hrdý*[1];
[1]*Institute of Immunology and Microbiology, First Faculty of Medicine, Charles University, Prague, Czech Republic,* [2]*Institute for the Care of Mother and Child, Prague, Czech Republic.*

Allergic diseases represent a major issue in both clinical and experimental immunology. Despite intensive research, allergy status of the mother remains the strongest universally accepted predictor of increased risk of allergy development.
Dysregulation of balance among branches of immune response, chiefly an excess of Th2 polarization, is a key underlying cause of allergic diseases. Regulatory T cells (Treg) are crucial for maintaining the correct balance and inducing tolerance towards allergens. Functional deficiency of Treg may therefore contribute to increased risk of allergy.
We studied Treg in cord blood of children of healthy mothers (with lower risk of allergy development) and allergic mothers (with relatively higher risk) by flow cytometry, aiming to find markers which could help predict allergy development. We observed higher percentage of Treg in cord blood of high-risk children compared with lowrisk group. However, expression of several markers of Treg function (intracellular IL10 and TGF-β, MFI of FoxP3, PD1) was decreased in Treg of high-risk children. These results may be explained by an expansion of Treg population trying to compensate for inadequate regulatory capacity.
We attempted to further characterize functional ability of Treg directly (inhibition of proliferation of CFSE stained target cells) and by expression analysis of selected genes (qPCR). Using flow cytometry we also analyzed expression of Helios, a transcription factor originally considered specific for thymic-derived Treg, which may also be upregulated during T cell activation.

Cytokine patterns and impaired cytotoxic activity ofNK cells in children withatopic dermatitis

E. Cetin Aktas[1], *N. Akdeniz*[1], *S. Baris*[2], *E. Karakoc-Aydiner*[3], *I. Barlan*[2], *G. Deniz*[1];
[1]*Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology, İstanbul, Turkey,* [2]*2Marmara University , Research and Training Hospital, Division of Pediatric Allergy and Immunology, İstanbul, Turkey,* [3]*Marmara University , Research and Training Hospital, Division of Pediatric Allergy and Immunology, Istanbul, Turkey.*

Atopic dermatitis (AD) is the most common chronic, and pruritic inflammatory skin disease skin disease, and primarily affects children. The role of NK cells in development of this disease is still poorly documented. The current study was undertaken to determine NK1, NK2 and NK regulatory cytokine profiles, the expression of activatory receptors as well as the cytotoxic activity of NK cells in children with AD. The study group consists of atopic (n=10), non-atopic (n=6) and healthy subjects (n=13). Patients were multisensitized and had high serum total IgE levels. Cytotoxic capacity, expression of $CD56^{bright}$ and $CD56^{dim}$ NK cell subsets, NKG2D, NKp46 and CD94 expressions, and intracellular IL-4, IL-10 & IFN-γ levels were determined by flow cytometry. The percentages of $CD3^{-}CD16^{+}CD56^{+}$and $CD56^{dim}$ NK cells were significantly diminished in atopic patients compared to healthy subjects, $CD56^{dim}CD16^{bright}$ NK cell subset was significantly increased in non-atopic children than atopic group. In contrast to diminished cytotoxic capacity, expression of $CD56^{bright}CD3^{-}IFN\text{-}\gamma^{+}$ NK cells, increased expression of activatory receptor NKp46, $CD56^{bright}CD3^{-}IL\text{-}4^{+}$ and $CD56^{bright}CD3^{-}IL\text{-}10^{+}$ NKcells in whole AD children compared to those with healthy subjects were obtained. High percentages of IL-4 and IL-10 producing NK cell subsets demonstrating an Th2 and regulatory type cytokine tendency of NK cells in AD patients. Our findings suggested impaired NK cell functions in AD patients implying high activation, accompanied by decreased cell cytotoxicity, which would contribute to the pathogenesis of disease and partially explain the tendency to the skin viral infections observed in those patients.

P.C5.03.05

Toll-like receptor 2 ligation enhances therapeutic effects of mesenchymal stem cells on murine model of asthmatic inflammation

H. Yu, ***T. Chen****, B. Chiang;*
Graduate Institute of Clinical Medicine, Taipei City, Taiwan.

Introduction: Under current therapeutic strategies, the cure to asthma remains elusive; thus- novel approaches for treating asthma are desperately needed. Despite that mesenchymal stem cells (MSCs) have recently been established as potential candidates by virtue of their immunomodulatory properties, the underlying heterogeneity of MSCs diminishes their therapeutic efficacy.
Materials and Methods: Here we evaluated a toll-like receptor (TLR) 2 ligation protocol of MSCs to augment their therapeutic benefits on asthma.
Results: We surmise that a TLR2 ligand, Pam_3CSK_4, enhanced the therapeutic effects of MSCs on asthmatic inflammation in mice at low concentration (1 μg/mL) for a longer induction period (96 h) in a post-treatment manner. We further validated this regimen by demonstrating that Pam_3CSK_4 activated STAT3 in BM-MSCs through IL-6, which was likely stimulated with NF-κB signaling. NO, the key suppressive molecule of Pam_3CSK_4-primed BM-MSCs, was later highly increased through upregulation of iNOS, which was in the downstream of STAT3 phosphorylation. The intensified suppressive functions of BM-MSCs were then executed by inducing $CD4^{+}CD25^{+}Foxp3^{+}$ regulatory T cells in a post-treatment manner.
Conclusion: The results demonstrated that TLR2 ligand, Pam_3CSK_4, could modulate the function of BM-MSCs and alleviate airway inflammation. The consistent therapeutic outcomes and the valid suppressive mechanisms in the study might shed light on eliminating the proinflammation-prone uncertainties of MSCs, and enhancing the future feasibility of obtaining long-term effects with this regimen.

Are eosinophils major contributors to oxidative stress during asthma exacerbations?

L. E. S. de Groot[1], *Y. S. Sabogal Piñeros*[1], *S. M. Bal*[1], *M. A. van de Pol*[1], *W. Kulik*[1], *T. A. van der Veen*[2], *B. N. Melgert*[2], *F. O. Martinez*[3], *J. Hamann*[1], *R. Lutter*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*University of Groningen, Groningen, Netherlands,* [3]*University of Surrey, Guildford, United Kingdom.*

Introduction: Asthma exacerbations are predominantly triggered by respiratory viral infections and characterized by eosinophilic airway inflammation and increased oxidative stress. Eosinophils can produce reactive oxygen species (ROS) and a link between eosinophils and oxidative stress during exacerbations is thus likely. Attenuation of eosinophils using anti-IL-5 (Mepolizumab) in severe asthmatics significantly reduces exacerbation rates and corticosteroid dependency. Yet, the impact of reduced eosinophils on ROS production has not been investigated so far. Therefore, we aimed to study the contribution of eosinophils to oxidative stress during virus-induced asthma exacerbations.
Methods: Mild asthmatics received one high dose of Mepolizumab or placebo and after two weeks were subjected to rhinovirus 16 (RV16) infection. Exhaled breath condensate was collected before and after RV16 and levels of malondialdehyde (MDA), asymmetric dimethylarginine, nitrotyrosine, bromotyrosine, chlorotyrosine and dityrosine were measured using ultra-performance liquid chromatography-tandem mass spectrometry.
Results: Mepolizumab effectively attenuated eosinophil numbers in the circulation and locally in the airways. Oxidative stress levels before RV16 challenge were comparable between the groups. MDA near-significantly and nitrotyrosine significantly increased after virus exposure in the placebo group, but not in the Mepolizumab group. When stratified for patients with high and low eosinophil counts, MDA levels significantly increased in the high eosinophilic placebo group only.
Conclusion: RV16 infection in mild asthmatics is accompanied by enhanced oxidative stress levels, which can be ameliorated by Mepolizumab. Our findings suggest that eosinophils drive oxidative stress during virus-induced asthma exacerbations.

Amelioration of itch and reduced mast cell degranulation by single-stranded oligonucleotides

A. Dondalska[1], *E. Rönnberg*[2], *H. Ma*[3], *S. Pålsson*[1], *E. Magnusdottir*[3], *L. Adam*[1], *G. Nilsson*[2], *M. Lagerström*[3], *A. Spetz*[1];
[1]*Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm, Sweden,* [2]*Immunology and Allergy Unit, Department of Medicine, Karolinska Institute, Solna, Sweden,* [3]*Department of Neuroscience, Uppsala University, Uppsala, Sweden.*

Introduction: Itch is a large problem in numerous skin disorders. The Mas-related G protein-coupled receptor X2 (MRGPRX2) has been shown to modulate itch by inducing non-IgE-mediated mast cell degranulation and the release of endogenous inducers of pruritus such as histamine. Various basic cationic substances, including inflammatory peptides and certain drugs, can trigger MRGPRX2 and thereby induce pseudo-allergic reactions characterized by histamine release and inflammation. Here, we investigated the capacity of an immunomodulatory single-stranded oligonucleotide (ssON) to inhibit itch and mast cell degranulation. Materials and Methods: To determine the effect of ssON on itch, we performed behavioral studies in established mouse models and collected skin biopsies. We examined the effect of ssON on MRGPRX2 activation *in vitro* by measuring degranulation (flow cytometry, ELISA) in a human mast cell line and calcium influx in MRGPRX2-transfected cells. Results: We observed that intradermal injection of ssON in mice was able to inhibit itch induced by the basic secretagogue C48/80 in a dose-dependent manner. Evaluation of histological staining at the injection site revealed that ssON appeared to inhibit mast cell degranulation in murine skin treated with C48/80. SsON also demonstrated the capacity to inhibit MRGPRX2 activation *in vitro* by blocking mast cell degranulation and calcium influx in MRGPRX2-transfected cells induced by certain basic secretagogues in a dose-dependent manner. Conclusions: SsON can inhibit IgE-independent mast cell degranulation and itch. Since there is a need for small molecules to block MRGPRX2-mediated activation of mast cells, ssON could be utilized to ameliorate itch in certain pathological settings

P.C5.03.08

The non-obese diabetic mouse as a novel model for severe allergic asthma: the respective roles for T_H2 and IL-17-producing cells

A. Foray[1,2,3], *C. Marquet*[1,2], *C. Pecquet*[1,2], *C. Dietrich*[1,3], *F. Machavoine*[1,3], *M. Dy*[1,2,3], *J. Bach*[1,2,3], *L. Chatenoud*[1,2,3], *M. Leite de Moraes*[1,2,3];
[1]*Faculté de Médecine Paris Descartes, Université Paris Descartes, Paris, France,* [2]*Institut National de la Santé et de la Recherche Médicale, Unité 1151, Laboratory of Immunoregulation and Immunopathology, Institut Necker-Enfants Malades, Paris, France,* [3]*Centre National de la Recherche Scientifique, UMR 8253, Laboratory of Immunoregulation and Immunopathology, Institut Necker-Enfants Malades, Paris, France.*

Paradoxically, the Non-Obese Diabetic (NOD) mouse, a prototypic model of T_H1-mediated autoimmune diabetes, is highly prone to develop allergic reactions. Here, in a classical house-dust mite (HDM)-induced asthma model, we compared NOD and BALB/c mice responses and dissected the pattern of cytokine-producing cell subsets *in situ*.
NOD mice exhibited exacerbated airway hyper-reactivity as assessed, using the FlexiVent device, by the resistance after methacholine challenge (10±1.9 vs. 4±0.8 $cmH_2O.s.mL^{-1}$ at 25mg MCh, in NOD and BALB/c respectively, *P*<0.01). Allergic airway inflammation was enhanced, as reflected by increased eosinophil counts in the bronchoalveolar lavage fluids of NOD mice ($5.1x10^5$ cells±0.6 vs. $0.7x10^5$±0.2, *P*<0.01), as were circulating anti-HDM IgG1 levels (0.76±0.15 vs. 0.26±0.01 OD, *P*<0.01). Interestingly, the pattern of cytokine-producing cells was clearly distinct in the lungs of asthmatic NOD mice as compared to BALB/c. First, the proportions of IL-4, IL-13 and IL-5 producing $CD4^+$ T cells were increased (13.2%±3.1 vs. 6.7%±0.6, 9.1%±0.5 vs. 2.7%±0.2, and 5.9%±0.6 vs. 2.0%±0.3 respectively, all *P*<0.01). Secondly, CD4+ T cells were the major IL-5 producers in NOD mice (60.8±4.0% $TCR\beta^+CD4^+$ among $IL\text{-}5^+$ cells) while in BALB/c the source of IL-5 were type 2 ILCs (60.6±6.7% Lin^-CD127^+). Third, an exacerbated production of IL-17 was found of NOD mice which sources included conventional $CD4^+$ T cells (3.1%±0.3 vs. 1.1%±0.2, *P*<0.01), iNKT17 cells (11.2%±1.5 vs. 1.6%±0.1, *P*<0.01) and IL-17-producing $V\gamma1^+$ T cells (2.8%±0.4 vs. 0.9%±0.4, *P*<0.05). Our results demonstrate that the NOD strain develops a unique form of severe allergic-induced asthma associated with exacerbated TH2 and IL-17-biaised immune responses.

Efficacy of montelukast in the treatment program of persistent atopic asthma

I. Garmish, *O. Shtepa;*
SE "Dnipripetrovsk medical academy of Health Ministry of Ukraine", Dnipro, Ukraine.

The aim of our study was to evaluate the effectiveness of montelukast in the treatment program of persistent atopic asthma in women and to estimate the diagnostic value of general serum IgE and forced expiratory volume on first second (FEV_1) during the decreasing level of bronchial obstruction. Materials and Methods. We observe 95 patients (pts) with persistent atopic asthma. They were divided into groups: main group - 60 pts who received montelukast (10 mg, orally), as add-on therapy to inhaled corticosteroids (ICS) and bronchodilators, group of compared - 35 pts who received only ICS and bronchodilators. IgE antibodies were assayed with electrochemiluminescence immunoassay analyzer in addition to general examination and spirometry. Results. This study indicated that main group IgE levels were 306,5+/-17,98 IU/ml, while the group of compared - 301,1+/-26,16 IU/ml. Following the montelukast therapy there was a statistically difference in general IgE levels (p□0.001) in main group (IgE 128,6+/-8,54 IU/ml) and wasn□t significantly reduced (p□0.05) in group of compared (IgE 295,6+/-8,54 IU/ml). The indicators of the FEV_1 at main and comparison groups after treatment significantly increased (p□0.05), also there was statistically difference (p□0.05) between main group (FEV_1 - 82,2+/-0,18 %) and group of compared (FEV_1 - 87,3+/-0,32 %). The data indicated a correlation between serum IgE levels and FEV_1 (R=0,712, p□0.05). Conclusions. Montelukast significantly better increase FEV_1 and decrease general IgE level, improving clinical, functional manifestations of persistent atopic asthma in women and increasing anti-inflammatory effects.

Structure and biochemical characterization of wheat β-amylase, a clinically relevant food allergen

G. Hofer[1], *S. Wieser*[2], *M. Bogdos*[1], *P. Gattinger*[2], *R. Valenta*[2], *W. Keller*[1];
[1]*Institute of Molecular Biosciences, University of Graz, Graz, Austria,* [2]*Division of Immunopathology, Department of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria.*

Introduction: Wheat is one of the most important staple foods worldwide and has been recognized as a potent allergen source. However not all known potential allergens of wheat have been characterized so far. The wheat β-amylase has been found to bind IgE of wheat allergic patient, but its structure and allergenic activity have not been studied.
Methods: Wheat β-amylase was expressed in native and non-native (aggregated) forms in *E. coli* and biochemically characterized by size exclusion chromatography, circular dichroism spectroscopy, differential scanning fluorimetry and activity assays. Finally, the enzyme was crystallized and the structure solved to 2 Å.
Results: The crystal structure of wheat β-amylase shows the same $(\beta/\alpha)_8$-barrel architecture found for other plant and bacterial β-amylases. The enzyme shows a tolerance for low pH, showing maximum activity at pH 5 and retaining over 80% of its maximum activity even at pH 4. However, more than 50% activity is lost at pH 8. The protein is most thermally stable in slightly acidic conditions. A maximum in melting temperature is seen at pH 5.5 with 59°C, with a tail off to lower values as pH increases and a sharp drop in stability at pH 4.
Conclusion: The recombinant expression of natively folded wheat β-amylase was successful and provides a useful tool for screening since the IgE recognition of allergic patients shows a clear difference between natively and non-natively folded recombinant β-amylase.

P.C5.03.11

Analysis of nutrient composition of breast milk with the allergic severity in infantile atopic dermatitis

Y. Huang[1], *L. Wang*[2], *B. Lin*[3], *B. Chiang*[2];
[1]*Department of Pediatrics Taipei Medical University-Wan Fang Hospital, Taipei City, Taiwan,* [2]*Department of Pediatrics National Taiwan University Hospital, Taipei City, Taiwan,* [3]*Department of Biochemical Science and Technology, College of Life Science, National Taiwan University, Taipei City, Taiwan.*

Introduction: Atoptic dermatitis (AD) is a chronic allergic skin disease with a typical symptom of pruritic rash. We aim to determine the differences of nutrient components in the breast milk, maternal diet pattern analysis during lactation, between atopic dermatitis and healthy infants. Methods: We conducted a prospective study to determine the differences of components(oligosaccharides, microbiota, Vitamin A, Vitamin D and fatty acid), in the breast milk, between infantile AD and healthy infants. We collected breast milk at 2 and 6 month postpartum and the mothers are interviewed by the dietician for the diet questionnaireat (diet pattern analysis) at the same time.Results: We enrolled 87 infants in our prospective study, of which 52 infants with infantile atopic dermatitis (study group) and 35 of them was healthy infants (control group). Infants with infantile atopic dermatitis might have a tendency of having parental history of atopic dermatitis (N=35, 81.4%, P value=0.27) than that of healty infants (N=16, 69.6%,P value=0.27). The fatty acids analysis of breast milk at 2-month post-partum showed that no significant difference between two groups. However, Vitamin D level in the breast milk for healthy infants was higher then those for infants with atopic dermatitis (P value < 0.01).Conclusion. It is suggested that dietary factors might play a critical role in immune modulation and disease severity of allergic diseases. We demonstrated that lower vitamin D level was noted in the breast milk of mother having baby with infantile atopic dermatitis.

P.C5.03.12
Characterization of urticaria in children

P. H. Huang[1,2], *J. H. Lee*[2], *B. L. Chiang*[2];
[1]*Department of Pediatrics, Cardinal Tien Hospital, New Taipei City, Taiwan,* [2]*Department of Pediatrics, National Taiwan University Hospital, Taipei, Taiwan.*

Introduction: The etiologies of acute urticaria vary, with the leading cause is infection in pediatric group. In contrast, infection only accounts for a minority of cause in the adult group. A previous study indicated that atopic diseases are related to acute urticaria, but not chronic urticaria. In addition, the percentage of acute versus chronic urticaria are different in children and adults. This study is to evaluate the age distribution of urticaria types, etiologies, and relationship with atopy in children.
Material and methods: Patients' data are obtained retrospectively by chart review. Types of urticaria are classified according to 2018 revision of EAACI/GA2LEN/EDF/WAO Guidelines for Definition, Classification, Diagnosis and Management of Urticaria. Identification of etiologies are from notes and questionnaires to the family if necessary. The included patients are divided into 4 age groups (0-<3, 3-5, 6-11, 12-18) to compare the differences among age groups.
Results: The results showed the ratio of acute versus chronic urticaria is 4:1. The overall age statistics revealed a male predominance and the female/male ratio is 0.76. Of all the identifiable etiologies, infection is the leading cause of acute urticaria (33.5%), whereas there is only 2.4% patients with chronic urticaria caused by infection. Allergic diseases were found in over one third patients with acute urticaria while only 11% in that with chronic urticaria.
Conclusion: Our findings suggested there was much difference in etiologies and relationship with atopy between acute and chronic urticaria in overall age groups. Further analysis addressing the different age groups will be further reported.

P.C5.03.13
The transcription factor EPAS1 links DOCK8 deficiency to atopic skin inflammation via IL-31 induction

K. Kunimura[1], *K. Yamamura*[1], *Y. Fukui*[1,2];
[1]*Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan,* [2]*Research Center for Advanced Immunology, Kyushu University, Fukuoka, Japan.*

Introduction: Mutations of DOCK8 in humans cause a combined immunodeficiency characterized by atopic dermatitis. However, the molecular link between DOCK8 deficiency and atopic skin inflammation is unknown. Materials and Methods: The skin disease development was compared between Dock8$^{-/-}$ and Dock8$^{+/-}$ mice expressing TCR transgene. After stimulation with the cognate antigen, CD4$^+$ T cells were used for cytokine production assay, microarray analysis and ChIP assay. IL-31 promoter activation, EMSA and immunoprecipitation were performed by standard techniques. Nuclear translocation of EPAS1 was examined in mouse embryonic fibroblasts generated from wild-type and Dock8$^{-/-}$ mice.
Results: We found that unlike Dock8$^{+/-}$ mice, Dock8$^{-/-}$ mice spontaneously developed severe atopic skin inflammation, when crossed with transgenic mice expressing TCR with a particular antigen specificity. Upon stimulation, CD4$^+$ T cells from Dock8$^{-/-}$ mice produced large amounts of IL-31, a major pruritogen associated with atopic dermatitis. This IL-31 induction critically depended on the transcription factor EPAS1, and its conditional deletion in CD4$^+$ T cells abrogated skin disease development in Dock8$^{-/-}$ mice. Although EPAS1 is known to form a complex with aryl hydrocarbon receptor nuclear translocator (ARNT) and control hypoxic responses, EPAS1-mediated Il31 promoter activation was independent of ARNT, but in collaboration with SP1. In addition, we found that DOCK8 acted as an adaptor and negatively regulated nuclear translocation of EPAS1. Conclusions: EPAS1 links DOCK8 deficiency to atopic skin inflammation via IL31 induction in CD4$^+$ T cells.

P.C5.03.14
The role of CD133 in the development and immune modulation of SSEA-1$^+$ lung stem/ progenitor cells

C. Liao[1], *C. Chiu*[1], *B. Chiang*[1,2];
[1]*Graduate Institute of Immunology, College of Medicine, National Taiwan University, Taipei, Taiwan,* [2]*Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.*

Introduction: In the previous studies, we had identified a subset of lung stem/ progenitor cells from neonatal mice lungs, SSEA-1$^+$ pulmonary stem/ progenitor cells (SSEA-1$^+$PSCs). SSEA-1$^+$PSCs are able to self-renew and differentiate into airway ciliated and alveolar cells. Interestingly, SSEA-1$^+$PSCs but not SSEA-1$^-$ cells are capable to suppress allergic airway inflammation in OVA-induced allergic asthma mouse model. However, we found that SSEA-1$^+$PSCs are further divided into two cell populations by CD133 expressing or not. In the present studies, we analyzed the stem-ness and functions of CD133$^+$SSEA-1$^+$PSCs and CD133$^-$SSEA-1$^+$PSCs. **Materials and Methods:** CD133$^+$SSEA-1$^+$PSCs and CD133$^-$SSEA-1$^+$PSCs were isolated from neonatal mice lungs. Cells were analyzed by qPCR, cell differentiation assays and 3D culture. OVA-induced allergic airway inflammation were used to analyze the immuno-regulatory function of the cell populations. **Results:** In comparison with the gene expression profile, CD133$^+$SSEA-1$^+$PSCs are expressed higher levels of airway-related genes than CD133$^-$SSEA-1$^+$PSCs. Although both the cell populations could differentiate into alveolar cells, only CD133$^+$SSEA-1$^+$PSCs are able to differentiate into airway ciliated cell. To evaluate the stem/ progenitor properties, cells are subjected to 3D culture. We found that both CD133$^+$SSEA-1$^+$PSCs and CD133$^-$SSEA-1$^+$PSCs generated organoids during 3D culture, suggesting the stem-ness of both cell populations. To determine the immuno-regulatory ability of CD133$^+$SSEA-1$^+$PSCs and CD133$^-$SSEA-1$^+$PSCs in allergic airway inflammation, cells are intravenously transferred into murine model of asthma. Results showed that the allergic airway inflammation are suppressed by both cell populations. **Conclusions:** We demonstrated that neonatal mice lung-derived CD133$^+$SSEA-1$^+$ and CD133$^-$SSEA-1$^+$ cell populations exhibited the stem cell activities and immuno-regulatory functions.

P.C5.03.15
Effect of chronic stress in a mouse model of contact hypersensitivity

A. MacKerracher[1], *A. Sommershof*[1], *M. Groettrup*[1,2];
[1]*University of Konstanz, Konstanz, Germany,* [2]*Biotechnology Institute Thurgau, Kreuzlingen, Switzerland.*

Chronic stress is known to have a suppressive effect on the immune system via the secretion of glucocorticoids mediated by the hypothalamus-pituitary-adrenal (HPA) axis. Interestingly, chronic stress is known to increase the susceptibility and disease progression of inflammatory skin diseases in humans. We studied inflammatory skin reactions in a well-established mouse model of contact dermatitis termed contact hypersensitivity (CHS) using the established contact allergens DNTB (2,4-dinitrothiocyanobenzene) and DNFB (2,4-dinitrofluorobenzene). DNTB is a weak contact allergen that does not trigger allergic reactions in non-allergic individuals, but instead has been shown to induce tolerance to the strong contact allergen DNFB. Tolerance induction in this model is facilitated by Langerhans cells (LC), which migrate from the epidermis to draining lymph nodes (dLNs), where they activate regulatory T cells and lead to the inactivation of specific cytotoxic CD8+ T lymphocytes. We have shown that tolerance induction in response to the weak contact sensitizer is strongly reduced in stressed mice. Furthermore we were able to prove that the reduced tolerance induction is accompanied by significantly impaired migration of LCs from the epidermis to dLNs following application of DNTB. We could further show that impaired migration of LCs in stressed mice is due to a reduced activation of LCs in the sensitized skin. Collectively our results suggest that chronic stress alters the reactivity towards contact allergens leading to a higher susceptibility to establish CHS reactions even towards weak contact allergens.

P.C5.03.16
Immunological effects of omalizumab in a group of long-term treated asthma patients

L. Maggi[1], *B. Rossettini*[1], *G. Montaini*[1], *A. Matucci*[2], *A. Vultaggio*[2], *A. Mazzoni*[1], *E. Maggi*[1], *F. Liotta*[1], *F. Annunziato*[1], *L. Cosmi*[1];
[1]*University of Florence, Florence, Italy,* [2]*Azienda Ospedaliero-Universitaria Careggi, Florence, Italy.*

Background: The anti-IgE monoclonal antibody, omalizumab, has proven to be effective in the treatment of allergic severe uncontrolled asthma. The aim of the study was to evaluate the immunological effects of omalizumab, in a group of severe allergic asthma patients, treated since at least three years
Methods: Immune cell subsets have been evaluated in a cohort of 15 allergic asthmatic patients treated with omalizumab, and the data have been compared with 12 allergic asthma patients treated with standard therapy.
Results: Omalizumab treated asthmatic patients showed lower frequencies of circulating plasmacytoid dendritic cells, and lower CD154 expression on CD4 T helper cells respect to the control group. Moreover, basophils and DCs from omalizumab treated patients had lower levels of IgE on their surface respect to the control group, and this was the consequence of the reduction of FcεRI expression, but also some FcεRI free of IgE were detected. In a longitudinal evaluation of two patients that started omalizumab treatment, the presence of FcεRI free of IgE was evident just after the first administration of the drug. Finally we performed in vitro experiments on basophils obtained from healthy donors, that show that omalizumab is able to detach IgE from their receptors.
Conclusions: Collectively these data indicate that long-term omalizumab treatment dampen type 2 inflammation acting on different cell types that play a pivotal role in the pathogenesis of allergic asthma, Moreover a possible novel activity of omalizumab, the ability to detach IgE from their receptors, is suggested.

P.C5.03.17

Targeting the IL-7R alpha as a potential therapeutic approach for allergic asthma

H. L. Mai[1,2], *E. Nguyen*[1,2], *G. Bouchaud*[3], *K. Henrio*[4], *M. Cheminant*[4], *S. Dehmani*[1,2], *A. Magnan*[4], *S. Brouard*[1,2];
[1]*Centre de Recherche en Transplantation et Immunologie UMR 1064, INSERM, Université de Nantes, Nantes, France,* [2]*Institut de Transplantation Urologie Néphrologie, CHU Nantes, Nantes, France,* [3]*INRA BIA UR 1268, Nantes, France,* [4]*INSERM UMR 1087, Institut du Thorax, Nantes, France.*

Introduction: Asthma remains an important cause of morbidity and mortality. We herein provide for the first time a preclinical proof-of-concept for a novel therapeutic approach for allergic asthma using an anti-IL-7Rα mAb, which blocks both IL-7R and TSLPR. Methods: We used a murine asthma model in which mice received 4 weekly percutaneous sensitizations followed by 2 weekly intranasal (IN) challenges with total house dust mite (HDM) extracts as allergen. This model corresponds to a mixed asthma phenotype in which the bronchoalveolar inflammation comprises both neutrophils and eosinophils. Asthmatic mice were then treated with an anti-IL-7Rα mAb or an isotype control every other day during the 2 weeks of IN challenges. Results: Anti-IL-7Rα mAb blocks STAT5 phosphorylation in mouse CD4+ T cells induced by either IL-7 or TSLP. Compared to control animals, anti-IL-7Rα-treated mice showed significantly lower airway resistance in response to methacholine as measured by flexiVent, associated with an improvement in lung histology. Anti-IL-7Rα treatment significantly decreased the mRNA expression of Th2 cytokines (IL-4, IL-5, and IL-13) and chemokines (CCL5/RANTES) in lung tissue, decreased the secretion Th2 cytokines (IL-4, IL-5, and IL-13) and chemokines (CXCL1 and CCL11/eotaxin) in bronchoalveolar lavage fluid (BALF) as measured by luminex, and decreased serum HDM-specific IgE as measured by ELISA. Leukocyte phenotyping by flow cytometry revealed a reduction of eosinophils, total lymphocytes, T cells, and especially ILC2 in lung and BALF of anti-IL-7Rα-treated mice. Conclusion: Targeting the IL-7Rα by a mAb, through its broad mechanisms of action, presents as a potential therapeutic approach for asthma.

P.C5.03.18

Whole-proteome profiling of primary human mast cells reveals evolutionary conservation of cell-type specific pathways

T. Plum[1], *T. Feyerabend*[1], *M. Rettel*[2], *J. Krijgsveld*[1], *H. Rodewald*[1];
[1]*German Cancer Research Center, Heidelberg, Germany,* [2]*European Molecular Biology Laboratory, Heidelberg, Germany.*

Mast cells are bone marrow-derived immune cells that are present in tissues lining the environment. In these tissues mast cells sense environmental allergens, and upon recognition, become activated to release granules and generate inflammatory mediators. Mast cell-derived products confer protection against snake venoms and some parasite infections. However, aberrant activation of mast cells contributes to pathologies such as allergy, asthma and adverse drug reactions. To better understand the biology of mast cells and to identify novel functions, we assessed the proteome of primary human mast cells isolated from two different anatomical compartments by quantitative mass spectrometry. Using this approach, we identified a mast cell-specific proteomic signature consisting of prototypic mast cell markers such as KIT and FcεRI as well as proteins like VWA5A and FAM129B that were highly enriched in mast cells but for which no function has been reported yet. Protein expression of the most enriched mast cell-specific cell surface proteins was verified by flow cytometry, demonstrating marked differences between connective-tissue-type and mucosal-type mast cells in humans. We also compared proteome signatures of human and mouse mast cells which revealed striking conservation across species, in particular in pathways governing granule biosynthesis and secretion, as well as proteoglycan- and neurotransmitter metabolism, suggesting evolutionary maintenance of mast cell functions. This mast cell protein expression atlas shall aid in uncovering novel functions for this enigmatic cell type.

P.C5.03.19

Dupilumab in real life practice: patient's atopic profile, efficacy on atopic dermatitis and change in specific IgE

M. Tauber[1,2], *P. Apoil*[3], *C. Richet*[1], *G. De Bonnecaze*[4], *E. Mouchon*[4], *M. Cassagne*[5], *M. Marguery*[1], *S. Hegazy*[1], *M. Konstantinou*[1], *M. Severino*[1], *C. Uthurriague*[1], *F. Giordano-Labadie*[1], *A. Didier*[6], *C. Paul*[1,2];
[1]*Toulouse University, Dermatology and Allergology Department, Larrey Hospital, Toulouse, France,* [2]*INSERM-Paul Sabatier Toulouse University, U1056 UDEAR, Purpan Hospital, Toulouse, France,* [3]*Toulouse University, Immunology Department, Rangueil hospital, Toulouse, France,* [4]*Toulouse University, Ear Nose and Throat Department, Larrey Hospital, Toulouse, France,* [5]*Toulouse University, Ophtalmology Department, Pierre Paul Riquet Hospital, Toulouse, France,* [6]*Toulouse University, Pneumology and Allergology Department, Larrey Hospital, Toulouse, France.*

Introduction. Dupilumab is an antagonist of the Interleukin-4/13 receptors and was recently approved in Europe for use in adults with moderate-to-severe atopic dermatitis (AD). Our objective was to assess the impact of dupilumab therapy on both clinical (cutaneous, pulmonary, nasal and ocular symptoms) and biological (total and specific IgE, sIgE) parameters in real-life practice. Methods. Dupilumab was administered as labelled in the context of a Temporary Use Authorisation. Patients were evaluated initially (week 0, W0) and 16 weeks (W16) after the first injection. Follow-up parameters were: SCORing AD (SCORAD), visual analogue scale (VAS) for sleep and pruritus, Dermatology Life Quality Index (DLQI), Asthma Control Test (ACT), fraction of exhaled nitric oxide (FeNO), expiratory flow-volume curves, ophthalmologic and nasal symptoms, dosages of total and sIgE, using both single-tests and ImmunoCAP™ ISAC 112 biochip. Results. Nineteen patients were included (median age: 38 years). The median SCORAD was 49 at W0. SCORAD, DLQI, pruritus and sleep VAS decreased significantly at W16. There was no difference for ACT or the flow-volume curves but a significant decrease was observed for the FeNO. Eight patients presented either a de novo conjunctivitis (n=3) or a worsening of their ophthalmologic symptoms at W16. Four patients improved their rhinitis and one experienced worsening. Total IgE, sIgE against Malassezia or Staphyloccocus toxins, and ISAC sIgE (total of 517 values) decreased significantly at W16. However, there was no correlation with the SCORAD improvement. Conclusion. Dupilumab improves AD condition in real-life practice and modifies the sIgE sensitisation profile of the patients.

Plasma cytokine profiles during peanut oral immunotherapy in severely peanut allergic adolescents.

M. van der Heiden[1], *C. Carvalho-Queiroz*[1], *C. Nilsson*[2,3], *A. Nopp*[3], *E. Sverremark-Ekström*[1];
[1]*Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm University, Stockholm, Sweden,* [2]*Sachs' Children and Youth Hospital, Södersjukhuset, Stockholm, Sweden,* [3]*Department of Clinical Science and Education, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden.*

Peanut allergy is a major cause of anaphylaxis, hence effective treatment strategies for peanut allergy are warranted. Our previous work has shown that individualized omalizumab treatment (OT) allows a safe initiation and rapid up-dosing of peanut oral immunotherapy (pOIT) in severe peanut allergic adolescents.
We aimed to longitudinally follow the cytokine profiles in plasma samples of severely peanut allergic adolescents (n=19) undergoing combined OT and pOIT and subsequently compare these profiles between treatment failures (TF) (n=6) and successes (TS) (n=13).
Concentrations of plasma cytokines (IL2, IL4, IL5, IL9, IL10, IL12p70, IL13, IL21, GM-CSF, IFNg, TNFa) were determined by multiplex bead-based immunoassays and ELISA at 4 different time-points; before starting OT (baseline), at the peanut challenge after OT prior to starting pOIT (challenge), at maintenence dose pOIT prior to OT reduction (stepdown), and at the final peanut protein challenge (final visit).
Cytokine levels were relatively low and stable between the time-points. We noted an increase of IL-5 and IL-9 levels at the maintenence dose pOIT prior to OT reduction (stepdown time-point) in most individuals. Further, we observed higher concentrations of GM-CSF at the challenge time-point in the TF group.
These data indicate that most individuals have an ongoing Th2/Th9-type of response during pOIT. The higher GM-CSF levels at the challenge time-point in the TF group suggest a more active basophil compartment in these individuals. Future research will focus on chemokine responses as well as B and T cells underlying the treatment.

P.C5.03.21

Human immunoglobulin: an effective treatment for severe atopic dermatitis

P. E. Walo Delgado[1], *P. Lapuente Suanzes*[1], *A. Roncancio Clavijo*[1], *M. A. Ballester Martinez*[2], *A. De Andres Martin*[1];
[1]*Servicio de Inmunología, Madrid, Spain,* [2]*Servicio de Dermatología, Madrid, Spain.*

Introduction. Atopic dermatitis is the most prevalent inflammatory skin disease. Currently, there is a wide range of treatments that include phototherapy, topical treatment, cyclosporine and biological therapy with monoclonal antibodies. In severe cases, patients undergo prolonged therapy and high doses of drugs, which leads to the appearance of more adverse effects and comorbidity, such as increased risk of infections. **Materials and method.** We included 3 patients (42-year-old men, 58-year-old women, and 27-year-old women) with severe atopic dermatitis who had failed conventional treatment (including phototherapy, prednisone, cyclosporine, and Omalizumab). We have treated them with human immunoglobulin (IVIG), at doses of 0.8 mg / kg every 3-4 weeks, after signing informed consent and approval by the pharmacy committee of our hospital. **Results** All 3 patients had an important improvement of their symptom, with decreased pruritus and eczema. Two patients with asthma have presented improvement of respiratory symptoms. No adverse effects related to the treatment have been reported, except post-infusion headache. **Conclusion.** IVIG is an effective and safe alternative to treat severe atopic dermatitis due to its high capacity of immunomodulation. However, due to its high cost and limited production, it should be used in cases of refractory patients or when conventional treatment is contraindicated due to comorbidities.

P.C5.03.22

Structural characterization of different profilin allergens towards IgE-epitope prediction

***J. Wortmann**, J. Schöpp, A. M. Reisenbichler, G. Hofer, W. Keller;*
Institute of Molecular Biosciences, University of Graz, Graz, Austria.

Members of the profilin family are important panallergens causing respiratory allergy and oral allergy syndrome. Because of the high structural conservation within this family, profilin allergens serve as important targets for IgE-binding and epitope prediction studies. The aim of this project is the structure determination and biophysical characterization of five profilin allergens. The folded, recombinantly produced proteins will also be used for experimental determination of cross-reactivity between important respiratory as well as food allergens. The profilin family members included in this research project are the food allergens Cuc m 2 from melon (Cucumis melo) and Cit s 2 from orange (Citrus sinensis), the pollen allergens from olive tree Ole e 2 (Olea europaea), and timothy grass Phl p 12 (Phleum pratense) as well as the allergen Tyr p 36 from the storage mite Tyrophagus putrescentiae.
So far, all five profilin allergens could be recombinantly expressed and purified. Biophysical characterization including Circular Dichroism, Differential Scanning Fluorimetry and Size Exclusion Chromatography revealed the structural integrity of the allergens. Obtaining immunological data regarding cross-reactivity will enable more accurate IgE-epitope predictions using a structure based IgE-epitope mapping approach (Dall'Antonia et al.).

P.C5.04.01

Activated intestinal epithelial cells conditioned with 2'-Fucosyllactose and CpG-ODN might instruct moDC to drive Th1 differentiation

***V. Ayechu-Muruzabal**[1], A. Kostadinova[1], S. Overbeek[2], B. Stahl[2], J. Garssen[1], B. van't Land[2], L. Willemsen[1];*
[1]Utrecht Institute for Pharmaceutical Sciences (UIPS), Utrecht, Netherlands, [2]Nutricia Research, Utrecht, Netherlands.

The immunomodulatory capacities of 2'-Fucosyllactose (2'FL) were compared to short chain galacto- and long chain fructo-oligosaccharides 9:1 (GF), which previously showed to promote Th1 and regulatory type immune polarization in the presence of CpG in an *in vitro* co-culture model. Additionally, the ability of 2'FL-exposed intestinal epithelial cells (IEC) to instruct immature monocyte derived dendritic cell (moDC) function was evaluated.
IEC co-cultured with anti-CD3/CD28 activated peripheral blood mononuclear cells (PBMC), was apically exposed to 2'FL, GF or 2'FL/GF mixture (0.25, 0.5, or 1.0 w/v%) either or not combined with CpG (0.5 uM). IEC were washed and co-cultured with moDC. moDC were then used in an allogeneic assay where their capacity to induce naïve CD4+ T-cell differentiation was evaluated.
In presence of CpG, GF as well as 2'FL and 2'FL/GF enhanced IFN-gamma and IL-10 secretion of activated PBMC co-cultured with IEC compared to CpG alone ($p<0.05$), while IL-13 and IL-5 remained low. IEC-derived galectin-3, TGF-beta1 (both $p<0.001$), galectin-9 and galectin-4 (both $p<0.05$) of CpG-exposed cells was further increased by GF, 2'FL and/or 2'FL/GF compared to CpG alone. Only moDC co-cultured with activated IEC conditioned with 2'FL and CpG increased IFN-gamma secretion by CD4+ T-cells ($p<0.05$).
Similar to GF, exposure of IEC to 2'FL alone or 2'FL/GF combined with CpG polarize the immune response towards a Th1 and regulatory type. IEC-derived galectins might be involved in the immunomodulatory effects. moDC exposed to 2'FL and CpG-conditioned IEC instructed Th1 differentiation, suggesting that 2'FL can shape the adaptive immune response by affecting IEC function.

P.C5.04.02

Allergen exposure promotes eosinophil development in murine bone marrow via IL-33/ILC2/IL-5 axis

***E. Winberg**, K. Johansson, C. Malmhäll, J. Weidner, M. Rådinger;*
Institute of Medicine, Gothenburg, Sweden.

Introduction: Type 2 innate lymphoid cells (ILC2s) have been implicated in several inflammatory diseases including asthma. Eosinophilia is a hallmark of allergic airway inflammation where interleukin (IL)-5 is crucial for eosinophil development. The alarmin cytokine IL-33 activates ILC2s to produce IL-5. We investigated the role of IL-33/ILC2/IL-5 axis for eosinophil development in murine bone marrow in IL-33-induced inflammation and allergen-induced airway inflammation.
Methods: Wild type (WT) mice, Rag1 knockout (KO) mice, which lack T and B cells, and lymphocyte deficient Rag2Il2rg KO mice received intranasal doses of recombinant IL-33. Additionally, WT mice received intranasal doses of house dust mite to develop allergic airway inflammation. Flow cytometry was applied for quantification of bone marrow eosinophils and ILC2s. Further, expression of the IL-33 receptor (ST2) was evaluated on bone marrow ILC2s and IL-5+ILC2s were quantified.
Results: Rag1 KO mice demonstrated increased eosinophil numbers and bone marrow ILC2s produced IL-5 *in vitro* similar to WT mice in response to IL-33 challenge. Lymphocyte deficient mice, which lack ILC2s were unable to develop eosinophilic inflammation. Increased levels of ST2 on bone marrow ILC2s were observed for allergen exposed WT mice and correlated with elevated levels of eosinophil progenitors.
Conclusion: Allergen-induced eosinophilic inflammation involves IL-33-responsive bone marrow ILC2s that may support eosinophil development at an early stage. Rag1 KO mice develop bone marrow eosinophilia which demonstrates that adaptive immunity is dispensable for IL-33-driven eosinophil production. Eosinophilia is absent in Rag2Il2rg KO mice which might suggest that IL-5-producing ILC2s are needed for eosinophil induction and development.

P.C5.04.04

Antibody PIPEline by PIPEcloning: Efficient production of Bet-v-1-specific antibodies of different classes sharing the same variable region

***V. K. Köhler**[1,2], J. F. Singer[1,2], K. M. Ilieva[3,4], C. L. Pranger[1,2], S. N. Karagiannis[3,4], E. Jensen-Jarolim[1,2];*
[1]Interuniversity Messerli Institute/Institute of Pathophysiology and Allergy Research, Vienna, Austria, [2]Institute of Pathophysiology and Allergy Research, Center of Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, [3]St. John's Institute of Dermatology, School of Basic & Medical Biosciences, King's College London & NIHR Biomedical Research Centre at Guy's and St. Thomas' Hospital and King's College London, London, United Kingdom, [4]Breast Cancer Now Research Unit, School of Cancer & Pharmaceutical Sciences, King's College London, London, United Kingdom.

The creation of tailor-made antibodies is interesting both in the clinics and in research. PIPE (Polymerase Incomplete Primer Extension) cloning is a cutting-edge method that allows fast assembly of antibody constructs. It furthermore enables the creation of antibodies of several classes sharing the same binding region (Ilieva et al., 2017). We here present PIPE-cloned IgE, IgG_1 and IgG_4 targeting the major birch pollen (Betula verrucosa) allergen Bet v 1.
PIPE cloning was used to create vectors of several antibody classes (IgE, IgG_1, IgG_4) sharing the same variable region against Bet v 1 (Levin et al., 2014). Plasmids were expressed in Expi293F cells and purified with affinity chromatography. Concentration was measured via BCA protein assay and purity and correct assembly was confirmed by SDS PAGE; the specificity of all classes of recombinant antibodies against Bet v 1 was tested in a dot blot, of IgE additionally in an ISAC112 microarray. Affinity chromatography resulted in specific isolation of correctly assembled antibodies, as was confirmed via SDS PAGE. Overall yields were in the range of several hundred micrograms (IgE) to milligrams (IgG_1, IgG_4). All of the produced antibodies specifically bound to Bet v 1 in a dot blot, IgE recognised Bet v 1 in an ISAC112 allergen microarray with high specificity. PIPE cloning is a time-efficient method to obtain a PIPEline for antibodies targeting Bet v 1 for studying class-specific antibody function in type 1 allergy. The work was supported by the Austrian Science Fund FWF grants MCCA W1248-B30SFB and F4606-B28 to EJJ.

Antibody PIPEline by PIPE cloning: Fast production of human monoclonal IgG1, IgG4 and IgE antibodies specific for beta-lactoglobulin from milk

***C. L. Pranger**[1,2], J. F. Singer[1,2], V. K. Köhler[1,2], K. M. Ilieva[3,4], S. N. Karagiannis[3,4], E. Jensen-Jarolim[1,2];*
[1]The interuniversity Messerli Research Institute, Vienna, Austria, [2]Institute of Pathophysiology and Allergy Research, Center of Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, [3]St. John's Institute of Dermatology, School of Basic & Medical Biosciences, King's College London & NIHR Biomedical Research Centre at Guy's and St. Thomas' Hospital and King's College London, London, United Kingdom, [4]Breast Cancer Now Research Unit, School of Cancer & Pharmaceutical Sciences, King's College London, London, United Kingdom.

Background: Immediate type I allergy mediated by specific IgE to milk affects between 1.8 - 7.5% of children during the first year of life (Luyt et al., 2014). Precise tools are missing to establish cellular and molecular models for investigating the role of IgE and, especially IgG1 and IgG4, in milk allergy. Aims: Polymerase Incomplete Primer Extension (PIPE) cloning is the newest approach for the production of monoclonal antibodies (Ilieva et al., 2017). Here we use this method to generate antibodies of diverse subclasses (IgE, IgG1 and IgG4) against the major milk allergen beta-lactoglobulin, termed Bos d 5. Methods: Vectors of antibodies with the variable region against Bos d 5 (Jylhä et al. 2016) were assembled using the PIPE cloning method and transformed into E. coli. Clones were validated by colony-PCR and afterwards expressed in the Expi293F cells. After affinity chromatography, antibody yields were measured with BCA protein assay and recombinant antibodies were controlled by SDS-PAGE for correct assembly and checked for specificity to BLG in dot blot. Results: The recombinant expression yielded 2.2 mg of IgE, 0.6 mg of IgG1 and 1.9 mg of IgG4 antibodies. Correct assembly of all antibodies and their specific binding to BLG was confirmed. Conclusion: In summary, PIPE-cloning enabled us to produce various human antibodies in a short time frame at substantial yields. With the products we aim to contribute important and innovative tools for mechanistic studies on milk allergy. The work was supported by Austrian Science Fund FWF, grants MCCA W1248-B30 and SFB F4606-B28.

P.C5.04.06

T cell responses to sublingual treatment with recombinant Mal d 1

***C. Kitzmueller**, B. Nagl, T. Kinaciyan, B. Bohle;*
Medical University Vienna, Vienna, Austria.

Background: More than 70% of birch pollen-allergic individuals develop birch pollen-related food allergy (BPRFA), most frequently to apple. We recently conducted a clinical study of sublingual immunotherapy (SLIT) with recombinant birch allergen, (r)Bet v 1, apple allergen, rMal d 1, or placebo for 16 weeks. Interestingly, only the patients receiving rMal d 1 significantly improved BPRFA. In the current study, we analysed changes in the T cell compartment of the rMal d-treated patients over the course of treatment. Methods: We investigated T cell reactivity and the expression levels of the key cytokine IL-4, Il-5, IL-13, IFNγ, IL-10 and TGFβ in response to specific stimulation by thymidine incorporation and RT-qPCR, respectively. Additionally, we analysed changes in the relative numbers of $CD4^+$ memory T cell subsets, namely Th1, Th2, Treg and Tfh, with subset-specific surface markers and flow cytometry. Results: The proliferative response to rMal d 1 was reduced over the course of treatment, however, this was not accompanied by changes in the expression levels of cytokines. Almost all of the $CD4^+$ memory T cell subsets analysed were unchanged with the notable exception of pro-allergic Th2 cells ($CD27^-$, $CRTh2^+$, $CCR4^+$), which were significantly decreased already after 4 weeks of treatment. Conclusion: SLIT with recombinant apple allergen shows promising results, however, despite clinical improvements, only minor changes in the T cell compartment were observed. Supported by: OeNB project 16620, the Austrian Science Fund (projects KLI96 and SFBF4610), Biomay AG, and the Christian Doppler Research Association, Vienna, Austria.

P.C5.04.07

EFFECT OF AIR POLLUTION ON PATIENTS WITH BRONVHIAL ASTHMA IN GEORGIA

***R. Sepiashvili**[1], M. Chikhladze[2], S. Gamkrelidze[2];*
[1]Peopels Friendship University of Russia, Moscow, Russian Federation, [2]National Institute of Allergology,Asthma and Immunology of Georgian Academy of Sciences, Tskhaltubo, Georgia.

The study aimed to establish the correlation between the concentration of phadiatop, total IgE levels in the blood in patients with bronchial asthma and the concentration of specific air pollutants in terms of annual calendar of flowering plants in West Georgia. In the study were involved 45 patients (24 males and 21 females) of different ages with bronchial asthma. The study included: I step - allergodiagnostic using "Immuno- CAP 100",
II step - monitoring of aeropollutants concentration by using aeropolinometer "Burkard Trap".Patients had high titers of total IgE, which amounted to an average of 273 (N 33-90), while the average concentration of phadiatop was 96 (N <70).Patients with bronchial asthma of a specific positivity of specific IgE to the weeds (Wx2) - ambrosia, plantain, clasp/tarragon, atriplex -in 25 (55%) on average; tree dust (Tx9) - alder, lactarius piperatus, nuts, oak, willow - 16 (35%) ; and cereals (Gx1) - festuca pratensis, lolium temulentum, timoti grass, poa - 8 (17%); Mx2 -Penicillium notatum, Cladosporium herbarum, Aspergillus fumigatus, Candida albicans, Alternaria alternate- 11 (24%) was revealed , only in 6 (13%) patients we cannot established the allergy specific IgE. From January to April 2017, there were revealed a high concentration of aeropollutants, by high allergenization and widespread; especially high concentrations were found in alder, birch tree and common hazel, while from aeropollutants of low allergenization poplar, elm, willow and plane tree were distinguished. High degree correlation between the above-mentioned markers proves its clinical importance/value with respect to bronchial asthma.
This publication was prepared with the support of the"RUDN University Program 5-100".

P.C5.04.08

In vivo T regulatory cell regulation during human rhinovirus infection

***K. Jansen**[1], O. F. Wirz[1], G. Tan[1], W. van de Veen[1], D. Mirrer[1], S. L. Johnsthon[2], N. G. Papadopoulos[3], C. A. Akdis[1], K. C. Nadeau[4], M. Akdis[1];*
[1]SIAF, Davos Platz, Switzerland, [2]Imperial College London, London, United Kingdom, [3]University of Athens, Athens, Greece, [4]Sean N. Parker Centre for Allergy & Asthma Research - Stanford University, Stanford, United States.

Rationale: Respiratory infections with human rhinoviruses (HRV) are strongly associated with asthma exacerbations and pose a severe health risk for allergic individuals. How HRV infections and chronic allergic diseases are linked, and which role HRV plays in the breaking of allergen-specific tolerance is unknown. T regulatory cells (Tregs) play an important role in the induction and maintenance of immune tolerance. Therefore, the aim of this study is to investigate the effects of HRV on Tregs during asthma exacerbations.Methods: Healthy and asthmatic individuals were experimentally infected with HRV16 in vivo. Peripheral blood mononuclear cells (PBMCs) were obtained before infection and three days after infection. Tregs were sorted from the PBMCs according to their flow cytometric profile CD4+CD3+CD25+CD49d-CD127- and were analyzed with NGS.Results: We have found that upon viral infection in both asthmatics and healthy individuals an antiviral response is induced in Tregs, including upregulation of MX1, STAT1, IFI44L, IRF7/9, OAS3. In healthy individuals there is an additional upregulation of FOS and JUN, and the suppressor molecules SOCS3, CTLA-4 and ICOS, while these were downregulated in asthmatics. Furthermore, in healthy individuals CCL5 was downregulated, while unchanged in asthmatics.Conclusion: Tregs from healthy and asthmatic individuals both show an anti-viral response after RV infection. However there are also clear differences in response between Tregs from healthy and asthmatic individuals. These differences in response might affect Treg functions, level of inflammation, chronicity and viral clearance. Together this data suggest that Treg functions might be altered or impaired during HRV infections, which may contribute to asthma exacerbations.

P.C5.04.09

Qualitative and quantitative comparison of pollen allergen exposure between horses and humans. A collaborative study with the Austrian Pollen Information Service

***A. D. J. Korath**[1], K. Bastl[2], G. Hofstetter[1], K. Hufnagel[1], M. Kmenta[2], U. E. Berger[2], E. Jensen-Jarolim[1,3];*
[1]1) The Interuniversity Messerli Research Institute, University of Veterinary Medicine Vienna, Medica, Vienna, Austria, [2]2) Medical University of Vienna Department of Oto-Rhino-Laryngology Aerobiology and Pollen Information Research Unit, Vienna, Austria, [3]3) Institute of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria.

Background: In our recent study we revealed that IgE patterns in ISAC allergen microarray (Einhorn et al, Allergy 2018) differed between horses and humans, suggesting different allergen exposure.
Aims: We therefore aimed to collect pollen and plants from horse paddocks and meadows and compare to the pollen counts assessed for humans by the Austrian pollen Information Service.
Methods: Pollen were collected, on paddocks and pastures in four different horse stables, using pollen traps in April and in June 2018. The surrounding vegetation was examined botanically to correlate the pollen with the occurrence of allergenic plants.
Results: The overall pollen count was higher in early summer. In spring mostly pollen from Picea, Quercus and Fagus were found and in summer Poaceae, Urticaceae, Sambucus and Plantago pollen. The same pollen species as relevant for humans occur in the equine environment, however, largely differing in terms of quantitative composition.
Conclusions: This study will provide evidence whether the human APIS (Austrian Pollen Information Service) can be useful for owners of sensitized horses.
This study is supported by Austrian Science Fund FWF grant SFB F4606-B28 to EJJ.

P.C5.04.10

Qualitative multiplex detection of allergen-specific IgG and IgA on a microarray

***G. Feyzkhanova**[1], O. Smoldovskaya[1], S. Voloshin[1], M. Filippova[1], E. Antonova[2], L. Pavlushkina[2], T. Filatova[2], A. Rubina[1];*
[1]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation, [2]Filatov Moscow City Pediatric Clinic No. 13, Moscow, Russian Federation.

Allergen specific IgE (sIgE) is the main marker of the hypersensitivity type I in atopic individuals. However, in certain cases adverse reactions or their absence cannot be explained only via IgE diagnostics. Detection of allergen-specific immunoglobulins of other classes, such as specific IgG (sIgG) or specific IgA (sIgA), and specification of their role in allergic disorders can give additional information that might improve allergy diagnostics.
For that purpose a microarray for multiplex qualitative determination of sIgG and sIgA to 31 allergens was developed. Microarray includes semispherical gel pads containing allergen extracts or individual proteins belonging to different groups: pollen, indoor or food allergens. 10µl of the blood serum is necessary for the analysis. After the incubation of microarray with diluted blood serum (1:15) microarray is developed with anti-human antibodies conjugated with fluorescent dyes.
sIgG and sIgA profiles were obtained on the microarrays for 30 patients with different allergic diseases, using as developing antibodies anti-IgG-Cy3, anti-IgA-Cy5 or the mix of these antibodies. The signals for individual antibodies and for their mixture agreed within standard deviation of the analysis, which indicates that the developing system was selected properly. Also, the obtained patterns of sIgG and sIgA responses didn't coincide with the pattern of sIgE response defined previously.
The assay procedure developed is simple and may be used for screening both in adults and children to specify the relation between immunoglobulins G and A against allergens of different origin.
This work was supported by the Russian Science Foundation, Grant No. 14-50-00060.

Maternal exposure to antibiotics increases asthma severity in offspring mice

I. Lingel[1], *J. Gray*[2], *H. Deshmukh*[2], *P. Koenig*[1], *I. Lewkowich*[3];
[1]*Institute of Anatomy, Luebeck, Germany,* [2]*Division of Neonatology, Perinatal and Pulmonary Biology, Cincinnati Children´s Medical Center, Cincinnati, United States,* [3]*Division of Immunobiology, Cincinnati Children´s Medical Center, Cincinnati, United States.*

Within the last 40 years, asthma prevalence has tripled. As genetics do not change this rapidly, it is thought that recent changes in life-style in developed nations is increasing the risk of developing allergic asthma in genetic susceptible individuals. Recent epidemiological studies link early life exposure to antibiotics or other microbiota-changing events with an increased risk of the child to develop asthma. In this study, we seek to understand the role of early life microbiota disruption on asthma pathogenesis in mice. Offspring of mothers exposed to antibiotics (ABX) in drinking water (1mg/mL of Ampicillin, Gentamicin and Vancomycin) from embryonic day 15 (E15) to postnatal day 14 (P14) displayed a markedly exacerbated allergen-induced asthmatic phenotype with high airway hyperresponsiveness (AHR), increased numbers of IL-17A^{+} innate lymphoid cells (ILCs), neutrophilia, and high levels of IL-22 in the bronchial lavage. A more limited ABX exposure regimen (day E15 to birth) was associated with less severe exacerbation of AHR, recruitment of ILC3s, but had limited impact on airway neutrophilia and BAL cytokine levels. Interestingly, the limited ABX exposure regimen was also associated with alveolar enlargement, and increased airway permeability. These observations suggest that early microbial exposures in critical windows after birth limit pathogenic immune responses in a sequential manner, and suggests that proper microbial colonization might have a previously unrecognized role in promoting normal lung maturation. Disrupting such colonizations may cause inadequate immune responses later in life.

Mechanisms underlying allergy development and maintenance still remain obscure. IgE produced by B-cell lineage cells is the known causative agent triggering clinical manifestations. The cell subsets, responsible for production of IgE and its persistence in human body are not well characterised. Little is known about structure and seasonal dynamics of B-cell repertoire of allergic individuals. In this study we aimed to characterize IGH repertoires of key cell subsets of B-cell lineage from the peripheral blood of donors, susceptible to birch pollen allergy.
Using state-of-the-art technique for IGH library preparation which allows molecular-barcode based error correction and data normalisation, we studied the full-length IGH repertoires in several time points during 1 year, including of-season and peak of birch pollen periods. Clonal groups with IgE clonal sequence were detected in 3 of 4 allergic and 1 of 2 healthy donors. In contrast to IGH repertoires of healthy donors, we found IgE-containing clonal groups in repertoires of multiple cell subsets of allergic individuals. Such clonal groups also contained IgG, IgM and IgA members, and persisted in several time points. In memory B cells of 4 out of 6 donors we found clonal sequences of IgE isotype. These IGH clonotypes were hypermutated at the rates, similar to those of IgG and IgA clonotypes from IgE-containing clonal groups.
The study was supported by Council on Grants of Russian Federation President (grant #MK6000.2018.4 to ZIV) and Foundation for Assistance to Small Innovative Enterprises in Science and Technology (UMNIK grant #10861GU2016(0024432) to MAI).

Immunomodulation effect of biosynthetic dressing loaded with silver nanoparticles and TNF inhibitor in a non-traumatic wounds experimental model

A. Aguilar-Hernandez[1], *N. Garcia-Becerra*[1], *L. Fernandez-Avila*[2], *A. Zamudio-Ojeda*[2], *D. A. Lopez-de la Mora*[3];
[1]*Universidad de Guadalajara- UAG, Guadalajara, Mexico,* [2]*Universidad de Guadalajara, Guadalajara, Mexico,* [3]*Universidad de Guadalajara- LAMAR, Guadalajara, Mexico.*

The chronic wounds are stopped in the inflammatory phase, thus preventing the regeneration of the same. Silver-like nanoparticles have antibacterial properties, these have been used in a wide range of biomedical applications due to their selective toxicity in microorganisms and low immunogenicity. In addition, the use of immunomodulators contributes to inflammatory regulation to promote healing and regeneration.
Aim. Formulate a biosynthetic dressing loaded with silver nanoparticles and a TNFa inhibitor that promotes tissue regeneration and bacterial inhibition in an experimental model of chronic wounds.
Methodology. Chitosan gel was formulated. Silver nanoparticles were synthesized and their size was corroborated by SEM, TEM and IR. Dissolution time tests of the pharmaceutical form were carried out according to the Mexican pharmacopoeia. A bacterial inhibition test was performed in solid culture media type antibiogram. An experimental model of chronic wounds was established. Tissue histologies were performed. The genes of TNFa, TGFb1, MMP8, IL-1 and IL-17 were measured.
Results. Chitosan with 90% purity was obtained. Subsequently, the chitosan was solubilized until it became semi-solid. Silver nanoparticles of 30 nm were synthesized by chemical synthesis. A formula was standardized with previous compounds and a TNFa inhibitor. In the solubility tests, formula was kept releasing drug for 5 days at different pH. Bacterial inhibition was achieved by visualizing agar bacteria inhibition. The inflammation was decreased histologically. As well as a decrease in the expression of proinflammatory cytokines was observed in the treated group. Healing of the wound was achieved before 15 days compared to the negative control.

HIV-induces IL-18 from intestinal epithelial cells that causes cell death, increased intestinal permeability & microbial translocation

A. Ahmad*, O. Allam, S. Samarani;*
CHU Ste-Justine/University of Montreal, Montreal, Canada.

IL-18 is a pro-inflammatory cytokine belonging to the IL-1 family. It has been shown that HIV infection is accompanied by an imbalance in the production of IL-18 and of its natural antagonist, the IL-18 Binding Protein (IL-18BP). The infection is also accompanied by intestinal inflammation, increased intestinal permeability and microbial translocation. However, little is known concerning the potential role of the cytokine in the causation of the intestinal pathology. Here we show that incubation of HIV with human intestinal epithelial cells (IEC) increases production of IL-18 and decreases that of IL-18BP from the IEC. The cytokine induces apoptosis in IEC in a time and dose dependent manner via activating caspase-1 and -3. It modulates the expression of several Tight and Adherens Junction proteins e.g., occludin, claudin 2 and β-catenin. It also disorganizes F-actin expression in the IEC. The cytokine decreases transepithelial electrical resistance (TEER) and increases permeability in the IEC monolayers. It also increases the expression of phosphorylated myosin II regulatory light-chain (p-MLC) and myosin light-chain kinase (MLCK), and decreases activation of STAT-5 in the IEC. A Rho-kinase (ROCK)-specific inhibitor suppresses the cytokine-induced increase in p-MLC. Interestingly, the levels of the cytokine correlate with those of LPS in the circulation in HAART-naïve and HAART-treated HIV-infected individuals, Elite controls as well as in healthy controls. Taken together, our results suggest that the increased concentrations of IL-18 play a role in increased intestinal permeability and microbial translocation observed in HIV-infected individuals. Thus targeting the cytokine may ameliorate intestinal pathology in HIV-infected individuals.

Higher frequencies of lymphocytes expressing the natural killer group 2D receptor and cytotoxic potential of NK cells in patients with Behcet disease

M. Bonacini*, A. Soriano, Z. Alessandro, E. Calò, L. Cimino, F. Muratore, L. Fontana, M. Parmeggiani, C. Salvarani, S. Croci;*
Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy.

Aim: This study aimed to identify a specific profile of circulating Natural Killer (NK), NKT and T cells able to discriminate patients with Behçet disease (BD) and Healthy controls (HC). **Methods:** Peripheral blood mononuclear cells (PBMCs) were collected from 38 BD patients and 15 HC. The frequencies of NK, NKT and T cells expressing CD16, CD69, NKG2D, Nkp30, Nkp46 and NKG2A were assessed by flow cytometry. Cytotoxic potential of NK cells was evaluated by flow cytometry as the percentage of cells expressing the degranulation marker CD107a after incubation with K562 cells. The levels of 27 cytokines were determined in plasma with a multiplex bead-based assay. **Results:** Higher percentages of NK, NKT and T cells expressing NKG2D were detected in PBMCs of BD patients than HC. ROC curve analysis showed that the evaluation of NKG2D^{pos} NK, NKT and T cell percentages discriminated between BD patients and HC. Moreover, there was a positive correlation between the BD Current Activity Form (BDCAF) scores and the frequencies of NKG2D^{pos} NK and NKT cells. A higher frequency of NK cells expressing CD107a was induced in PBMC from BD patients than HC after incubation with K562 cells. Concentrations of IL-5, IL-10, IL-12, IL-13, IP-10 and MIP-1β were higher in plasma of BD patients than HC. **Conclusion:** monitoring the frequencies of NKG2D^{pos} lymphocytes, and CD107a^{pos} NK cells after the degranulation assay could help the clinicians in BD patients management. The increased expression of NKG2D in BD patients is likely involved in disease pathogenesis.

Evolutionary conserved cell- and immunobiological processes during tissue regeneration: comparative studies in an invertebrate model

*K. Bodó[1], É. Rumpler[2], B. Kokhanyuk[1], P. Németh[1], **P. Engelmann**[1];*
[1]Department of Immunology and Biotechnology, Clinical Center, Medical School, University of Pécs, Pécs, Hungary, [2]Department of Comparative Anatomy and Developmental Biology, Faculty of Sciences, University of Pécs, Pécs, Hungary.

It is well known that annelid (segmented) worms possess strong regeneration capacity. However limited information is available about the interactions of regeneration and immune-related mechanisms in earthworms. Our aim was to compare cell proliferation vs. cell death and the expression of certain immune-related genes in the course of anterior/posterior regeneration of the earthworm *Eisenia andrei.* To enumerate cell proliferation Click-iT EdU assay was applied following 2 and 4 weeks of regeneration. It was combined with FITC-coupled anti-EFCC mAbs to assess the involvement of different immunocytes (e.g. coelomocyte) subsets in the restoration process. Apoptotic activity was detected by TUNEL assay. Q-PCR analysis was executed to evaluate the expression of mRNA targets in the regenerating segments of *E. andrei*. A high number of proliferating cells were detected after 2 weeks that is decreased by the 4 weeks only in the posterior blastema. In contrast, the apoptotic activity was observed throughout the restoration. Immunostaining revealed that coelomocyte subsets were accumulated in the blastema mainly during the posterior regeneration. Pattern recognition receptor genes evidenced a decreased pattern (except scavenger receptor) compared to intact animals. Several genes have similar expression pattern (TLR, LBP) during anterior/posterior regeneration, except the antimicrobial molecules (lysozyme). Evaluation of cell biological events and immune-related gene expression revealed characteristic differences during anterior/posterior regeneration that is a novel observation in the field of invertebrate (earthworm) immunity. This work was supported by the János Bolyai Research Scholarship of the Hungarian Academy of Sciences and Medical School Research Foundation, University of Pécs.

Soluble triggering receptor expressed on myelocytes -1 is strongly correlated with disease activity in systemic lupus erythematous

***I. Gkougkourelas**, A. Gkantaras, A. Georgiadou, P. Boura;*
Clinical Immunology Unit, 2nd Internal Medicine Department, Hippokration General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Background: Soluble Triggering Receptor Expressed on Myelocytes -1 (sTREM-1) is an innate immunity receptor, which participates in inflammatory reactions. Its serum levels reflect the magnitude of systemic inflammatory response and can discriminate between infectious and non-infectious causes. Its role in systemic lupus erythematosus (SLE) is unknown. In this study we examined sTREM-1 in SLE patients with regard to disease activity. **Patients and Methods:** Sixteen patients with SLE were enrolled. Diagnosis was based on the revised 1997 American College of Rheumatology criteria. Disease activity was measured with the SLE Disease Activity Index-2000 (SLEDAI-2K). sTREM-1 levels were determined by Enzyme Linked Immunosorbent Assay (ELISA) in serum samples. Seventeen age- and sex-matched healthy individuals comprised the control group. Statistical analysis was performed with the SPSS package; $p<0.05$ was considered significant. **Results:** Serum sTREM-1 was significantly higher in SLE patients than in normal controls. Its levels were strongly correlated to SLEDAI-2K. **Conclusions:** Serum sTREM-1 is strongly correlated to disease activity in SLE, probably reflecting the generalized activation of the innate immunity response in this disease and may be an additional biomarker in SLE. **Conflict of interest** None **Acknowledgements** To IKY fellowships of excellence in postgraduate studies in Greece -Siemens program

P.C6.01.06

Investigating the innate training potential of the vaccine adjuvant alum

***A. L. Gorman**, E. C. Lavelle;*
Trinity Biomedical Sciences Institute, Dublin, Ireland.

Vertebrate immunity is classically divided into innate and adaptive immune responses. Recent findings have challenged the classical view of innate versus adaptive immunity, suggesting that innate cells can retain some "memory" of past immunological insults. This "trained immunity" which allows for primed cellular responses to secondary infections is independent of T and B cells and is mediated by innate cells such as monocytes/macrophages and NK cells. While it has been shown that certain live vaccines such as BCG can induce trained immunity, the effects of particulates such as the widely used vaccine adjuvant alum have not been addressed. Alum has been predominantly used in many vaccines due to its humoral immunopotentiation and safety profile.
However, how this widely used adjuvant elicits its effects remains elusive. We have shown that alum-trained macrophages adopt a distinct morphology in addition to an altered capacity for cytokine secretion upon re-stimulation with lipopolysaccharide *in vitro*. Using a NanoString inflammation panel to characterize the transcriptional profile of alum-trained cells we have found that training by this adjuvant globally downregulates proinflammatory genes. Further investigation into the *in vitro* effects of alum-trained macrophages will help shed light on the mechanism by which this particulate exerts its innate training effects in macrophages.

P.C6.01.07

Complement C3 and C4 are useful markers for predicting Bipolar disease severity and monitoring patients under psychotropic treatment

***H. Hachicha**[1], N. Halouani[2], R. Feki[2], S. Feki[1], F. Ayadi[1], A. Maatoug[1], A. Ayadi[1], S. B.Hamadou[1], j. Aloulou[2], H. Masmoudi[1];*
[1]Immunology Department, CHU Habib Bourguiba, Sfax, Tunisia, [2]Psychiatric department, CHU hedi Chaker, Sfax, Tunisia.

Abnormalities of the immune system have recently been shown to be implicated in bipolar disease (BD). BD patients have been also reported to exhibit increased proinflammatory cytokine levels indicating the role of inflammation in this disease. In our study we aimed to find out whether complement system (C3 and C4 fractions) and immunoglobulins (Ig) are abnormal in BD and to explore the effect of psychotropic treatment on these variables This study was conducted during 36 months on 90 subjects (45 patients with manic relapse in type I BD (DSM 5 criteria) having no history of autoimmune disease and 45 age and sex matched controls. Mean plasma IgG and complement C3 levels were significantly higher in bipolar patients with manic relapse (p = 0.034, p = 0.040). The plasma level of the C3 and C4 fraction was correlated with EGF score (r = 0.375, p = 0.016, r = 0.340, p = 0.016). After treatment, there was a statistically significant increase in mean plasma IgG and IgA levels (p = 0.006, p = 0.009) and a decrease in the mean plasma C4 complement level (p = 0.004). Mean plasma IgM levels were significantly lower on sodium valproate treated patients (p = 0.004). Under atypical antipsychotics, the mean plasma level of the C3 fraction was statistically lower (p = 0.028) whereas under conventional antipsychotic it was statistically higher (p = 0.048). Among the variables studied, the complement system seems to be closely related to manic relapse, its severity, and psychotropic treatment.

P.C6.01.09

Assessment of autophage function in systemic lupus erythematosus in respect of hyperlipidemia and immunosuppressive drugs

***A. S. Hamada**[1], m. i. aref[1], a. m. rabee[2];*
[1]Al Azhar university hospital, cairo, Egypt, [2]aswan university hospital, aswan, Egypt.

Background: Autophagy is an orchestrated homeostatic process to eliminate unwanted proteins and damaged organelles in addition to regulation of lipids.
Objective: Assessment of autophagy focusing on lipids regulation in patients with SLE .
Patients and Methods: Subjects were divided into three groups. Group 1 included 60 newly diagnosed SLE patients before receiving any treatment, group2 included the same subjects of group 1 after three months of treatment with immunosuppressive drugs and group 3 included 30 matched healthy donors as a control group. Disease activity was assessed by (SLEDAI) score, lipid profile was measured in addition to evaluation of lipids uptake, enhanced phagocytosis and intracellular killing ability of monocytes and neutrophils using Sudan Black B & Nitroblue tetrazolium stains.
Results:There was a positive correlation between total cholesterol, LDL and triglycerides and disease activity(SLEDAI score) (r= 0.677, r= 0.603 and r= 0.718; respectively).On the contrary, There was a negative correlation between HDL and disease activity(r= -0.396). Furthermore, there was a negative correlation between lipid content of cells and intracellular killing and disease activity(r= -0.258 and r= -0.324; respectively) . After 3 months, comparing group 2 to group 1, there was significant increase in cholesterol, LDL and trigycerides (P=0.027, P=0.021 and P=0.017; respectively) while HDL showed insignificant difference(P=0.0740). Lipid content in cells and intracellular killing significantly decreased(P=0.0322 and P=0.0271; respectively).
Conclusion: Autophagy is deficient in patients with SLE so they are more susceptible to infections and dyslipidemia, aggravated by immunosuppressive drugs. Consequently, lipid lowering drugs are definitely required to decrease comorbidity .

P.C6.01.10

The "Who is Who" of dermal infiltration in fibrosis developing *fos- related antigen- 2* mice

***J. Haub**[1,2], V. K. Raker[1,2], N. Lorenz[1,2], F. Steinbach[3,2], E. Wagner[4], D. Schuppan[3,2], K. Steinbrink[1,2];*
[1]Department of Dermatology, Mainz, Germany, [2]Research Center for Immunotherapy, University Medical Center Mainz, Germany, [3]Institute of Translational Immunology, Mainz, Germany, [4]National Cancer Research Center, Madrid, Spain.

Systemic sclerosis is a complex and incompletely understood disease, resulting in skin and organ fibrosis. Cutaneous fibrosis is characterized by disproportionate accumulation of collagens and other extracellular matrix substances. However, involvement of innate immune cells and the sequence of inflammatory events in the early inflammatory phase of the disease have not been addressed so far.

Therefore we studied the murine model of systemic sclerosis: The *fos-related antigen-2* mouse (fra-2). Fra-2 mice overexpressing fra-2 under MHCI promotor control and spontaneously developing vasculopathy and fibrosis in the skin and internal organs. In Fra-2 mice the inflammatory response peaks at week 7-9 of life. By week 12 mice develop massive dermal and pulmonary fibrosis leading to dyspnea by week 17.
At week 12 histological analysis of Fra-2 mice showed a significant enhancement of dermal thickness and a pronounced cutaneous collagen accumulation (H&E, Goldner´s trichrome, hydroxyproline assay).
Flow cytometric analysis of the blood and skin demonstrated an early cellular infiltrate consisting of activated myeloid cells (Ly6C$^+$MHCII$^+$). This myeloid infiltration peaked at week 9 and comprised CD11b$^+$CD301b$^+$ as well as CD11b$^+$CD206$^+$ cells, indicating an infiltration of terminally differentiated macrophages in Scl-prone skin.
Along with myeloid cells Fra-2 mice exhibit pronounced levels of activated T-cells (CD4$^+$CD25$^+$), but a reduced proportion of CD4$^+$Foxp3$^+$ regulatory T-cells in the skin, lymph nodes, lung.
Our findings suggest that reduced Treg frequencies accompanied by a massive myeloid and lymphoid infiltration contribute to fibrosis development in Fra-2 mice.
This study is financially supported by the German Research Foundation (Collaborative Research Center (CRC/TR156).

2B4 RECEPTOR REGULATE COLITIS DEVELOPMENT VIA TISSUE REPAIR MECHANISM.

***T. Kim**, J. Kim, B. Park, G. Park, S. Lim, K. Lee;*
Korea University College of Medicine, Seoul, Korea, Republic of.

Ulcerative colitis is a chronic relapsing form of inflammatory bowel disease (IBD) that causes inflammation and ulcers in the colon. Innate immune responses are important in the initiation and progression of inflammatory bowel disease (IBD). 2B4 (CD244), a member of SLAM family play a crucial role in inflammatory disease. 2B4 is expressed by a large number of innate immune cells in intestinal lamina propria (LP). However, the role of 2B4 receptor in intestinal inflammation is still unknown.
Since 2B4 is highly expressed on some of lamina propria lymphocyte (LPL) in intestine, we hypothesized that 2B4 might play and crucial role for intestinal inflammation. Indeed, we found that 2B4 is expressed dendritic cells, macrophage, ILCs in intestinal lamina propria, and upregulated expression level after DSS administration. The progression and disease score of intestinal inflammation induced by DSS in 2B4$^{-/-}$ mice was much faster and severe than that observed in wild-type mice. At the cellular and tissue level, we found increased colonic inflammation and reduced intestinal epithelial cell proliferation, along with severely diminished number of dendritic cells in colon. Tissue repair related cytokines (IL-22, IL-18) are significantly reduced in 2B4 deficient mice, and replenishing these cytokine could recover colonic inflammation in 2B4 deficient mice group. Taken together, these data identify a novel function of CD244 as a gate guard in intestinal inflammation in IBD
This work was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (Grant#; NRF-2016R1A6A3A04009698 and NRF-2017R1A2B3004828)

P.C6.01.12
ADSCs treatment hinders the advancement of fibrosis in liver in the early stage of NASH by reducing the Il17a-mediated inflammation

***A. Nasti**[1], Y. Sakai[2], M. Yamato[1,2], K. Kawaguchi[2], T. Ho[2], K. Yoshida[1], T. Komura[1], M. Takamura[1,3], T. Wada[1,4], M. Honda[2], S. Kaneko[1,2];*
[1]System Biology, Kanazawa University, Kanazawa, Japan, [2]Department of Gastroenterology, Kanazawa University Hospital, Kanazawa, Japan, [3]Department of Cardiology, Kanazawa University Hospital, Kanazawa, Japan, [4]Department of Laboratory Medicine, Kanazawa University, Kanazawa, Japan.

Non-alcoholic steatohepatitis (NASH) liver is defined by a steatotic/inflamed condition with advancing fibrosis, eventually becoming cirrhotic. There is no established therapy and pathogenesis is not completely uncovered. We demonstrated previously that adipose tissue derived stromal/stem cells (ADSCs) decreased fibrosis in NASH mice, now we investigated the mechanism between NASH and simple steatosis and, the effect of ADSCs treatment on early stage of NASH. C57Bl/6J mice were used for ADSCs isolation; simple steatosis or NASH was established in mice and hepatic inflammatory cells (HIC) isolated for DNA microarray analysis and cytokine secretion assay. Anti-Il17a or anti-CD4 antibody was administered weekly for 8 weeks, liver tissues isolated on week 9. Separately, ADSCs were administered on weeks 4 and 8, then liver collected on week 12. Fibrosis was assessed by AZAN staining, FACS and qRT-PCR. DNA microarray of HIC highlighted 868 up-regulated genes in NASH compared to simple steatosis, biological processes were associated to CD4$^+$ T-cell immune response. Frequency of Il17-secreting cells in NASH-HIC was higher (37%) than control (15%). Anti-Il17a antibody decreased fibrosis ($p<0.01$), and down-regulated *Col4a1* in NASH livers ($p<0.05$), anti-CD4 antibody was not effective. Administered ADSCs decreased *Il17a* expression in NASH-HIC, reduced the Il17a-secreting cells population in HIC (25%) compared to control (37%), decreased fibrosis ($p<0.01$) and expressions of *Col4a1* and *Col1a1* in liver tissue ($p<0.05$). In conclusion, Il17a is involved in fibrosis development in NASH mice, and ADSCs administration reduced fibrosis by suppressing the Il17a-mediated inflammation in early stage of NASH.

P.C6.01.13
Differential innate immunity signature associated with disease activity in autoimmune diseases: systemic lupus erythematosus, rheumatoid arthritis, and systemic sclerosis

***A. Petrackova**[1], A. Smrzova[1], M. Schubertova[1], M. Skacelova[1], R. Fillerova[1], V. Smotkova Kraiczova[1], M. Radvansky[2], M. Kudelka[2], F. Mrazek[1], P. Horak[1], E. Kriegova[1];*
[1]Faculty of Medicine and Dentistry, Palacky University and Hospital Olomouc, Olomouc, Czech Republic, [2]Technical University of Ostrava, Ostrava, Czech Republic.

Introduction: Mounting evidence indicates that innate immunity, especially Toll-like-receptors (TLR) and interleukin (IL)-1/IL-1R families, play essential roles in the pathogenesis of autoimmune diseases. The differential innate expression pattern associated with disease activity in systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and systemic sclerosis (SSc) has not been established. Objective of the study was to elucidate the underlying differences in innate immunity signatures associated with disease activity in major autoimmune diseases.
Methods: We investigated gene expression of *TLR1-10*, 7 members of *IL-1/IL-1R* family, and interleukin 8 (*IL-8/CXCL8*) in peripheral blood mononuclear cells from patients with autoimmune disorders taken at time of active disease: SLE (n=28, SLEDAI>6), RA (n=36, DAS28≥3.2), and SSc (n=22, revised EUSTAR index>2.25) using high-throughput SmartChip Real-Time-qPCR system (WaferGen). Statistics were performed by R statistical software, *P*-value<0.05 was considered as significant.
Results: RA differed from SLE and SSc by the upregulated expression of six genes (*TLR2*, *TLR3*, *TLR5*, *SIGIRR*, *IL-1RAP*, and *IL-18R1*; *P*<0.05). Active SLE and SSc showed high similarity in term of immunity gene expression signatures. In SSc, downregulated expression of *IL-18R1* (*P*<0.05) was observed when compared to SLE and RA. In SLE, downregulated expression of *IL-1R1* (*P*<0.05) was detected when compared to RA and upregulation of *IL-18R1* (*P*<0.05) when compared to SSc.
Conclusions: Innate immune gene expression signature in patients with autoimmune diseases in active disease stage was identified, showing high similarity between SLE and SSc.

Systemic inflammation induced by administration of TLR-7/8 agonist Resiquimod causes severe thrombocytopenia, myocardial erythrocyte accumulation and iron deposition in CFN mice

*N. Baxan[1], A. Papanikolaou[2], I. Salles-Crawley[3], R. Chowdhury[2], O. Dubois[1], N. Rosenthal[2], L. Zhao[1], S. E. Harding[2], **S. Sattler**[2];*
[1]Imperial College London, Biological Imaging Centre, London, United Kingdom, [2]Imperial College London, NHLI, London, United Kingdom, [3]Imperial College London, Centre for Haematology, London, United Kingdom.

Introduction: Topical application of the TLR-7/8 agonist Resiquimod has been suggested as inducible model of systemic lupus erythematosus. In response to Resiquimod administration, CFN (C57Bl/6xFVBxNOD) mice develop acute myocarditis accompanied by myocardial haemorrhaging, followed by fibrosis and development towards inflammatory dilated cardiomyopathy. Importantly, we have shown previously that CFN mice show a degree of Resiquimod-induced cardiac damage which is significantly more severe than the levels observed in all three parental strains. **Methods:** CFN mice were treated with topical application of Resiquimod to the ear three times a week for two weeks. Magnetic resonance imaging was performed *in vivo*, blood collected for analysis of platelet count and hearts collected for histological analysis of inflammatory damage and fibrosis. **Results and conclusion:** Magnetic resonance imaging shows a significant drop in T_2^* relaxation times (3.7+/-0.17ms and 2.75+/-0.29ms; p-value 0.014, n=3-5), localized primarily in the subepicardial regions of the intraventricular septum of Resiquimod-treated mice, suggestive of the presence of paramagnetic iron. This observation was confirmed by staining for iron in corresponding histology sections, which showed a significant iron accumulation (score: 0.096+/-0.07 and 1.36+/-0.22; p-value 0.005, n=3-10) in areas of low T2* values. We also detect severe thrombocytopenia in Resiquimod-treated CFN mice (platelet count/ul 700+/-132x103 and 17+/-16x103; p-value 0.033, n=3), suggesting that cardiac erythrocyte accumulation may be caused by acute bleeding problems and that haemoglobin is the source of interstitial iron. **Acknowledgements:** This work was supported by the British Heart Foundation RM/13/1/30157 to SEH and PG/16/93/32345 to SS.

Investigating neutrophil impairment in patients with Neuromyelitis Optica

M. Schroeder Castagno[1], *S. Romero Suarez*[1], *N. Borisow*[2], *F. Paul*[3], *C. Infante Duarte*[1];
[1]*Institute for Medical Immunology, Experimental Neuroimmunology, Charité - Universitätsmedizin Berlin, Berlin, Germany,* [2]*NeuroCure Clinical Research Center NCRC, Clinical Neuroimmunology, Charité - Universitätsmedizin Berlin, Germany, Berlin, Germany,* [3]*NeuroCure Clinical Research Center NCRC, Clinical Neuroimmunology, Charité - Universitätsmedizin Berlin, Department of Neurology, Charité - Universitätsmedizin Berlin, Germany, Berlin, Germany.*

Introduction: Our group has recently shown that peripheral blood neutrophils of patients with neuromyelitis optica (NMO) show a deficient respond to migratory and oxidative burst stimuli when compared compared to Multiple Sclerosis (MS). It is well established that in contrast to the observations in MS, neutrophils accumulate in NMO lesions and contribute to the damage cascade inside the CNS. However, it remains unclear, which factors lead to this accumulation. Defective neutrophil apoptosis accompanied by neutrophil accumulation promoting a pro-inflammatory environment has been already shown for other chronic inflammatory diseases. Thus, we here hypothesize that a generalized impaired cell death of NMO neutrophils might support their accumulation in inflammatory lesions.
Methods: We performed an assay to monitor death susceptibility of peripheral blood neutrophils from 20 NMO patients as well as 20 sex and gender matched healthy controls. Neutrophilic death was induced by incubating purified granulocytes with 25 nM PMA for 30 min at 37 °C. Cell death was analyzed by flow cytometry in CD16b$^+$ neutrophils using 7- AAD and Annexin V staining.
Results: Neutrophils from NMO patients show reduced cell death susceptibility compared to HC in our in vitro set-up.
Conclusion: Impaired cell death of neutrophil from NMO patients may contribute to neutrophil pathological accumulation in lesions. However, since the majority of the NMO patients are under immunomodulatory treatments, further evidences from untreated patients are needed to support this conclusion.

Development and characterisation of a 4-dimensional *in vitro* model of ANCA-associated vasculitis

C. A. Walls[1], *N. Basu*[2], *L. P. Erwig*[1], *D. Kidder*[3];
[1]*Institute of Medical Sciences, Aberdeen, United Kingdom,* [2]*Institute of Applied Health Sciences, Aberdeen, United Kingdom,* [3]*NHS Grampian, Aberdeen, United Kingdom.*

Introduction: ANCA-associated vasculitis (AAV) is a group of devastating autoimmune diseases affecting small/medium sized blood vessels. The interaction of neutrophils and monocytes with the endothelial lining of blood vessels is key to understanding disease pathophysiology. There is limited knowledge about the temporal dynamics of these interactions and how they alter throughout the course of disease. We therefore aimed to develop a 4-dimensional *in vitro* model of AAV which would allow investigation of these crucial leukocyte-endothelial interactions.
Materials and Methods: Neutrophils and monocytes were isolated from peripheral venous blood collected from patients with AAV (Granulomatosis with Polyangiitis, Microscopic Polyangiitis and Eosinophillic Granulomatosis with Polyangiitis) and healthy donors. Using live cell spinning disc confocal microscopy, neutrophil/monocyte-human umbilical vein endothelial cell interactions were imaged in three dimensions for 3 hours. Video analysis software (Volocity 6.3) enabled quantification of leukocyte migration, adhesion, transmigration and degranulation.
Results: Degranulation and transmigration was significantly higher in neutrophils isolated from patients with active disease, compared to those in remission and healthy donors. Transcellular, rather than paracellular, transmigration of monocytes was significantly increased in the ANCA-positive patient cohort, compared to those who were ANCA-negative and healthy donors.
Conclusion: We have developed a novel 4-dimensional *in vitro* model of AAV encompassing several crucial leukocyte-endothelial functions at the forefront of disease pathophysiology. These preliminary experiments have highlighted key areas which are likely to be crucial in the development of the disease. Future work will include collecting longitudinal patient samples which will further verify the findings of this model.

P.C6.01.17

Epithelial IL-33 is regulated by the lymphoid stress-surveillance (LSS) response and confers protection against skin carcinogenesis

S. Ward, *R. Castro Seone, G. Crawford, M. Hayes, J. Strid;*
Imperial College London, London, United Kingdom.

Lymphoid stress-surveillance (LSS) refers to the capacity of tissue resident intraepithelial lymphocytes (IEL) to directly sense epithelial cell (EC) dysregulation and initiate a restorative response. γδTCR$^+$ IEL in the skin are potent producers of IL-13 upon epithelial dysregulation, which is key to the LSS response and directly regulates EC function, promotes tissue homeostasis and protects against skin carcinogenesis. This may be due to its prominent effect on skin EC, where IEL-derived IL-13 enables a canonical EC stress-response with production of IL-33 mRNA. IL-33 is an abundant cytokine 'alarmin' constitutively expressed in the nucleus of basal skin EC. Here we show that LSS regulates the level of EC IL-33 protein at steady state, as well as the release of IL-33 following topical exposure to the carcinogen 7,12-dimethylbenz[a]anthracene (DMBA).
We also demonstrate that IL-33 protects against DMBA-induced epithelial carcinogenesis in the skin but not against subcutaneous tumour growth in a cell line-derived model. Furthermore, IL-33 restrains cellular infiltrate and epithelial hyperplasia during skin inflammation. This is possibly due to signaling via its receptor, ST2, on FoxP3$^+$ regulatory T cells (Treg), as ST2 is predominately expressed on the abundant Treg infiltrate in the DMBA-induced tumours and ST2-deficient mice are also more susceptible to inflammation-driven carcinogenesis. Together our data suggests that IL-33 is part of the LSS response to tissue dysregulation and regulates both skin immunity, EC homeostasis and carcinogenesis.

P.C6.01.19

Regulatory Innate Lymphoid Cells in tissue homeostasis and graft versus host disease

M. M. Shikhagaie, *N. Haverkade, Y. van Lier, B. Blom, M. Hazenberg;*
Amsterdam UMC, Amsterdam, Netherlands.

Background: Allogenic hematopoietic stem cell transplantation (allo-HSCT) is a curative treatment for patients with hematologic malignancies, including acute myeloid leukemia. However, 50-70% of allo-HSCT recipients develop graft-versus-host-disease (GvHD). Damage of host tissues, such as the skin and gastrointestinal tract, caused by conditioning therapy are key in the pathophysiology of GvHD since release of danger-associated molecular patterns (DAMPs) activate allo-reactive immune responses. ILCs have an essential role in tissue homeostasis and -healing, for instance in the context of allo-HSCT and GvHD, due to their location at barrier surfaces and responsiveness to cytokines produced by activated cells in their local environment. DAMPs, such as extracellular ATP (eATP),interact with ectonucleotidases that are involved in the hydrolysis of eATPinto the immunosuppressive metabolite adenosine. We studied ectonucleotidase expression on ILC and the role of eATP on ILC function.
Methods & Results: Using flow cytometry, we demonstrated that tissue-derived human ILCs, particular IL-22 producing ILC3 contributing to tissue healing, express ectonucleotidases (Ecto$^+$ILCs). Ecto$^+$ILCs hydrolysed eATP into adenosine, measured by tandem Mass-spectrometry. Genes and cytokines that regulate expression of ectonucleotidaseson tissue and peripheral blood (PB) ILC were analysed by *in vitro* studies. Moreover, altered ectonucleotidase expression was observed on ILC, but also T cells, from PB and intestinal biopsies taken from patients with GvHD when compared to controls.
Conclusion: We hypothesise that Ecto$^+$ILCs represent a novel subset of innate immune cells with immunosuppressive ability, that can control mucosal homeostasis and contribute to protective immunity during early stages of GvHD development.

Identification of IL-17A as a predictive marker of clinical severity in pediatric ichthyosis

E. Bernaldo de Quirós[1], *R. Kennedy*[1], *V. Pérez*[1], *Á. Hernández-Martín*[2], *M. Campos*[3], *M. Pion*[1], *R. Correa-Rocha*[1];
[1]*Laboratory of Immune-regulation, Gregorio Marañón Health Research Institute, Madrid, Spain,* [2]*Pediatric Dermatology Division, Hospital Infantil Universitario Niño Jesús, Madrid, Spain,* [3]*Pediatric Dermatology Division, Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

Introduction: Ichthyosis is a heterogeneous group of genetic cutaneous disorders that alter the structure of the skin and where the immune mechanisms are not well elucidated. Specific therapies have not been identified and the treatment is currently symptomatic. Our aim is to identify the immunological profile in ichthyosis pediatric patients and determine the effect of ustekinumab (a monoclonal antibody that targets IL-12/23p40) on their immune system.
Materials and methods: We carried out an exhaustive analysis of immunological cell subsets by flow cytometry from peripheral blood (<3ml). Percentages and absolute counts of up to 75 subsets were analyzed.
Results: We have evaluated four samples of a 2-year-old male patient: one before starting the treatment with ustekinumab and the three others over 4 months. We observed high values of TCD4+ IL-17A-producing cells (Th17) before treatment. The frequency of Th17 was initially reduced by 30% associated with a clinical improvement of the patient. Although neither the Th17 frequency decrease nor the clinical improvement remained, we observed reduction in the itch.
Conclusions: We tried to evaluate a possible benefit of ustekinumab and draw a parallel between the frequency of Th17 lymphocytes and the clinical outcome. Even though we observed a clear improvement of the symptoms associated to a Th17 frequency reduction during the first month, this amelioration was not sustained over time. However, we proposed the use of Th17 frequency as a diagnostic and predictive marker for severity, as well as a follow-up marker in these patients in a larger study group.

INNATE LYMPHOID CELL SUBSETS IN THE PATHOGENESIS OF MULTIPLE SCLEROSIS

***G. C. Birch**, M. Sim, A. Harris, C. Reynolds, R. Nicholas, R. Boyton, D. Altmann;*
Imperial College London, London, United Kingdom.

Senior and corresponding authors, d.altmann@imperial.ac.uk and r.boyton@imperial.ac.uk
Multiple sclerosis (MS) is considered a disease of T cell autoimmunity. However, cellular studies and genetic association studies indicate the importance of interactions with innate immune subsets in pathogenesis[1,2]. For example, alterations in natural killer cell (NKC) phenotype or number have been correlated with MS disease.
Previous work in our laboratory identified two distinct subsets of $CD56^{dim}$ NKCs, based on differential expression of CD56, CD8, CD27 and CD57. The NKC subsets were defined as double positive (DP) $CD56^{dim}$CD8+CD57+CD27- and triple negative (TN) $CD56^{dim}$CD8-CD57-CD27-. Beta-interferon treatment was associated with similar ratios of DP/TN subsets to those seen in healthy controls. Transcriptomic analysis showed that the TN subset expressed markers indicative of innate lymphoid cells (ILC3), confirmed by FACS. Individuals with MS in acute relapse had a higher proportion of the TN compared to the DP $CD56^{dim}$ NKC subset.
Innate lymphoid cells are lineage-negative cells lacking RAG-mediated rearranged receptors that react rapidly to changes in their micro-environment[3]. Flow cytometric analysis of ILC3 cells in stable MS compared to acute relapsing MS patients and healthy controls has been carried out. Further analysis of selected populations using next generation RNA sequencing is underway to further understand the role of these cells in MS.

IL-17E participates in the recruitment of neutrophils in psoriasiform skin inflammation

*L. Senra[1], A. Mylonas[2], J. Borowczyk-Michalowska[1], R. Stalder[1], C. Conrad[2], W. Boehncke[1,3], **N. C. Brembilla**[1];*
[1]Departement of Pathology and Immunology, University of Geneva, Geneva, Switzerland, [2]Department of Dermatology and Venereology, University Hospital of Lausanne, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, [3]Division of Dermatology and Venereology, University Hospitals of Geneva, Geneva, Switzerland.

Introduction: IL-17E (IL-25) is over-expressed in psoriatic lesional skin, and dermal macrophages represent a main target of IL-17E. We aimed at understanding the role of IL-17E in psoriasis. **Methods**: Macrophages were differentiated from peripheral blood monocytes of 5 healthy donors. Skin inflammation was provoked in BALB/c mice by tape-stripping or imiquimod application. Injection of rmIL-17E or anti-IL-17E blocking antibodies was used to study IL-17E-dependent effects *in vivo*. Skin-infiltrating cells were profiled by multi parameter-flowcytometry and immunohistochemistry, and gene transcript modifications revealed by nanostring and qPCR. **Results:** *In vitro,* IL-17E induced the production of inflammatory mediators by human M2 macrophages through NFkB, p38 and STAT3 activation. Supernatants of IL-17E-stimulated macrophages contained high levels of IL-8 and enhanced the chemotaxis of neutrophils compared to supernatants of resting macrophages. p38-activation was required for these effects. *In vivo*, intradermal injection of rmIL-17E in mice provoked a sustained inflammatory response compared to saline-injection. The resulting inflammatory infiltrate was skewed towards a preferential recruitment of neutrophils in disfavor of T cells. The neutrophil chemokine CXCL1, along with IFN type I-related genes, TNFα and amphiregulin, were abundantly expressed *in situ*. Noteworthy, IL-17E transcripts were upregulated in murine psoriasiform inflammation induced by tape-stripping and imiquimod, and neutralization of IL-17E led to significant reduction in the infiltration of neutrophils. In human lesional psoriatic skin, the number of IL-17E+ cells correlated with the number of neutrophils. **Conclusions:** Our data show that IL-17E favors the preferential recruitment of neutrophils in psoriasiform inflammation and define a novel role for IL-17E in psoriasis.

P.C6.02.04
First steps towards a human *in vitro* 3D arthritic joint model

***A. Damerau**, A. Lang, M. Pfeiffenberger, F. Buttgereit, T. Gaber;*
Charité - Universitätsmedizin Berlin, Berlin, Germany.

Our ultimate goal is to develop a valid human *in vitro* 3D joint model in order to simulate the pathogenesis of arthritis. The *in vitro* 3D joint model consists of different components including an (1) osteogenic and (2) chondrogenic part, (3) the joint space with synovial fluid and (4) the synovial membrane and will contain all involved cell types and thus enable interactions between cells by cell contacts and signaling molecules. Human bone marrow derived mesenchymal stromal cells (hMSC) are used to develop the different 3D tissue components that are characterized in detail using histological, biochemical and molecular biological methods as well as in vitro µCT and scanning electron microscopy. Results for single and co-cultivation are promising with respect to a successful colonization of hMSC on the used β-tricalcium phosphate particles (osteogenic component) and verification of the scaffold-free 3D chondrogenic component. Hyaluronic acid was applied to the osteochondral model (synovial fluid component) and was used for the cultivation of the confluent monolayer of hMSC, formed on a polycarbonate membrane (synovial membrane component).
One aspect of the inflammatory processes in the inflamed joint is simulated by applying human $CD15^+$ granulocytes in combination with cytokines distinctive of rheumatoid arthritis. Subsequently, we analyse the effect of the inflammation. By combining the different components in a standard 96 well format, we aim for a high throughput system for preclinical drug testing as well as a valid *in vitro* 3D disease model to study the immune mediated pathogenesis of arthritis using human material.

P.C6.02.05
Interaction of mesothelial CX3CL1 with monocytic CX3CR1 promotes peritoneal fibrosis

***A. Helmke**, J. Nordlohne, M. Balzer, N. Shushakova, H. Haller, S. von Vietinghoff;*
Division of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.

Introduction: Monocytes and macrophages express the chemokine receptor CX3CR1. It has been ascribed differential roles in fibrosis development. Its ligand fractalkine (CX3CL1) is expressed on endothelial cells, but has also been reported in the peritoneal cavity. Peritoneal fibrosis can develop after chronic exposure to otherwise biocompatible solution in peritoneal dialysis, a form of renal replacement therapy used by approximately 11% of patients with renal failure. It significantly limits the use of this therapy. The role of CX3CR1 and CX3CL1 in this process has not been described.
Methods: Fibrosis development and CX3CR1 expression were investigated in a murine peritoneal dialysis model in vivo and in murine and human primary cells in vitro by histology, flow cytometry, qPCR and ELISA.
Results: CX3CR1 expression increased in chronic peritoneal fibrosis in vivo and in mouse $CD11b^+$ monocytic cells in vitro during co-culture with fibroblasts. We identified the pro-fibrotic cytokine TGFβ as a mediator. CX3CR1 promoted chronic peritoneal fibrosis induced by sterile, pyrogen free dialysis solution. Mesothelial cells expressed its ligand CX3CL1, which exists as stalked membrane-bound and soluble form. Both forms were enhanced by peritoneal dialysis in vivo and by macrophage cytokines IL-1β, TNFα and TGFβ in vitro in the mesothelium more than in endothelial cells. IL-1β and TNFα significantly increased CX3CL1 and, in combination with TGFβ, TGFβ expression itself in human mesothelium. Serum CX3CL1 was elevated in patients recently started on peritoneal dialysis.
Conclusions: Our data identify CX3CR1-CX3CL1 interaction as a pro-fibrotic pathway in peritoneal fibrosis.

P.C6.02.06
Alarmin IL33/ST2 axis function during mucosa inflammation and cancer

***M. A. HERMOSO**[1], K. Dubois[1], M. De la Fuente[1], G. Landskron[1], D. Diaz-Jimenez[1], D. Simian[2], R. Quera[2];*
[1]Facultad de Medicina, Santiago, Chile, [2]Clinica Las Condes, Santiago, Chile.

The Interleukin-33 (IL33)/ST2 axis has been noted in numerous diseases, including asthma, rheumatoid arthritis, inflammatory bowel diseases and, more recently, in cancer and Alzheimer's disease. IL33, a member of the IL1 cytokine family is mainly associated with the induction of T-helper 2 (Th2) and alternative macrophage M2 immune responses through ST2 receptor (encoded by the *IL1RL1* gene). It is expressed as both a membrane-anchored receptor (ST2L) activated by IL33 and as a soluble receptor (sST2) with anti-inflammatory properties. Here we showed that during pathological conditions of the intestinal mucosa, such as in ulcerative colitis (UC) or colon cancer (CRC), levels of IL33 and sST2 are increased in tissue and the periphery. In UC, serum/mucosal ST2, and fecal calprotectin (FC) content correlated with clinical/endoscopic activity of patients, becomes a useful biomarker in the clinical practice. Also, IL33 content in left-sided CRC increases in patients with lymphatic metastasis and its tumor localization is associated with abundant desmoplasia. IL33 transcript levels from CAFs directly correlate with their capacity to induce cell migration and a mesenchymal phenotype in CRC cell lines, suggesting that IL33/ST2 mediates processes associated with invasion and interaction, specifically between CAFs and epithelial tumor cells. We also aimed to demonstrate that single-nucleotide polymorphisms (SNPs) in *IL1RL1* appear to be associated with gene expression regulation in UC patients. Finally, we propose that the IL-33/ST2 system in innate and adaptive immunity regulates cellular and molecular mechanisms, thus impacting on mucosal inflammatory disorder treatment and aiding prognosis.Fondecyt 1170648.

P.C6.02.08

Oncostatin M and the inflamed blood brain barrier: good, bad or both?

***E. Houben**, B. Broux, N. Hellings;*
Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium.

In healthy brain, leukocyte infiltration into the central nervous system (CNS) is limited by the blood-brain barrier (BBB). In multiple sclerosis (MS), this tightly regulated immune surveillance is hampered, leading to infiltration of myelin-specific T-cells into the CNS parenchyma. Oncostatin M (OSM) is produced in lesions of MS patients and we demonstrated in previous research that OSM protects against demyelination and enhances neurite outgrowth. Here, we hypothesize that OSM also has a protective role in CNS damage via the BBB. *In vitro* experiments reveal a decrease ($p<0.05$) in vascular cell adhesion protein 1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1) expression (mRNA and protein) on mouse BBB endothelial cells after OSM treatment under inflammatory conditions. mRNA levels of tight and adherens junctions were not affected, although the effect on the protein level needs to be examined. To investigate the effect of OSM on the BBB *in vivo*, experimental autoimmune encephalomyelitis (EAE) was induced in OSMR KO animals. OSMR deficiency leads to a reduced disease score ($p=0.0351$, $F(1,42)=4.743$) during the acute phase. In contrast, tissue analysis revealed a persistent inflammatory environment in the chronic phase of EAE in OSMR KO mice. The *in vitro* data imply a protective effect of OSM on the BBB, while the *in vivo* data suggest both a disease promoting effect in the acute phase and a disease limiting effect in the chronic phase of EAE. Additional *in vitro* and *in vivo* experiments are necessary to reveal the true role of OSM on the inflamed BBB.

P.C6.02.09

Association of NLRP3 single nucleotide gene polymorphisms with the susceptibility to Relapsing-Remitting Multiple Sclerosis

***M. Izad**, D. Imani, A. Azimi, Z. Salehi;*
Medical Faculty, Tehran, Iran, Islamic Republic of.

NLRP3 inflammasome is a multi-protein complex that controls production of pro-inflammatory cytokines, IL-18 and IL-1β, through caspase-1 activation. These inflammatory cytokines play an important role in the development of multiple sclerosis (MS). The inflammasome NLRP3 gene variations and expression level have been suggested to affect the immune system activity. In this case-control study we determined the association of NLRP3 genetic variants and expression with MS. We analyzed four common single nucleotide polymorphisms (SNPs) of NLRP3 (rs-10754558, rs-35829419, rs-3806265, rs-4612666) in a group of 150 Iranian patients with relapsing remitting MS (RRMS) in comparison to 100 healthy controls using the TaqMan method. For analysis of NLRP3gene expression level, we studied a group of 37 RRMS patients (18 patients at relapse phase and 19 at remission phase, treated with IFN-β) in comparison to 22 healthy controls using Realtime PCR. In this study, we found that NLRP3 rs3806265 C allele and CC genotype were significantly more frequent in the RRMS patients t). While, the frequency of T allele significantly decreased in controls ($P<0.05$.The frequency of CG genotype at position rs10754558 was also significantly higher in the controls compared with patients ($P=0.03$). Moreover, expression level of the NLRP3 in patients at remission phase was significantly reduced in comparison with patients at relapse phase and also healthy controls ($P=0.01$ and $P=0.04$, respectively). The association of NLRP3 polymorphisms with the susceptibility of MS and reduced its expression after IFN-β therapy support the idea that NLRP3 inflammasome could have a critical role in inflammatory responses in MS.

P.C6.02.10

The link between angiogenesis and osteogenesis in spondyloarthritis

***M. H. Kaaij**[1,2], J. van Hamburg[1,2], G. Kollias[3,4], D. L. Baeten[1,2], L. M. van Duivenvoorde[1,2], S. W. Tas[1,2];*
[1]Department of Experimental Immunology, AMC/University of Amsterdam, Amsterdam, Netherlands, [2]Amsterdam Rheumatology & immunology Center, AMC/University of Amsterdam, Amsterdam, Netherlands, [3]Division of Immunology, Biomedical Sciences Research Center Alexander Fleming, Vari, Greece, [4]Department of Physiology, Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Background: Spondyloarthritis is characterized by inflammation, extensive angiogenesis and pathological osteogenesis. Transmembrane (tm)TNF transgenic (tg) mice that overexpress tmTNF exhibit features of spondyloarthritis, including chronic inflammation and pathological osteogenesis. tmTNF ligation to TNF receptor 2 in endothelial cells (ECs) can induce signal transduction pathways, that may promote these processes. Of note, angiogenesis and osteogenesis are coupled by EC differentiation towards a type H ($CD31^{hi}endomucin^{hi}$) phenotype. We investigated the link between pathological angiogenesis, inflammation and osteogenesis in tmTNF tg mice.
Methods: Vertebrae from 6 and 12 weeks and 8 months old tmTNF tg mice or non-tg littermates (n=18) were prepared by cutting 60 µm thick cryosections for confocal imaging.
Results: tmTNF tg mice exhibited ectopic osteogenesis which was not observed in non-tg littermates. Immunostainings showed that type H vessels are in the vicinity of the ectopic osteogenesis and $osterix^{+}$ osteoprogenitors. Furthermore, there is increased osteogenesis, type H vessel presence and a different vessel architecture within the vertebrae of tmTNF tg mice compared to non-tg littermates that progresses with age. Non-tg littermate vertebrae only have physiological osteogenesis, which is in the metaphysis and periosteum. In addition, tmTNF tg mice exhibit altered bone marrow (BM) architecture containing extensive lymphoid aggregates, which predominantly consisted of $B220^{+}$ aggregates and contain high endothelial venules.
Conclusions: tmTNF overexpression in mice leads to development of type H vessels associated with ectopic osteogenesis. In addition, extensive lymphoid aggregates develop in the BM. Current studies are aimed at identification of signaling pathways in ECs that contribute to these processes.

P.C6.02.12

Targeting EphA signaling by dasatinib inhibits intestinal inflammation

***A. Kim**, S. Shim, S. Park, J. Myung;*
Korea Institute of Radiological & Medical Science, Seoul, Korea, Republic of.

Irradiation functions a crucial role in the pathogenesis of intestinal inflammatory diseases, which regulated by vascular permeability and leukocyte infiltration. Thus, a potential therapeutic strategy for the treatment of radiation-induced inflammatory diseases would be to administer drugs that could induce the regulation of vascular barrier and leukocyte extravasation at sites of inflammation. In the present study, we demonstrate that the clinically approved cancer drug dasatinib, a tyrosine kinase inhibitor, to control inflammation. To evaluate whether irradiation affects immune cell activity, we exposed to irradiation in human or mice-derived endothelial cell and leukocyte. Irradiated HUVEC showed increased permeability, inflammatory cytokine, and adhesion to leukocyte. In addition, irradiation activates inflammatory cells including monocyte, macrophage and neutrophil in lamina propria of mice. However, HUVEC treated with dasatinib decreased inflammatory cytokine level and adhesion to leukocyte through inhibition of p-VE-cadherin and ICAM. We next investigate what molecular signaling was regulated by dasatinib. We showed that irradiation triggered Eph/ephrin signaling, inducing inflammatory effects whereas dasatinib reduced phosphorylated Eph/ephrin. Moreover, decreased Eph/ephrin signaling can inhibit inflammation-associated cytokine and adhesion molecules in HUVEC. Treatment with dasatinib inhibits irradiation-induced vessel permeability and leukocyte infiltration in vivo. Therefore, irradiation-induced damage of endothelial and leukocyte activates inflammatory response but treatment with dasatinib could useful strategy for reducing inflammation.

P.C6.02.13

Synovial osteoprogenitor phenotype in patients with rheumatoid arthritis

*K. Barbaric Starcevic[1], N. Lukac[2,3], M. Jelic[1], A. Sucur[4,3], D. Grcevic[4,3], **N. Kovacic**[2,3];*
[1]Department of Orthopaedic Surgery, University Hospital Center Zagreb, University of Zagreb School of Medicine, Zagreb, Croatia, [2]Department of Anatomy, University of Zagreb School of Medicine, Zagreb, Croatia, [3]Laboratory for Molecular Immunology, University of Zagreb School of Medicine, Zagreb, Croatia, [4]Department of Physiology and Immunology, University of Zagreb School of Medicine, Zagreb, Croatia.

Introduction: Rheumatoid arthritis (RA) is a chronic, autoimmune joint inflammation, which results in disability due to irreversible joint destruction. Current treatments can slow the progression of the disease, but are still ineffective in a number of individuals and mainly target inflammation. Since there is increasing evidence on the ability of mesenchymal cells to promote regeneration and suppress inflammation, we focused on the phenotype of non-hematopoietic progenitor populations in synovial tissue of patients with arthritis. Materials and methods: We analyzed cellular composition of synovial tissue from 9 RA patients undergoing surgery, and 6 control patients undergoing arthroscopic treatment. Cells were released by collagenase digestion and analyzed by flow cytometry after labeling with two panels: 1. CD3-FITC, CD14-PE, 7-AAD, CD11b-PECy7, CD235a-APC, CD19-APCeF780, and 2. CD140a-PE, 7-AAD, CD105-PECy7, CD45/CD31/CD235a-APC, CD200-APCeF780. Results: Synovial infiltrate in RA had higher proportions of $CD3^{+}$ and $CD19^{+}$ cells, and similar variable proportions of $CD11b^{+}$ and $CD14^{+}$ in comparison to control samples. Amongst non-hematopoietic ($CD45^{-}CD31^{-}CD235a^{-}$) cells, proportion of $CD105^{+}$ cells was significantly increased in RA patients, whereas proportion of CD200+ cells was similar to controls. Amongst $CD200^{+}$ cells, $CD200^{+}CD105^{+}$ population was more abundant, while $CD200^{+}CD105^{-}$ cells were slightly less abundant in RA samples in comparison to healthy controls. Conclusions: There are significant differences in the composition of synovial non-hematopoietic compartment between RA patients and healthy synovia. According to experimental studies, $CD200^{+}CD105^{-}$ cells are considered as earliest osteoprogenitors, and also implicated in regulation of myeloid cell accumulation and activity. Loss of these cells might favor inflammation and arthritis progression.

P.C6.02.14
Modulation of immune cell infiltration by S1PR4

***C. Ringel**, B. Bruene, A. Weigert;*
Institute of Biochemistry I, Frankfurt am Main, Germany.

Sphingosine-1-phosphate is an immune-modulating lipid that has been shown to influence the immune response through five G-protein coupled receptors. For instance, migration of T lymphocytes into the circulation depends on sphingosine-1-phosphate receptor 1 (S1PR1). The less well understood S1PR4, mainly expressed on immune cells, has been found to modulate inflammatory responses but whether it is also involved in migration of immune cells is currently discussed. There is some indication that it is involved in neutrophil homeostasis and potentially trafficking. In an Imiquimod-induced mouse model of psoriasis we observed that a knockout of S1PR4 reduced inflammation, accompanied by a reduced infiltration of neutrophils and macrophages into the psoriatic lesions. At the same time we found a reduction in pro-inflammatory cytokines and chemokines such as IL-6, CCL2, and CXCL1. Similar data were also obtained in a model of Zymosan-induced peritonitis. This suggests a role of S1PR4 in the early stages of inflammation by promoting neutrophil and macrophage trafficking via chemokine production. Using RNAScope in mouse tissues and in vitro signaling pathway analysis, we identify the cellular source of these chemokines and the pathways downstream of S1PR4 that regulate their expression. Together, our data provide a novel feature of inflammation regulation by S1P and S1P receptors.
Supportet by the Else Kröner-Fresenius-Stiftung and the Graduate School for “Translational Research Innovation - Pharma” (TRIP).

P.C6.02.15
Adipocyte function in the mesenteric fat tissue depends on the innate immune system

***F. Schmidt**, I. Freise, R. Glauben, M. Letizia, C. Weidinger, B. Siegmund;*
Charité Universitätsmedizin Berlin, Berlin, Germany.

In Crohn’s disease the mesenteric fat tissue is creeping around the inflamed intestine. Previous data indicate that adipocytes express functional receptors of the innate immune system. Thus, translocalizing bacteria might serve as trigger for this unique finding. To address this question MyD88$^{-/-}$ and adipocyte-specific MyD88 knockout (MyD88^{AdipoqCre}) mice were studied.
MyD88$^{-/-}$ but not MyD88^{AdipoqCre} mice presented with an increased mortality upon dextran sodium sulfate (DSS)-treatment. The effector response in the mesenteric fat was reduced, paralleled by an increased bacterial translocation. MyD88^{AdipoqCre} mice revealed less severe disease as indicated by lower concentrations of IL-6 and TNF in *ex vivo* colon tissue supernatants and higher expression of IL10 in the mesenteric fat.
Creeping fat is characterized by a strong cellular infiltrate. To determine phenotypic and functional differences of the mesenteric fat tissue between MyD88$^{-/-}$, MyD88^{AdipoqCre} and wildtype (WT) mice, cellular composition as well as chemoattractive function was analyzed. In health, no differences with regard to macrophage and T cell populations were observed. To assess chemoattractive function of the mesenteric fat tissue, transmigration assays were performed. WT or MyD88^{AdipoqCre} but not LPS-stimulated MyD88$^{-/-}$ fat did attract CD4^{+} T-cells. However, LPS-stimulated fat from MyD88$^{-/-}$ and MyD88^{AdipoqCre} mice attracted less monocytes than WT fat. Remarkably, the phenotype of bone marrow-derived macrophages shifted to an anti-inflammatory upon treatment with either WT or MyD88^{AdipoqCre} fat.
These data indicate that adipocytes contribute to the milieu in the mesenteric fat with regard to cellular infiltrate as well as local mediators and depend on the innate immune system.

P.C6.02.16
Increased intra-articular granzyme M and local proinflammatory cytokine release in Rheumatoid Arthritis

***L. Shan**[1], A. C. Wensink[1], L. L. van den Hoogen[1], J. Meeldijk[1], H. M. Kok[1], L. H. Jongeneel[1], M. Boes[1], M. H. Wenink[2], C. E. Hack[1], T. R. Radstake[1], J. A. van Roon[1], N. Bovenschen[1];*
[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands.

Objective: Granzymes are serine proteases involved in eliminating tumor cells and virally infected cells. In addition, extracellular granzyme levels are elevated in inflammatory conditions, including several types of infection and auto-immune diseases, such as rheumatoid arthritis (RA). While GrA and GrB have been associated with RA, a role for the other three granzymes (GrH, GrK and GrM) in this disease remains unclear. Here, we investigated the presence and role of GrM and GrK in serum and synovial fluid of patients with RA, psoriatic arthritis, and osteoarthritis.
Methods: Granzyme levels were determined in serum, synovial fluid, peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) of RA patients and relevant control groups. In addition, the link between GrM and other inflammatory cytokines in synovial fluid was investigated.
Results: Serum GrM and GrK levels were not affected in RA. GrM, but not GrK, levels were elevated in synovial fluid of RA patients. GrM was mainly expressed by cytotoxic lymphocytes in SFMCs with a similar expression pattern as compared with PBMCs. Intra-articular GrM expression correlated with IL-25, IL-29, XCL1, and TNFα levels. Intriguingly, purified GrM triggered the release of IL-29 from human fibroblasts *in vitro*.
Conclusions: These data indicate that GrM levels are increased in RA synovial fluid and that GrM can stimulate proinflammatory IL-29 release from fibroblasts, suggesting a role of GrM in the pathogenesis of RA.

P.C6.02.17
The anti-microbial peptide LL-37 shapes the response of keratinocytes to psoriasis related stimulations

***H. Sigurgrímsdóttir**[1,2], J. Freysdottir[1,3,2], B. R. Lúðvíksson[1,2];*
[1]Immunology department, Landspitali - The National University Hospital of Iceland, Reykjavík, Iceland, [2]Faculty of Medicine, Biomedical Center, University of Iceland, Reykjavík, Iceland, [3]Center for Rheumatology Research, Landspitali – The National University Hospital of Iceland, Reykjavík, Iceland.

Introduction: Psoriasis is a common inflammatory disease of the skin. It is characterized by infiltration of immune cells into the skin, hyperproliferation of keratinocytes in the basal layer of the epidermis and an imbalanced cytokine and chemokine environment. LL-37 is an anti-microbial peptide that is a part of the innate immune system. It is upregulated in psoriatic patients, both in blood and skin. The main goal of this research was to map out the effects that LL-37 has on the secretion of keratinocytes. Material and methods: A HaCaT keratinocyte cell line and primary keratinocytes were cultured and stimulated with psoriasis related stimulations or left unstimulated, all in the presence or absence of LL-37. Cell supernatant was collected and analysed with Luminex for 27 soluble analytes. Results: All chemokines, cytokines and growth factors analysed were measureable in one or more of the culture conditions. LL-37 had measurable effects on the secretion of both immortalized and primary keratinocytes. LL-37 had diverse effects and was able to decrease secretion of some analytes and increase secretion of other analytes. Keratinocytes were shown to produce IL-17A but the addition of LL-37 did not affect the secretion. Other analytes affected included IL-10, IL-17E, IL-12p70, CXCL8, CCL11, CCL19 and VEGF. Conclusions: Keratinocytes secrete many types of chemokines, cytokines and growth factors and LL-37 has a considerable effect on the secretion. Keratinocytes seem to have a bigger role in the pathogenesis of psoriasis than previously thought and that role seems to be, in part, shaped by LL-37.

P.C6.02.18
Au nanorod-induced NLRP3 inflammasome activation is mediated by ER stress

***R. J. Vandebriel**[1], S. Remy[2], J. Vermeulen[1], E. Hurkmans[1], N. Bastus[3], B. Pelaz[4], V. Puntes[3], W. Parak[4], J. Pennings[1], I. Nelissen[2];*
[1]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [2]VITO NV, Mol, Belgium, [3]Institut Catala de Nanociencia i Nanotecnologia (ICN2), Barcelona, Spain, [4]Philipps Universitat, Marburg, Germany.

The widespread and increasing use of engineered nanomaterials (ENM) increases the risk of human exposure, generating concern that ENM may provoke adverse health effects. In this respect, their physicochemical characteristics are critical. The immune system may respond to specific ENM properties by inflammatory reactions. Inflammasome activation has drawn significant attention since inflammasomes, especially NLRP3 respond to a wide range of stimuli including nanoparticles, and their activation is associated with various inflammatory diseases, including lung fibrosis, obesity and type-2 diabetes. Inflammasomes are intracellular multiprotein complexes that assemble upon stimulation, resulting in activation of caspase-1 that in turn induces production of IL-1β and IL-18, which are potent mediators of inflammation. Endoplasmic reticulum (ER) stress has been reported as one of the mechanisms underlying NLRP3 inflammasome activation.
In this study, PEGylated Au ENM of ≈60 nm, having different shapes (stars, spheres and rods) were extensively characterized, and tested for possible LPS contamination. PMA-activated THP-1 cells were exposed to these ENM, and cell viability and IL-1β production were measured to assess NLRP3 activation. In addition, the exposed cells were subjected to gene expression analysis using microarray analysis to investigate related signalling pathway regulation.
PEGylated Au nanorods (NR), but not nanostars or nanospheres, showed NLRP3 inflammasome activation. Cells deficient in the NLRP3 scaffold or ASC adaptor did not show this effect. Only NR-exposed cells showed down-regulation of ER-associated cholesterol metabolism.
This may suggest that ER stress mediates NLRP3 inflammasome activation by Au NR.
Supported by the EU funded project FutureNanoNeeds (Grant agreement N° 604602).

Imiquimod inhibits mitochondrial Complex I for K^+ efflux-independent NLRP3 inflammasome activation and cancer cell growth arrest

*D. Dittlein[1], C. J. Groß[2], J. Smollich[2], D. Stößel[3], E. Neuwirt[4], O. Gorka[4], C. Traidl-Hoffmann[1], **O. Groß**[4];*
[1]Institute of Environmental Medicine, Helmholtz Center Munich, Munich, Germany, [2]Institute of Clinical Chemistry and Pathobiochemistry, Klinikum rechts der Isar, Munich, Germany, [3]Metabolomic Discoveries GmbH, Potsdam, Germany, [4]Institute of Neuropathology, Freiburg, Germany.

Imiquimod is a small-molecule ligand of TLR7 licensed for topical treatment of skin cancers. It has TLR7-independent activities that are mechanistically unexplained, including NLRP3 inflammasome activation and induction of cancer cell growth arrest. We reported that imiquimod triggers K^+ efflux-independent NLRP3 activation in myeloid cells by inferring with cellular respiration and triggering mitochondrial ROS (Groß CJ *et al., Immunity,* 2016). Using chemoproteomics, metabolomics, and functional assays, we find that imiquimod directly inhibits mitochondrial respiratory chain Complex I, causing vast changes in cancer cell metabolism. Complex I regenerates NAD^+ required for oxidizing nutrients to support the biosynthetic pathways fueling cancer cell growth. Indeed, restoring NAD^+ regeneration by bypassing Complex I rescues proliferation. Together, our data suggest that inhibition of Complex I by imiquimod contributes to its growth-suppressive therapeutic effects on cancer, and that tissue targeting through topical application avoids systemic toxicity of respiratory chain inhibitors and is likely involved in the clinical success of imiquimod.

P.C6.02.20

Context-specific regulation of monocyte surface IL7 expression and soluble receptor secretion by a common autoimmune risk allele

***H. Al-Mossawi**, C. Taylor, N. Yager, E. Lau, S. Danielli, J. De Wit, J. Gilchrist, I. Nassiri, E. A. Mahe, W. Lee, L. Rizvi, S. Makino, J. Cheeseman, M. Neville, J. C. Knight, P. Bowness, B. P. Fairfax;*
University of Oxford, Oxford, United Kingdom.

IL-7 is a key factor in T-cell immunity and *IL7R* polymorphisms are implicated in autoimmune pathogenesis. IL7R mRNA is induced in stimulated monocytes in a genetically determined manner, yet a role for IL7R in monocyte biology remains unexplored. Here we characterize genetic regulation of IL7R at the protein level across multiple cell subsets and conditions in healthy individuals. We find monocyte surface and soluble IL7R (sIL7R) protein is markedly expressed in response to lipopolysaccharide (LPS). We further demonstrate alleles of rs6897932, a non-synonymous IL7R polymorphism associated with susceptibility to Multiple Sclerosis, Ankylosing Spondylitis and Primary Biliary Cirrhosis, form the key determinant of both surface IL7R and sIL7R in the context of inflammation. No effect of this allele was observed in unstimulated monocytes or in other lymphoid cells. Monocyte-derived sIL7R was greatly in excess of that produced by $CD4^+$T-cells, and strongly associated with both rs6897932 genotype and expression of the splicing factor gene DDX39A. Stimulated monocytes are sensitive to exogenous IL-7, which elicits a defined transcriptional signature. Flow cytometry and single cell sequencing of synovial fluid derived monocytes from patients with Spondyloarthritis shows an enlarged subset of IL7R+ monocytes with a unique transcriptional profile that markedly overlaps the in-vitro IL-7 induced geneset and the previously described mono4 subset. These data demonstrate disease-associated genetic variants at *IL7R* specifically impact monocyte protein IL7R and sIL7R following innate immune stimulation, suggesting a previously unappreciated key role for monocytes in IL-7 pathway biology and IL7R-associated diseases.

P.C6.03.01

Gastrointestinal helminth infection improved insulin sensitivity and decreased systemic inflammation in mouse models of T2D

***Z. Agha**, R. Alhallaf, M. Field, A. Kupz, J. Sotillo, A. Loukas;*
AITHM, Cairns, Australia.

The incidence of type 2 diabetes (T2D) is rapidly increasing worldwide and is becoming a major health problem particularly in western countries. Microorganisms, including parasitic worms and gut microbiota, have co-evolved with their host over millennia. It has been suggested that helminth infections might protect against T2D by inducing a T-helper-2 polarization of the immune system. On the other hand, recent data suggest that many inflammatory diseases, and in particular T2D, might be associated with gut microbiota alternations. Moreover, other studies have highlighted the role of helminth infections in altering the composition of the gut microbiota.
We here demonstrated that infection with the parasitic nematode *Nippostrongylus brasiliensis* significantly reduced body weight, fasting blood glucose and oral glucose tolerance test in mouse models of T2D. We also found that this infection was associated with boosted type 2 immune responses measured by an increase in the eosinophil number. We further investigated the effect of this helminth infection on the gut microbiota composition. Interestingly, we found that *N. brasiliensis* infection altered the gut microbiota composition, resulting in a general increase of bacteria belonging to phyla Firmicutes, Bacteroidetes and Actinobacteria, in particular orders; Clostridiales, Bacteroidales and Coriobacterials.
Our findings show that *N. brasiliensis* infection is associated with changes in the gut microbiota and in local and systemic cell populations. These changes might restore gut homeostasis and improve systemic inflammation, suggesting that this helminth might be a novel therapeutic approach for preventing T2D.

P.C6.03.02

P2X7receptor stimulation could differentially induce activation or inhibition of theNLRP3 inflammasome

***D. Angosto Bazarra**, J. J. Martínez García, H. Martínez Banaclocha, C. de Torre Minguela, P. Pelegrín Vivancos;*
Instituto Murciano de Investigación Biosanitaria IMIB-Arrixaca, Murcia, Spain.

Inflammasomes are important signaling complexes formed by a subgroup of intracellular pattern recognition receptors that activate caspase-1 and promotes the release of the proinflammatory cytokines as interleukin (IL)-1b. Among all inflammasomes the NLRP3 could be activated in response to different microbial- or damage-associated molecules, as high extracellular concentrations of the nucleotide ATP that activates the P2X purinoceptor 7 (P2X7). The NLRP3 inflammasome signals through aggregation ASC into large particle-like structures, termed ASC-specks, that could be found in biological fluids upon inflammasome activation. Our results show that stimulation of the P2X7 receptor before LPS priming and NLRP3 activation decreased the formation of intracellular ASC specks and impaired the release of IL-1b. NLRP3 priming was decreased when P2X7 was activated before LPS stimulation by studying gene expression for *Nlrp3* and *Il1b*. Treatment of the cells with the antioxidant pyrrolidine dithiocarbamate (PDTC) during initial P2X7 receptor stimulation restored IL-1b release induced by NLRP3 activation, suggesting that P2X7 receptor induced NLRP3 inhibition could be mediated by mitochondrial dysfunction. P2X7 receptor activation leads to a fast mitochondrial depolarization. To support this idea, NLRP3 activation was also reduced when mitochondrial membrane depolarization was induced by antimycin A. Similarly, mitochondrial membrane depolarization induced by antimycin A resulted in a reduction of *Nlrp3 and Il1b* gene induction by LPS. In conclusion, our data supports a novel model of NLRP3 inhibition induced by P2X7 receptor affecting mitochondrial membrane potential that affected LPS priming.

Involvement of VEGF -1154A/G and VEGF -2758A/C in genetic susceptibility to develop RA among Algerian patients

***M. Benidir**[1], S. S. Salah[1], M. Djennane[2], H. Boulares[1], D. Zaoui[1], A. Hamdi[1], F. Mechid[3], D. Acheli[4], A. Moussa Mebarek[4], H. Balaouane[1], C. Dahou-Makhloufi[3], H. Djoudi[4], H. Amroun[5], R. Tamouza[6], N. Attal[1];*
[1]Immunology. Pasteur Institute of Algeria, Algiers, Algeria, [2]Rheumatology. Tizi-Ouzou university hospital, Tizi-Ouzou, Algeria, [3]Rheumatology. Bab El Oued university hospital, Algiers, Algeria, [4]Rheumatology. Douera university hospital, Algiers, Algeria, [5]Immunology. Hussein Dey university hospital, Algiers, Algeria, [6]Immunology and Immunogenetics. Saint Louis hospital, Paris, France.

Introduction: Inflammatory process, in RA, leads to joints destruction and can reach lungs, skin and other organs. This is important in understanding genetic background as well as role of environment in this condition. In addition, overlap of risk alleles in RA with those of other autoimmune diseases suggests existence of common mechanisms underlying these conditions. The aim of our study is to analyze possible contribution of VEGF SNPs in RA susceptibility among Algerian patients.
Methods: Our study included 228 RA patients (age: 47±13 years; Sex Ratio: 1:6; Disease duration: 9.4±8.2 years) compared to 188 healthy controls (age: 35±10 years; Sex Ratio: 1:2). Genomic DNA from RA patients and controls was genotyped, using TaqMAN technology, for VEGF-2578A/C, -1154A/G and -634C/G SNPs. Allele and genotype frequencies were compared using chi-square test. We used Phase 2.1 software to generate haplotypes.
Results: Allelic frequency analysis of VEGF-2578A/C SNP shows that allele C is more common in RA patients (OR=1.5) and that allele A is more common in healthy controls (OR = 0.67), CC genotype is more common in RA patients (OR=1.91) and AC is more common in healthy controls (OR=0.51). For VEGF-1154A/G, allele G is more common in RA patients (OR=1.53) and allele A is more common in healthy subjects (OR=0.65). In addition, GG genotype is more common in RA patients (OR=1.9) and AG genotype more common in healthy controls (OR=0.47). Finally, our results are in agreement with literature data.
Conclusion: Our results show a combination of VEGF-1154A/G and VEGF-2758A/C SNPs in RA development.

P.C6.03.04

RNA and histones in dead cells synergistically provoke FSAP activation in serum

I. Bulder[1]*, G. Marsman*[1]*, F. Stephan*[1]*, B. Luken*[1]*, S. Zeerleder*[1,2]*;*
[1]*Sanquin Research, Dept of Immunopathology and Landsteiner Laboratory, Academical Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [2]*Department of Hematology, Acedemical Medical Center, Amsterdam, Netherlands.*

The plasma serine protease Factor VII-activating protease (FSAP) has been implicated in thrombosis and vascular remodeling. Moreover, FSAP is crucially involved in the release of chromatin from dead cells. FSAP circulates in an inactive form and is activated upon contact with late apoptotic or necrotic cells. FSAP binds to purified negatively charged molecules, e.g. RNA and DNA, and positively charged molecules, e.g. histones, which have both been implicated in the auto-activation of FSAP albeit through different mechanisms. We aimed to identify the component(s) from dead cells that mediate FSAP auto-activation in serum.Binding of FSAP to late apoptotic Jurkat cells was studied using (confocal) microscopy and flow cytometry. Digestion of RNA in late apoptotic cells markedly reduced the binding of FSAP to these cells, and concurrently the activation of FSAP induced by these cells was also reduced. In contrast, DNA digestion strongly enhanced both the binding and activation of FSAP. Upon cellular fractionation, the cytoplasmic fraction containing most RNA did not induce FSAP activation, whilst the nuclear fractions that predominantly contained histones did induce the activation of FSAP. In serum, the addition of histones induced FSAP activation, whilst activation did not occur upon addition of RNA. However, when RNA was combined with histones this markedly enhanced the activation of endogenous FSAP in serum. Our results indicate that both RNA and histones are involved in the activation of FSAP by dead cells. RNA does not directly induce the auto-activation of FSAP, but may promote/facilitate auto-activation of FSAP induced by histones.

P.C6.03.05

An immunosuppressive tick salivary gland protein DsCystatin interferes with Toll-like receptor signaling by downregulating TRAF6

J. Dai*;*
Institute of Biology and Medical Sciences, Soochow University, Suzhou, China.

Ticks, blood-feeding arthropods, secrete immunosuppressive molecules that inhibit host immune responses and provide survival advantages to pathogens. In this study, we characterized the immunosuppressive function of a novel tick salivary protein, DsCystatin, from *Dermacentor silvarum* of China. DsCystatin directly interacts with human Cathepsins L and B and inhibited their enzymatic activities. DsCystatin impaired the expression of inflammatory cytokines such as IL1β, IFNγ, TNFα and IL6 from mouse bone marrow derived macrophages (BMDMs) that stimulated with LPS or *Borrelia burgdorferi.* Consistently, DsCystatin inhibited the activation of mouse BMDMs and bone marrow derived dendritic cells (BMDCs) by downregulating the surface expression of CD80 and CD86. Mechanically, DsCystatin inhibited LPS or *B. burgdorferi* induced NFκB activation. For the first time, we identified that DsCystatin attenuated TLR4 signaling by targeting TRAF6. DsCystatin enhanced LPS induced autophagy, mediated TRAF6 degradation *via* an autophagy dependent manner, thereby impeded the downstream phosphorylation of IκBα and the nuclear transport of NFκB. Finally, DsCystatin relieved the joint inflammation in *B. burgdorferi* or Complete Freund's adjuvant induced mouse arthritis models. These data suggest that DsCystatin is a novel immunosuppressive protein and can be potentially used in the treatment of inflammatory diseases.

P.C6.03.06

Signaling through purinergic receptor P2Y2R enhances macrophage IL-1beta production

G. de la Rosa*, A. Gómez, P. Pelegrín;*
IMIB-Arrixaca, El Palmar, Murcia, Spain.

Release of nucleotides during processes such as necrosis or apoptosis have been described to have both proinflammatory and antiinflammatory effect on the surrounding cells. Purinergic receptors expressed sentinel macrophages will be able to modulate the inflammatory response depending on the context. Here we describe how UTP and ATP enhance IL-1beta production during Lipopolysaccharide(LPS)-induced murine resident peritoneal macrophage activation. Inhibition of the purinergic receptor P2Y2R with AR-C 118925xx reverted this increase induced by nucleotides. Moreover, blockade of Jnk activity with SP600125 also showed a reduction in IL-1beta by nucleotide-treated macrophages, indicating that this kinase is downstream P2Y2R and involved in the synergistic effect of nucleotide signaling with LPS. However, production of another proinflammatory cytokine such as TNF-**α** was clearly decreased, as per activation of adenosine receptors. This novel unique proinflammatory signature might be relevant in future inflammation studies.

P.C6.03.07

C-reactive protein promotes inflammation through metabolic reprogramming of human macrophages

M. Newling[1]*, L. Sritharan*[1]*, A. van der Ham*[2]*, M. van Weeghel*[1]*, L. de Boer*[1]*, S. Zaat*[1]*, D. Baeten*[1]*, R. Houtkooper*[1]*, B. Everts*[2]*,* ***J. den Dunnen***[1]*;*
[1]*AMC, Amsterdam, Netherlands,* [2]*LUMC, Leiden, Netherlands.*

C-reactive protein (CRP) is an acute-phase protein produced in high quantities by the liver in response to infection and during chronic inflammatory disorders, and is therefore in widespread clinical use as a marker of inflammation. Although CRP is known to facilitate the uptake of dead cells and particular strains of bacteria by phagocytic cells, it still remains largely elusive whether CRP displays additional immunological functions.
Strikingly, we here provide evidence that CRP is not only a marker, but also a cause of inflammation by strongly amplifying pro-inflammatory cytokine production. We show that complexed CRP (c-CRP), as a result of binding to its ligand phosphocholine on dead cells or bacteria, but not soluble CRP, strongly enhances TNF, IL-1β, and IL-23 production by human macrophages. While c-CRP does not induce cytokine production individually, c-CRP synergizes with particular pattern recognition receptors such as Toll-like receptors (TLRs) to amplify cytokine gene translation.
By screening with specific blocking antibodies we identified Fc gamma receptor I and IIa (FcγRI and FcγRIIa) as the main receptors responsible for initiating c-CRP-induced inflammation. Furthermore, we demonstrate that the increased production of pro-inflammatory cytokines was dependent on signaling through kinases Syk, PI3K, and Akt, resulting in enhanced pro-inflammatory cytokine production through metabolic reprogramming, particularly through amplified glycolysis, amplified fatty acid synthesis, and strongly reduced oxidative phosphorylation.
These data indicate that c-CRP-induced metabolic reprogramming provides a novel mechanism of host defense against bacteria, but may also exacerbate pathology in the context of various CRP-associated inflammatory disorders, including rheumatoid arthritis and atherosclerosis.

P.C6.03.08

Potential beneficial effects of Poly (ADP-ribose) polymerase-1 inhibition in COPD pathogenesis

V. Dharwal*, A. S. Naura;*
Department of Biochemistry, Panjab University, Chandigarh, India.

Chronic obstructive pulmonary disease (COPD) is one of the leading causes responsible for global morbidity and mortality, and has no effective treatment available till date. We have previously reported that PARP-1 plays a crucial role in the establishment of airway inflammation associated with asthma/acute lung injury. In the present work, we have evaluated the beneficial effects of PARP-1 inhibition on COPD pathogenesis utilizing elastase-induced mouse model of the disease. Our data show that PARP-1 inhibition by olaparib (5mg/kg b.wt (*i.p.*)) significantly reduced the elastase induced recruitment of inflammatory cells particularly neutrophils. Reduction in the lung inflammation was associated with suppressed myeloperoxidase activity and restoration of redox status in the lung tissues towards normal. Further, the normalization of redox status in lungs was coupled with suppressed PARP-1 activity as reflected by reduced ribosylation of tissue proteins. Western-blot analysis showed that olaparib administration prior to elastase instillation blunted the phosphorylation of P65-NF-κB at Ser 536 without altering the phosphorylation of its inhibitor IκBα in the lungs. The elastase-induced expression of NF-κB dependent pro-inflammatory cytokines (TNF-α, IL-6), chemokine (MIP-2), and growth factor (GCSF) was down-regulated severely both at the mRNA and protein levels upon olaparib administration. A significant protection against the elastase-induced emphysema was also observed. Additionally, it was observed that PARP-1 heterozygosity has similar effects as exhibited by olaparib on elastase-induced inflammation and emphysema. Overall, our data strongly suggest that PARP-1 plays a critical role in elastase induced lung inflammation, and thus might act as a potential drug target against COPD.

P.C6.03.09

ATF4 and XBP1 regulate the expression of ULBP1 in kidney cells upon endoplasmic reticulum stress activation

P. Díaz Bulnes[1]*, A. S. Sanz Bartolome*[2]*, A. Baragaño Raneros*[1]*, R. M. Rodriguez*[1]*, C. López Larrea*[1]*, B. Suarez-Alvarez*[1]*;*
[1]*Traslational Immunology Laboratory, Instituto de Investigación Sanitaria del Principado de Asturias, Oviedo, Spain,* [2]*Laboratory of Nephrology, IIS-Fundacion Jimenez Diaz, Madrid, Spain.*

Acute kidney injury may result from a variety of processes such as hypoxia, inflammation and proteinuria that lead to development and progression of kidney disease. As consequence, dysfunction of Endoplasmic Reticulum (ER) is triggered causing the activation of unfolded protein response (UPR). Expression of NKG2D ligands in damaged kidneys can induce the activation of cytotoxic cells (NK and $CD8^+$ T) through the interaction with NKG2D receptor. Our aim was to analyse the influence of ER stress on the NKG2DL expression during the induced kidney damage. Activation of UPR by tunicamycin and thapsigargin in human and mouse renal tubular cell lines induces the expression of protein sensors (ATF6, PERK and IRE1α) that initiate the three major signalling pathways of UPR. Moreover, that correlates with a significant increased of human ULBP1 ligand and its murine homologous MULT1. Similar results were observed in experimental renal damage models (AKI /UUO) where UPR activation is associated with an increased MULT1 expression.

Activation with specific inducers of each signalling pathway and gene silencing assays showed that PERK (ATF4) and IRE1α (XBP1) are directly involved in the ULBP1 and MULT1 expression. Additionally, PERK-ATF4 signalling positively regulates the IRE1α expression increasing the *XBP1* mRNA splicing. Chromatin immunoprecipitation assays revealed that both transcription factors, ATF4 and XBP1s, bind to the ULBP1 promoter regulating its expression in renal cells. Thus, blockage of the UPR signalling pathway through PERK-ATF4 and IRE1α-XBP1 could inhibit the immune recognition of renal tubular cells mediated by the NKG2D-NKG2D ligands engagement diminishing the renal damage.

P.C6.03.10

Epidermal growth factor and mannan binding lectin in serum and saliva of patients with recurrent aphthous stomatitis

Z. Jiraskova Zakostelska[1], *Z. Stehlikova*[1], *K. Klimesova*[1], *M. Kverka*[1,2], *J. Bartova*[3], *A. Fassmann*[4], *L. Izakovicova-Holla*[4], *J. Petanova*[3], *H. Tlaskalova-Hogenova*[1];
[1]*Institute of Microbiology of the CAS, Prague, Czech Republic,* [2]*Institute of Experimental Medicine of the CAS, Prague, Czech Republic,* [3]*School of Dental Medicine, General University Hospital in Prague, Prague, Czech Republic,* [4]*Clinic of Stomatology, Institutions Shared with St. Anne's Faculty Hospital, Masaryk University, Brno, Czech Republic.*

Introduction: Recurrent aphthous stomatitis (RAS) is a multifactorial disease with unknown etiopathogenesis. Genetic and immunological background of individual together with environmental factors plays an important role in onset, progression and remission of this disease. The aim of our study was to measure changes in epidermal growth factor (EGF), a cytoprotective factor against injuries, and mannan binding lectin (MBL), a pattern recognition molecule of the innate immune system that activates lectin pathway, in saliva and serum of patients with RAS. **Methods:** Whole saliva and serum samples were collected from healthy controls (n= 15) and RAS patients in active (with oral ulceration; n= 33) or inactive (absence of oral ulceration; n= 28) stage of disease. Measurement of EGF or MBL concentration was performed by ELISA. **Results:** The levels of EGF in serum from patients in active and passive stage of RAS were significantly decreased when compared to healthy controls. In saliva, we found similar trend for EGF when we compared patients with active and passive stage of RAS and healthy controls but those result were not statistically significant. We have not found any significant differences in levels of MBL in RAS patients compared to healthy controls. **Conclusions:** EFG is one of the essential factors in tissue regeneration and its low concentration in serum or saliva may hinder healing or regeneration in patient with recurrent aphthous stomatitis. This study was supported by Ministry of Health of the Czech Republic, grant nr. 15-29336A.

P.C6.03.11

SIRPá signaling inhibits macrophage polarization towards the proinflammatory phenotype while promoting the anti-inflammatory polarization through biased activation of SHP-1 or SHP-2

Y. Liu*;*
Georgia State University, Atlanta, United States.

Macrophages undergo polarization into the proinflammatory M1 phenotype, which is required for host defense, or the alternative M2 phenotype, which is involved in wound healing and tissue remodeling. SIRPα is an Immunoreceptor Tyrosine-based Inhibitory Motif (ITIM)-containing receptor expressed on macrophages and functions through the extracellular interaction with CD47, the broadly expressed cellular ligand, which triggers SIRPα ITIMs phosphorylation leading to activation of the SH2-containing tyrosine phosphatases, SHP-1 and SHP-2. Here we examined the role of SIRPα in regulating macrophage phenotypic polarization. With SIRPα extracellular ligation by CD47 (mCD47-AP), macrophages display a defective response to M1 phenotypic activation but an enhanced reaction following the M2-polarized induction, as indicated by reduced expressions of the M1-related markers CD86, MHC-II, iNOS, IL-1β, IL-12 and TNF-α under LPS/IFNγ treatment but increased expressions of anti-inflammatory mediators CD206, Arg1, IL-10 and TGFβ under IL-4 treatment. Consistently, macrophages deficient of SIRPα obtained from $SIRP\alpha^{-/-}$ mice demonstrate enhanced M1 activities under proinflammatory challenges while showing repressed M2-associated, tissue supporting function. Interestingly, although both polarized activations induce SIRPα ITIMs phosphorylation, differential associations with SHP-1 and SHP-2 are exhibited with M1 and M2 respectively, leading to distinctive activations of the PI3k-Akt pathway, the Erk1/2 MAP kinase and IL-4-induced Jak-STAT6. Overall, our findings demonstrate for the first time that SIRPα plays an important role in modulating macrophage polarized activation, inhibiting M1 while promoting M2 phenotypic polarization through biased activation of SHP-1 and SHP-2 signaling.

P.C6.03.12

Priming of macrophages with air particulate matter SRM 1648a induces hyperinflammatory response upon LPS challenge

A. Gawda, ***G. Majka****, B. Nowak, M. Śróttek, M. Walczewska, J. Marcinkiewicz;*
Chair of Immunology, Jagiellonian University Medical College, Kraków, Poland, Kraków, Poland.

Introduction: Exposure to air particulate matter (PM) has been implicated in both chronic inflammatory as well as autoimmune diseases. Macrophages are responsible for the regulation of chronic inflammation. However, whether PM affects macrophage polarization remains unclear. The aim of this study was to evaluate if urban PM at nontoxic concentrations is able to prime macrophages to altered inflammatory response upon LPS challenge.
Methods: Two forms of the urban particulate matter SRM 1648a were used: intact PM and PM-deprived of organic compounds (PMΔC). Peritoneal murine macrophages were incubated with different concentrations of PM samples for 24h and then challenged with LPS. Production of inflammatory mediators by macrophages was measured to test immunostimulatory/priming capacity of PM.
Results: PM at non-cytotoxic concentrations induced a dose-dependent production of proinflammatory cytokines (TNF-α, IL-6, IL-12p40). By contrast, PMΔC were not able to stimulate macrophages. However, macrophages primed with both forms of PM show proinflammatory response upon LPS challenge. The ratio of proinflammatory to anti-inflammatory cytokines (TNF-α to IL-10) was significantly increased upon incubation with urban particulate matter.
Conclusion: Our data demonstrate that exposure of macrophages to low non-stimulating concentrations of PM may prime the cells to hyperinflammatory response upon contact with LPS. It is possible that exposure of patients suffering from chronic inflammatory diseases to particulate matter may be responsible for the aggravation of clinical symptoms during bacterial infections. This work was financed by the National Science Centre (Poland, project number 2015/16/W/ST5/00005).

Identification of rare variants in genes of the inflammasome pathway in Behçet disease patients using next generation sequencing techniques

S. Burillo Sanz[1], ***I. Olivas Martinez***[1], *M. Montes Cano*[1], *J. Garcia Lozano*[1], *L. Ortiz Fernandez*[1,2], *M. Gonzalez Escribano*[1];
[1]*Hospital Virgen del Rocio, Sevilla, Spain,* [2]*Institute of Parasitology and Biomedicine "Lopez Neyra", Granada, Spain.*

Behçet's disease (BD) is an uncommon immune-mediated systemic disorder with a well-established association with HLA class I and other genes. BD has shown to have clinical overlap with many autoinflammatory diseases (AIDs). Thereby, the aim of the study was to investigate the role in BD of rare variants in seven genes involved in AIDs: CECR1, MEFV, MVK, NLRP3, NOD2, PSTPIP1 and TNFRSF1A by using a next generation sequencing (NGS) approach in 355 BD patients. To check global association of each gene with disease, 4 tests: SKAT, CollapseBt, C(α) and weighted KBAC were used. Databases: 1000 Genomes Project Phase 3, Infevers, HGMD and ClinVar and algorithms: PolyPhen2 and SIFT were consulted to collect information of the 62 variants found. All the genes resulted associated using SKAT, but only 3 (MVK, NOD2 and PSTPIP1) with C(α) and weighted KBAC. When all the genes are considered, 40 variants were associated to AIDs in clinical databases and 25 were predicted as pathogenic at least by one of the algorithms used. Including only MVK, NOD2 and PSTPIP1, the associated to AIDs variants found in BD were 20 and the predicted as pathogenic, 12. The maxima contribution corresponds to NOD2. This study supports the influence of rare variants in genes involved in AIDs in the pathogenesis of BD.

Hidradenitis suppurativa (HS) is a chronic inflammatory disease of the hair follicles (HF) leading to abscessing inflammation. We showed that Outer Root Sheath cells (ORS), HF stem cells, have a pro-inflammatory phenotype (Hotz, JID, 2016). We investigate molecular mechanisms involved in this phenotype.
Materials and Methods: ORS were isolated from skin surgery after HF dissection. RNA and protein expression were studied by RT-qPCR and Western Blot, detection of cytosolic single-stranded DNA (ssDNA) and nuclear 53BP1 foci, by immunocytochemistry, and cell cycle and HF phenotype, by flow cytometry. Replication fork progression was measured by DNA fiber spreading.
Results: The transcriptomic analysis of HS-ORS revealed (i) a type I interferon (IFN) signature confirmed by an overexpression of IFNβ and associated interferon-stimulated-genes by RT-qPCR and (ii) a deregulation of genes involved in cell proliferation and differentiation. Cytoplasmic ssDNA was observed in HS-ORS but not HS-keratinocytes. IFNβ mRNA decreased in HS-ORS transfected by siSTING compared to siControl, suggesting STING involvement in ssDNA detection. Cell cycle analysis reveals an accumulation of cells in S or G2 phase in 7 out of 11 patients, which also showed deregulated replication fork progression. CHK1 phosphorylation and 53BP1 foci observed in HS-ORS indicate an activation of DNA damage pathway. HF cells phenotype's ex-vivo analysis showed enrichment of progenitor cells compared to stem cells suggesting stem cells differentiation.
Conclusion: This suggests that in HS patients, cell cycle deregulation in the ORS leads to replicative stress and accumulation of cytoplasmic ssDNA, inducing IFN synthesis involved in establishment of chronic inflammation.

Long term outcomes and treatment response in patients with TNF receptor-associated autoinflammatory syndrome (TRAPS): retrospective experience from a national referral centre

R. Papa[1], *D. M. Rowczenio*[2], *C. Papadopoulou*[3], *T. Rezk*[2], *P. Brogan*[3], *T. Youngstein*[2], *P. N. Hawkins*[2], *H. J. Lachmann*[2];
[1]*Autoinflammatory Diseases and Immunodeficiencies Centre, Pediatric and Rheumatology Clinic, Giannina Gaslini Institute, University of Genoa, Genoa, Italy,* [2]*National Amyloidosis Centre, Division of Medicine, Royal Free Campus, University College London, London, United Kingdom,* [3]*Department of Infection, Inflammation and Rheumatology, Great Ormond Street Institute of Child Health, London, United Kingdom.*

Introduction. Secondary, AA amyloidosis and infertility are most common and severe complications of Tumour necrosis factor Receptor-Associated Periodic Syndrome (TRAPS) in adults. **Objectives**. To define the best treatment approach in TRAPS and the effect on long-term outcomes. **Methods.** We reviewed all data of 100 patients carrying a total of 40 *TNFRSF1A* gene variants. The Auto Inflammatory Diseases Activity Index (AIDAI) was used to estimate the long-life disease severity. **Results.** 29 patients had intronic variants of the *TNFRSF1A* gene and displayed milder disease than the 71 patients with mutations affecting coding regions (P<0.005), less abdominal pain and skin rashes but more frequent headache or mouth ulcers during fever attacks (P<0.001 and P<0.05, respectively), none developed secondary amyloidosis. Almost 70% of patients required maintenance therapy and anti-interleukin (IL) 1β drugs were the most frequently used (53 patients) with the highest efficacy rate (86% complete response). No patients on anti-IL1β treatment developed amyloidosis and 10 patients with amyloidosis have been successfully treated with anti-IL1β agents with preservation of native renal function in 7 and excellent long term transplant function in 2. Seven women with a history of failure to conceive had successful pregnancies without fertility treatment following anti-IL1β therapy. **Conclusion**. Anti-IL1β drugs are the best maintenance treatment in TRAPS with potential to reverse the most serious disease complications. The diagnosis of TRAPS should be considered very carefully in patients carrying intronic variants of the *TNFRSF1A* gene. **Acknowledgments.** The presenting author thanks the European Federation of Immunological Societies for the Short-term Fellowship.

Molecular mechanism of peptide against calcium oxalate crystals induced NLRP3-mediated IL-1β secretion

S. Saha*, R. J. Verma;*
Gujarat University, Ahmedabad, India.

Even though the prevalence of nephrolithiasis is increasing, our understanding of the underlying mechanisms has not kept pace and new therapeutic approaches have not yet emerged. Nephrolithiasis can lead to inflammation and subsequent tissue remodeling. Calcium oxalate (CaOx) is the main component of kidney stones. The present study identifies the role of a designed peptide in decreasing induction time of CaOx crystals nucleation, cytokine expression, neutrophil recruitment and subsequent renal injury. By using combination of confocal microscopy and atomic scale molecular dynamics simulations (MD), we find that FITC labeled peptide adsorb specifically with the edges of CaOx crystals. Molecular modeling of peptide onto crystal surfaces also confirms their adsorption to CaOx crystal {110} and {101} surfaces and suggests increased stabilization of the CaOx surface by peptide adsorption. Furthermore, the peptide potently inhibits the outcomes of NLRP3 inflammasome activation, including IL-1β secretion, caspase-1 cleavage, and lactate dehydrogenase release using the LPS-primed murine bone marrow-derived macrophages in the presence of ATP and/ or calcium oxalate crystals. The peptide also showed significant inhibition of the functionality of the NLRP3 inflammasome and resulting anti-inflammatory activity *in vivo* using calcium oxalate-induced nephrolithiasis in female Wistar rat model. These inhibitory effects of peptide were observed in a dose-dependent manner. These findings suggests new avenue for rational design of peptide based therapeutic agents for kidney stone diseases as well as other NLRP3 inflammasome-related diseases.

Hyaluronic acid improve Immune modulatory effect of mesenchymal stem cells

S. Shim*, J. Lee, H. Jang, J. Myung, S. Lee, M. Kim, W. Jang, S. Lee, H. Kim, S. Park, K. Kim;*
Laboratory of Radiation Exposure and Therapeutics, National Radiation Emercency Medical Center, Seoul, Korea, Republic of.

Mesenchymal stem cells (MSCs) display a powerful immunosuppressive potential, and this potential can be employed for the treatment of inflammatory-based diseases. In this study, we investigated the cytokine expression of MSCs rely upon the expression of CD44, a putative stem cell marker and observed interesting expression changes involved in immune regulation. CD44 knock-down leads to a decreased expression of CD200, an anti-inflammatory factor, and Hyaluronic acid (HA), a ligand of CD44, increased the expression of CD200 in MSCs. Furthermore, the effect of HA-treated on MSCs was functionally determined in mouse model. HA-treated MSC demonstrated a significant reduction in inflammation as demonstrated by the decrease in the expression of pro-inflammatory markers and by the induction of a regenerative environment. Together, our results establish that CD44 pathway contributes to immunosuppressive functions of MSCs and HA treatment could improve outcomes of MSC therapies of inflammatory diseases.

P.C6.03.18

MFB, a critical regulator of inflammatory resolution, induced M1 macrophage selective apoptosis through TNF/TNFR1, modulated survival M1 conversion into M2 depended on leptin-PI3K or -Akt pathway

H. Lu, H. Zhu, R. Chen, Y. Tian, H. Xu, ***Z. Su****;*
School of Medicine, Zhenjiang, China.

Inflammatory monocytes/macrophages and tissue-resident macrophage are key regulators of tissue injury, would healing, organ remodeling and regeneration. After tissue injury, most monocytes/macrophages infiltrate into injury sites, undergo phenotypic and functional changes: differentiation into proinflammatory M1 phenotype and anti-inflammatory M2 in milieu. The polarized M1 and M2 macrophages involve in inflammatory initiation, development, resolution, and organ function remodeling, respectively. Disturbances in macrophage reprogramming can lead to aberrant repair or uncontrolled inflammatory response. Timely modulation of macrophages reprogramming is essential for the treatment of inflammatory diseases. Therefore, it becomes fatal to clarify the M1 fate or the functional shift of M1 and M2 and to explore the factor of inducing inflammatory resolution during tissue injury development. In the present work, we demonstrated that cardiac fibroblasts (MCF) pretreated by angiotensin II (ANG II) (myofibroblast, MFB) could not only promote macrophage reprogramming toward M1 but also induced M1 macrophage selective apoptosis through TNF/TNFR1 axis independent on Fas/FasL; furthermore, in co-culturing system, leptin produced by MFB or polarized macrophage could promote the survival M1 conversion into M2 macrophage via PI3K or Akt pathway. *In vivo*, TNF-α blockade significantly ameliorated experimental autoimmune myocarditis (EAM) development. Our data highlighted a novel and exciting topic: MFB is a critical and active regulator of inflammatory resolution. Our data also suggested a potential checkpoint for inflammatory disease therapy target on macrophage.

P.C6.03.19

New diagnostic markers: NLR and PLR for rheumatoid arthritis

N. Kikodze[1,2], *N. Tsiskarishvili*[3], *M. Iobadze*[1,2], *N. Janikashvili*[1], *I. Pantsulaia*[1,2], *T. Chikovani*[1];
[1]*Tbilisi State Medical University, Tbilisi, Georgia,* [2]*V.Bakhutashvili Institute of Medical Biotechnology, Tbilisi, Georgia,* [3]*Clinical Medicine Scientific-Research Institute – Todua Clinic, Tbilisi, Georgia.*

Systemic inflammation response is closely associated with many life-threatening diseases: cancer, autoimmune disorders, etc. Seeking for reliable and inexpensive markers to assess inflammation is of importance to envisage long-term outcome as well for treatment monitoring in the patients. Changes in the composition of the circulating blood cells as possible inflammatory markers are intensively investigated in the last years. We studied correlations of new inflammatory markers neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) with the known inflammatory markers: erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) in the patient with rheumatoid arthritis (RA). Newly diagnosed patients both in disease active (>2.3 by DAS28 score) and in non-active (<2.3 by DAS28 score) stages have high levels of NLR and PLR compared to healthy individuals. NLR and PLR positively correlated with ESR in rheumatoid arthritis. The association between NLR, PLR, CRP and RA was not observed in our study. The correlation of between NLR, PLR and disease activity was also revealed.

Critical contribution of NKG2D expressed on iNKT cells in Con A-induced liver hepatitis in mice

d. al dulaimi[1,2], *j. klibi*[1,2], *v. olivo pimentel*[1,2], *v. parietti*[1,3], *m. allez*[1,2], *a. toubert*[1], ***k. benlagha***[1,2];
[1]*inserm, paris, France,* [2]*1INSERM, UMR-1160, Institut Universitaire d'Hématologie, Paris, France, Université Paris Diderot, Sorbonne Paris Cité, Paris, France., Paris, France,* [3]*3Département d'Expérimentation Animale, Institut Universitaire d'Hématologie, Paris, France, Université Paris Diderot, Sorbonne Paris Cité., Paris, France.*

Natural killer group 2D (NKG2D) is a well-characterized activating receptor expressed on many immune cells including Invariant Natural Killer T (iNKT). iNKT cells were shown to be responsible of liver injury in the model of Concanavaline A (Con A)-induced hepatitis, considered to be an experimental model of human autoimmune hepatitis. In this study, we investigated whether NKG2D plays a role in the hepatitis induced by iNKT cell-mediated immune response to Con A. By using killer cell lectin-like receptor subfamily K, member 1 deficient *(Klrk1***-/-**)** mice, we found that the absence of NKG2D reduced the hepatic injury upon Con A administration. This was not due to an intrinsic functional defect of NKG2D-deficient iNKT cells. The reduced pathogenic effect of Con-A in the absence of NKG2D correlates with a reduction in pathogenic cytokine production and FAS-Ligand (FAS-L) expression by iNKT cells.

We also found that ConA administration led to an increase in the retinoic acid early-inducible 1 (RAE-1) surface expression on wild type hepatocytes. Finally, we found that Con A has no direct action on FAS-L expression or cytokine production by iNKT cells, and thus propose that NKG2D-L expression on stressed hepatocytes promote cytotoxic activity of iNKT cells via its interaction with NKG2D contributing to hepatic injury. Conclusion: our results highlight NKG2D as an essential receptor required for activation of the iNKT cells in Con A-induced hepatitis and indicate that it represents a potential drug target for prevention of autoimmune hepatitis.

P.C6.04.02
Role of neutrophils in the Imiquimod (IMQ)-induced mouse model of Psoriasis

S. Costa[1]*, D. Bevilacqua*[1]*, O. Marini*[1]*, E. Caveggion*[1]*, C. Lowell*[2]*, G. Girolomoni*[3]*, M. Cassatella*[1]*, P. Scapini*[1]*;*
[1]Department of Medicine-Section General Pathology, University of Verona, Verona, Italy, [2]University of California, San Francisco, California, United States, [3]Department of Medicine-Section of Dermatology and Venereology, University of Verona, Verona, Italy.

Psoriasis is a chronic skin disease associated with deregulated interplays between immune cells and keratinocytes. Neutrophil accumulation in the skin is one of the histological features that characterize psoriasis. However, the role of neutrophils in psoriasis development remains poorly understood. In this study, we utilized the imiquimod (IMQ)-induced mouse model of psoriasis to elucidate the specific contribution of neutrophils to psoriasis development. We report that neutrophils act as negative modulators of disease propagation and exacerbation by inhibiting γδ T cell effector functions *via* NADPH oxidase-mediated reactive oxygen species (ROS) production, as revealed by analysing disease development/progression in neutrophil-depleted mice. We also report that Syk functions as crucial molecule mediating neutrophil and γδ T cell interactions. In support of the latter findings, we demonstrate that the selective impairment of Syk-dependent signalling in neutrophils only, is sufficient to reproduce the enhancement of skin inflammation and γδ T cell infiltration observed in neutrophil-depleted mice. Overall, our findings add new insights into the specific contribution of neutrophils to disease progression in the IMQ-induced mouse model of psoriasis. Considering that, similarly to mouse psoriasis, the important role of IL-17 producing γδ T cells in human psoriasis has just started to emerge, it is likely that inhibitory crosstalk between neutrophils and γδ T cells may exist also in human psoriasis. Neutrophils may indeed act as unexpected negative players of disease development in specific types or clinical stages of human psoriasis. Consequently, also the utilization of therapeutic interventions targeted to inhibit neutrophil functions should be carefully evaluated.

P.C6.04.03
Innate-like T-lymphocyte deficiencies in the pathogenesis of chronic obstructive pulmonary disease

P. Engelmann[1]*, K. Bodó*[1]*, N. Farkas*[2]*, V. Sárosi*[3]*, Z. Balikó*[3]*, T. Berki*[1]*, M. Szabó*[3]*;*
[1]Department of Immunology and Biotechnology, Clinical Center, Medical School, University of Pécs, Pécs, Hungary, [2]Department of Bioanalysis, Medical School, University of Pécs, Pécs, Hungary, [3]Division of Pulmonology, 1st Department of Internal Medicine, Clinical Center, Medical School, University of Pécs, Pécs, Hungary.

Chronic inflammation of the small airways and the damage of lung parenchyma are considered as the major mechanisms in COPD. Recent observations claim that innate-like T-lymphocytes such as invariant natural killer T (iNKT) cells and mucosal-associated invariant T (MAIT) cells connect innate and adaptive immunity. Up to now data are scarce about their involvement in the pathogenesis of COPD. We aimed to observe the proportions of iNKT and MAIT cells in the peripheral blood and sputum samples of stable and exacerbating COPD patients. By means of multicolor flow cytometry the frequencies of total iNKT and MAIT cells and their subsets were enumerated. In addition, the expression levels of iNKT, and MAIT TCR genes, along with CD1d, MR1 genes were assessed by qPCR in the study cohorts. Proportions of total iNKT and MAIT cells were dramatically dropped in COPD blood samples. In the sputum of COPD patients reduced numbers of iNKT cells were observed. Furthermore decreased DN and increased CD4+ iNKT subsets, while elevated DN and dropped CD8+ MAIT subpopulations were measured in COPD samples. Reduced invariant TCR mRNA levels in COPD patients had confirmed these findings. CD1d and MR1 mRNA expression were increased in stable and exacerbating COPD patients. In contrast, both molecules were decreased following antibiotic and systemic steroid treatments. Our observations support the notion that iNKT and MAIT cells are involved in COPD. These innate-like T-lymphocytes deserve further analysis to validate their usefulness as potential biomarkers in the pathogenesis of this disease.

P.C6.04.04
The effects of intravenous immunoglobulin (IVIg) on peripheral blood polymorphonuclear cells

B. Geçkin*, B. Kayaoğlu, M. Gürsel;*
Department of Biological Sciences, Middle East Technical University, Ankara, Turkey.

IVIg has been used in clinical treatment of primary immune deficiencies (PIDs) and several autoimmune diseases. Neutrophil dysregulation frequently observed in a variety of PIDs improve after IVIg treatment. This study aimed to assess the effects of IVIg on neutrophil functions as well as the response of IVIg treated innate immune cells to various TLR and/or nucleic acid sensor ligands. PBMCs from healthy subjects were isolated by density gradient separation. For neutrophil isolation, polymorphonuclear cells that pelleted with the erythrocytes were further separated by dextran sedimentation. Neutrophils were stimulated with LPS, Zymosan or PMA in the absence or presence of increasing concentrations of IVIg (0.2, 1, 5, 25 mg/ml).
Reactive oxygen species (ROS) production was quantified using DHR123 staining and flow cytometry. Similarly, the effect of IVIg treatment on LPS, Zymosan or PMA-induced NETosis was assessed using nucleic acid probes and fluorescence microscopy. Additionally, response of PBMCs to various pattern recognition receptor ligands was determined in the presence of four different concentrations of IVIg by cytokine ELISA. Results revealed that response to potent ROS inducers like PMA was significantly suppressed with the highest dose of IVIg, whereas immunoglobulin treatment synergized with LPS to increase ROS production. Our data reflects that IVIg exerts either stimulatory or anti-inflammatory activity on granulocytes in a dose and stimulant-dependent manner.

P.C6.04.05
Fragile neutrophils in the peripheral blood: a new phenomenon in critically ill patients.

L. Hesselink*, R. Spijkerman, P. Hellebrekers, A. Huisman, I. E. Hoefer, M. ten Berg, L. Koenderman, L. P. Leenen, F. Hietbrink;*
UMC Utrecht, Utrecht, Netherlands.

Introduction: Non-viable (propidium iodide/PI-positive) neutrophils are incidentally found in blood samples of critically ill patients. Not much is known regarding the function of these neutrophils and the clinical implications of these neutrophils in the circulation. The aim of this study was to investigate overall neutrophil function and clinical course of patients who have non-viable neutrophils.
Methods: The percentage of PI-positive neutrophils is routinely measured in every blood analysis, as indicator for timely analysis. However, surgical ward and ICU samples are immediately analyzed. Surgical patients who had > 5% PI-positive neutrophils, were included. After inclusion, the percentage of PI-positive neutrophils was reassessed by flow analysis. In addition, phagocytosis was analyzed.
Results: Thirteen surgical patients were included. The high PI signal originated either from increased neutrophil autofluorescence (n = 7) or the presence of fragile neutrophils (n = 6). Fragile neutrophils were neutrophils that became PI-positive after minimal *ex vivo* manipulation (red blood cell lysis) or when kept in EDTA tubes. Four of 6 patients with fragile neutrophils died. In contrast, no patients with autofluorescent neutrophils died. Phagocytosis of patients with fragile neutrophils was not impaired.
Conclusion: Non-viable neutrophils detected by the hematology analyzer are either true fragile neutrophils or autofluorescent neutrophils. Fragile neutrophils are easily missed during in vitro experiments as they are typically lost during standard isolation procedures. The presence of fragile neutrophils was associated with a high mortality rate and thus renders more attention to determine their role in the clinical course of critically ill patients.

P.C6.04.06
Extracelluar neutrophil-derived glycosidases - new post-secretional modifiers of human Immunoglobulin G glycosylation?

J. Knopf*, L. E. Munoz, M. Herrmann;*
Universtaetsklinikum Erlangen - Medizin 3, Erlangen, Germany.

Glycosylation of Asparagine[297] of Immunoglobulin G (IgG) heavy chain influences the effector functions of IgG and contributes to the pathogenesis of chronic inflammatory autoimmune diseases such as Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA). We employed mass spectrometry to analyze the glycosylation of total IgG from patients with SLE or RA compared to acute inflammatory diseases such as sepsis, as well as healthy controls. Patients with sepsis showed a similar IgG glycosylation pattern as RA patients with low levels of galactose and bisecting N-acetylglucosamine. Surprisingly, the glycosylation pattern of IgG from patients with SLE displayed only minor changes when compared to healthy controls. This is most likely due to the successful treatment and the concomitant low disease activity in our SLE cohort.
We tested whether the changes observed for sepsis and RA patients are due to post-secretional modifications by neutrophil extracellular traps (NETs)-borne glycosidases of IgG glycans. The potential glycan modifiers neuraminidase1, beta-galactosidase and beta-N-acetylglucosaminidase were expressed in human neutrophils and aggregated NETs contained enzyme activities as assessed by specific substrate conversion. Strikingly, co-incubation of IgG with aggregated NETs reduced the percentage of bisecting N-acetylglucosamine.
To further analyze the role of glycosidases in modifying IgG glycans, we are going to express the specific glycosidases and analyze their effect on the glycans of circulating IgG and its functional implications *in vivo*.

Implication of type 2 innate lymphoid cells in skin fibrosis during systemic sclerosis

P. Laurent[1], *M. Jeljeli*[2], *P. Manicki*[3], *V. Jolivel*[1], *C. Richez*[1,3], *P. Duffau*[1,4], *E. Lazaro*[1,4], *J. Déchanet-Merville*[1], *P. Blanco*[1,5], *T. Pradeu*[1], *C. Contin-Bordes*[1,5], *M. Truchetet*[1,3];
[1]*ImmunoConcept, UMR 5164,, Bordeaux, France,* [2]*Immunology laboratory, EA 1833, Paris, France,* [3]*Rheumatology department, CHU Bordeaux Hospital,, Bordeaux, France,* [4]*Internal Medicine department, CHU Bordeaux Hospital, Bordeaux, France,* [5]*Immunology department, CHU Bordeaux Hospital, Bordeaux, France.*

Systemic sclerosis (SSc) is an autoimmune disease characterized by vascular abnormalities, immune disorders and fibrosis. Recently, some reports highlighted the fundamental role of type 2 innate lymphoid cells (ILC2s) in fibrosis. We hypothesized that ILC2s could be involved in SSc fibrosis, offering new therapeutic perspectives.
Methods: We quantified circulating and cutaneous ILCs in healthy donors and SSc patients by flow cytometry and immunofluorescence. In HOCl-induced SSc mice, we phenotyped ILC2s in skin, lung and spleen.
Results: In 39 SSc patients, circulating ILCs decreased in absolute value (0.019 for HD vs 0.055 for patients, p<0.0001) compared to 18 controls, mainly in ILC2s (0.0138 for HD vs 0.00767 for SSc, p=0.0496) and ILC3s (0.02152 for HD vs 0.003839 for SSc, p<0.0001). We observed an inverse correlation between circulating ILC2s and rodnan scores in SSc patients (R=-0.03, p=0.02). A skewing toward ILC2 was also observed in SSc skin patients. HOCl-induced SSc mice showed an early increase in absolute count of ILC2s in skin (p=0.02), which was also correlated with collagen content and IL-13 mRNA expression while it remained unchanged in spleen.
Conclusion: We observed a decrease of circulating ILC2s and an increase of ILC2s in SSc skin, correlated with the extent of cutaneous fibrosis. In SSc mice, an increase of skin ILC2 is observed suggesting that these cells could be the trigger of fibrosis in SSc and may constitute a future therapeutic target.

Toll-like receptor 3(TLR3) L412F differentially modulates TLR1-9 and non-TLR responses inidiopathic pulmonary fibrosis (IPF) patients: implications for acceleratedisease progression

A. N. McElroy[1], *D. N. O'Dwyer*[2], *A. Tynan*[1], *L. Mawhinney*[1], *P. G. Fallon*[1], *A. G. Bowie*[3], *C. M. Hogaboam*[4], *N. Hirani*[5], *M. E. Armstrong*[1], *S. C. Donnelly*[6];
[1]*School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland,* [2]*School of Medicine and Medical Science, College of Life Sciences, UCD Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland,* [3]*School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland,* [4]*Department of Pathology, University of Michigan Medical School, Michigan, United States,* [5]*Queen's Medical Research Institute, University of Edinburgh, Edinburgh, United Kingdom,* [6]*Department of Clinical Medicine, Trinity Centre for Health Sciences, Tallaght Hospital, Dublin, Ireland.*

Introduction: In this study, we investigated the role of defective toll-like receptor 3 (TLR3) and *TLR3* Leu412Phe (*TLR3* L412F; rs3775291) in the pathogenesis of the fatal interstitial lung disease, idiopathic pulmonary fibrosis (IPF). Previously, we established that *TLR3* L412F
was associated with a significantly greater risk of mortality and an accelerated rate of decline in lung function in IPF patients (*AJRCCM* 2013; 180: 1442). Here, we investigated the effect of *TLR3* L412F on responses of primary human lung fibroblasts from IPF patients to TLR1-9 and a number of non-TLR agonists.
Materials and Methods: Patients with IPF were genotyped for *TLR3* L412F and its effect was assessed in primary human lung fibroblasts treated with a panel of TLR1-9 agonists and non-TLR agonists. Cytokine, chemokine and type I interferon levels in IPF fibroblasts weredetermined by ELISA and qPCR, respectively.
Results: We demonstrated that *TLR3* 412F reduced NF-κB-induced IL-8 production following activation of: TLR3, TLR4, TLR5, TLR1/2, TLR2/6 and TLR9 in fibroblasts from 412F-heterozygote IPF patients compared with wild-type patients. *TLR3* L412F also attenuated TLR3- and TLR4-induced activation of IRF3-dependent IFN-β and RANTES production in 412F-heterozygote IPF patients. Interestingly, 412F-heterozygote IPF fibroblasts also had attenuated responses to the non-TLR ligands, Poly(dA:dT) and PMA.
Conclusions: This study demonstrates that the effects of *TLR3* L412F are not limited to TLR3 and that *TLR3* L412F can attenuate additional TLR and non-TLR signalling pathways. These findings may have implications for IPF patients during bacterial or viral infection and hence, accelerated disease progression in 412F-heterozygote patients.

P.C6.04.09

Inhibition of peptidyl-arginine deiminases impairs NLRP3 inflammasome assembly and the release of pro-inflammatory IL-1β in macrophages

n. mishra[1], *F. Ahmed*[2], *L. Ghebremariam*[1], *M. M. Lerch*[3], *R. E. Schmidt*[4], *L. Bossaller*[1];
[1]*Section of Rheumatology, Department of Medicine A, Greifswald, Germany,* [2]*Department of Dermatology, University of Heidelberg, Heidelberg, Germany,* [3]*Department of Medicine A, University Medicine Greifswald, Greifswald, Germany,* [4]*Department of Clinical Immunology and Rheumatology, Hannover Medical School, Hannover, Germany.*

Inflammasomes are cytosolic pattern recognition receptors of the innate immune system. They assemble into multi-protein complexes secondary to the recognition of pathogenic stimuli as well as host derived molecules. The macromolecular aggregation of the receptor protein Nod like receptor (NLRs) with the adaptor protein ASC and the effector protein caspase-1 through homotypic domain-domain interactions into 'ASC specks' controls the release of proinflammatory cytokine IL-1β. Of the host derived molecules, high extracellular calcium concentrations or calcium mobilization from endoplasmic reticulum stores triggers NLRP3 inflammasome activation in macrophages. Peptidyl-arginine deiminase (PAD) are class of calcium dependent enzymes that catalyze the post-translational modification of arginine residues into citrulline amino acid. Of the five known PAD isoforms, only PAD2 and PAD4 are expressed in macrophages.
High intracellular calcium concentration is essential for PAD activity that can be reached in dying cells. We examined protein citrullination and role of PAD enzymes in inflammasome activation. We report here that protein citrullination is common following NLRP3 inflammasome activation in murine macrophages. Interestingly, ASC specks are citrullinated as well. Furthermore, PAD enzyme inhibition resulted in a dose-dependent reduction in the release of active caspase-1 and IL-1β in macrophages. Consistently, we observed a reduction in ASC speck formation following PAD inhibition. Genetic deficiency of PAD-4 alone was not sufficient to block IL-1β release. However, siRNA knockdown of PAD-2 within PAD-4$^{-/-}$macrophages blocked IL-1β release. In conclusion, we find that PAD enzymes fulfill a previously unknown role in NLRP3 inflammasome assembly and IL-1β maturation.

P.C6.04.10

Polyunsaturated omega-3 fatty acids have immunosuppressing effects on NK cell phenotype *in vitro*

S. Y. Omarsdottir[1,2], *K. N. Jensen*[1,2], *J. Freysdottir*[1], *I. Hardardottir*[2];
[1]*National University Hospital of Iceland, Reykjavik, Iceland,* [2]*University of Iceland, Reykjavik, Iceland.*

Dietary fish oil, rich in omega-3 polyunsaturated fatty acids (n-3 PUFA), enhanced resolution of antigen-induced inflammation in mice and induced an early increase in the number of NK cells at the inflamed site, indicating that NK cells may play a role in the resolution of inflammation. The objective of this study was to examine the effects of n-3 PUFA on NK cells *in vitro*. NK cells were isolated from buffy coat using MACS negative selection. They were cultured for 18 hours with/without 50 μM of the omega-3 PUFA EPA or DHA, or with the omega-6 PUFA arachidonic acid (AA), and then stimulated with IL-2, IL-12 and IL-15 for 24 hours. Cytokine concentration in the medium was measured by ELISA and expression of surface markers by flow cytometry. NK cells cultured with DHA secreted less TNF-α (14%), CCL3 (17%) and CCL20 (44.5%) than NK cells cultured without fatty acids. NK cells cultured with DHA also had lower mean expression of the surface markers CX_3CR1 (14%), NKG2A (6.3%) and CXCR3 (5%). NK cells cultured with EPA secreted less TNF-α (13.5%) but more IFN-γ (12%) than NK cells cultured without fatty acids. DHA decreased NK cell secretion of neutrophil recruiting cytokines and chemokines (TNF-α, CCL3 and CCL20) and decreased NK cell expression of chemokine receptors (CX_3CR1 and CXCR3) that mediate migration of immune cells to the inflammation site. These results indicate that n-3 PUFA may modulate NK cell activity and thereby affect inflammation and its resolution.

P.C6.04.11

The cytotoxic function of NK cells in immune disorders is regulated by CD69

M. Relaño Orasio[1], *A. Tsilingiri*[1], *C. Torroja*[1], *M. J. Gómez*[1], *A. Angulo*[2], *C. Muñoz*[3], *C. Schwärzler*[4], *M. Toulson*[4], *P. Martín*[1];
[1]*Spanish National Center for Cardiovascular Research, Madrid, Spain,* [2]*Faculty of Medicine, Barcelona University, Barcelona, Spain,* [3]*La Princesa Hospital, Madrid, Spain,* [4]*Ecole Polytechnique Fédéral de Lausanne, Lausanne, Switzerland.*

Introduction: CD69 is a C-type lectin family receptor that is expressed upon activation and exerts anti-inflammatory effects. Previous works have shown that *Cd69-/-* mice are resistant to tumour growth and vaccinia virus infection in part due to NK cells activity. However, the specific contribution of these cells and the mechanism by which CD69 could be regulating their function has not been described. The activation of NK cells depends on the balance between activating/inhibitory signals. Thus, in this work we study the membrane receptor repertoire of *Cd69-/-* NK cells and it's regulation by CD69. Finally we propose anti-CD69mAbs treatment as a potential therapy in GvHD.
Materials and methods: We used the new mass cytometry (CyTOF) technology to perform an unbiased multiparametric phenotyping of *Cd69-/-* NK cells and using different animal models we studied the *in vivo* consequences of this phenotype in contexts such as anti-viral and anti-tumour immunity and GvHD resistance (allogenic cells recognition).
Results: Our multiparametric study revealed that *Cd69-/-* NK cells present an altered inhibitory/activating receptor repertoire with higher levels of non-self and missing self recognition receptors. This makes them more efficient in the killing of allogenic and tumour cells, being Cd69-/- mice resistant to aGvHD. All these effects can be reproduced by an anti-CD69 mAb treatment.
Conclusions: Cd69-/- NK cells are more efficient in the killing of tumour and allogenic cells due to different expression of activating/inhibitory receptors. This study suggests that anti-CD69mAb treatment could be employed in the clinics to reduce GvH effects potentially maintaining GvL effects.

P.C6.04.12

Identification of different subsets of ILC group I in the healthy and inflamed murine CNS

S. Romero Suarez[1], *A. del Rio Serrato*[1], *D. Brunotte-Strecker*[1], *L. Hertwig*[2], *C. Infante Duarte*[1];
[1]*Institute for Medical Immunology, Charité Universitätsmedizin Berlin, Germany,* [2]*Center for Infectious Medicine, Karolinska Institute, Stockholm, Sweden.*

Natural killer (NK) cells are emerging as important regulators of autoimmune inflammation in multiple sclerosis and its animal model the experimental autoimmune encephalomyelitis (EAE). They have been recently reclassified as part of innate lymphoid cells (ILCs) group I. The helper like ILC1 reside in the mucosae while the cytotoxic ILC1 are represented by the circulating conventional (c)NK cells. In addition, tissue resident (tr)NK cells have been described in various organs like liver and uterus and share properties with mucosal ILC1s and cNK cells. We investigated the CD3-NK1.1+ NK cells present in the CNS of the C57/Bl6 mouse during steady state conditions and identified three distinct NK populations based on the expression of the integrins CD49a and CD49b. Upon the analysis of the expression of their transcription factors, cNK cells were defined as CD49a-CD49b+ Tbet+ Eomes+; trNK cells as CD49a+CD49b-Tbet+Eomes-; and the intermediate population (intNK) as CD49a+CD49b+Tbet+Eomes+/-. The three NK cells subsets were further characterized by flow cytometry analysis. Next, we investigated the response of these populations to autoimmune inflammation of the CNS using the EAE mouse model. Our data show a differential activity of the three populations in their proliferative response, IFN-γ and TNF-α production and chemokine receptor, death ligand and activation markers regulation during EAE. In sum, our data show for the first time the presence and response to inflammation of tissue resident NK cells of the CNS.

P.C6.04.13

Circulating extracellular vesicles from patients with granulomatosis with polyangiitis stimulate neutrophils to generate reactive oxygen species and neutrophil extracellular traps

M. Surmiak[1], *A. Gielicz*[1], *D. Stojkov*[2], *R. Szatanek*[3], *K. Wawrzycka-Adamczyk*[1], *S. Youssefi*[2], *H. Simon*[2], *J. Musial*[1], *M. Sanak*[1];
[1]*Department of Internal Medicine, Jagiellonian University Medical College, Krakow, Poland,* [2]*Institute of Pharmacology, University of Bern, Bern, Switzerland,* [3]*Department of Clinical Immunology, Jagiellonian University Medical College, Krakow, Poland.*

Introduction Activation of neutrophils is a one of the key mechanisms observed in pathology of granulomatosis with polyangiitis (GPA). In this study we evaluate if extracellular vesicles circulating in plasma of GPA patients can contribute to this process. **Material and methods** Extracellular vesicles (EV) from plasma of GPA patients in active stage of the disease (n=10) and healthy controls (n=10) were isolated by ultracentrifugation and characterized by flow cytometry (CD9, CD63, CD81 expression) or nanoparticle tracking analysis. Targeted oxylipins lipidomics of EV was performed by LC-MS. Neutrophil extracellular traps formation (NETs) by neutrophils stimulated with EV or oxylipins was analyzed by fluorescent microscopy or Pico Green assay. ROS production and neutrophils EV binding/ uptake were evaluated by flow cytometry. **Results** EV isolated from plasma of GPA patients stimulated neutrophils to produce reactive oxygen species and release of mitochondrial DNA. However this was observed only when neutrophils were primed with GM-CSF. Priming with GM-CSF increased neutrophils EV binding/ uptake as well. Extracellular vesicles isolated from plasma of GPA patients had higher concentration of leukotriene B4 (LTB4) and 5-oxo-eicosatetraenoic acid (5-oxo-ETE) comparing to EV from healthy controls. Moreover, neutrophils stimulated with these oxylipins (LTB4 or 5-oxo-ETE) responded in ROS and NETs production in a concentration dependent manner. **Conclusions** Presented results reveal the potential of extracellular vesicles to activate neutrophils. ROS production and NET formation by stimulated neutrophils is probably linked to EV oxylipins cargo. The study was supported by National Center of Science in Poland, grant number: 2016/21/D/NZ6/02123

P.C6.04.14

The presence and characterization of Mucosal Associated Invariant T-cells in renal tissue

M. L. Terpstra[1,2], *M. J. Sinnige*[2], *E. Remmerswaal*[2], *M. C. Van Aalderen*[2], *J. Kers*[3,4], *S. E. Geerlings*[5], *F. J. Bemelman*[1];
[1]*Renal Transplant Unit, Division of Nephrology, Department of Internal Medicine, Academic Medical Center, Amsterdam, Netherlands,* [2]*Department of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands,* [3]*Department of Pathology, Academic Medical Center, Amsterdam, Netherlands,* [4]*University of Amsterdam, Van 't Hoff Institute for Molecular Sciences (HIMS), Amsterdam, Netherlands,* [5]*Division of Infectious diseases, Department of Internal Medicine, Academic Medical Center, Amsterdam, Netherlands.*

Introduction Mucosal Associated Invariant T (MAIT) cells are innate-like T-cells involved in the antibacterial and fungal response by recognizing riboflavin metabolites produced by these organisms. MAIT cells are present in human blood and are highly abundant in the mucosa of the liver, lungs and intestines. It is unclear whether MAIT cells are present in renal tissue and how they phenotypically compare to circulatory MAIT cells.
Methods We used a fluorescently-labelled MR1-tetramer in conjunction with 14-color flowcytometry to identify and characterize MAIT cells in healthy tissue collected from kidneys surgically removed because of renal cell carcinoma (adjacent non-tumorous tissue) (n=5), in renal allografts explanted after allograft failure (n=14) and in blood from healthy donors (n=9).
Results The mean percentage of MAIT cells within the lymphogate was 0.11% (control kidneys) vs 1.10% (renal allografts) and 0.93% (blood) ($p>0.05$). Due to MAIT cell counts <25 (predefined cutoff value) characterization of MAIT cells was impossible in the control kidneys.
MAIT cells in renal allografts appeared to have a relative cytotoxic, activated and tissue resident profile compared to the healthy blood samples, with a significantly higher expression of granzyme B, Ki-67 and CD69/CD103 ($p<0.01$) and a lower expression of CD95, CD127, CD161 and KLRG1 ($p<0.01$).
Conclusion MAIT cells can be detected in renal tissue. Though non-significant, MAIT cells percentages seemed to be higher in renal allografts than in healthy renal tissue. MAIT cells in renal allografts consist of a distinct population with a different expression profile than MAIT cells that are present in healthy blood.

Altered phenotype and cytotoxic potential of NK cells in patients with systemic juvenile idiopathic arthritis and macrophage activation syndrome

J. Vandenhaute[1], *M. Imbrechts*[1], *K. Put*[1], *O. Rutgeerts*[2], *L. De Somer*[3], *C. Wouters*[3], *P. Matthys*[1];
[1]*Rega Institute for Medical Research, KULeuven, Leuven, Belgium,* [2]*Laboratory of Experimental Transplantation, KULeuven, Leuven, Belgium,* [3]*Pediatric Rheumatology, University Hospitals Leuven, Leuven, Belgium.*

Introduction. Systemic juvenile idiopathic arthritis (sJIA) is a severe immune-inflammatory childhood disease characterized by arthritis and systemic features. About 10% of sJIA patients develop macrophage activation syndrome (MAS), a life-threatening hyperinflammatory cytokine storm syndrome characterized by excessive activation of T cells and macrophages.
Objective. sJIA and MAS are linked to defects in cytotoxicity of NK cells. In this study we investigated the phenotype and cytotoxic potential of NK cells in sJIA and MAS patients.
Results. Extensive phenotypic analysis of blood cells from active and inactive sJIA and active MAS patients revealed a decreased expression of cytotoxic proteins (i.e. perforin and granzyme K) and alterations in the expression of inhibitory and activating receptors, with decreased expression of CD57 and Killer Immunoglobulin Receptors (KIR) and increased levels of NKp44 by NK cells. In addition, the activation status and expression of ligands for NK cell receptors was analyzed on monocytes of sJIA and MAS patients. To investigate the cytotoxic potential of NK cells against autologous activated monocytes we optimized a protocol, which allows us to compare NK-specific cytotoxicity against K562 tumor target cells and autologous activated monocytes from patients and healthy controls. sJIA patients showed a defective IL-18-induced IFN-γ expression in NK cells, which is absent in MAS patients and partially resolved in inactive sJIA patients.
Conclusion. NK cells of sJIA and MAS patients show an altered phenotype. Subtle defects in their IFN-γ production and autologous killing of activated immune cells may underlie the immune-inflammatory dysregulation in sJIA.

P.C6.04.17

IMMUNOPATHOGENESIS OF GESTACIONAL DISORDERS AND PATHOLOGY OF FETUS /NEWBORN BABY THYMUS

R. Sepiashvili[1], *E. Levkova*[2], *L. Dilanyan*[1];
[1]*Peopels Friendship University of Russia,RUDN University, Moscow, Russian Federation,* [2]*RUDN University, Moscow, Russian Federation.*

In the conducted studies, mechanisms of impaired immunological tolerance in the fetus / newborn baby are shown. Sharp changes in cellular composition were characteristic the threat of interruption of pregnancy and OPG - gestosis 3 rd group. IRI in the both groups was 1.03 ± 0.11 and 1.32 ± 0.06, respectively, compared with the 1st group - 0.92 ± 0.04. In the thymus in newborn children of the 1 st group, the cells with the phenotype CD25 +, CD16 + were not detected. In the 2nd and 3rd groups, the level of designated cell markers was higher ($p<0.05$). Such cytokines as IL-1, IL-2, TNF-alpha, IL-8, interferons alpha and gamma were sharply increased ($p<0.05$) in the 2nd and 3rd groups compared to the 1st group. The abolition of the suppressor dominant was indicated by the values of IL-10 and IL-4, which in the comparison groups were 0.13 ± 0.05, 47.43 ± 2.9 pg / ml and 0.09 ± 0.009, 25.65 ± 2, 41 pg / ml, respectively, compared with the 1 st group - 0.82 ± 0.28 and 49.14 ± 5.49 pg / ml. The confirmation of the damage of the thymus was the reaction of the accidental transformation of the thymus, which reached its irreversible degree IV in the 2 nd group, in the 3 rd to the 3 rd degree, in the 1 st group - the III and IV stages of the accidental transformation were fixed.This publication was prepared with the support of the "RUDN University Program 5-100".

P.C6.04.18
ETIOPATHOGENETIC AND IMMUNOLOGICAL CHARACTERISTICS OF INFERTILITY

***R. Sepiashvili**, E. Levkova, T. Slavyanskaya;*
Peopels Friendship University of Russia,RUDN University, Moscow, Russian Federation.

It was shown that the predominant majority of married couples were identified by the HLA-DRB1 gene, which was more often associated with herpesvirus infections. Despite the fact that the level of PCR-positive results in the group of married couples with primary infertility was higher than in married couples with secondary sterility (100 and 92%, respectively), the maximum values of titres of specific antibodies to herpesviruses, including the detection rate of markers Exacerbations of infection (IgM antibodies) in the group of married couples with secondary sterility were higher than in the group of married couples with primary infertility, and significantly higher than in married couples with normal fertility. Therefore, it is this histocompatibility antigen - HLA-DRB1 - that is associated with a significant frequency of sterility and infectious contamination with herpesviruses (HSV 1, 2 types, CMV, VEB) in married couples with secondary infertility. The marker HLA-DRB1, most often found in married couples with infertility, including idiopathic, is associated in this contingent not only with significant contamination with herpesviruses, but also with the presence of a chronic infectious process in the reactivation stage. Conducted clinical and immunological studies clearly demonstrate the need for a comprehensive examination of women with functional disorders in the immunogenesis system with mandatory assessment of the level of infectious (virus) contamination and allows us to propose a comprehensive examination algorithm for functional disorders in the immunogenesis system, including the study of the level of the viral load as a necessary component.This publication was prepared with the support of the “RUDN University Program 5-100”.

P.C6.04.19
Evidence of the NLRP3 Inflammasome-Complement Axis in Osteoarthritis

*J. Bramhall, C. Bessant, J. Neisen, **I. Osuch**, A. Dawson, K. Triantafilou, E. Nichols;*
GlaxoSmithKline, Stevenage, United Kingdom.

Osteoarthritis (OA) has long been considered a “wear and tear” disease, but recent findings suggest that chronic low-grade inflammation plays a role in its pathogenesis. The synovial tissue has also taken centre-stage as target and producer of inflammatory stimuli. Evidence from patient and rodent studies strongly implicates complement in OA pathology. However, the downstream mechanisms have not been elucidated. An improved mechanistic understanding will enable design of therapeutic strategies. This study aimed to explore how complement may mediate synovial inflammation.
Analysis of patient tissues (synovial fluid, synovium) confirmed complement activation in OA. Membrane attack complex (MAC) deposition and increased IL-18 suggest involvement of the NLRP3 inflammasome. This led to the hypothesis that chronic inflammation in OA may depend on a synergistic complement-inflammasome interaction.
To validate the patient data, we examined MAC-mediated inflammasome activation in cell lines and primary synovium. Sub-lytic MAC challenge of the synovial membrane biopsies and synovial cell line resulted in an IL-1β response, suggesting a complement-inflammasome interaction. This response was dependent on both C5, NLRP3 and PI3K. Our data suggests that C5a provides a priming signal for inflammasome activation. MAC was found to provide signal 2, but is also able to trigger inflammasome activation independently of C5a.
In conclusion, terminal pathway effectors can trigger both signals of inflammasome activation, providing a mechanism in which the terminal pathway of complement may perpetuate inflammation in OA.

StemBell therapy stabilizes atherosclerotic plaques after myocardial infarction

*L. Woudstra[1,2], **A. van Broekhoven**[1,2,3], E. Meinster[1], M. Koopman[1], M. C. Morrison[4], A. C. van Rossum[5,2], M. N. Helder[6], L. J. Juffermans[5,2], H. W. Niessen[1,2,3], P. A. Krijnen[1,2];*
[1]Department of Pathology, VU University Medical Centre, Amsterdam, Netherlands, [2]Amsterdam Cardiovascular Sciences, Amsterdam, Netherlands, [3]Department of Cardiothoracic Surgery, VU University Medical Center, Amsterdam, Netherlands, [4]Department of Metabolic Health Research, The Netherlands Organization for Applied Scientific Research (TNO), Leiden, Netherlands, [5]Department of Cardiology, VU University Medical Centre, Amsterdam, Netherlands, [6]Department of Oral & Maxillofacial Surgery, VU University Medical Centre, Amsterdam, Netherlands.

Background: Myocardial infarction (MI) accelerates atherosclerosis through increased plaque inflammation and destabilization resulting in an increased risk of recurrent MI. Mesenchymal stem cells (MSC) are a promising therapeutic option for atherosclerosis. Here we investigated the effect of StemBell therapy (MSC-microbubble complexes combined with ultrasound) on atherosclerotic plaques after MI.
Methods: MI was induced in atherosclerotic ApoE$^{-/-}$ mice. Six days post-MI, intravenous StemBells or vehicle were given, followed by 1 minute of transthoracic ultrasound. The effects of StemBell treatment on plaque size and stability and the infarcted heart were determined 28 days post-MI. Moreover, monocyte subtypes and lipids in the blood were studied.
Results: StemBell treatment significantly increased cap thickness, decreased intra-plaque macrophage density and increased the percentage of intra-plaque anti-inflammatory macrophages. Plaque size and serum cholesterol and triglycerides were not affected. Furthermore, StemBell treatment significantly increased the percentage of anti-inflammatory macrophages within the infarcted myocardium, but did not affect cardiac function nor infarct size. Finally, the percentage of anti-inflammatory monocytes in the circulation was increased after StemBell therapy.
Conclusion: Systemic StemBell therapy decreased plaque inflammation and destabilization, predominantly associated with local and systemic effects on macrophages/monocytes. Hence, StemBell therapy may be a therapeutic option to prevent atherosclerosis acceleration after MI.
This study was funded by ZonNW (Translational Adult Stem Cell Research program, grant number 116005003) and by a grant from the ICaR-VU institute, Amsterdam, The Netherlands.

Arginine metabolism during Behçet disease : correlation with the clinical expression

***H. Belguendouz**[1], M. L. Ahmedi[1], A. Chekaoui[1], K. Lahmar[1], D. Hakem[2], Z. Djeraba[1], F. Otmani[3], C. Touil-Boukoffa[1];*
[1]Cytokines and NO Synthases team, LBCM, USTHB, Algiers, Algeria, [2]Internal medicine department, CHU Bab ElOued, Algiers, Algeria, [3]Internal medicine department, CHU Mustapha Bacha, Algiers, Algeria.

Behçet disease (BD) is a chronic systemic inflammatory disorder with uncertain etiology. In previous studies, we showed an increase in nitric oxide (NO) production during disease active stages. NO is the product of NO synthases. It is synthetized from L-Arginine. However, this amino-acid is also the substrate of other enzymes. In this study, we investigated the activity of the other enzymes implicated in arginine metabolism.
65 patients fulfilling BD diagnosis criteria were included in the study (35 active and 30 inactive) and 25 healthy controls (HC). The activity of NOS, ARG, ADC, AGAT and GAMT were assessed through their products measurement. IL1β and IL-27 were measured by ELISA. Mann Witney U test was used for statistical comparison. Spearman test was used for correlation study.
Our results showed a significant increase in all enzymes activity during BD in comparison to HC ($p<0.05$). In addition, we observed a significant increase of NOS and ADC activities and IL-1β during active BD in comparison to inactive BD ($p<0.01$) or HC ($p<0.001$). Also, NOS and ADC showed increased activities during inactive BD in comparison to HC ($p<0.05$). Correlation analyses showed no significant correlations between the different enzymes however a significant positive correlation was observed between NOS and IL-1β ($r=0.62$, $p<0.05$) while a negative correlation was observed between IL-27 and arginase ($r= -0.45$, $p=0.021$).
In conclusion, our results showed an increased activity in arginine metabolism during BD especially NOS and ADC in relation with disease activity. Moreover, this activity seems to be related to cytokines production.

P.C6.05.03
Gastro protective and anti inflammatory activities of *Pistacia lentiscus L.* extracts against gastric ulcer in rats

***I. BOUTEMINE**[1], M. Amri[1], Z. Amir[2], C. Fitting[3], J. Cavaillon[3], C. Touil-Boukoffa[1];*
[1]University of Sciences and Technology Houari Boumediene, algiers, Algeria, [2]Pathology department, Mustapha Pacha Hospital, Algiers, Algeria., algiers, Algeria, [3]Cytokines & Inflammation, Pasteur Institute, Paris, France.

Aim of the study: In the present study, we investigated the anti-ulcerogenic and anti-inflammatory activities of fatty oil (PLFO) and aqueous extract (PLAE) of *Pistacia lentiscus* on ethanol-induced gastric ulcers in Wistar rats. **Material and methods:** PLFO and PLAE were orally administered to rats before gastric ulcer induction by ethanol. The lesions of the gastric mucosa were evaluated by macroscopic and histopathological examination. In addition, the amount of nitric oxide (NO) and pro-inflammatory cytokines (tumor necrosis factor-α (TNF-α) and interleukin-6 (IL-6)) were assessed in the plasma and the supernatant of explants cultures of gastric mucosa. Finally, the mucus production and iNOS (inducible NO synthase) expression were determined by histochemical and immunohistochemical analysis respectively. **Result:** Our results indicated that the pretreatment with PLFO and PLAE significantly reduced the areas of gastric’ ulceration and hemorrhage. Interestingly, pretreatment with these extracts highly reduced the plasmatic concentration of NO.

In addition, a significant decrease of NO, IL-6 and TNF-α levels was observed in explants culture. Moreover, iNOS expression was also reduced in the gastric mucosa. In contrast, mucus production by goblet cells was enhanced. Interestingly, the histological analysis of the gastric mucosa has indicated that PLFO and PLAE pretreated groups displayed normal histology. **Conclusion:** Our results demonstrate that PL extracts display significant prophylactic effects against gastric ulcer. Importantly, the mechanism underlying PLFO and PLAE activities might implicate the inhibition of inflammatory responses during gastric ulcer.

P.C6.05.04

Engagement of Fas differentially regulates the production of LPS-induced pro-inflammatory cytokines and type I Interferons

*C. Lyons[1], K. Brennan[2], S. Doyle[3], A. Houston[1], **E. Brint**[1];*
[1]University College Cork, Cork, Ireland, [2]Trinity College Dublin, dublin, Ireland, [3]Trinity College Dublin, Dublin, Ireland.

Best known for its role in apoptosis, recent reports suggest that Fas (CD95) signalling is also involved in other cellular responses including inflammation. Whilst Fas and its adaptor protein FADD have been previously shown to negatively regulate LPS-induced pro-inflammatory responses, their role in LPS-induced type-1 Interferon production is unknown. Here we demonstrate that Fas engagement on THP-1 macrophages using an agonistic Fas antibody CH11, augments LPS-induced NF-κB responses, causing an increase in the production of TNFα, IL-10, IL-8, IL-6 and IL-12. Conversely, co-stimulation with both LPS and CH11 causes a significant reduction in the level of IFNβ production. This differential effect involves the Fas adaptor FADD as, whilst LPS-induced IL-6 production was increased in $FADD^{-/-}$ murine embryonic fibroblasts, LPS-induced IFNβ production was significantly reduced in these cells. Overexpression of a dominant negative form of FADD, the FADD-Death Domain (FADD-DD), in the RAW264.7 macrophage cell line, inhibits LPS-induced IFNβ-luciferase but not LPS-induced NF-κB luciferase. In contract, overexpression of full-length FADD inhibited LPS-induced NF-κB-luciferase activation but was seen to augment LPS-induced IFNβ-luciferase. Moreover, the FADD-DD inhibits TLR-4-, TRIF- and TRAM-induced IFNβ -luciferase production, indicating that FADD may be interacting with the TLR-4 pathway at the level of these TLR4 adaptor proteins. In conclusion, these data identify FADD as a novel component of the MyD88-independent pathway leading from TLR4 to Type-1 Interferon production and moreover demonstrate that both Fas and its adaptor FADD can differentially regulate the production of LPS-induced pro-inflammatory cytokines and type I Interferons

P.C6.05.05

miRNA-147 targets the electron transport chain component NDUFA4 in response to inflammatory stimuli

***S. A. Clayton**[1,2], S. W. Jones[1], M. Kurowska-Stolarska[3,2], A. R. Clark[1,2];*
[1]University of Birmingham, Birmingham, United Kingdom, [2]Arthritis Research UK Rheumatoid Arthritis Pathogenesis Centre of Excellence (RACE), Glasgow, Birmingham, Newcastle, United Kingdom, [3]University of Glasgow, Glasgow, United Kingdom.

Introduction: MicroRNAs (miRNAs) are an important class of post-transcriptional regulator, with many being described as instrumental in immune cell inflammatory responses. MiRNAs can alter cellular metabolism by targeting essential components of specific metabolic pathways. Macrophage phenotype and function is now known to be intimately linked to cellular metabolic status, and consequently miRNAs have the potential to achieve immunomodulatory effects by targeting macrophage metabolic pathways.
Methods: MiRNA and mRNA expression was measured by RT-qPCR in primary human monocyte derived and mouse bone marrow derived macrophages in response to pro-/anti-inflammatory stimuli. Several miRNA target prediction tools were used (TargetScan, miRanda, miRDB, miRTarBase). NDUFA4 protein expression was detected by Western blotting. Cells were transfected with miRNA mimics (Dharmacon) to validate targets.
Results: Expression of microRNA-147 in macrophages was induced by pro-inflammatory stimuli such as LPS. LPS-induced miR-147 expression was inhibited by the synthetic glucocorticoid dexamethasone in mouse macrophages by up to 93%, and the human homologue miR-147b by up to 81%.
Bioinformatic analysis found that miR-147(b) was predicted to target the 3'UTR of electron transport chain component NDUFA4. Expression of human NDUFA4 mRNA and protein were both significantly downregulated by LPS treatment of macrophages, and NDUFA4 protein expression was rescued by co-treatment with dexamethasone. This is consistent with the regulation of miR-147b by these stimuli. Ectopic expression of miR-147b confirmed that this miRNA functionally targets NDUFA4.
Conclusions: MiR-147 has the potential to regulate macrophage metabolism in response to pro-inflammatory signals by downregulating a key electron transport chain component.

ERAP1 depletion mimics the effects of the Behçet's Disease associated enzyme variant on the HLA-B*51 peptidome

***P. Guasp**[1], M. Compagnone[2], E. Barnea[3], J. J. Kuiper[4], D. Fruci[2], A. Admon[3], J. López de Castro[1];*
[1]Centro de Biología Molecular Severo Ochoa (CSIC-UAM), Madrid, Spain, [2]Immuno-Oncology Laboratory, Pediatric Haematology/Oncology Department, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy, [3]Faculty of Biology, Technion-Israel Institute of Technology, Haifa, Israel, [4]Department of Ophthalmology, University Medical Center Utrecht, Utrecht, Netherlands.

The Endoplasmic Reticulum Aminopeptidase ERAP1 trims peptides to the correct length for presentation by HLA class I molecules. HLA-B*51 shows a high preference for peptides that carry Proline or Alanine at position 2. The Pro2 subpeptidome shows higher affinity for HLA-B*51 than the Ala2 subpeptidome.
ERAP1 was knocked out in the transfectant cell line 721.221-HLA-B*51 using the CRISPR Cas9 technology. The B*51 bound peptidome presented by the WT and ERAP1 KO cells was comparatively analyzed by quantitative mass spectrometry, and the surface expression of HLA-B*51 was measured by flow cytometry. The theoretical affinity of the identified peptides for HLA-B*51 was calculated using predictive algorithms.
The absence of ERAP1 drastically altered the ratio between the Ala2 and Pro2 subpeptidomes. This effect dramatically reduced the affinity of the peptidome presented by the ERAP1 KO cells due to the overrepresentation of the low affinity subpeptidome of Ala2 ligands. ERAP1 KO did alter neither the surface expression of HLA-B*51 nor the levels of Free Heavy Chain in this transfectant cell line.
Overall, we demonstrate that ERAP1 is required to maintain the balance between Ala2 and Pro2 ligands in HLA-B*51 cells, and its absence leads to a peptidome of much lower affinity. The effects of ERAP1 depletion on the HLA-B*51 peptidome are very similar to those observed in the presence of the low activity and Behçet's associated ERAP1 Hap10 variant. Being the interaction between HLA-B*51 and KIR3DL1 sensitive to the HLA-B*51 peptidome, it is very likely that ERAP1 depletion may affect the NK cell reactivity.

P.C6.05.07

IgA versus IgG: the potential and danger of IgA as potent immune cell activator

***M. H. Heineke**;*
VU medical centre, Amsterdam, Netherlands.

Antibody-opsonized pathogens can activate immune cells via Fc receptors. Both IgA Fc receptor (FcαRI) and IgG Fc receptor IIA (FcγRIIA) are thought to initiate similar signaling pathways and responses, but we previously showed that only IgA triggering of neutrophils led to leukotriene B4 release with concomitant neutrophil migration. In this study we investigated cellular activation through IgA or IgG in more detail using different methods, including live cell imaging, (phospho)proteomics and metabolomics. No differences were observed in uptake of IgG- or IgA-coated beads and subsequent release of reactive oxygen species and neutrophil extracellular traps. However, crosslinking of FcαRI led to a slower but stronger and more sustained signaling profile, exemplified by increased intracellular calcium and phosphotyrosine levels. Only IgA stimulation induced downstream events, like release of cytokines, chemokines and pro-inflammatory lipids. Importantly, enhanced activation through FcαRI is not neutrophil specific, as stimulation of monocytes with IgA also led to increased activation. These results support 1) that signaling routes of FcγRIIA differ from those that are initiated by FcαRI, resulting in distinct functional profiles, and 2) IgA is a more potent activator of immune cells than previously anticipated. This may have significant implications in autoimmunity, as IgA auto-antibodies are found in a multitude of autoimmune diseases. Moreover, IgA may represent a potent novel immune activator during cancer immunotherapy.

P.C6.05.08

Lunasin regulates obesity-related inflammation in C57BL/6 mice fed with high fat diet

***C. C. Hsieh**[1,2], M. J. Chou[2], S. H. Peng[2];*
[1]School of Life Science, Programs of Nutrition Science, National Taiwan Normal University, Taipei, Taiwan, [2]Department of Human Development and Family Studies (Nutritional Science & Education), National Taiwan Normal University, Taipei, Taiwan.

Accumulating evidence has shown that extra adiposity influences the progression of various chronic diseases. The process of adiposity induces the infiltration of macrophages, accompanied by multiple inflammatory mediators. Lunasin, a natural seed peptide, exhibits several biological activities, such as anti-carcinogenesis, anti-inflammatory, and antioxidant activities. The aim of this study is to investigate whether lunasin regulates obesity-related inflammation in mice fed with high fat diet. C57BL/6J mice were fed a low fat (LF), or high fat (HF) diet, and HF intraperitoneal injected by lunasin 4 mg/kg bw (HF-LL) and 20 mg/kg bw (HF-HL) for 7 weeks. Our results showed that the HF mice have significant higher body weight and organs weight including spleen, liver, and adipose tissue than the LF mice. The oxidized lipid malondialdehye value was significantly higher in the HF group. The mice received lunasin significantly decreased malondialdehye values in the adipose and liver. Interleukin (IL)-1β production by LPS-stimulated peritoneal cells was increased in HF mice, and were decreased in mice received lunasin treatment.

Histological analysis of the epididymal adipose tissue of HF groups with lunasin treatment showed less F4/80+ macrophage infiltration, especially lower CD11c+M1 phenotype, compared to HF and LF groups. More related mediators should be analyzed in the future. In summary, lunasin regulates obesity related mediators in C57BL/6 mice fed with high fat diet, suggesting the intake of lunasin from diet or a supplement, for auxiliary prevention or therapy in obesity-related applications. The authors acknowledge the funding from Ministry of Science and Technology, Taiwan (MOST 106-2311-B-003-005-MY3).

Frequency and activation status of myeloid cells in the Guillain-Barre syndrome

W. van Rijs, W. Fokkink, A. Tio-Gillen, M. Brem, B. Jacobs, ***R. Huizinga****;*
Erasmus MC, University Medical Center, Rotterdam, Netherlands.

The Guillain-Barré syndrome (GBS) is an acute immune-mediated neuropathy, which may develop after relatively common infections, including *Campylobacter jejuni* and cytomegalovirus. Macrophages are important in the pathogenesis of GBS by phagocytosing myelin and axons in the nerve. However, little is known about their precursors in the peripheral blood. Here we assessed the composition and phenotype of monocytes and dendritic cell (DC) subsets in peripheral blood of GBS patients. Peripheral blood mononuclear cells (PBMC) were isolated from GBS patients (n=20), before and after immunomodulatory treatment, and age and gender-matched, healthy controls (n=20). The frequency and phenotype of six myeloid cell subsets was determined by 13-color flow cytometry. The frequency of total monocytes, determined as percentage of CD45+ cells, was significantly increased in GBS patients compared to controls. The monocyte population was skewed towards more intermediate (CD14+CD16+; $p<0.05$) and less non-classical (CD14-CD16+; $p<0.01$) monocytes. Increased expression of CD40, TLR2 and Siglec-7 on non-classical monocytes suggested an enhanced differentiation towards non-classical monocytes. Immunomodulatory treatment strongly reduced the frequency of non-classical monocytes and all DC populations in CD45+ PBMC, as well as expression of CD40, HLA-DR and TLR4 on classical monocytes. In conclusion, our data identify significant changes in the monocyte compartment in GBS. Further analysis should reveal whether these changes are related to preceding infections, disease severity and treatment response.

Dietary fish oil enhances the proportion of mature NK cells in murine antigen-induced peritonitis

K. N. Jensen*[1,2], J. Freysdottir[1], I. Hardardottir[2];*
[1]Landspitali - the National University Hospital of Iceland, Reykjavik, Iceland, [2]University of Iceland, Reykjavik, Iceland.

Unresolved inflammatory responses may lead to chronic inflammation, which is linked to the pathogenesis of a number of degenerative diseases in Western countries. We have previously shown that dietary omega-3 PUFA induced an early peak in the number of NK cells in antigen-induced peritonitis in mice and also enhanced the resolution of the inflammation. Furthermore, depletion of NK cells prevented the timely resolution of inflammation in the same model. The aim of this study was to determine the effects of dietary omega-3 PUFA on the NK cells at the peak of the inflammation. Mice were fed either a control or a fish oil enriched diet, immunized with methylated BSA (mBSA) and mBSA injected into the peritoneum. Peritoneal cells were harvested at the peak of inflammation, sorted and assessed by flow cytometry. As was shown in the previous study, mice fed the fish oil enriched diet had a lower number of neutrophils and a higher number of total NK cells at the peak of inflammation. More specifically, mice fed the fish oil diet had a higher number of mature NK cells but a lower number of immature NK cells in their peritoneum than mice fed the control diet. These results suggest that dietary fish oil may enhance maturation of NK cells and that these mature NK cells may play an important role in the resolution of inflammation either by limiting the infiltration of neutrophils or inducing neutrophil apoptosis in a more effective manner.

DNase I treatment ameliorates mouse experimental colitis

E. Y. H. Lin*[1], Y. H. Hsu[1], C. S. Hsueh[2], H. W. Chang[2], H. S. Chiang[1];*
[1]Department of Life Science, National Taiwan University, Taipei, Taiwan, [2]School of Veterinary Medicine, National Taiwan University, Taipei, Taiwan.

Neutrophils are the most abundant white blood cells with potent antimicrobial activities. Neutrophil extracellular trap (NET) is one of the defense mechanisms utilized by neutrophils to control microbial infections. A recent proteome and microscopy analysis of intestinal biopsies of patients with ulcerative colitis indicated an increased neutrophil abundance and aberrant NETs in inflamed colon tissues. However, the impact of NET in colitis has yet been fully illustrated. Here we demonstrated that administrations of DNase I, an endonuclease that dissolves the NET structure, suppressed colitis in a dextran sulfate sodium (DSS) mouse model. DNase I treatments had a tendency to reduce weight loss and clinical symptoms in mice during DSS-induced colitis. DNase I treatments also alleviated DSS-induced colon shrinkage and intestinal architecture disruption. Furthermore, immunofluorescence microscopy revealed a reduced levels of histone H3 citrullination in the colons of DSS-induced colitis mice with DNase I administration. Overall our results suggested that DNase I treatment has the potential capability to alleviate experimental colitis in mice.

Identifying the components of the ubiquitin proteasome system that target the p50 subunit of NF-κB for degradation

J. P. Mitchell*, R. J. Carmody;*
Institute of Infection Immunity and Inflammation, Glasgow, United Kingdom.

Introduction: The NF-κB subunit p50 is a critical regulator of inflammation and is a major transcription factor in most cell types. In macrophages, p50 homodimers act as repressors of transcription to limit the expression of pro-inflammatory cytokines and promote the resolution of inflammation, which is essential for avoiding the damaging effects of prolonged inflammation on the host. The stability of p50 homodimers is an important determinant of this repressor function and is controlled by ubiquitin-triggered proteasomal degradation. Despite its importance, little is known about the molecular mechanisms that target p50 for degradation, or the cellular factors that initiate p50 ubiquitination.
Methods: By using a panel of putative ubiquitin E3 ligases for p50 and a library of p50 mutants containing specific lysine to arginine substitutions, we aim to identify the components of the ubiquitin proteasome system (UPS) that target p50 for ubiquitination and degradation.
Results: Initial data has identified a novel role for SOCS1 as an E3 ligase that ubiquitinates p50. We have also identified a lysine residue of p50 that is targeted for ubiquitination but for which we have not yet identified the specific E3 ligases responsible.
Conclusions: These findings indicate that p50 ubiquitination is orchestrated by a complex network of UPS factors with significant implications for our understanding of this regulatory mechanism in the control of inflammation.

P.C6.05.14

Metabolic alterations in airway macrophages during pulmonary fibrosis

P. P. Ogger*[1], R. J. Hewitt[1], P. L. Molyneaux[1,2], T. M. Maher[1,2], C. M. Lloyd[1], A. J. Byrne[1];*
[1]National Heart and Lung Institute, Imperial College London, London, United Kingdom, [2]NIHR Respiratory Biomedical Research Unit, Royal Brompton Hospital, London, United Kingdom.

Background: Idiopathic pulmonary fibrosis (IPF) is a fatal disease with limited treatment options. Evidence suggests that IPF is in part due to dysregulated wound-healing orchestrated by macrophages. While metabolic reprogramming of macrophages drives inflammation, its contribution to IPF is unknown. We hypothesise that airway macrophage (AM) metabolic reprogramming underlies IPF and that manipulation of AM metabolism represents a potential novel therapeutic strategy for IPF. **Methods:** First we assessed AM number and phenotype in patient bronchoalveolar lavage (BAL) by flow cytometry. Subsequently AMs were enriched and metabolic functionality was analysed by extracellular flux analysis and PCR array of key metabolic enzymes. To investigate the metabolic phenotype of tissue resident and monocyte recruited airway macrophages in pulmonary fibrosis, we utilised the bleomycin mouse model and measured expression of metabolic genes and mitochondrial function in sorted macrophage populations. **Results:** IPF AMs show increased expression of *ENO2* and *IDH2*, while *SDHC* gene expression is decreased and oxygen consumption rate is similar compared to healthy controls. Upon bleomycin treatment, Siglec-F^{int} monocyte recruited airway macrophages gradually replaced Siglec-F^{hi} tissue resident airway macrophages and show higher gene expression of *HK3* and *IDH2*. **Conclusions:** Together these data indicate that during pulmonary fibrosis, AMs undergo metabolic alterations. The differential gene expression of *IDH2* and *SDHC* is particularly interesting considering these are major oncogenes. Future work aims to further characterise the metabolic phenotypes of resident and recruited AMs in the lung and to investigate how alterations in AM metabolic intermediates in IPF may contribute to the disease.

P.C6.05.15

Bosentan therapy modulates miR-21-TGF-β1-bFGF-Let-7d axis and attenuates the development of pulmonary artery hypertension after bleomycin injury

A. Pandey;
Vallabhbhai Patel Chest Institute, Delhi, India.

Introduction: Pulmonary artery hypertension(PAH) develops in 30-40% cases of pulmonary fibrosis. Pathogenesis of PAH is associated with differential expression of miRNAs. MiR-21 inhibits endothelin receptor(ET-B), drives VSMC differentiation and fibrosis. Let-7d binds to endothelin-1and is proangiogenic. The effects of Bosentan, on miRNAs and bFGF, TGF-β1 signaling cascades remain to be elaborated. **Method**: Wistar rats were euthanized on day 7, 14, 28 after bleomycin/saline instillation: GroupI (control, n=18), GroupII (bleomycin, 7 IU/kg, n=18), GroupIII (Bleomycin+Bosentan, 100mg/kg/d, n=18). Let-7d, miR-21, bFGF, TGF-β1 mRNA and protein levels were assessed. **Result:** Bleomycin instillation caused upregulation of miR 21 and downregulation of Let-7d from day 7. An associated upregulation of TGF-β1 and bFGF mRNA and protein levels was seen. bFGF increased in AECs, peribronchiolar fibroblasts and reduced in endothelial cells from day 7. Progressive perivascular inflammation, vasoconstriction and vascular smooth muscle cell hypertrophy(VSMCH) was seen. After bosentan therapy, miR-21 downregulation and Let-7d upregulation was seen on day 28. This correlated with a reduction in TGF-β1 and bFGF mRNA and protein levels, reduction in perivascular inflammation and remodelling while vasoconstriction persisted till 28 day, after bosentan therapy. **Conclusion:** The miR-21-TGF-β1-bFGF-Let-7d axis plays a key regulatory role in the pathogenesis of PAH. TGF-β1 has an autoregulatory feedback loop with miR-21 and bFGF. Loss of endothelial bFGF downregulates Let-7d, increases TGF-β1 and promotes endothelial-mesenchymal transition, leading to VSMCH and vascular remodelling. Bosentan therapy, downregulates miR-21, reduces TGF-β1 signalling, upregulates let 7d and attenuates VSMCH and pulmonary hypertension.

P.C6.05.16

Specialized Pro-Resolving Mediators' receptors expression in peripheral blood derived leukocytes in Rheumatoid Arthritis

***S. Perniola**, L. Dinoia, N. Lacarpia, D. Natuzzi, R. Bizzoca, F. Iannone;*
Rheumatology Unit - Department of Emergence Medicine and Transplantation, Bari, Italy.

Background: Resolution process downregulates the inflammation and promotes tissue repair by the Specialized Pro-Resolving Mediators (SPMs), that act by interacting with specific cellular receptors: CMKLR1, BLT1, FPR2 and GPR32. In rheumatoid arthritis (RA) the reactive inflammation becomes persistent and the innate immune response turns into the adaptive immune activation.
Objectives: nowadays there is no evidence whether SPMs are involved in RA pathogenesis so we evaluated the expression of CMKLR1, FPR2 and BLT1 in RA patients.
Methods: Patients affected with RA were enrolled in this study. At entry, ESR, CRP, DAS28-ESR, CDAI and HAQ were collected. Patients were divided into high-moderate (H-Mo/RA if DAS28-ESR ≥ 3.2) and low-remission (LRem/RA if DAS28 < 3.2) disease activity group. The expression of CMKLR1, FPR2 and BLT1 in peripheral T cells (CD3) and monocytes (CD14) was evaluated by flow-cytometry assay.
Results: Thirty RA patients were studied. SPMs receptors were differently expressed on CD14. BLT1+CD14+ cells were significantly higher in L-Rem/RA than in H-Mo/RA (p: 0.0001). Likewise, FPR2+CD14+ cells were significantly higher in L-Rem/RA than in H-Mo/RA (p: 0.01). We demonstrated an inverse correlation between BLT1 level in monocytes and ESR (p: 0.01), CRP levels (p: 0.008), DAS28-ESR (p: 0.03), CDAI (p: 0,0076) and HAQ (p: 0,0138) and a weak correlation between FPR2 expression and HAQ (p: 0.05).
Conclusions: FPR2 and BLT1 expression seems to be regulated by the activity of RA disease. It might be hypothesized that a defective signalling through these SPMs receptors may contribute to sustain chronic inflammation in active RA.

P.C6.05.17

Surfactant protein D regulates cigarette smoke-induced lung inflammation through inhibition of ceramide synthesis

***B. Pilecki**[1], H. Wulf-Johansson[1], P. Djiadeu[2], C. Støttrup[1], P. T. Jørgensen[1], A. Schlosser[1], S. W. Hansen[1], J. Madsen[3,4,5], H. W. Clark[3,4,5], C. H. Nielsen[6], J. Vestbo[7,8], U. Holmskov[1], G. L. Sørensen[1];*
[1]Department of Cancer and Inflammation Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark, [2]Program in Translational Medicine, Lung Innate Immunity Research Laboratory, The Hospital for Sick Children Research Institute, Toronto, Canada, [3]Department of Child Health, Sir Henry Wellcome Laboratories, Academic Unit for Clinical and Experimental Sciences, Faculty of Medicine, University of Southampton, Southampton, United Kingdom, [4]Institute for Life Sciences, University of Southampton, Southampton, United Kingdom, [5]National Institute for Health Research, Southampton Respiratory Biomedical Research Unit, Southampton, Centre for Biomedical Research, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [6]Institute for Inflammation Research, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark, [7]Department of Respiratory Medicine, Odense University Hospital, Odense, Denmark, [8]Division of Infection, Immunity and Respiratory Medicine, Manchester Academic Health Science Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom.

Introduction: Surfactant protein D (SP-D) is a pulmonary collectin with established anti-inflammatory functions. SP-D-deficient mice exhibit pulmonary emphysema together with lipid and alveolar macrophage accumulation. SP-D has been linked to chronic obstructive pulmonary disease (COPD), while exposure to cigarette smoke (CS), main COPD risk factor, upregulates pulmonary SP-D in mice. Ceramides, pro-inflammatory lipid mediators, are known to be involved in CS-induced disease.
Aim: In the current study we hypothesized that SP-D deficiency leads to aggravation of CS-induced lung inflammation.
Methods: C57BL/6N male WT and SP-D-deficient mice were subjected to whole body CS exposure 5 days/week for 12 weeks (chronically) or daily for 3 days (acutely). Recombinant fragment of human SP-D (rfhSP-D) was administered intranasally one hour prior to each CS exposure in the acute regimen.
Results: CS exposure resulted in macrophage-rich airway inflammation that was aggravated in SP-D-deficient mice. In addition, local levels of macrophage inflammatory protein-1 alpha were significantly higher in SP-D-deficient mice than in WT animals after chronic CS exposure and correlated positively with airway total cell count. Furthermore, CS-treated SP-D-deficient mice showed pulmonary accumulation of long-chain ceramides as well as ceramide synthase genes, crucial for ceramide generation. Finally, CS-induced macrophage accumulation and upregulation of ceramide synthase genes could be reversed by rfhSP-D treatment.
Conclusion: Our results indicate that SP-D protects from CS-induced pulmonary inflammation and ceramide generation and that SP-D-based therapy might be a future potential treatment of COPD.

P.C6.05.19

Resident, sessile airway macrophages clear infiltrating neutrophils before monocyte arrival with a minimal neutrophil lymphatic entry

***J. Vuononvirta**[1], D. F. Patel[1], J. Secklehner[2], J. B. Mackey[2], K. De Filippo[1], W. Branchett[1], L. G. Gregory[1], M. B. Headley[3], M. F. Krummel[3], R. J. Snelgrove[1], C. M. Lloyd[1], L. M. Carlin[2];*
[1]Inflammation, Repair & Development, National Heart & Lung Institute, Imperial College London, London, United Kingdom, [2]Cancer Research UK Beatson Institute, Glasgow, United Kingdom, [3]Department of Pathology, University of California, San Francisco, United States.

In the lung, resident airway macrophages (AMs) are often the first immune cells encountered where they provide sentinel function against inhaled pathogens. During infection or inflammation, pro-inflammatory cytokine and chemokine production leads to recruitment of neutrophils into the alveoli to tackle pathogens. During resolution of inflammation, neutrophils are thought to be cleared by airway macrophages to prevent further tissue injury, termed efferocytosis. Since much of our understanding of AM function is based on studies in which AMs were isolated and studied *ex vivo* or depletion studies *in vivo* we lack data on AM behaviour, dynamics and interactions with neutrophils in their natural microenvironment. To address this, and the mechanisms and kinetics of neutrophil clearance during inflammation, we used lung intravital microscopy and imaging of agarose inflated precision cut lung slices in a well characterised LPS mouse model at different time points post instillation (24h, 48h and 72h). Using lung intravital microscopy, we demonstrated that AMs are sessile during steady state and inflammation, but they protrude and retract dramatically post-LPS indicating more active behaviour.
Strikingly, we observed that AMs are able to clear neutrophils efficiently (halving neutrophil numbers in the BAL between 24 and 48 hrs), largely before recruited monocytes arrive by engulfing several neutrophils at a time. Post-LPS, neutrophils are cleared rapidly by AMs with a small percentage entering the lymphatics. Overall, we provide new insights into AM function and behavior during LPS induced lung inflammation *in vivo*.

The absences of Growth Differentiation Factor 15 aggravates adverse cardiac remodeling upon pressure-overload

***M. Wesseling**[1,2,3], J. J. de Haan[1], G. Sanchez-Duffhues[3], L. Bosch[1], M. A. Brans[1], S. J. Lee[4], J. C. Deddens[1], G. Pasterkamp[2,5], J. P. Sluijter[1,5,6], M. J. Goumans[3], S. C. de Jager[1,7];*
[1]Department of Cardiology, Laboratory of Experimental Cardiology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Molecular Cell Biology, Leiden University Medical Center, Leiden, Netherlands, [4]Department Molecular Biology and Genetics, The Johns Hopkins University School of Medicine, Baltimore, United States, [5]Utrecht University, Utrecht, Netherlands, [6]UMC Utrecht Regenerative Medicine Center, Utrecht, Netherlands, [7]Laboratory of Translational Immunology, Department of Immunology, University Medical Center Utrecht, Utrecht, Netherlands.

Background: Growth differentiation factor 15 (GDF15) belongs to the TGF-β family. Under normal conditions, GDF15 is not highly expressed, but sharply increased upon injury. GDF15 influences many processes, such as inflammation, apoptosis and fibrosis. In heart failure (HF) patients, GDF15 plasma levels are increased and high GDF15 levels are associated with increased mortality. Yet, the exact role of GDF15 in adverse cardiac remodeling leading to HF is not known.
Purpose: We therefore studied GDF15 knock-out ($^{-/-}$) mice and wild type (WT) in a pressure-overloaded HF model using transverse aortic constriction (TAC).

Results: After 6 weeks of TAC, GDF15$^{-/-}$ mice have increased end diastolic volume (EDV) and end systolic volume (ESV) (EDV: 93 µl versus 64 µl, p<0.001, ESV: 72 µl versus 38 µl, p<0.001). The accelerated worsening in GDF15$^{-/-}$ mice were already visible 7 days after TAC in both ESV as in global longitudinal strain (-11.8±2.8 % vs. -15.5 ±2.7 %). Immunohistochemistry showed no differences in cardiomyocyte hypertrophy, fibrosis and inflammation. Another mechanism involved in adverse remodeling is endothelial to mesenchymal transition. To assess the role of GDF15 in this process we exposed human primary coronary microvascular endothelial cells to recombinant hGDF15 which resulted in morphological changes representing endothelial to mesenchymal transition. Furthermore protein and reporter assays confirmed this observations.
In conclusion: Lack of GDF15 aggravates adverse remodeling upon pressure-overload. Our data suggests that GDF15 directly induces coronary microvascular dysfunction by endothelial to mesenchymal transition. Further studies will determine to which extent endothelial to mesenchymal transition affects adverse cardiac remodeling.

P.C6.06 Innate control of inflammation and tissue repair - Part 6

P.C6.06.01
The crosstalk between autophagy and inflammation in plasmacytoid Dendritic Cells

C. R. Almeida[1], *C. Silva*[1], *P. Antas*[1], *V. Camosseto*[2], *E. Gatti*[1,2], *P. Pierre*[1,2];
[1]*Institute for Biomedicine – iBiMED, Aveiro, Portugal,* [2]*CIML - Centre d'Immunologie de Marseille-Luminy, Marseille, France.*

Autophagy contributes to cellular homeostasis by eliminating damaged organelles and pathogens, as well as protein aggregates, which might act as inflammasome triggers. Autophagy contributes therefore to proteostasis but also controls inflammation. Dendritic cells (DCs) orchestrate innate and adaptive immunity mostly due to its role as antigen presenting cells and as cytokine producers. Activation of DCs by LPS stimulates the mTORC1 pathway, decreasing the autophagy flux and leading to accumulation of newly synthesized poly-ubiquitinated proteins in dendritic cell aggresome-like induced structures (DALIS). Here we studied the interplay between autophagy, inflammation and protein aggregation on plasmacytoid dendritic cells (pDCs), which are a subset specialized in production of type I interferon (IFN) with an important role in antiviral responses and in the pathogenesis of autoimmune diseases. We found that inhibiting autophagy on the pDC cell line CAL-1 impacts the production of cytokines and protein aggregation. The results suggest a link between autophagy, protein aggregation and inflammation in human pDC. These findings can ultimately be used for future development of novel therapeutic approaches in autoimmune diseases or against infection. This work was supported by Fundação para a Ciência e a Tecnologia and Portugal2020 (FEDER) - reference PTDC/IMI-IMU/3615/2014 - and through POCH (SFRH/BPD/109322/2015).

P.C6.06.02
Efficient engagement of inhibitory receptor ILT4, LILRB2 with complement split products

C. Battin[1], *A. De Sousa Linhares*[1], *J. Hofer*[2], *G. Zlabinger*[1], *J. Leitner*[1], *W. Paster*[3], *P. Steinberger*[1];
[1]*Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria,* [2]*Department of Medicine II, Division of Nephrology and Dialysis, Vienna, Austria,* [3]*CCRI - Children´s Cancer Research Institute, Vienna, Austria.*

The complement system is an evolutionary ancient defense mechanism of innate immunity but plays also an important role in maintaining immune homeostasis during the clearance of immune complexes and apoptotic material. Surfaces of invading pathogens or altered self, trigger complement activation and deposition via a cascade of enzymatic reactions resulting in the release of complement split products CSPs. Deficiencies in C4 are linked to diseases like systemic lupus erythematosus and deposition of the CSP C4d on renal transplants is a strong predictor of graft rejection. Recent data demonstrate a novel interaction between C4d and the inhibitory cell surface receptor immunoglobulin-like transcript 4 (ILT4, also known as LILRB2) present on monocytes and dendritic cells. The major ligands for ILT4 are MHC class I molecules, which inhibit proinflammatory immune responses via the immunoreceptor tyrosine-based inhibitory motifs ITIMs. The exact functional role of C4d and its involvement in the ILT4 signaling pathway is still unknown. The current study therefore investigates the interaction of C4d molecule and other CSP with ILT4. Multimeric C4d molecules were generated to achieve improved receptor engagement. In addition we have developed a novel reporter system to investigate the consequences of ILT4 engagement by engineered C4d molecules without interference by MHC-class I – ILT4 interactions. We anticipate that our data will provide rationales to exploit the immunosuppressive function of C4d in novel therapeutic approaches.

P.C6.06.03
Sepsis induces long-term changes in the transcriptome and epigenome of naïve bone marrow monocytes

K. Bomans*, J. Schenz, D. Schaack, M. A. Weigand, F. Uhle;*
Heidelberg University Hospital, Department of Anesthesiology, Heidelberg, Germany.

"Sepsis-induced immunosuppression" is a typical hallmark of post-septic patients, characterized by a hypo-responsiveness of the host's immune system. This condition renders the host vulnerable to a persisting or the occurrence of secondary, often opportunistic infections, along with increased mortality.
The mechanisms underlying the immunosuppressive phenotype are yet unknown, but the involvement of epigenetic alterations of immune cells seem obvious. Our project aims to unravel these underlying molecular mechanisms.
Epigenetic (ChIP-seq for H3K4me3) and transcriptomic (RNA-seq) analysis of post-sepsis naïve bone marrow monocytes (three months after insult) were analyzed using a cecal ligation and puncture (CLP) mouse model of polymicrobial abdominal sepsis. Also, immune cell composition and functionality in blood, spleen, and peritoneum were assessed by flow cytometry.
Principal component analysis of global gene expression of naïve bone-marrow monocytes revealed a sustained deregulation of certain genes after CLP conditions: 75 genes were differentially expressed, with 2 down- and 73 up-regulated genes. Furthermore, an increase of H3K4me3 was observed in 77 promoter regions of post-septic naïve monocytes. No correlation between changes in H3K4me3 and altered gene expression could be determined. Furthermore, a robust change of immune cell abundance, especially of the lymphoid lineage, in spleen and peritoneum was obvious.
Our results prove the remains of transcriptomic scars in naïve bone marrow monocytes even months after the insult, potentially indicating an *ab initio* altered functional state of naïve monocytes. Interestingly, the increase in gene expression was not associated with histone alterations, leaving the question of the involved regulatory tier open for further research.

P.C6.06.04
Ouabain reduces adhesion molecule CD18 expression on neutrophils

L. Cavalcante-Silva[1], *É. Lima*[2], *D. Carvalho*[2], *J. Galvão*[1], *J. Costa*[2], *S. Rodrigues-Mascarenhas*[2];
[1]*Health Science Center, João Pessoa, Brazil,* [2]*Biotechnology Center, João Pessoa, Brazil.*

Introduction: Ouabain, a hormone which inhibits Na^+,K^+-ATPase, is capable to modulate many aspects of the inflammatory process. We have previously demonstrated that ouabain inhibits neutrophil migration in several inflammatory models, but little is known about the mechanisms involved. Thus, the aim of this work was to evaluate ouabain effect on molecules related to neutrophil migration. Materials and Methods: Neutrophils obtained from mice bone marrow (ethical committee number 039/2015), after Percoll gradient separation, were seeded into 96-well plates and treated with ouabain (1 nM, 10 nM and 100 nM) at different times (2, 4 and 24h). Possible ouabain cytotoxicity was assessed by anexin V/propidium iodide staining. Ouabain effect on adhesion molecule CD18 and chemokine receptor CXCR2 was evaluated by flow cytometry. Statistical analysis was performed using ANOVA one way followed by Dunnet test. Results: Ouabain treatment did not reduce neutrophil viability at the periods studied. However, neutrophil basal viability was reduced after 4h, thus we assessed ouabain effect on adhesion molecule CD18 and chemokine receptor CXCR2 only after 2h of treatment. CXCR2 expression on neutrophil membrane was not affected by ouabain treatment (1, 10 and 100 nM). On the other hand, 1 nM ouabain reduced CD18 expression (30%), an integrin beta chain protein. Conclusion: These data suggest that ouabain inhibitory effect on neutrophil migration was related to CD18 reduced expression, suggesting a new mode of action of this substance. Funding support: CNPq (fellowship nº 140856/2016-1) and CAPES/PROCAD (grant nº 2951/2014).

Allele-specific Alternative Splice Transcripts for MHC class I-like MICA encode Novel NKG2D Ligands with Agonist or Antagonist function

B. CHARREAU[1], *P. Gavlovsky*[1], *P. Tonnerre*[1], *N. Gérard*[1], *Y. Hamon*[1], *S. Nedellec*[2], *A. Daman*[3], *B. J. McFarland*[3];
[1]*CRTI, Nantes, France,* [2]*Plateforme MicroPICell SFR Santé –IRT, Nantes, France,* [3]*Department of Chemistry and Biochemistry, Seattle Pacific University, Seattle, United States.*

Major histocompatibility complex (MHC) class I chain-related proteins A and B (MICA and MICB) and UL16 Binding Proteins (ULBPs) are ligands of the activating NKG2D receptor involved in cancer and immune surveillance of infection. Structurally, MICA/B proteins contain a α3 domain, while ULBPs do not. We identified novel alternative splice transcripts (AST) for MICA encoding five novel MICA isoforms: MICA-A, -B1, -B2, -C, and -D. Alternative splicing selectively associates with MICA *015 and MICA*017 alleles and results from a point deletion (G) in the 5' splice donor site of MICA intron 4 leading to exon 3 and exon 4 skipping and/or deletions. These changes delete the α3 domain in all isoforms, and the α2 domain in the majority of isoforms (A, B1, C, and D). Endothelial, hematopoietic and tumor cells from MICA *015 and MICA*017 individuals display endogenous AST and isoforms. MICA-B1, -B2 and -D bound NKG2D by surface plasmon resonance and were expressed at the cell surface. Functionally, MICA-B2 contains two extracellular domains (α1 and α2) and is a novel potent agonist ligand for NKG2D. MICA-D is a new truncated form of MICA able to bind NKG2D despite deletions of α2 and α3 domains that may functionally impair NKG2D activation. In conclusion, truncated MICA isoforms exist and exhibit a range of functions that may drive unexpected immune mechanisms and provide new tools for immunotherapy.

P.C6.06.06

Inflammatory/pro-degradative protein signature in tissues obtained from around aseptically loosened total knee arthroplasty

T. Dyskova[1], *J. Gallo*[2], *S. Zehnalova*[3], *M. Kudelka*[3], *P. Schneiderova*[1], *R. Fillerova*[1], *V. Smotkova-Kraiczova*[1], *E. Kriegova*[1];
[1]*Dept. of Immunology, Palacky University, Olomouc, Czech Republic,* [2]*Dept. of Orthopaedics, Palacky University&University Hospital, Olomouc, Czech Republic,* [3]*Dept. of Computer Science, Faculty of Electrical Engineering and Computer Science, VSB-Technical University, Ostrava, Czech Republic.*

Introduction: Inflammatory responses to biomaterial particles released from the bearing surfaces of joint replacements play a crucial role in the initiation and progression of periprosthetic osteolysis (PPOL). There exist only limited data on the immune protein signature in tissues from aseptically loosened (AL) total knee arthroplasty (TKA) and no information is relevant to pre-osteolytic stages in TKA. Methods: Therefore, we aimed to elucidate the protein signature of 92 inflammation-related proteins using a high-sensitive Proximity Extension Assay (PEA) in pseudosynovial tissue lysates obtained from patients re-operated for PPOL/AL (TKA, n=12) and those with TKA and no clinical and radiographic signs of PPOL/AL (C-TKA, n=9), re-operated for pain or fracture. Results: Late osteolysis was associated with elevated levels of TNF-family members TNFR2, TNFSF14, FasL, and BAFF, interleukins IL-8/CXCL8, IL-1RA/IL-36, sIL-6R, and growth factors AREG and CSF1 comparing to pre-osteolytic stages. Interestingly, analysis of time-axis revealed only weak association of inflammatory/pro-degradative protein signature and time from index surgery in periprosthetic tissues, thus further supporting particle-dose- rather than time-dependent inflammatory processes around TKA. Conclusion: The characterization of inflammatory signature and its dynamic changes during PPOL development may lead to better understanding the osteolytic process and thus proposal of effective preventative/therapeutic strategies contributing to reduction of this most common late complication in TKA.

Silver nanoparticles induced neutrophil extracellular trap formation: reactive oxygen species-dependent citrullination and cleavage of histones

H. Kang*, J. Seo, I. Choi;*
Department of Microbiology and Immunology, Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine and Institute for Immunology and Immunological Disease, Seoul, Korea, Republic of.

Introduction: Neutrophils are responsible for the first line of defense in innate immune systems. As one of the immune responses, they expel their own DNA to trap and eliminate pathogens known as neutrophil extracellular traps (NETs). However, excessive NET formation causes several autoimmune diseases such as rheumatoid arthritis, lupus erythematosus and atherosclerosis. Silver nanoparticles (AgNPs) have been used in a variety of fields because of their antimicrobial property. However recent studies showed that AgNPs induce reactive oxygen species (ROS) generation which is a key factor for NET formation.
Materials and Methods: Human neutrophils were isolated from healthy donors and seeded in cell culture plates. After that, AgNPs were treated for 4 h. To investigate the mechanism of AgNP-induced NET formation, various inhibitors were pretreated. NETs were quantified using the Picogreen dsDNA quantification assays and visualized by confocal imaging of extracellular DNA and granular components. Citrullination and cleavage of histones were detected by western blot.
Results: 5 nm AgNPs induced NET formation. On the other hand, 100 nm AgNPs not induced NET formation in the same concentration or surface area. N-acetylcystein, ROS scavenger, strongly reduced 5 nm AgNP-induced NET formation. Under the downstream of the ROS, peptidyl arginine deiminase and neutrophil elastase inhibitors reduced 5 nm AgNP-induced NET formation.
Conclusions: In this study, we revealed that 5 nm AgNPs induce NET formation through ROS dependent citrullination and degradation of histones. Based on these results, we are planning to investigate relationship between NET related diseases and AgNPs.

Effects of Quinton solution on human neutrophils' respiratory burst

A. B. López-Jaén[1], *P. Martínez-Peinado*[1], *S. Pascual-García*[1], *G. Peiró-Cabrera*[1,2], *F. J. Navarro-Blasco*[1,3], *J. M. Sempere-Ortells*[1];
[1]*University of Alicante, Alicante, Spain,* [2]*General University Hospital of Alicante, Alicante, Spain,* [3]*General University Hospital of Elche, Elche, Spain.*

Introduction. Quinton® Isotonic Solution consists in ultrafiltered diluted seawater with a final concentration of 9 g/l NaCl, obtained from nutrient-rich areas (marine vortices). The solution contains most of the mineral elements necessary for the correct functioning of the body's cells. In our previous studies, Quinton® isotonic solution has shown different immunomodulatory activities on lymphocytes. Neutrophils phagocytic response generates reactive oxygen species (oxidative burst), with a key role in the defense against pathogens. The aim of this study is to analyse the effect of Quinton® isotonic solution on neutrophils function. Materials and Methods. Human neutrophils were isolated by density gradient centrifugation with Percoll, from anticoagulated blood samples of healthy donors. 100.000 neutrophils were cultured in rounded 96-well plates, with different ratios of RPMI and Quinton® isotonic solution (100%, 50%, 25%, 12,5%, 0%) for 12 hours, in a final volume of 200 uL. PBS solution was used as a control. Respiratory burst was induced by incubating cells with phorbol 12-myristate 13-acetate (PMA) (0,3 ng/mL) for 30 minutes at 37 ºC, 5% CO_2, and measured by flow cytometry after adding dihydrorhodamine 123 (DHR). Results. Quinton® isotonic solution increased the percentage of positive neutrophils for respiratory burst, with and without stimulation. In the case of stimulated cultures, the increase was significant for the 50% concentration, with nearly significant p-value for the 25% concentration. Conclusion. Quinton® isotonic solution, under proper concentrations, seems to modulate neutrophils' function in vitro through an increase in their respiratory burst, which could translate into a higher bactericidal activity.

Experimental mouse Graft-versus-Host-Disease (GvHD) is ameliorated by mesenchymal stem cell derived extracellular vesicle treatment and might involve innate immune activity

R. J. Madel[1], *C. Chebrolu*[1], *V. Börger*[2], *P. A. Horn*[2], *H. A. Baba*[3], *D. Beelen*[4], *L. Kordelas*[4], *A. Bleich*[5], *J. Buer*[1], *B. Giebel*[2], *C. J. Kirschning*[1];
[1]*Institute of Medical Microbiology, University Hospital Essen, University Duisburg-Essen, Essen, Germany,* [2]*Institute of Transfusion Medicine, University Hospital Essen, University Duisburg-Essen, Essen, Germany,* [3]*Institute of Pathology, University Hospital Essen, University Duisburg-Essen, Essen, Germany,* [4]*Clinic of Bonemarrow Transplantation, University Hospital Essen, University Duisburg-Essen, Essen, Germany,* [5]*Laboratory Animal Science, Hannover Medical School, Hannover, Germany.*

Graft-versus-host disease (GvHD) is driven by an often-fatal immune reactivity to allogeneic bone marrow transplantation (BMT). In a previous, unique, and curative treatment at the local Hospital, mesenchymal stem cell derived extracellular vesicles (MSC-EVs) were administered to a steroid-refractory acute GvHD-patient, which persistently ameliorated pathology. BMT is preceded by preconditioning, namely self bone marrow ablation by chemotherapy or ionizing irradiation (IIR) to channel comprehensive graft stem cell homing. Preconditioning-driven tissue damage (TD) might collaterally promote formation of an inflammatory milieu, which might abet GvHD pathogenesis. MSC-EV validation and mechanistic analysis *in vivo* and *-vitro* is our program.
Given TD sensing's conceptual dependence upon innate immune activity, interference with pattern recognition receptor (PRR) activity - possibly encompassed in immune inhibitory MSC-EV function - might antagonize pathology. Experimentally modeling IIR-driven tissue impacting, we observed immune reactivity over an extended period of time *in vivo* and *-vitro*, which was rapid, largely independent upon bacterial colonization, and potentially inhibitable by MSC-EVs. Unexpectedly, BMT *Myd88⁄* mice succumbed to an early pathology, as if TLR/IL-1-type cytokine dependent activity might contribute to health maintenance rather than an adversativeness upon BMT. Notably, we observed in major histocompatibility mismatch BMT driven GvHD-mice a substantial attenuation of pathology upon MSC-EV administration at 3 consecutive days upon BMT. To narrow down a mechanistic cause, comparative analysis of distinct MSC-EV batches and other EVs as controls is being performed *in vivo* and *-vitro*. Our results imply a potential of MSC-EVs to interfere with GvHD pathology at different phases.

Innate signaling in central nervous system recruits myeloid suppressor cells

J. Marczynska[1], *R. M. Khorooshi*[1], *R. Storgaard Dieu*[1], *C. Rønn Hansen*[2], *S. Kavan*[3], *M. Thomassen*[3], *M. Burton*[3], *T. Kruse*[3], *G. A. Webster*[4], *T. Owens*[1];
[1]*Department of Neurobiology Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark,* [2]*Laboratory of Radiation Physics, Odense University Hospital, Denmark. Institute of Clinical Research, University of Southern Denmark, Odense, Denmark,* [3]*Unit of Human Genetics, Department of Clinical Research, University of Southern Denmark, Odense, Denmark,* [4]*Innate Immunotherapeutics, Auckland, New Zealand.*

Introduction: Regulation of neuroinflammation is necessary to maintain central nervous system (CNS) homeostasis and has therapeutic potential in diseases such as multiple sclerosis. The CNS contains parenchymal and extraparenchymal myeloid cells that can play a regulatory role. We have examined the capacity of innate-signaled myeloid cells to regulate experimental autoimmune encephalomyelitis (EAE) in mice.
Methods: Mice received a fluorescent-conjugated bispecific NOD2- and TLR9-agonist microparticle MIS416 either intravenously or by intrathecal injection to extraparenchymal leptomeningeal, ventricular and subarachnoid space. MIS416 has previously been shown to suppress EAE when given peripherally.
Results: Intravenous MIS416 induced significant extraparenchymal infiltration from blood of monocytic myeloid cells ($CD45^{high}$, Ly6C+, F4/80+, CD11b+, CD11c+) that had phagocytosed MIS416. Intrathecal MIS416 induced infiltration of similar magnitude but in contrast to peripheral injection, over 30% of the MIS416-phagocytosing cells were granulocytic ($Ly6G^{high}$, $Ly\text{-}6C^{low}$, $Gr1^{high}$, CD11b+, CD11c-). Both populations were also PDL1+. mRNA for the neutrophil-recruiting chemokines CXCL1 and CXCL2 were upregulated in CNS.
When given to mice showing first symptoms of EAE, intrathecal MIS416 suppressed disease - this did not occur in mice lacking the Type I IFN receptor. Extraparenchymal MIS416-phagocytosing cells, including polymorphonuclear neutrophils, were shown to produce IFNβ in reporter mice, and sorted monocytic and granulocytic cells expressed IRF7, indicating IFN response.
Conclusions: CNS-innate signaling uniquely recruits granulocytic myeloid-derived phagocytes from blood. These and co-infiltrating phagocytic monocytic myeloid cells produce IFNβ and suppress EAE by a Type I IFN-dependent mechanism. This endogenously-triggered pathway likely contributes to CNS homeostasis and may have therapeutic potential.

P.C6.06.11

Analysis of C-C chemokine receptor like 2 (CCRL2) heterodimerization with classical chemokine receptors

C. Mazzotti[1], *A. Bani*[1], *M. Mellado*[2], *A. Del Prete*[1,3], *S. Sozzani*[1];
[1]*University of Brescia, Brescia, Italy,* [2]*Centro Nacional de Biotecnologia, Madrid, Spain,* [3]*Humanitas Clinical and Research Centre, Rozzano, Italy.*

Introduction: Atypical chemokine receptors (ACKRs) are 7-transmembrane receptors able to bind and scavenge chemokines from the local environment. We recently published that the non-signalling receptor C-C chemokine receptor-like 2 (CCRL2), homologous to ACKRs, is devoid of scavenging ability, but it can heterodimerize and regulate the function of the chemokine receptor CXCR2 (Mazzotti et al Front Immunol 2017; Del Prete et al Blood, 2017). The present work aims to further investigate the ability of CCRL2 to regulate additional chemokine receptors.
Materials and Methods: Förster Resonance Energy Transfer (FRET) was employed to measure heterodimerization, using saturation curves and acceptor photobleaching. Measurement of mouse neutrophil adhesion under shear stress conditions was performed to evaluate functional interactions.
Results: Both the FRET saturation curves and acceptor photobleaching showed that CCRL2 can heterodimerize with two chemokine receptors, namely CXCR4 and CCR7. To evaluate the biological significance of these interactions, neutrophil adhesion under shear stress conditions was tested on channels coated with CXCL12, the CXCR4 ligand. Neutrophils lacking the expression of CCRL2 showed altered adhesion compared to wild-type cells.
Conclusions: CCRL2 lacks both signalling and scavenging ability. Our previous publications demonstrated that CCRL2 can regulate CXCR2 activity by heterodimerization. This work shows that CCRL2 can heterodimerize with the classical chemokine receptors CXCR4 and CCR7. The lack of CCRL2 modifies the response of CXCR4-expressing neutrophils to the ligand CXCL12. These results propose that CCRL2 heterodimerization may be a general mechanism to fine tune the biological action of chemokine receptors.
The Presenter was awarded a EFIS-IL Short-term Fellowship (2017)

P.C6.06.12

Minor immunomodulatory role of reactive oxygen species and nitrogen species (ROS/RNS) during T-cell driven neutrophil-enriched acute and chronic cutaneous delayed-type hypersensitivity reaction (DTHR)

R. Mehling[1], *J. Schwenck*[1,2], *B. Zhou*[1], *D. Hartl*[3,4], *M. Röcken*[5], *B. Pichler*[1], *M. Kneilling*[1,5];
[1]*Werner Siemens Imaging Center, Eberhard Karls University, Tübingen, Germany,* [2]*Department of Nuclear Medicine, Eberhard Karls University, Tübingen, Germany,* [3]*Department of Pediatrics I, Eberhard Karls University, Tübingen, Germany,* [4]*Discovery and Translational Area, Roche Pharma Research & Early Development, Basel, Switzerland,* [5]*Department of Dermatology, Eberhard Karls University, Tübingen, Germany.*

ROS and RNS are important regulators of inflammation. However, the impact of ROS/RNS mainly produced by neutrophils and macrophages during acute and chronic DTHR of the skin is discussed controversy. Our aim was to dissect the dominant ROS/RNS sources non-invasively in vivo using the ROS/RNS-sensitive chemiluminescence optical imaging probe L-012 in mice with differently impaired ROS/RNS (Myeloperoxidase ($MPO^{-/-}$), NADPH oxidase ($gp91^{phox-/-}$), inducible nitric oxide synthase ($iNOS^{-/-}$)) production during the acute and chronic trinitrochlorobenzene induced cutaneous DTHR.
Non-invasive *in vivo* optical imaging measurements revealed an abrogated L-012 signal intensity in ears of $gp91^{phox-/-}$ mice and an up to 70% decreased L-012 signal intensity in ears of $MPO^{-/-}$ compared to WT mice during acute and chronic cutaneous DTHR. In contrast, inflamed ears of $iNOS^{-/-}$ mice exhibited L-012 signal intensity similar to WT mice. Dihydrorhodamin 123 flow cytometry analysis of leucocytes derived from the spleen and the draining lymph nodes of knock-out and WT mice confirmed our optical imaging results. However, ROS/RNS depletion did not influence inflammatory symptoms as we observed almost equivalent ear-swelling responses in knock-out and the WT mice during acute and chronic DTHR. Also suppression of mitochondrial ROS in $gp91^{phox-/-}$ mice with MitoTEMPO revealed no relevant influence.
Collectively, we were able to identify MPO-mediated hypochlorous acid (HOCl) production and superoxide anion (O_2^-) produced by NADPH oxidase as the dominant sources for ROS in our model of DTHR. Nevertheless, ROS/RNS expression by neutrophils and macrophages seem to play a rather minor role in the modulation of acute and chronic cutaneous DTHR.

P.C6.06.13

Chemotactic, phagocytic and neutrophil extracellular trap (NET) forming properties of oral and circulatory blood neutrophils

C. G. J. Moonen[1], *J. Hirschfeld*[2], *L. Cheng*[1], *I. L. Chapple*[2], *B. G. Loos*[1], *E. A. Nicu*[1,3];
[1]*Academic Center of Dentistry Amsterdam (ACTA), University of Amsterdam and Vrije Universiteit Amsterdam, Amsterdam, Netherlands,* [2]*Birmingham Dental School and Hospital, Institute of Clinical Sciences, The University of Birmingham and Birmingham Community Health NHS Trust, Birmingham, United Kingdom,* [3]*Opris Dent SRL, Sibiu, Romania.*

Maintenance of oral health is, in part, managed by the immune-surveillance and antimicrobial functions of neutrophilic polymorphonuclear leukocytes (PMNs) that have migrated from the blood circulation (cPMN) through the oral mucosal tissues as oral PMNs (oPMNs). In any microorganism rich ecosystem, such as the oral cavity, PMNs migrate towards exogenous chemoattractants, phagocytose bacteria and produce NETs to immobilize and eliminate pathogens. cPMNs have been widely studied *ex-vivo* using various functional assays. We hypothesized that oPMNs offer a more appropriate model to study the role of PMNs in maintaining oral health.
oPMNs and cPMNs were isolated from healthy donors. Directional chemotaxis towards the chemoattractant fMLP was analysed using an Insall chamber and video microscopy. Phagocytosis was analysed by flow cytometry based on CD16+FITC+ gating of PMNs incubated with heat-inactivated FITC-labelled *Fusobacterium nucleatum (Fn*). NET formation by oPMNs and cPMNs was quantified fluorometrically using Sytox Green after stimulation with either PMA or RPMI medium (unstimulated control).
In contrast to cPMNs, chemotactic responses of oPMNs towards fMLP did not differ from unstimulated controls. oPMNs show reduced speed, velocity and directional movement towards fMLP when compared to cPMNs, which could be explained by exhausted chemotaxis capacity after having migrated through oral tissues into the oral cavity, being a highly 'hostile' ecosystem. oPMNs and bPMNs phagocytosed *Fn* similarly. Unstimulated and stimulated oPMNs formed significantly more NETs than cPMNs. Based on observed normal phagocytosis but hyperreactive NET production by unstimulated oPMNs, we conclude that oPMNs are primed due to their exposure to oral bacteria.

P.C6.06.14

Neutrophil extracellular traps in type 1 diabetes

Z. Parackova[1], *I. Zentsova*[1], *Z. Sumnik*[2], *S. Kolouskova*[2], *A. Klocperk*[1], *P. Vrabcova*[1], *A. Sediva*[1];
[1]*Department of Immunology, 2nd Faculty of Medicine Charles University, Faculty Hospital in Motol, Prague 5, Czech Republic,* [2]*Department of Pediatrics, 2nd Faculty of Medicine Charles University, Faculty Hospital in Motol, Prague 5, Czech Republic.*

Neutrophil extracellular traps (NETs) were demonstrated to be an effective defence mechanism against infections, being able to entrap and eliminate various pathogens. These structures, composed of decondensed chromatin and antimicrobial proteins, also have the capacity to stimulate other cell subsets, for instance macrophages and dendritic cells (DC). Additionally, NETs are implicates in several autoimmune diseases, such as lupus erythematodes, vasculitides or type 1 diabetes (T1D) but their contribution to pathogenesis is elusive.In T1D, insulin-producing pancreatic beta cells are destroyed by autoreactive T lymphocytes. Even though innate immunity involvement is also clearly demonstrated in the development of T1D, its exact mechanism still remains unclear. To examine how neutrophils contribute to the genesis of T1D, we investigated the effect of NETs on DC function in T1D patients. We found that NETs influence mDC phenotype differently between patients and controls, but not pDC phenotype. They also triggered T1D DCs to release inflammatory cytokines - IFNα and IL-1β.
On the contrary, T1D patient DCs primed with NETs (NET-DCs) produced lower level of IL-10. NET-DCs induced more IFNγ-producing CD4+ T lymphocytes and less T regulatory lymphocytes (Tregs) compared to controls. In addition, patients NET-DCs-induced Tregs expressed a low level of IL-2Rα, which implies their impaired function. Moreover, T1D-NETs contain more DNA and less antimicriobial peptides. So not only NETs differ between T1D and controls in effect on DCs, but also in their composition. Our findings shed light on the involvement of dendritic cells in pathogenesis of T1D, through their interaction with neutrophils.

P.C6.06.15

Redefining the functional site of the innate immune regulator 'complement Factor H'

C. Q. Schmidt, *A. Dopler, L. Guntau;*
Institute of Pharmacology of Natural Products & Clinical Pharmacology, Ulm University, Ulm, Germany.

Factor H (FH) is the major regulator of the complement alternative pathway (AP) and is built of 20 CCP domains. FH crucially controls the AP (i) with 'decay accelerating activity' (DAA) towards C3-convertases and (ii) with cofactor activity (CA) for the inactivation/degradation of the opsonin C3b which e.g. initiates C3-convertases. To achieve DAA and CA, FH needs to interact with C3b. It is established that the C3b binding activity necessary for these two functions resides within the first four N-terminal domains of FH, i.e. FH1-4. We prove that this N-terminal regulatory site extends CCPs 1-4 and spans across the first seven domains of FH.
We recombinantly expressed the FH domain constructs FH1-4, FH1-5, FH1-6 and FH1-7 and probed their different regulatory activities in following *in vitro* tests: determination of C3b affinity by surface plasmon resonance (SPR), fluid phase CA assay, SPR-based DAA assay and a protection assay of microvascular endothelial cells.
While FH1-5 binds only marginally better to C3b than FH1-4, we show that FH1-6 and FH1-7 surpass the affinity of FH1-4 for C3b about threefold and 15-fold, respectively. Despite the small difference in C3b affinity, FH1-5 substantially surpassed FH1-4 in DAA and CA. Both, FH1-6 and FH1-7, were substantially more active in DAA and CA than the shorter constructs tested. Consistent with these rankings FH1-6 and FH1-7 protected microvascular endothelial cells considerably better from complement attack than FH1-4 or FH1-5 did. Taken together, our study extends the established N-terminal regulatory site of FH1-4 by CCPs 5-7 (DFG-grant: SCHM 3018/2-2).

P.C6.06.16

The effect of catecholamines on spontaneous and lipopolysaccharide-induced production proinflammatory cytokines by human neutrophils *in vitro*

I. Shvydchenko[1], *E. Bykovskaya*[2], *S. Guryanova*[3], *V. Golubtsov*[4,5], *A. Tambovtseva*[5,1], *S. Sergeev*[1];
[1]*Kuban State University of Physical Education, Sport and Tourism, Krasnodar, Russian Federation,* [2]*Children's Regional Clinical Hospital, Krasnodar, Russian Federation,* [3]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation,* [4]*Kuban State Medical University, Krasnodar, Russian Federation,* [5]*Regional Clinical Hospital №2, Krasnodar, Russian Federation.*

Neutrophils are essential for innate immunity and resistance to infections. Adrenergic pathways represent the main channel of communication between the nervous system and the immune system. The purpose of this study was to investigate the effect of adrenaline and noradrenaline on cytokine production by human neutrophils *in vitro*. Neutrophils were isolated by two methods, as follows: by density gradient centrifugation of whole blood, dextran sedimentation and red cells osmotic lysis (*Neu1*); similarly to *Neu1*, but with an additional immunomagnetic negative selection step, using the EasySep Human Neutrophil Enrichment Kit (*Neu2*). According to morphological analysis and flow cytometry 92-98% pure neutrophils were in *Neu1* and > 99% was in *Neu2*. Neutrophils (1×10^6 cells/ml) were incubated in medium RPMI 1640 (37°C, 5% CO_2, 20 h) with DPBS or 10 ng/ml lipopolysaccharide (LPS), adrenaline (0,1 μM), noradrenaline (0,1 μM). IL-1β, IL-6, IL-8, TNF-α and MIP-1β in cell-free supernatants were measured by ELISA. IL-8 and MIP-1β, but not IL-1β, IL-6 and TNF-α were detected in supernatants from non-stimulated neutrophils in *Neu1* and *Neu2.* Secretion of IL-1β, IL-8 and MIP-1β by neutrophils in *Neu1* and *Neu2* was increased with LPS ($p<0.05$). Adrenaline did not affect on spontaneous and LPS-induced secretion of all cytokines by neutrophils in *Neu1* and *Neu2.* Noradrenaline increased production only of IL-8 by non-stimulated neutrophils in *Neu1* ($p<0.05$). Taken together, our results indicate that catecholamines have the limited role in secretion of proinflammatory cytokines by neutrophils. This work was supported by a grant from RFBR and Administration of Krasnodar Region (No 16-44-230391r_a).

P.C6.06.17

Inhibition of dendritic cell maturation and modulation of T cell polarization by the platelet secretome

J. Steuten[1], *A. S. Saris*[1], *S. M. van Ham*[1,2], *A. ten Brinke*[1];
[1]*Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands,* [2]*University of Amsterdam, Swammerdam Institute for Life Sciences, Amsterdam, Netherlands.*

Next to their primary function in hemostasis, currently there is increased attention for the immune modulatory capacity of platelets and how they are able to influence various cells of the immune system. We have found that platelets can inhibit pro-inflammatory properties of TLR-stimulated monocyte-derived dendritic cells (moDCs), as well as their capacity to prime both autologous and allogeneic T cells. Here, we further investigate the various immune modulatory capacities of platelets with respect to dendritic cells and the subsequent effect on T cell responses. First of all, by culturing moDCs in the presence of different maturation cocktails, we obtained moDCs with the capacity to induce different T helper phenotypes. Subsequently, we investigated the effect of platelets and platelet-conditioned medium on the moDCs themselves as well as ensuing T helper differentiation. Here we demonstrate that platelets can significantly inhibit pro-inflammatory properties of moDCs and modify subsequent T cell priming and differentiation of T helper cell phenotypes. Secondly, transwell assays revealed that a soluble factor is secreted by platelets which exerts the inhibitory effect on moDC maturation. Therefore, we are currently fractionating platelet-conditioned medium to identify which component in the platelet secretome is responsible for this immune modulatory effect of platelets. The results of these assays will eventually give us insight in the role of platelets in for example transfusion related immune modulation (TRIM) in the context of platelet concentrate transfusions.

P.C6.06.18

Systemic pDC death causes type I interferon-mediated reduction of appetite, fatal weight loss and immune cell attrition

S. Stutte[1], *J. Ruf*[1], *I. Kugler*[1], *H. Ishikawa-Ankerhold*[2], *A. Blutke*[3], *P. Marconi*[4], *U. von Andrian*[5], *M. Colonna*[6], *S. Massberg*[2], *T. Brocker*[1];
[1]*Institute of Immunology, LMU, Munich, Germany,* [2]*Medizinische Klinik und Poliklinik I, Ludwig-Maximilians-Universität, Munich, Germany,* [3]*Institute of Veterinary Pathology at the Centre for Clinical Veterinary Medicine, Ludwig- Maximilians-Universität Munich, Munich, Germany,* [4]*Department of Life Science and Biotechnology, University of Ferrara, Ferrara, Italy,* [5]*Microbiology and Immunobiology, Harvard Medical School, Boston, United States,* [6]*Washington University, School of Medicine, St. Louis, United States.*

Plasmacytoid dendritic cells (pDCs) develop in the bone marrow and are constantly released into the blood circulation from where they home to peripheral organs. pDCs belong to the innate immune cell compartment and are known to rapidly release very high amounts of type one interferon in response to viral infections. In addition, thereafter pDC die by apoptosis. Here we analyzed the consequence of pDC-death under "sterile" conditions (in absence of viral infection) using ablation of pDCs in a diphtheria toxin-mediated in vivo ablation model. We could show that loss of pDCs mediates systemic changes, resulting in reduced appetite, strong weight loss and fatal wasting disease. In addition, we observed an attrition of immune cells in lymphoid organs. We identified the innate signaling pathways leading to type I interferon production, which mediates alteration of key soluble factors central to these rapid changes and analyzed consequences for ongoing immune responses. Taken together, death of pDCs causes dramatic systemic changes in metabolism and immune cell homeostasis.

P.C6.06.19

Increased IL-22 levels in relapsing-remitting Multiple Sclerosis

I. Tahrali[1], *U. C. Kucuksezer*[1], *N. Akdeniz*[1], *A. Altintas*[2], *U. Uygunoglu*[2], *E. Cetin*[1], *G. Deniz*[1];
[1]*Aziz Sancar Institute of Experimental Medicine, Istanbul, Turkey,* [2]*Istanbul University, Cerrahpasa Faculty of Medicine, Istanbul, Turkey.*

IL-22 is a proinflammatory cytokine produced by different cell groups including NK22 cells. Several studies suggested that IL-22 might play a critical role in neurological diseases such as multiple sclerosis (MS), a chronic-inflammatory disease of central nervous system. However, the exact role of IL-22 in MS pathology is still a question. The possible role of IL-22 in MS patients was investigated in this study.
Plasma samples and peripheral blood mononuclear cells (PBMCs) were obtained from patients with relapsing-remitting (RR)-MS (untreated and treated with IFN-beta) and clinically isolated syndrome (CIS) as well as healthy subjects.
PBMCs were cultured with/without hrIL-2 and hrIL-12. IL-22 levels in plasma and culture supernatants were measured by ELISA. Cultured PBMCs were stained with anti-CD3, -CD16 and -CD56 monoclonal antibodies (mAb) to detect NK cell subsets by flow cytometry. Stained cells were fixed/permeabilized and labeled with anti-IL-22 mAb to evaluate the intracellular IL-22 contents of NK cell subsets.
After hrIL-2 stimulation, IL-22 content of $CD3^-CD16^-CD56^{bright}$ NK cell subset was increased in treated RR-MS patients compared to healthy subjects. In contrast, plasma IL-22 levels were higher in untreated RR-MS patients than CIS patients. IL-22 levels were also increased in unstimulated and hrIL-2 stimulated supernatants of untreated RR-MS patients compared to treated RR-MS patients and healthy subjects.
Increased IL-22 levels in plasma samples and supernatants of untreated RR-MS patients might indicate the proinflammatory role of IL-22 in RR-MS pathogenesis.

Study Of Toll-Like Receptor 7 (TLR7) Expression In Iraqi Patients With Chronic Hepatitis C Virus (HCV) Infection & their relationship with different genotypes

E. S. Al0beidy;
Ministry of Health, Baghdad, Iraq.

Introduction: The main etiologic agent of post-transfusion hepatitis is Hepatitis C (HCV) and is considered the principal cause of chronic liver disease in multi-transfused patients. TLR7 on the other hands, play a significant role in the viral hepatitis infection.
This study was established to estimate the concentration of TLR7 in patients with chronic HCV infection compared to healthy control group.
Patients and methods: Throughout the period from December 2016 to March 2017, a blood sample from 40 patients (17 male and 23 females) with chronic HCV infection and 16 healthy control group (7 male and 9 females) were collected from two hospitals in Baghdad city.
All serum samples (n=56) were screened for presence of HCV antibodies using the available commercial kits of the third generation enzyme immunoassay (Human-Gemeny).and for TLR7 by ELISA method (Shanghai-China).
Results: genotype 1b is most common one since they represent (52.5%)compared with other allele 1a,2,4 %),((22.5%), (5.0%), (20.0%) respectively. In addition, the current study noted a significant decrease in the TLR7 concentration in sera of patients affected with HCV compared with healthy control. In addition, our study revealed that there is no statistical differences in the age and gender between the studied groups. On the other hands, the mean concentration of TLR7 was decreased in HCV group in comparison with healthy control.
Conclusions:
The predominance of HCV genotype 1b in our population confirms the predominance of HCV genotype 1b in Iraqi and most of the Arab countries in the Middle East, this will effect the duration and response to treatment.

P.D1.01.02

Capture of IgA immune complexes and enrichment in IgA Ig gene expression both suggest a role for synovial FcRL4+B cells in the link between mucosal and joint inflammation

J. Cameron[1], *E. Clay*[1], *K. Amara*[2], *N. Sippl*[2], *A. Filer*[1], *K. Raza*[1], *V. Malmstrom*[2], *D. Scheel-Toellner*[1];
[1]*Institute of Inflammation and Ageing, Birmingham, United Kingdom,* [2]*Karolinska Institutet, Stockholm, Sweden.*

Mounting evidence points to the autoimmune process of rheumatoid arthritis (RA) originating at mucosal surfaces. FcRL4$^+$ B cells were originally identified in the mucosa associated lymphoid tissue. We recently detected and characterised these cells in the inflamed joints of patients with RA. They participate in the immune response to citrullinated autoantigens and produce RANKL, a cytokine driving bone destruction in RA. Recent *in vitro* work suggested that FcRL4 is a low affinity receptor for heat-aggregated IgA (HA-IgA). We explored the link between joint derived FcRL4+ B cells and mucosal immunity. We looked at the interaction between FCRL4+ B cells and IgA in RA synovial fluid (SF) and investigated the distribution of Ig subclasses via flow cytometry and PCR of constant region genes of single sorted B cells; and using antibodies cloned from their variable regions we assessed the antigen specificity of FcRL4+ and FcRL4- cells. SF FcRL4$^+$ B cells have a significantly higher load of surface-bound IgA than FcRL4$^-$ B cells. Following removal of surface-bound proteins, FcRL4+ B cells bound heat-aggregated IgA. A significantly higher proportion of FcRL4$^+$ B cells use IgA B cell receptors (BCRs). B cells transgenic for FcRL4 expression captured IgA immune complexes from SF and three out of eight of the antibodies recognizing citrullinated peptides were cloned from FcRL4$^+$ IgA$^+$ B cells. In conclusion, their specificity for citrullinated antigens, ability to capture IgA immune complexes in vivo, and enrichment in IgA BCRs support a role for FcRL4+ B cells in the mucosal origin of joint inflammation.

P.D1.01.03

The role of gut microbiome in the pathogenesis and therapeutic response in juvenile idiopathic arthritis

C. Changchien*, B. Chiang;*
National Taiwan University Hospital, Taipei, Taiwan.

Introduction: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children. However, the pathogenesis of JIA was still unclear. From previous animal study, gut microbiome played an important role in host immune systemic development, and defect in mucosal tolerance might attribute to chronic inflammation disease. The aim of the study is to clarify the therapeutic effects on gut microbome in JIA children. **Method**: We collected the samples from sibling healthy control and compare the gut microbiome between sibling healthy control, healthy control and JIA children. Children at the age between 5-17 year-old with JIA under anti-TNF treatment without any antibiotics in past 6 months or recent GI symptoms were enrolled in our study. DNA purified from stool was subject to PCR amplification and sequencing of the variable V3-V4 region from the 16S rDNA gene. The study protocol was approved by the Institutional Review Board of National Taiwan University Hospital (201411083RIN). **Result**: Twenty eight JIA patients and 20 healthy controls were enrolled to our study. The beta-diversity result showed the distribution of gut microbiome in JIA under TNF control was more similar to treatment naïve JIA patients' gut microbiome than JIA under DMARDs control. The observed number of OTUs and the Chao1 index of alpha diversity had significant reduction in JIA patients under TNF therapy compared to JIA patients under DMARDs therapy.**Conclusion**: The results suggested that treatment and the distribution of gut microbiome were highly related. Treatment could also partially restored dysbiosis status in JIA children. <!--EndFragment-->

P.D1.01.04

Interplay between Zika Virus and Decidual Natural Killer cells at the human maternal-fetal interface

Q. CHEN*, J. Gouilly, H. El Costa, N. Jabrane-Ferrat;*
Centre de Physiopathologie de Toulouse Purpan (CPTP), Toulouse, France.

BackgroundThe recent Zika virus (ZIKV) outbreak revealed unprecedented severe adverse pregnancy outcomes including microcephaly and diseases associated to placental dysfunctions. We recently provided evidence for ZIKV productive infection in the first trimester decidua basalis, one of the main maternal-fetal interfaces, and in fetal placenta. We also demonstrated that several cell types such as fibroblasts and macrophages from the maternal-fetal interface, fetal trophoblasts and Hofbauer cells as well as mesenchymal stem cells of the Warton jelly. The hallmark of the decidua basalis is the presence of a unique subset of Natural Killer (dNK) cells. In healthy pregnancy, these cells are devoid of cytotoxicity but they produce several soluble factors that are crucial for fetal tolerance and placental development. Our pioneer work demonstrated that dNK cells can adapt their effector functions and acquire cytotoxic function to protect the fetus from congenital Cytomegalovirus infection. Methodology & resultsWe show here that dNK cells can control ZIKV replication in the decidual stroma. Using double-chamber co-cultures, we demonstrate that the inhibition of ZIKV replication is mediated through the release of soluble mediators by dNK cells. However, changes in the local secretome following ZIKV infection may also modify dNK cell functions and impact their ability to effectively supervise the course of pregnancy. We are currently deciphering the cellular and molecular mechanisms underlying the control of ZIKV infection by dNK cells and the consequences of such control on the outcome of pregnancy.

Intestinal bacteria modulate the anti-inflammatory properties of filarial helminth product ES-62 in arthritis

J. Doonan[1], *A. Tarafdar*[2], *F. Lumb*[1], *J. Crowe*[2], *A. Khan*[2], *M. Pineda*[2], *P. Hoskisson*[1], *M. Harnett*[2], *W. Harnett*[1];
[1]*University of Strathclyde, Glasgow, United Kingdom,* [2]*University of Glasgow, Glasgow, United Kingdom.*

The Hygiene Hypothesis suggests that increased sanitation and decreased exposure to parasitic infections has resulted in aberrant immune responses that have given rise to autoimmune diseases, such as rheumatoid arthritis (RA). Parasitic helminth excretory-secretory products modulate the host's immune system and one such anti-inflammatory product is ES-62, a glycoprotein produced by the rodent filarial helminth *Acanthocheilonema viteae.* We aimed to address the role that intestinal bacteria exert on the anti-inflammatory properties of ES-62 in the collagen-induced arthritis (CIA) model of RA.
Antibiotic treatment (ABX) was used to eliminate intestinal bacteria in DBA/1 mice prior to CIA induction and ES-62 treatment. Histology, qPCR and FACS were used to address the effects of ES-62 and/or dysbiosis on arthritis in the periphery and gut. Metagenomic sequencing was employed to identify intestinal bacteria associated with arthritis or ES-62. Intestinal bacteria were found to be required for the development of arthritis in control animals and CIA was associated with changes in the microbiome. Strikingly, ES-62 required the presence of bacteria to prevent CIA and ES-62 treatment led to a normalisation of the gut microbiome to a naïve phenotype in addition to an outgrowth in butyrate-producing bacteria. In the periphery, ES-62 prevented joint pathology and also reduced Cathepsin K$^+$ osteoclast numbers in joints and stably rewired bone marrow progenitors to inhibit osteoclast differentiation compared to controls.
In summary, ES-62 is associated with normalisation of the gut microbiome and promotion of butyrate-producing bacteria to reduce inflammatory and pathological changes in the joints and gut during CIA.

P.D1.01.06

Modelling the effect of social isolation on susceptibility to sepsis: a murine model

A. Hamilton[1], *S. Brod*[1], *R. Rizzo*[1], *J. Dali*[1], *F. Marelli-Berg*[1], *F. D'Acquisto*[1,2];
[1]*William Harvey Research Institute, Queen Mary University of London, London, United Kingdom,* [2]*Health Science Research Centre, University of Roehampton, London, United Kingdom.*

A person's social network size and quality of life can affect the body at three levels: behavioural, psychological and physiological. Indeed, a socially isolated person is more likely to have a poor diet, suffer from depression and have an impaired immune system. A growing body of evidence has shown that social status correlates with susceptibility to sepsis-mediated death. The aim of this study was to investigate how social isolation effects sepsis and inflammation.
CD1 mice (6 weeks old) were assigned to cages of 4 or 5 mice, socially housed (SH), or singly housed, socially isolated (SI). After 2 weeks, mice were challenged with 1x10^{7}cfu *E.coli* 06:K2:H1[ATCC®19138™] via i.p injection to model bacterial sepsis. Weight loss, bacterial clearance and immune response were assessed. Microarray gene screening of basal whole blood was done to further elucidate changes in gene expression.
E.coli challenged SI mice exhibited enhanced bacterial clearance (~90%) compared to SH mice and lost less weight over the 6 hour period. SI mice also showed decreased levels of TNF-α (~50%) and IL-6 (~80%) systemically compared to SH mice and had increased macrophages present in the peritoneal cavity. Microarray analysis revealed changes in gene expression that promote apoptosis.
In summary, short-term social isolation appears to prime the immune response towards bacterial clearance. Further studies are required to fully elucidate the mechanism(s) by which social isolation impacts the immune system.

P.D1.01.07

Modulation of intestinal homeostasis and inflammation by *Prevotella intestinalis (nov. sp.)*

***A. Iljazovic**, U. Roy, E. Gálvez, B. Zhao, T. Strowig;*
Helmholtz Centre for Infection Research, Braunschweig, Germany.

Prevotella is a complex genus of anaerobic Gram-negative bacteria of the Bacteroidetes phylum. Several studies have suggested *Prevotella copri* may be a beneficial member of the gut microbiota since it has been found to improve glucose metabolism and it is predominantly prevalent in non-Westerners who consume a plant-rich diet. In mouse models, *Prevotella*-dominated microbiome was associated with higher susceptibility to chemically-induced colitis suggesting that *Prevotella* may have the ability to promote intestinal inflammation. Detailed investigation of the cause for divergent modulation of host physiology by *Prevotella* is however limited by the poor characterization of *Prevotella* species and the lack of diverse intestinal *Prevotella* isolates. Here we isolated a novel intestinal *Prevotella* specie (*Prevotella intestinalis)* and investigated the impact of its colonization on the interplay between host and the microbiota during intestinal homeostasis and inflammation. We found that *P. intestinalis* colonization of WT specific pathogen free (SPF) mice, devoid of any *Prevotella spp.* in the intestine, reshapes the resident intestinal microbial community and it significantly alters the metabolic profile in the intestine. *Prevotella*-induced changes in the levels of short-chain fatty acids (SCFA) modulated colonic interleukin (IL)-18 expression and production during homeostasis. Additionally, we found that *P. intestinalis* colonization of WT SPF mice exacerbated the disease in DSS-colitis model and promoted neutrophil-mediated intestinal inflammation. We are further investigating whether *Prevotella*-induced changes occurring during the homeostasis are directly linked to a more severe outcome during inflammation.

P.D1.01.08

Oral metronidazole has immediate microbiota-independent immunosuppressive and delayed microbiota-dependent immunostimulatory effect

***M. Kverka**[1,2], Z. Jiraskova Zakostelska[1], K. Klimesova[1,3], N. Galanova[1], T. Hudcovic[4], Z. Stehlikova[1], S. Coufal[1], A. Fajstova[1], M. Kostovcik[1], H. Tlaskalova-Hogenova[1];*
[1]Institute of Microbiology of the CAS, Prague, Czech Republic, [2]Institute of Experimental Medicine of the CAS, Prague, Czech Republic, [3]Institute of Molecular Genetics of the CAS, Prague, Czech Republic, [4]Institute of Microbiology of the CAS, Novy Hradek, Czech Republic.

Gut microbiota is critical stimulus for the development of immune system, thus shaping the individual's susceptibility to immune-mediated diseases. Immunomodulatory properties have been reported for some oral antibiotics (ATB). Here, we analyzed if these immunomodulatory properties are microbiota-dependent or -independent. We treated BALB/c mice with daily gavage of either placebo (P), colistin (C), vankomycin (V) or metronidazole (M) for 2 weeks and induced delayed-type hypersensitivity (DTH) during the second week. To analyze the role of microbiota, we performed similar experiment in germ-free conditions, in ex GF mice transferred with gut microbiota or in immunodeficient mice adoptively transferred with leukocytes from P- or M-treated mice. We analyzed effect of ATB on gut microbiota by 16S rRNA gene sequencing, on local or systemic immune response by gut fragment culture or flow cytometry *in vivo* and on TCR stimulation *in vitro.* We found that all ATB changes the gut microbiota composition and decreased DTH. Mice treated with M or V have lower production of pro-inflammatory cytokines in their Peyer's patches, but there were no differences in colons or *in vitro*. Next, we found that M decreases DTH even in absence of microbiota and its effect can be transferred by leukocytes. Interestingly, transfer of microbiota from M-treated mice or by DTH induction delayed by 3 weeks after the last dose of M has opposite effect. We conclude that oral M has microbiota-independent short time immunosuppressive effect but ATB-induced dysbiosis ultimately lead to immune system stimulation. P.D1.01.09

The effect of probiotic and nasal microbiota on inflammatory response, viral load, and symptom severity in experimental rhinovirus challenge

***M. J. Lehtinen**[1], A. A. Hibberd[2], S. Männikkö[3], N. Yeung[1], T. Kauko[3], S. Forssten[1], L. Lehtoranta[1], S. J. Lahtinen[1], B. Stahl[2], A. Lyra[1], R. B. Turner[4];*
[1]DuPont Nutrition and Health, Kantvik, Finland, [2]DuPont Nutrition and Health, Madison, United States, [3]4Pharma, Turku, Finland, [4]University of Virginia, Charlottesville, United States.

Introduction: Meta-analyses suggest that probiotics could be beneficial on reducing the risk of respiratory infections in humans, however, the role of nasal microbiota, or its modulation by probiotics, in viral respiratory infections has not been established in controlled clinical trial setting. Materials and Methods: We collected nasal swabs and washes, and fecal samples over time, in a randomized double-blind placebo controlled clinical study assessing the effect of prophylactic probiotic *Bifidobacterium animalis* subsp. *lactis* Bl-04 (Bl-04) supplementation on experimental rhinovirus infection in 115 healthy adults (NCT01669603). The nasal and fecal microbiota were characterized by 16S rRNA gene sequencing and the resulting data were compared with nasal inflammatory marker concentrations, viral load, and clinical symptoms during the infection. Results: Probiotic Bl-04 supplementation influenced nasal wash inflammatory response and reduced the viral load during the infection. The sequencing results showed that the nasal microbiota clustered into six types. The clusters predominant of *Staphylococcus, Corynebacterium/Alloiococcus, Moraxella, and Pseudomonadaceae*/Mixed had characteristic inflammatory marker and viral load profiles in nasal washes. The nasal microbiota types of subjects also influenced the severity of clinical cold symptoms during rhinovirus infection. Rhinovirus infection or probiotic intervention did not significantly alter the composition of nasal or fecal microbiota. Conclusions: Our results suggest that probiotic Bl-04 supplementation influences innate inflammatory response and viral load in nasal washes, and that the nasal microbiota type influences the virus load, host innate immune response, and clinical symptoms during rhinovirus infection. This study was funded by DuPont Nutrition and Health.

P.D1.01.10

***B. uniformis CECT 7771* restores the intestinal immune homeostasis in diet-induced obese mice**

***I. López Almela**, M. Romaní Perez, E. Fabersani, I. Campillo, K. Portune, Y. Sanz;*
Microbial Ecology, Nutrition and Health Research Unit, Institute of Agrochemistry and Food Technology, National Research Council (IATA-CSIC), Paterna (Valencia), Spain.

Obesity represents a major health challenge worldwide due to its high prevalence and associated comorbidities. Energy dense diet-induced dysbiosis impairs intestinal immunity which contributes to obesity by promoting systemic inflammation. Probiotic-based therapies are being investigated to combat obesity by promoting a healthy gut microbiota which favors the immune homeostasis and energy balance. Previously we have demonstrated that *Bacteroides uniformis* CECT 7771 has *in vitro* anti-inflammatory properties and restores the metabolic disturbances of diet-induced obese mice. Since the mechanistic understanding of these effects remains unexplored, herein we have investigated the possible immune-mediated effects of this bacterial strain in obesity. Mice were fed with standard or high fat high fructose diet (HFHFD) and orally received the probiotic ($1x10^9$ CFU) or placebo for 14 weeks. The probiotic reduced body weight gain and adiposity and normalized glucose tolerance in HFHFD-fed mice. The obese phenotype was linked to a pro-inflammatory state in blood and white adipose tissue (WAT). Obese mice also showed reduced gene expression of occludin (a gut integrity marker) and enhanced intestinal inflammation; i.e. increase of innate lymphoid cells (ILC)-1 and induced intestinal epithelial lymphocytes (IEL) and reduced ILC3 and natural IEL. The probiotic prevented inflammation in blood, WAT and small intestine and normalized occludin expression in HFHFD-fed mice. Herein, we demonstrated that *B. uniformis* CECT 7771 prevents the impact of the obesogenic diet on intestinal immunity and favours gut integrity. These effects probably contribute to reducing inflammation linked to HFHFD which in turn improves the metabolic phenotype in obesity.

P.D1.01.11

The *Brucella abortus* Cu2+/Zn2+ superoxide dismutase in the Th17 and Treg immune response

***M. C. Moreno-Lafont**[1], H. Velazquez-Soto[1], V. Paredes-Cervantes[2], M. R. Vieyra-Lobato[1], R. Lopez-Santiago[1];*
[1]ENCB-Instituto Politecnico Nacional, Mexico City, Mexico, [2]Hospital General. Centro Medico Nacional La Raza, IMSS, Mexico City, Mexico.

Brucellosis is considered the main zoonosis worldwide, with around half a million cases annually. This infectious disease is caused by intracellular bacteria of the genus *Brucellae*. Currently there is not a vaccine for use in humans and pharmacological treatment for this condition, although it is not expensive is very long. It is for this that the development of vaccines for clinical use is still a very active area in the field of research. The aim of this study consisted in assessing the protective capacity of the SOD Cu2+/ Zn2+ from *Brucella abortus* when administered intragastrically and otherwise evaluate the immunological mechanisms involved in response to this protein. Recombinant SOD was obtained from induction of transformed *E. coli* strain, the protein was purified first by affinity chromatography and subsequently by FPLC. In a murine model, it was shown SOD is able to induce systemic protection against *B. abortus strain 2308* challenge. When exploring the mechanisms that may be involved in the generation of protection, we found that immunized mice produced antibodies capable of recognizing SOD and also these mice increased the percentage of Th17 cells and decreasing the percentage of TGF-β producing regulatory T cells.

Characterisation of CD1a-restricted T cells using CD1a-lipid tetramers

C. V. Nguyen-Robertson[1,2], *S. J. Reddiex*[1,2], *J. M. Cheng*[1,2,3], *A. P. Uldrich*[1,2], *J. Rossjohn*[4,5], *I. Van Rhijn*[6], *S. J. Williams*[3], *B. Moody*[6], *D. I. Godfrey*[1,2], *D. G. Pellicci*[1,2];
[1]*Peter Doherty Institute, The University of Melbourne, Melbourne, Australia,* [2]*ARC Centre in Advanced Molecular Imaging at The University of Melbourne, Parkville, Australia,* [3]*School of Chemistry and Bio21 Molecular Science and Biotechnology Institute, The University of Melbourne, Parkville, Australia,* [4]*Department of Biochemistry and Molecular Biology, Monash University, Clayton, Australia,* [5]*ARC Centre in Advanced Molecular Imaging at Monash University, Clayton, Australia,* [6]*Brigham and Women's Hospital, Division of Rheumatology, Immunology and Allergy and Harvard Medial School, Boston, United States.*

In contrast to conventional T cells that recognise peptide antigens presented by MHC molecules, other T cells recognise lipid antigens presented by MHC-like CD1 family members, CD1a, CD1b, CD1c and CD1d. Recent studies have suggested that CD1a-restricted T cells comprise a unique T cell population in human blood and may also play a unique functional role in skin. Here, we have produced mammalian CD1a tetramers to investigate the phenotype and function of human CD1a-restricted T cells directly *ex vivo*. Interestingly, we have shown that CD1a-restricted T cells that recognise non-self lipid antigens, particularly dideoxymycobactin, a lipid antigen derived from *Mycobacterium tuberculosis*, can also be autoreactive to CD1a.
Additionally, we have defined the T cell receptor (TCR) usage of both self- and foreign-lipid-reactive CD1a-restricted T cells, demonstrating that while they exhibit a diverse TCR repertoire, there is some biased variable gene usage. Experiments with CD1a mutant cell lines revealed that different TCRs can bind across the entire binding cleft of CD1a, which is likely to increase the diversity of lipid antigens that can be recognised by CD1a-restricted T cells. Phenotypic analyses of these cells revealed that they are negative for IL-18R and CD161, markers typically used to define other unconventional, innate-like T cells, such as type I NKT cells and MAIT cells, thereby distinguishing CD1a-restricted T cells from other unconventional T cells. Collectively, these studies represent an important step forward in characterising CD1a-restricted T cells, and further understanding their role in infection and autoimmune responses.

Outbreak of anthrax-like disease in Nigeria from unusual pathogens: preliminary report

S. E. Idachaba, A. G. Rimfa, E. A. Abiayi, G. O. Agada, Y. M. Dashe, ***M. O. Odugbo****;
National Veterinary Research Institute, Vom, Nigeria.*

Introduction: Outbreaks of anthrax disease are making headlines everyday and across the sub regions and continents of the world.
Case Series: An outbreak of anthrax-like disease was reported in April 2016 in three herds of cattle in North Central Nigeria. Clinically, the signs and symptoms observed in the diseased cattle were anthrax-like resulting in four deaths. Microbiologically, the phenotypic characteristics of the pathogens incriminated a co-infection of *Bacillus laterosporus* and *Bacillus pantothenticus* isolated from spleen, blood, and nasal swabs of diseased cattle. *Bacillus anthracis*, the established causative agent of anthrax was not isolated either microscopically, culturally or with use of USA Navy field ELISA test kits for antigen detection; sensitivity of both *Bacillus* species to ciprofloxacin and penicillin were noted. There were reports of skin ulcers on humans that came in contact with infected blood of carcasses although no fatality, perhaps due to intervention using procaine penicillin and local herbs.
Conclusion: Anthrax aetiology is now been represented by quasi-species of *Bacillus*, in addition to traditional *B. anthracis*. Similar reports of anthrax symptoms due to *Bacillus cereus* was recently reported in neighbouring Cameroon and Cote d'Ivoire. Genomic characterization and the virulence of these pathogens in laboratory animals are currently underway. Although vaccination of farm animals with *Bacillus anthracis* spore vaccine strain $34F_2$ has long been the hub of control programmes against anthrax, the recent discoveries of other *Bacillus* species as aetiology of anthrax could undermine the current vaccines in use.
*Presenting author has applied for the "AAI 5th ECI Travel Grant"

alpha-Galactosylceramide administration induces reduction of bacterial load in murine model of brucellosis

O. Rodriguez-Cortes[1], *D. Cabello-Modesto*[2], *A. Hernández-Colín*[3], *R. Soria-Castro*[3], *R. Flores-Mejía*[1], *R. López-Santiago*[3], *M. C. Moreno-Lafont*[3];
[1]*SEPI. Escuela Superior de Medicina. Instituto Politécnico Nacional., México, D.F., Mexico,* [2]*Escuela Superior de Medicina. Instituto Politécnico Nacional., México, D.F., Mexico,* [3]*Deto. Inmunología. Escuela Nacional de Ciencias Biológicas. Instituto Politécnico Nacional, México, D.F., Mexico.*

Brucellosis is a chronic zoonoses whit 500,000 cases annually worldwide. Approximately 50% of the cases have presented with an insidious onset and high rate of chronicity and morbidity. NKTs are non-conventional T lymphocytes which have an invariant TCR to recognize glycolipid, are currently investigated like adjuvants in vaccines and treatment of infectious processes because are an early and strong source of IFN-γ. The aim of this work was determine if systemic activation of NKT lymphocytes induces a decrease in bacterial load in systemic brucellosis model of six weeks old BALB/c female mice infected IP with $3.5x10^6$CFUs *B. abortus* 2308. Groups: a) not treated (NT), b) vehicle (100 µL 1% PBS-tween), c) αGalcer (2 µg αGalcer/100 µL 1%PBS-tween). N=9 in each group. αGalcer and vehicle were IV administrated at -1d, +6d, +13d and +20d of the infection. At +7d, +14d and +21d postinfection a blood sample was taken, animals were sacrificed and was realized extraction of spleen. Were determined splenic index(SI), quantification of NKTs by FACS, CFUs and cytokines in serum by CBA. An increase in SI was observed at 21d in NT group, followed by αGalcer ($P<0.001$); however αGalcer induced a higher number of NKTs/organ at 7d and 21d compared to NT group $9.36x10^5$vs.$6.94x10^5$ and $2.79x10^6$vs.$2.19x10^6$ respectively ($P>0.05$). TNFα and IL-6 serum concentration was higher in αGalCer treated mice at 14d($P<0.001$, $P<0.05$) and a reduction of bacterial load of this group was observed with respect to NT group of $1.1x10^7$vs.$4.73x10^6$ and $2.47x10^6$vs.$5.35x10^5$ at 7d and 21d respectively ($P<0.05$). Grant SIP20170978.

P.D1.01.15

Microbiota promote lesion development during intradermal infection with vaccinia virus

E. V. Shmeleva*, B. J. Ferguson, G. L. Smith;
Department of Pathology, Cambridge, United Kingdom.*

There is a growing interest in the roles of commensal bacteria during viral infections. Vaccinia virus (VACV), which was used to eradicate smallpox, induces skin lesions after intradermal infection, but the pathophysiology of lesion formation is not well studied. While studying lesion formation, we observed a substantial infiltration of neutrophils into VACV-infected ears several days post infection, leading us to hypothesise the presence of secondary bacterial infection. CFU counts revealed a greater than 100-fold increase of bacteria in infected mouse ear tissue in comparison with controls. To investigate the role of skin microbiota in lesion development, mice were treated with a broad-spectrum antibiotic (AB) during infection. AB-treatment halved the size of lesions compared to controls animals, yet the viral titres remained unchanged. FACS analysis of the VACV-infected ear tissues revealed a significant reduction in the recruitment of different subpopulations of myeloid and lymphoid immune cells in AB-treated mice in comparison with controls. Indeed, lesion sizes correlated positively with the number of neutrophils and TCRαβ T cells. Levels of IL-1β, IL-6, TNFα and CCL7 were also reduced by AB treatment compared with controls. In conclusion, skin microbiota increases greatly following intradermal infection with VACV and promotes lesion development and the recruitment of leukocytes to the site of viral infection.

P.D1.01.16

Crohn's disease-associated *Escherichia coli* serotyping through the whole-genome sequencing of cultivated intestinal community

M. Siniagina*, M. Markelova, A. Laikov, E. Boulygina, T. Grigoryeva;
Kazan Federal University, Kazan, Russian Federation.*

Crohn's disease (CD) is chronic inflammatory bowel disease with unclear etiology. Exacerbation of CD is often associated with increase in the number of E.coli.
To characterize the variety of E.coli strains in gut microbiota, stool samples were collected from two patients - with diagnosed Crohn's disease and without any observed symptoms of gastrointestinal disorders (control). Different E.coli morphotypes on Endo medium tested for hemolytic activity as well as mixed colony suspensions from Endo plates were analyzed through whole-genome sequencing on Illumina Miseq platform.
In CD patient 2.76*10^7 CFU and in control 3.8*10^4 CFU were cultured. There were different colony morphotypes in the sample from CD patient represented by O166:H15 (86.7% colonies on plate), O-:H20, O154:H9, O-:H30, O4:H45 serotypes while among control sample morphotypes O6:H1 and O-:H4 serotypes were found. Whole-genome sequencing data of mixed colony suspensions allowed to detect additional E.coli serotypes O8, O68, O159 and O159, O180, O24, O25, O68; H17, H10 and H4, H14 in control and CD sample, respectively.
Thus, abundance of E.coli serotypes in CD sample differs from the control one. Prevalence of O166:H15 serotype, described earlier as an infectious agent caused gastroenteritis outbreak in Osaka (Japan) in 1997, may be associated with CD. This assumption will be checked in future research on an extended cohort of patients using omics technologies.
The reported study was funded by RFBR according to the research project № 17-00-00433.

P.D1.01.17

Effect of Methisoprinol on selected immunological parameters in the course of BRDC treatment in calves

A. K. Siwicki[1], *K. Żarczyńska*[2], *A. Pomianowski*[2], *J. Małaczewska*[1], *R. Wójcik*[1], *P. Schulz*[1];
[1]*Microbiology and Clinical Immunology Department, Veterinary Medicine Faculty, University of Warmia and Mazury in Olsztyn, Olsztyn, Poland,* [2]*Internal Diseases Department and Clinic,Veterinary Medicine Faculty, University of Warmia and Mazury in Olsztyn, Olsztyn, Poland.*

Bovine Respiratory Disease Complex (BRDC) is considered as one of the most important diseases of the respiratory system of calves and young cattle. It is also referred to as enzootic bronchopneumonia of calves (EBC) or shipping fever. BRDC is a polyetiological disease of the respiratory system. This include viruses: bovine herpesvirus-1, bovine respiratory syncytial virus, bovine parainfluenza virus3, bovine coronavirus, bovine adenovirus A-D and bovine viral diarrhea virus 1 and 2. In addition, the role of mycoplasma is emphasized. Bacteria are a secondary factor in the disease.Tests were carried out on 40 calfes qualified on the basis of a clinical trial and confirmation of the presence of at least one virus and one bacterium. Animals were divided into two groups. The experimental group received Methisoprinol three times intramuscularly at two-day intervals (day 1,3 and 5). The second group received a placebo. The level of T cell subpopulations in the plasma were determined. Blood for tests was collected at 1, 9 and 21 day of experiment. Significantly higher values were observed in the methisoprinol group on day 9 and 21 whereas the mean values remained relatively constant in control animals.The study was performed with the approval of the Local Ethics Committee for Experiments on Animal.This study was partially supported by the National Centre for Research and Development - project no: POIG.01.03.01-28-108/12.

P.D1.01.18

Changes in the skin microbiome during allogeneic hematopoietic stem cell transplantation

J. Strobl[1], *N. Bayer*[1], *L. Hammerl*[1], *D. Berry*[2], *V. K. Patra*[3], *G. Stary*[1];
[1]*Medical University of Vienna, Department of Dermatology, Vienna, Austria,* [2]*University of Vienna, Division of Microbial Ecology, Vienna, Austria,* [3]*Medical University of Graz, Department of Dermatology, Graz, Austria.*

The success of allogeneic hematopoietic stem cell transplantation (HSCT) remains limited due to severe side-effects, such as infections and graft-versus-host-disease (GVHD). Recent studies suggest that dysbiosis of intestinal microbes is associated with increased risk of GVHD, while the role of the cutaneous microbiome in this setting remains elusive. We obtained patient material (blood, stool, skin biopsies and -scales) at 5 time points before myeloablative conditioning and up to one year after HSCT (n= 20). The cutaneous and intestinal microbiome is analyzed with 16S ribosomal RNA sequencing. Interactions of bacteria with immune cells are investigated using multiple staining approaches, such as immunofluorescence stainings and fluorescence *in situ* hybridization (FISH). Bacterial numbers/mm² and distance calculations from $CD45^+HLA\text{-}DR^+$ cells are assessed via the StrataQuest Analysis Software (TissueGnostics GmbH).
We successfully established an extraction protocol for microbial DNA from stool and skin scales and can visualize bacteria by 16S rRNA FISH in the epidermis and dermis of skin sections. FISH revealed a decrease in bacterial numbers/mm² skin in the epidermis as well as upper (500µm) and lower (500µm) dermis at day 0 and day 14 after transplantation. Hundred days after HSCT bacterial numbers in skin were comparable to baseline before transplantation. Although often in close contact with $CD45^+HLA\text{-}DR^+$ antigen-presenting cells, no intracellular bacteria were observed. In this new and ongoing project, we aim to build individual risk-profiles for patients based on their skin and gut microbiome and further explore the interaction between the immune system and the residing microbiome in this unique cohort.

Gut microbiota have a major influence on the intestinal health of allogeneic hematopoietic stem cell transplantation (HSCT) recipients. For example, patients with intestinal dysbiosis after HSCT are more prone to develop Graft-versus-Host Disease (GvHD). Here, we tested if fecal microbiota transplantation (FMT) could restore symbiosis in GvHD patients and thereby would alleviate symptoms. Fifteen allogeneic HSCT recipients with biopsy-proven, steroid-dependent or steroid-refractory intestinal GvHD received a single FMT via nasoduodenal infusion from an unrelated, healthy donor. FMT procedure was well tolerated by all patients and no serious adverse events were observed that could be attributed to FMT. With 6-months follow-up still ongoing, so far 11 out of 15 patients showed improvement of GvHD. Completed follow-up for the first seven patients identified three complete responders (CR). In these patients, defecation frequency and consistency normalized and immunosuppressants were tapered successfully, without relapse of diarrhea. Two partial responders (PR) showed initial improvement of GvHD after FMT but relapsed upon prednisone taper. Analysis of fecal microbiota composition by 16S ribosomal RNA (rRNA) sequencing revealed overall low alpha diversity in patients pre-FMT, with the lowest diversity observed in non-responding participants. Future analysis of collected blood samples and sigmoid biopsies will give further insights into the immune cells involved in the beneficial effect of FMT. This study demonstrates that a single FMT is safe and effective in allogeneic HSCT recipients with steroid-refractory or steroid-dependent GvHD and provides a solid basis to further exploit its effectiveness in larger cohorts.

The enteric pathogen Citrobacter rodentium shapes intestinal bacterial communities to overcome colonization resistance

S. Wirtz, *R. Lakra, M. F. Neurath;*
Medical Department 1, Erlangen, Germany.

The enteric pathogen *Citrobacter rodentium* (CR) is widely used as model for infections with EHEC/EPEC and inflammatory bowel diseases (IBD). While the importance of the T3SS encoded in the locus of enterocyte effacement (LEE) is well established, the functional in vivo role of the endogenous type-VI-secretion-system (T6SS) for *CR* infection remains ill defined. Based on our experimental evidence that the T6SS actively secreted hallmark proteins *in vitro*, we disrupted conserved T6SS genes in a CR reporter-strain. Interestingly, we observed a significantly reduced colonization capacity of these mutants suggesting that CR requires a functional T6SS to infect the intestine efficiency and to exhibit full inflammatory activity. By competition experiments under aerobic and anaerobic conditions using stools/specific bacteria as prey and CR as predator, we found that the T6SS conferred strong interbacterial competition. Notably, this notion was further supported by infection experiments in germ-free mice. Furthermore, a 16S-based next generation sequencing strategy indicated that changes in the microbiome during CR infections largely depend on the presence of a functional T6SS. Collectively, our results suggest that T6SS-dependent effects on bacterial communities allow CR effective colonization of the intestinal ecosystem.

P.D1.01.21

Soluble TNF-like weak inducer of apoptosis (TWEAK) enhances poly(I:C)-induced RIP-mediated necroptosis

M. A. Anany, *J. Kreckel, C. Otto, D. Siegmund, H. Wajant;*
Wuerzburg university hospital, Wuerzburg, Germany.

TNF-like weak inducer of apoptosis (TWEAK) and inhibition of protein synthesis with cycloheximide (CHX) sensitize for poly(I:C)-induced cell death. Notably, while CHX preferentially enhanced poly(I:C)-induced apoptosis, TWEAK enhanced primarily poly(I:C)-induced necroptosis. Both sensitizers of poly(I:C)-induced cell death, however, showed no major effect on proinflammatory poly(I:C) signaling. Analysis of cells lacking TRADD, RIP and FADD or the combination of TRADD and RIP along with caspase-8 KO cells and transfectants expressing FLIPL and FLIPS revealed furthermore similarities and differences in the way how these molecules act in cell death signaling by poly(I:C)/TWEAK and TNF and TRAIL. RIP turned out to be essential for poly(I:C)/TWEAK-induced caspase-8-mediated apoptosis but was dispensable for these responses in TNF and TRAIL signaling. TRADD-RIP double deficiency differentially affected poly(I:C)-triggered gene induction but abrogated gene induction by TNF completely. FADD deficiency abrogated TRAIL- but not TNF- and poly(I:C)-induced necroptosis while TRADD and the two FLIP isoforms elicited protective activity against all three death inducers.Application funding Source

MMP-9-generated COOH-, but not NH_2-terminal fragments of SAA1 retain potentiating activity in neutrophil migration to CXCL8, with loss of direct chemotactic and cytokine inducing capacity

S. Abouelasrar Salama, M. De Buck, J. Vandooren, S. Knoops, N. Pörtner, L. Vanbrabant, G. Opdenakker, P. Proost, J. Van Damme, S. Struyf, ***M. Gouwy****;*
Rega Institute, Leuven, Belgium.

Serum amyloid A1 (SAA1) is an acute phase protein, induced to extremely high levels upon inflammation and infection. Human SAA and its NH_2-terminal part are studied extensively in the context of amyloidosis. In contrast, little is known about COOH-terminal fragments of SAA. Intact SAA1 chemoattracts leukocytes via the G protein-coupled receptor formyl peptide receptor like 1/formyl peptide receptor 2 (FPRL1/FPR2). In addition to direct leukocyte activation, SAA1 induces chemokine production by signaling through TLR2. We recently discovered that these induced chemokines synergize with intact SAA1 to chemoattract leukocytes. Gelatinase B or matrix metalloproteinase-9 (MMP-9) is induced by SAA1 during infection and inflammation. We here demonstrate that processing of SAA1 by MMP-9 yielded predominantly three COOH-terminal fragments: SAA1(52-104), SAA1(57-104) and SAA1(58-104).

To investigate the effect of proteolytic processing on the biological activity of SAA1, we chemically synthesized the COOH-terminal SAA fragments SAA1(52-104) and SAA1(58-104) and the complementary NH_2-terminal peptide SAA1(1-51). In contrast to intact SAA1, the synthesized SAA1 peptides did not induce interleukin-8 (IL-8)/CXCL8 in monocytes or fibroblasts. Moreover, these fragments possessed no direct chemotactic activity for neutrophils, as observed for intact SAA1. However, comparable to intact SAA1, SAA1(58-104) synergized with CXCL8 in neutrophil activation and migration, whereas SAA1(1-51) lacked this synergistic activity. This synergistic interaction between the COOH-terminal SAA1 fragment and CXCL8 in neutrophil chemotaxis was mediated by FPR2. Hence, proteolytic cleavage of SAA1 by MMP-9 fine-tunes the inflammatory capacity of this acute phase protein in that only the synergistic interactions with chemokines remain to prolong the duration of inflammation.

Excretion-secretion products from *Taenia crassiceps* cysticerci induce regulatory T cells

L. Adalid-Peralta[1], *D. López Recinos*[1], *V. Morales Ruiz*[1], *M. G. Castañeda Torrico*[1], *A. Guevara Salinas*[1], *S. Gómez Fuentes*[1], *C. Parada Colín*[2], *C. Espitia Pinzón*[2], *M. Hernández González*[2], *I. Mora Herrera*[2], *G. Fragoso*[2], *E. Sciutto*[1];
[1]*Instituto Nacional de Neurología y Neurocirugía, Mexico City, Mexico,* [2]*Instituto de Investigaciones Biomédicas, UNAM, Mexico City, Mexico.*

Introduction: Neurocysticercosis is caused by the establishment of *Taenia solium* larvae in the central nervous system. The *T. crassiceps* cysticercosis murine model has allowed us to study *T. solium* infections. While the parasite is known to induce regulatory T cells (Tregs), the components involved in Treg induction are unknown. This work is aimed to identify and characterize Treg-inducing excretion-secretion products (ESP) by cellular, proteomic, and bioinformatic analysis.
Materials and Methods: ESP were obtained from supernatants of *T. crassiceps* cysticercus cultures in DMEM at 120 days post-infection. ESP were dialyzed, lyophilized, and quantified. For Treg induction, 0, 250, 500, 700, or 1000 µg of protein of each extract per mouse were inoculated intraperitonially. Five days after inoculation, mice were sacrificed, peritoneal cells were obtained, and Treg percentage was evaluated by flow cytometry. Peptide fingerprint was determined by 2-dimension gels. The spots were cut and digested for mass spectrometry analysis, and the resulting peptides were characterized by bioinformatics.
Results: From the six different ESP analyzed, four were identified as Treg-inducing and two as non-Treg-inducing. The isoelectric point and molecular weight of one Treg-inducing and one non-Treg-inducing ESP were compared, and 34 differential spots were identified for the Treg-inducing ESP-6. Spots were sequenced, and 21 candidate proteins were identified and classified by function in metabolic and immunological processes.
Conclusions: ESP from *T. crassiceps* include Treg-inducing proteins, which could participate in the establishment and permanence of cysticerci in an immunocompetent host. These ESP could provide new therapeutic tools against chronic inflammation in human diseases.

Immunemodulatory effects of malaria co-infection with *Mycobacterium ulcerans* disease in Ghana

D. Antwi-Berko[1,2], *N. Nausch*[3], *W. Owusu*[1], *E. Owusu-Dabo*[1], *L. Batsa-Debrah*[1], *A. Y. Debrah*[1,4], *M. Jacobsen*[3], *R. O. Phillips*[1,5];
[1]*Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana,* [2]*Department of Basic and Applied Biology, University of Energy and Natural Resources, Sunyani, Ghana,* [3]*Pediatric Pneumology and Infectious Diseases Group, Department of General Pediatrics, Neonatology, and Pediatric Cardiology, University Children's Hospital, Heinrich-Heine University, Duesseldorf, Germany,* [4]*Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [5]*Department of Medicine, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana.*

Introduction: Buruli ulcer disease (BUD) caused by *Mycobacterium ulcerans* (*Mu*) is endemic in tropical regions; hence there is a concomitant risk of co-infection with other infections including *Plasmodium falciparum* (malaria). However, immunomodulatory effect of malaria co-infection among BUD patients has not been elucidated. This study sought to determine the immune-modulation by malaria and its impact on host immunity and clinical presentation of BUD in children.
Methods: This observational study recruited 42 children with BUD (1.5-17 years) and 29 healthy contacts (2-15 years) from the Agogo Presbyterian Hospital and screened serologically for *P. falciparum*. Heparinized whole blood samples of participants were stained and CD4+ T cells analyzed for expression of CXCR3, CD161, and CRTH2 receptors. After overnight stimulation with *Mu* antigen, CD4+ T cells were analyzed for TNFα, IFNγ, CD40L, IL-5, GM-CSF, IL-4, IL-9, IL-22, IL-17A, IL-10, IL-2 and IP-10 levels by flow cytometry. Proportions and profile of chemokine receptors/cytokine producing CD4+ T cells was compared and correlated with disease progression and severity.
Results: 50% of BUD patients and 58% of healthy contacts were sero-positive for malaria. Malaria positive BUD patients showed significantly reduced CRTH2+CXCR3+ CD4+ T cells, elevated proportions of CD40L+ and IFNγ-TNFα+ whilst there was non-significant increased TNFα+ and CD40L-TNFα+ producing CD4+ T cells compared to BUD/malaria sero-negatives. IFNγ-TNFα+ producing CD4+ T cells correlated with the widest diameter of lesions in BUD/malaria sero-positive patients.
Conclusion: These findings suggest that the increase in IFNγ-TNFα+ and CD40L+ producing T cell subset may reflect a strong inflammatory response in BUD patients.

P.D1.02.03

An *in vivo* [^{11}C] PBR28 positron emission tomography (PET) study of microglia and astrocytes cells activation in pneumococcal meningitis.

T. Barichello[1], *V. V. Giridharan*[1], *G. Scaini*[1], *J. S. Generoso*[2], *L. R. Simoes*[2], *A. Collodel*[2], *D. Dominguini*[2], *S. Sudhakar*[1], *F. Petronilho*[3], *F. Dal-Pizzol*[2];
[1]*The University of Texas Health Science Center at Houston, Houston, United States,* [2]*Universidade do Extremo Sul Catarinense - UNESC, Criciuma, Brazil,* [3]*Universidade do Sul Catarinense - UNISUL, Tubarao, Brazil.*

Translocator protein (TSPO) is localized in the outer membrane of the mitochondria and it is expressed in activated microglia and astrocytes cells. TSPO interacts with voltage-dependent-anion channels (VDACs) and adenine-nucleotide translocators (ANTs) thereby increasing the permeability of the mitochondrial membrane facilitating cardiolipin oxidation and cytochrome-c liberation. *Aim:* to quantify neuroinflammation in terms of fixation and distribution of [^{11}C]-PBR28 and to study its relationship with cognitive impairment after pneumococcal meningitis. At 24 h and 10 days after pneumococcal meningitis induction, Wistar rats were subjected to PET with [^{11}C]-PBR28, a radiotracer with high binding specificity for the TSPO. The expression of cytokines, TSPO, VDAC, ANT, cytochrome-c, microglia and astrocytes markers were evaluated in the rat brain. The 10 days group was subjected to behavior task and was evaluated the aforementioned biomarkers. *Results: 24 h group:* IL-1α, IL-1β, IL-6, IL-18, IFN-γ, and TNF-α levels (Bioplex) and the microglial marker ionized calcium-binding adapter molecule-1 (Iba-1), cluster of differentiation molecule-11b (CD-11b), astrocyte marker glial fibrillary acidic protein (GFAP), cytochrome-c, TSPO expression were higher compared with control group (Western-blot/HIC). In the PET imaging all brain structures presented a higher uptake of [^{11}C]-PBR28. *10 days group:* The meningitis group presented impairment of habituation, aversive, and long-term recognition memories. In amygdala, hippocampus, and thalamus uptake of [^{11}C]-PBR28 were higher in the meningitis group. TNF-α levels, cytochrome-c, Iba-1, CD-11b, TSPO, and GFAP expression were higher in the brain 10 days after meningitis induction. Pneumococcal meningitis survivor's rats presented cognitive impairment that was associated with microglia and astrocyte cells activation.

P.D1.02.04

Gut microbiota is associated with the responsiveness of *in vitro* generated human dendritic cells to stimuli

J. Djokic[1], *D. Mihajlovic*[2], *M. Tolinacki*[1], *S. Bojic*[3], *B. Pavlovic*[4], *D. Vucevic*[2], *N. Golic*[1], *M. Colic*[5], *S. Tomic*[5];
[1]*Laboratory for molecular microbiology, Institute for Molecular Genetics and Genetical Engineering, University in Belgrade, Belgrade, Serbia,* [2]*Medical Faculty of the Military Medical Academy, University of Defence, Belgrade, Serbia,* [3]*HITTest, d.o.o., Belgrade, Serbia,* [4]*Pharmaceutical Faculty, University in Belgrade, Belgrade, Serbia,* [5]*Institute for the Application of Nuclear Energy, Belgrade, Serbia.*

The properties of *in vitro* generated dendritic cells (DC) vary greatly between different donors, leading to variable success upon their application in immunotherapies. Although gut microbiome was shown to influence the efficacy of various immunotherapeutic approaches, similar studies for *in vitro* generated DC are missing. Here we included 15 heathy donors to analyse association of gut microbiota by 16S rRNA sequencing with the responsiveness of their monocyte-derived DC to lipopolysaccharide (LPS) and IFN-γ stimulation. Although all DC down-regulated completely CD14 expression after the differentiation, their responsiveness to LPS/IFN-γ stimulation varied greatly, considering the expression of maturation markers and cytokines production. The expression of ILT-3 by DC negatively correlated with CD83 and CD86 expression, as well as IL-12p70 production. Additionally, the increase in pro-tumorigenic IL-22 production by DC, negatively correlated with the production of proinflammatory cytokines (IL-12p70, TNF-α, IL-6) after LPS/IFN-γ treatment. The frequency of *Sutterella* in feces correlated positively with the capacity of DC to produce IL-12p70, and negatively with expression of ILT-3.
Additionally, the up-regulation of ILT-3 by DC correlated negatively with the frequency of *Lachnospiraceae* in the gut microbita. In contrast, the amount of short-chain fatty acids (SCFA) and the frequency of SCFA producers in gut microbiota, correlated negatively with the capacity of DC to produce proinflammatory cytokines production after stimulation. These results showed that gut microbiota significantly affect the capacity of *in vitro* generated DC to respond to stimuli, suggesting that the manipulation of gut microbiota in patients might improve the immunotherapeutic protocols based on DC vaccines.

P.D1.02.05

Effects of human gut mycobiome *in vitro*

N. Galanova[1], *L. Bajer*[1,2], *M. Kostovcik*[3], *M. Kolarik*[3], *M. Kverka*[1], *K. Klimesova*[1];

Although the connection between microscopic fungi and inflammatory bowel disease (IBD) has been discussed ever since the discovery of anti-*Saccharomyces cerevisiae* antibodies, the mechanisms of action on gut inflammation have been studied only marginally. We therefore focused on the proinflammatory potential of the gut fungi. We cultivated fresh fecal samples of IBD patients and healthy controls and isolated morphologically different fungal colonies. These we dereplicated using primer Eric1R and identified by Sanger sequencing. Finally, we processed them into lysates, which we used for stimulation of various cells, such as immune and epithelial cell lines and primary cell cultures. We analyzed their effects using flow cytometry and ELISA. The preliminary data on RAW 264.7 cells showed increased proliferation with reducing concentration of the stimuli. The only exception was stimulation by filamentous fungi *Mucor plumbeus,* which also increased MHCII and IL-6 response. The yeast *Candida parapsilosis* induced the strongest immune response associated with increased expression of costimulatory molecules such as CD80, CD86 and CD40. Proinflammatory response was further validated by increased TNF-α and IL-6 production. Interestingly, the highest stimulation was exhibited by *C. parapsilosis* isolated from healthy control, which in several parameters, e.g. CD80, iNOS, NO_2^- and IL-6, exceeded the stimulation by positive controls. We have shown the proinflammatory effect of *Candida parapsilosis* and *Mucor plumbeus* on the RAW cells. Interestingly, different isolates of the same species induced dissimilar response, emphasizing the complexity of involved mechanisms. The research was funded by GAUK (1366217), GACR (17-066324 and 17-09869S), AZV (15-27580A and 15-28064A).

The composition of the intestinal microbiota plays a critical role for the shaping of the immune system. Recent studies suggest that the microbiota may have a role in immune-mediated central nervous system diseases such as multiple sclerosis (MS).
We find that a distinct population of lymphocytes, named MAIT (mucosal-associated invariant T cells), is expanded in individuals with MS. We collected faecal samples from 27 MS patients and 18 healthy subjects (HS) and we studied the composition of the cultivable gut mycobiota. We find a tendency towards higher fungal abundance and richness in the MS group. Analyzing MS-twin and HS-twin individuals, we observed that MS twins show a much higher rate of *S. cerevisiae (SC)*, and a decrease of Candida Albicans (CA).
We then studied the response of MAIT cells to SC and CA strains isolated from faecal samples. Multicolour flow cytometry was used to study MAIT cells' responses. We find that MAIT cells from MS patients are significantly more activated and have higher proliferative rates than those from healthy donors. We find that MAIT cell activation and proliferation are mediated by IL-12 and IL23 produced by monocytes.
Finally, immunohistochemistry of MS post mortem brains show that MAIT cells can cross the blood-brain barrier and produce pro-inflammatory cytokines in the brain. These results are in agreement with the hypothesis that dysbiosis of the gut microbiota may determine a dysfunction of mucosal responses and may favour the development of systemic inflammatory and autoimmune diseases.

P.D1.02.07

Antileishmanial and immunodulatory effect of Babassu-loaded PLGA micro and 1 nanoparticles: An useful drug target to Leishmania amazonensis infection

R. N. M. Guerra[1], *M. C. Silva*[1], *F. R. Nascimento*[1], *R. Nicolette*[2], *J. M. Brito*[1], *A. M. Vale*[1], *A. P. Santos*[1], *P. V. Soeiro*[1];
[1]*Federal University of Maranhão, São Luís, Brazil,* [2]*FIOCRUZ CEARA, Fortaleza, Brazil.*

Introduction: It was evaluated the immunological and the anti-*Leishmania amazonensis* activity of babassu-loaded *poly [lactic-co-glycolic acid) [*PLGA] micro/nanoparticles. Material and Methods: The Anti- *Leishmania* activity was evaluated against promastigotes or amastigotes forms, in Balb/c macrophages. Results: The size of the micro/nanoparticles ranged from 3 to 6.4 µm, with a zeta potential of −25 mV and encapsulation efficiency of 48%. The anti-*Leishmania* activity of MMP (IC_{50}) was 10-fold higher than that free extract (Meso). MMP exhibited overall bioavailability and was very effective in eliminating intracellular parasites. MMP also reduced *ex vivo* parasite infectivity probably by the increased the production of nitric oxide, hydrogen peroxide and TNF-alfa indicating the activation of M1 macrophages. The over expression of TNF-alfa did not impair cell viability, suggesting anti-apoptotic effects of MMP. Conclusions: These findings indicate that babassu-loaded micro/nanoparticles could be useful for drug targeting because of their immunomodulatory effects on macrophage polarization and the increased efficacy as anti-*Leishmania* product.

P.D1.02.08

Dietary modification reduces multiple sclerosis-like disease in adult marmoset monkeys

Y. Kap[1], *H. Harmsen*[2], *B. Eggen*[2], *J. Bauer*[3], *N. van Driel*[1], *C. Bus-Spoor*[2], *M. Dubbelaar*[2], *C. Grit*[2], *S. Kooistra*[2], *J. Laman*[2], *B. 't Hart*[1];
[1]*Biomedical Primate Research Centre, Rijswijk, Netherlands,* [2]*University Medical Center Groningen, Groningen, Netherlands,* [3]*Brain Research Institute, Vienna, Austria.*

After the introduction of a new dietary supplement (yoghurt-based and vitamin-enriched) in our marmoset colony, the frequency of marmosets in which clinically evident experimental autoimmune encephalomyelitis (EAE), a model of multiple sclerosis (MS), could be induced had decreased from 100 to ~60%. This finding prompted the here reported controlled study in marmoset twins where the effects of the new and classic dietary supplement on factors contributing to EAE susceptibility were compared. One sibling of eight adult twin pairs raised on the new diet were fed the classic diet starting eight weeks before EAE induction with rhMOG/IFA; the other sibling was maintained on the new diet. In the monkeys reverted to the classic diet a 100% EAE incidence was observed. In monkeys fed the new diet the EAE incidence was 75%, spinal cord demyelination was significantly lower, RNA-sequencing analysis of CNS tissue provided evidence for reduced apoptosis and enhanced myelination. In addition, a reduced autoimmune response to the immunized protein was observed in new diet animals. Next, we analyzed whether diet-related changes in microbiota were detectable and associated with disease progression. Despite the dietary modification, twin siblings displayed an essentially unaltered microbiota composition before EAE induction. However, three weeks after immunization, divergence of the fecal microbiota composition between both groups was first detectable, which was even more clear seven weeks after immunization. In conclusion, we report a marked effect of dietary modification on the CNS and gut microbiota and thereby affecting the susceptibility of adult, outbred, conventionally-housed marmosets to MS-like disease.

P.D1.02.09

The combined effect of probiotic and chondroitin sulfate on the levels of cytokines and matrix metalloproteinases in the serum of rats with monoiodoacetate-induced osteoarthritis

O. Korotkyi, *A. Vovk, T. Halenova, K. Dvorshchenko, O. Savchuk, T. Falalyeyeva, L. Ostapchenko;*
ESC "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

Cytokines (CK) and matrix metalloproteinases (MMP) play a major role in the pathogenesis of osteoarthritis (OA). The recent studies showed the effect of probiotics (PBs) and chondroitin sulfate (CS) on inflammatory processes during OA, but available results are limited and conflicted. We used a single injection of monoiodoacetate through the infrapatellar ligament of Wistar male rats to start OA model. Therapeutic groups got an intramuscular injection of CS ("Drastop", World Medicine, UK) daily from 2nd to 29th days of experiment and intragastric feeding of PB ("Symbiter" O.D. Prolisok, Ukraine) from 8th to 21st days of the experiment. Sampling was provided on the 30th day. The levels of CKs (interleukins (ILs) IL-1β, IL-4, IL-10, IL-12β, tumor necrosis factor (TNF)-α, interferon (IFN)-γ) and MMPs (MMP-1, MMP-2, MMP-3, MMP-8) were measured in serum by enzyme-linked immunosorbent assay (Biotrak ELISA System, Healthcare, USA). A histologic analysis of knee cartilage tissue made followed according to international recommendation (hematoxilin&eosin, x200). OA caused a significant increase the level of all CKs and MMPs (except IL-4, it was in norm) comparing to control group. Separated administration of CS and PB has decreased all parameters, but they did not reach the control group. PB effect was less significant than CS. The combined administration of PB and CS significant decreased the levels of CKs and MMPs and it was approaching to control values. This data has correlated with histological findings. Thus, the synergetic action of PB and CS is promising and further investigations are waited with interest.

P.D1.02.10

Different gut microbial communities in murine asthma model with obesity

G. Gu, W. Chang, K. Kim, S. Lee, S. Kim, J. Lim, ***J. Lee****;*
Division of Allergy and Chronic Resipiratory Diseases, Center for Biomedical Sciences, Korea National institute of Health, Korea Centers for Disease Control and Prevention, Osong, Chungcheongbuk-do, Korea, Republic of.

Introduction: Obesity is considered as a risk factor for asthma. However, the mechanisms linking obesity and asthma are poorly understood. Recently, it is reported that obesity-related alterations in gut microbiota contributes to obesity-related asthma. To address the relationship between alteration of gut microbiota and pathogenesis of asthma, we analyzed the gut microbiota in murine model.
Material and Methods: Male C57BL/6 mice were fed with a high-fat diet or Low-fat diet to induce obese, and then were exposed to house dust mite extract to induce the lung inflammation. Disease severity was assessed by measuring airway hypersensitivity, infiltration of immune cell in lung, serum immunoglobulin, and cytokine production. In addition, microbial community analysis were performed on cecum via 16S rRNA pyrosequencing.
Results: First, we found that obese-asthma group exhibited significantly increased airway responsiveness and infiltration of immune cells. Total IgE and cytokine production were slightly increased in obese-asthma group compared to chow group, but they have no significance. Second, the composition of gut microbiota was showed to be clustered according to groups. Diversity and richness of gut microbiota was decreased in obese-asthma group than in chow group. Lastly, *Roseburia, Lachnospiraceae, Oscillibacter, Hydrogenoanaerobacterium, Ruminococcacea,* of Firmicutes were decreased in obese and/or asthma group, whereas *Enterococcus* of Firmicutes were increased in obese and/or asthma group.
Conclusion: Our finding suggest that alterations in gut microbiota might be associated with severity of obese-asthma. Further studies on the major effector bacteria in obese-asthma pathogenesis will be necessary to clarify the association of gut microbiome with the obese-asthma.

P.D1.02.11

Streptococcal pyrogenic exotoxin A induces regulatory T Cells via TNFa-TNFR2 signaling

J. Ma[1]*, C. Lu*[1]*, M. Lin*[2,3]*, C. Chiang-Ni*[1,2]*, M. Kuo*[1,2]*;*
[1]*Graduate Institute of Biomedical Sciences, Chang Gung University, Taoyuan City, Taiwan,* [2]*Department of Microbiology and Immunology, Chang Gung University, Taoyuan City, Taiwan,* [3]*Institute of Molecular Medicine, National Taiwan University, Taipei city, Taiwan.*

Introduction: Superantigens non-specifically cross-link T cell receptor and MHC class II to prompt T cell proliferation and activate antigen presenting cells. Several studies indicated that superantigens can induce regulatory T (Treg) cells proliferation. Tregs are characterized as $CD4^+CD25^{hi}Foxp3^+$ cells, whereas Foxp3 expression is important for Tregs function. Although only 1~2% of $CD4^+$ T cells are Tregs, they play critical roles on regulating immune responses. Cytokines such as IL-2, IL-10, TGF-β and TNF-α play important roles to support Tregs expansion and suppressive functions. In this study, we tested whether bacterial superantigen, streptococcal pyrogenic exotoxin (SPE) A, can induce functional Tregs and understanding possible mechanisms. Material and methods: Peripheral blood mononuclear cells were co-cultured with SPEA and Tregs population was analyzed by flow cytometry. The suppressive function of SPEA-induced Tregs was determined by culturing with anti-CD2/CD3/CD28 Dynabeads activated $CD4^+$ T cells. In order to investigate the potential modulatory pathway, neutralizing antibodies were used to test whether TGF-β, IL-10 or TNF-α contributes to the induction of Tregs. Results: SPEA increased $CD25^+Foxp3^+$ cells with the presence of antigen presenting cells. These SPEA-induced Tregs remain their suppressive function and down-regulates IL-2, which is an important cytokine for T cell activation. TGF-β and IL-10 were not involved in $CD25^+Foxp3^+$ cells induction, while neutralizing TNF-α or blocking TNF-α receptor 2 (TNFR2) reduced the population of $CD25^+Foxp3^+$ cells. Conclusions: This study implicated that TNFR2 signaling was involved in SPEA stimulating functional Tregs. This result suggests a new option for drug design against autoimmune diseases or graft transplantation.

P.D1.02.12

Commensal bacteria drive systemic dendritic cell maturation via induction of type-I interferons

S. Muth[1,2]*, L. Rogell*[3,2]*, S. Lienenklaus*[4,5]*, U. Kalinke*[6]*, H. Schild*[1,2]*, A. Diefenbach*[7,3,2]*, H. C. Probst*[1,2]*;*

Dendritic cell activation is essential for the priming of adaptive immune responses. To ensure immune homeostasis T cell activation by dendritic cells in the immuological steady state must be prevented. We have recently shown that direct interaction of FoxP3+ regulatory T cells with dendritic cells is essential to keep dendritic cells in a resting state. In the absence of regulatory T cell-mediated suppression dendritic cells lose their immature phenotype and activate naive T cells rather than inducing peripheral T cell tolerance, which finally leads to the development of autoimmunity. Here, we sought to identify the activating signals that act on DC in the steady state and drive their maturation when not counterbalanced by regulatory T cells. Using a transgenic mouse model that allows inducible expression of CTL epitopes in dendritic cells without influencing their activation state we identify the commensal flora as a driver of DC activation in the steady state. We show that activation is independent of direct pathogen recognition receptor signaling on the DC but critically depends on tonic levels of type I interferons, which are induced in response to the commensal flora. Our data highlight how the activation threshold for adaptive immune responses is set by the DCs continuous integration of activating and inhibitory signals and identify commensal induced type I interferons and regulatory T cells as opposing forces in this balance.

Prophylactic treatment with simvastatin modulates the immune response and increases animal survival following lethal sepsis infection

J. F. Braga-Filho[1]*, A. G. Abreu*[2]*, C. P. Rios*[1]*, D. Luz*[1]*, D. Cysne*[1]*, J. R. Nascimento*[1]*, L. A. Silva*[1]*, T. S. Fortes*[1]*, R. N. Guerra*[1]*, M. C. Maciel*[1]*, C. Serezani*[3]*,* ***F. R. F. Nascimento***[1]*;*
[1]*UFMA, Sao Luis, Brazil,* [2]*UNICEUMA, Sao Luis, Brazil,* [3]*Vanderbilt University School of Medicine, Nashville, United States.*

Statins may have anti-inflammatory action, promoting immunomodulation and survival in patients with sepsis. The aim here was to analyze the effects of pretreatment with simvastatin in lethal sepsis induced by cecal ligation and puncture (CLP) in mice.
Swiss mice received prophylactic treatment with simvastatin in a single daily dose for 30 days. Then the CLP was performed and the survival was monitored. A half of mice was euthanized after 12h to analyze hematological parameters; cytokines production; cellular influx to peritoneum and bronchoalveolar lavage (BAL); colony-forming units (CFUs); lymphoid organs cellularity; immunophenotyping of T cells and antigen presenting cells and nitric oxide (NO) and hydrogen peroxide (H_2O_2) production.
Simvastatin induced an increase in survival, a decrease in the CFU count on the peritoneum, and a decrease in cells in BAL, in particular lymphocytes. In the blood, there were no differences in the total leukocyte count, but there was a relative lymphocytosis and thrombocytosis in the simvastatin group. The simvastatin induced a greater activation and proliferation of CD4+ T cells in the mesenteric lymph node, as well as an increase in IL-6 and MCP-1 production. The simvastatin induced a decrease in chemotaxis to the peritoneum, but there was an increase in NO and H_2O_2 secretion. Thus, these data suggest that treatment with simvastatin has an impact on the survival of animals, as well as immunomodulatory effects in sepsis induced by CLP in mice.Supported by: FAPEMA, CNPq and CAPES.

Comparative evaluation of microbial translocation products (LPS, sCD14, IgM Endocab) in HIV-1 infected Indian Individuals

N. Negi*, R. Singh, A. Sharma, B. K. Das, M. Vajpayee;*
All India Institute of Medical Sciences, New Delhi, India.

Introduction: Microbial translocation of lipopolysaccharides (LPS), soluble CD14 and Endocab levels have been associated with disease progression during HIV-1 infection. In this longitudinal study, plasma levels of different microbially translocated products (LPS, sCD14, Endocab) was investigated in HIV-1 infected Indian Individuals further stratified as Rapid (R), Viremic slow (VS), Slow progressors (S) and healthy controls.
Materials and Methods: Ten healthy and twenty HIV-1 infected individuals were enrolled. Plasma levels of LPS, sCD14, Endocab was examined using commercially available Limulus Amebocyte assay and enzyme-linked immunosorbent assay (ELISA) enzyme linked immunosorbant assay.
Results: Elevated levels of soluble CD14, IgM EndoCab and LPS were observed in HIV-1 infected individuals compared to healthy controls. Rapid progressors had higher levels of sCD14, IgM EndoCab, LPS (median% 1553, 3596, 202.2) compared to viremic slow, slow progressors and healthy controls both at baseline and follow up visits. At baseline, LPS correlated positively with IgM Endocab and negatively with sCD14 levels while at follow significant positive correlation was observed with IgM Endocab and sCD14 (IgM EndoCab r= 0.490, p=0.05; sCD14 r= 0.051, p= 0.830). Plasma levels of soluble CD14 correlated positively with viral load in rapid, viremic slow and slow progressors while CD+ T cell count correlated positively with soluble CD14 and IgM EndoCab levels in viremic slow and slow progressors.
Conclusion: Our findings indicate that elevated levels of soluble CD14, IgM EndoCab and LPS in HIV-1 infected individuals are strong predictors of disease progression and could be considered as candidate biomarkers for disease monitoring.

P.D1.02.15
Differences in immune responses among unvaccinated adults

***R. M. Noah**;*
Universiti Kuala Lumpur, Kajang, Malaysia.

Outbreaks in certain countries of classified vaccine-preventable infections stormed the headlines for the past 5 years. Countries most affected are those with the influx of immigrants and illegal foreign workers in which majority have not received any childhood vaccinations. The Malaysian Health Ministry issued statement of great concern in the increase of 15% death caused by tuberculosis closely linked to the increase in the number of foreign workers in the country. The investigation was conducted to evaluate the immune function of unvaccinated foreign workers in view of the question whether the immune status in the unvaccinated adults contribute to the transmission of the microbial infections to the vaccinated local populations. Twenty foreign workers and 20 local residents volunteered in the study. Oxidative bursts of lymphocytes were assessed by chemiluminescence assay while a colorimetric assay was used to determine the cellular proliferation of lymphocytes. To analyse the innate immunity status, levels of specific antibodies were measured. There was a significant increment in the oxidative stress of lymphocytes isolated in 60.0% of the unvaccinated individuals. In the proliferative assessment of lymphocytes, 50.0% of the samples recorded absence or lack of proliferation. The humoral immune response on the other hand displayed a significant difference between the unvaccinated and the vaccinated adults suggestive of the effects in individuals not receiving any form of vaccinations. Variations in the immunity of the unvaccinated adults could be responsible for the emergence of microbial infections. These individuals are also at risk of developing complications in non-communicable diseases.

P.D1.02.16
Plasmacytoid dendritic cells regulate inflammation during dysbiosis

***S. Pöysti**, S. Silojärvi, A. Hänninen, R. Toivonen;*
University of Turku, Turku, Finland.

Dendritic cells (DC) are first in line to sense invading microbes and to deliver the signal to other immune cells. Plasmacytoid dendritic cells (pDC) are one subset of DCs and are mainly known for their ability to produce high amounts of type I interferons (IFN). The role of pDCs in bacterial infections is still poorly understood. Our recent studies show high pDCs activation after *Citrobacter rodentium* infection in colon draining mesenteric lymph nodes (coMLN). Here we show an essential role of pDCs in regulating immune response to dysbiosis using a specific pDC-depleted mouse model and *Citrobacter*-induced dysbiosis. We found that dysbiosis had a more severe effect on pDC-depleted mice when compared to wild type mice. Deficiency of pDC during dysbiosis caused 20 % weight loss when no change in wild type mice were seen. Colon epithelium was damaged, epithelial stress genes were upregulated and overall colon length was shorter in pDC depleted mice. T cell analysis showed that the lack of pDCs during dysbiosis blocks the induction of Foxp3+ regulatory T cells in coMLN and increases IFNγ production by both CD4 (T helper) and CD8 (T cytotoxic) cells. Our results indicate that pDCs have regulative functions and in conjunction with Treg cells they control inflammation in the gut during dysbiosis.

P.D1.02.17
Hyperinsulinemia following IFNgamma induced insulin resistance in skeletal muscle boosts the antiviral CD8 T cell response

***M. Šestan**[1], S. Marinović[1], I. Kavazović[1], D. Cekinović[2], S. Wueest[3], T. Turk Wensveen[4], I. Brizić[1], S. Jonjic[1], D. Konrad[3], F. M. Wensveen[1], B. Polić[1];*
[1]University of Rijeka; School of Medicine, Rijeka, Croatia, [2]Infectious diseases department, Clinical Hospital Center Rijeka, Rijeka, Croatia, [3]Division of Pediatric Endocrinology and Diabetology and Children's Research Centre, University Children's Hospital, Zurich, Switzerland, [4]Department of Endocrinology, Clinical Hospital Center Rijeka, Rijeka, Croatia.

Diabetes Mellitus type 2 (DM2) is a chronic metabolic disorder, defined by an inability of the pancreas to properly control blood glucose levels mainly because of systemic insulin resistance (IR). Patients with pre-diabetes may have years of IR without loss of glycemic control, followed by an abrupt increase of blood glucose levels beyond DM2 threshold values. Which event causes this acute loss of glycemic control is unknown. Here we investigated whether and how different viral infections (MCMV, LCMV, Influenza A) influence glucose homeostasis in lean and pre-diabetic obese subjects. We found that viral infections cause a transient systemic IR in lean mice and humans. Virally-induced IFNγ specifically targets skeletal muscle to downregulate the insulin receptor. In lean mice, infection does not cause loss of glycemic control because of increased production of insulin by the pancreatic β-cells. Activated CD8 T cells express the insulin receptor and in vitro activation of these cells in the presence of insulin enhances antiviral immunity through direct promotion of CD8 effector T cell function. Infection-induced hyperinsulinemia therefore boosted anti-viral CD8 T cell responses in vivo. However, in pre-diabetic mice with hepatic insulin resistance caused by diet-induced obesity, viral infection resulted in loss of glycemic control and aggravation of microvascular complications of DM2. Altogether, we identified a new immune-endocrine regulatory feed-back mechanism of antiviral immunity and provided valuable new insights in the underlying pathophysiology of DM2.

P.D1.02.18
Opposing effects of *A. muciniphila* and *C. rodentium* on autoimmune diabetes in NOD mice

***S. Silojärvi**[1], S. Pöysti[1], R. Toivonen[1], A. Hänninen[1,2];*
[1]Institute of Biomedicine, Turku, Finland, [2]Turku University Hospital, Hospital District of Southwest Finland, Turku, Finland.

Akkermansia muciniphila is a common symbiont in healthy gut of both humans and mice, while *Citrobacter rodentium* is a mouse pathobiont which promotes colitis in mice. Since gut microbiota is implicated in type 1 diabetes (T1D), the effects of these microbes were tested on diabetes and autoimmunity in the non-obese diabetic (NOD) mouse. While *A. muciniphila* delayed diabetes incidence compared with vehicle control, *C. rodentium* accelerated it in NOD mice. Although no significant differences were found in the amount of mucin, bacterial count or localization between colons of bacteria-administrated and control mice, lymph node fluorescence *in situ* hybridization (FISH) -stainings indicate that *C. rodentium* effects the emanation of bacterial DNA from colon to colon mesenteric and pancreatic lymph nodes. Colon microbiota also effects autoimmunity, which can be seen as differences in pathogen induced TLR2 and TLR4 -levels (Toll-like receptor) and in bacterial lipopolysaccharide (LPS) and interferon-gamma (IFN-γ) induced CXCL10-levels (C-X-C motif ligand) in pancreatic islets. Different levels of islet-invading white blood cells (insulitis) indicate that colon microbiota effects islet inflammation and beta-cell apoptosis. We conclude that the autoimmune process leading to islet-destruction in the NOD mouse is affected by gut microbiota and that it can be modified by oral administration of an isolated single symbiont or pathobiont.

P.D1.02.19
A potential link between age-related changes in the gut microbiome and changes in the germinal centre response of Peyer's patches

***M. Stebegg**, S. Innocentin, C. Gilbert, M. Linterman;*
Babraham Institute, Cambridge, United Kingdom.

The germinal centre (GC) response generates memory B cells and long-lived plasma cells that secrete high-affinity antibodies. In the gut, the GC response in Peyer's patches (PPs) is an important source of IgA-secreting plasma cells. IgA antibodies are secreted into the gut lumen where they have an important role in controlling the composition of the gut microbiome. In ageing, the GC response in lymph nodes has been shown to be impaired, leading to reduced antibody affinity maturation and memory responses. We hypothesised that an impaired GC response in PPs affects the affinity and quantity of secreted IgA antibodies and thereby drives some of the age-related changes in the gut microbiome. When analysing the GC response of Peyer's patches from aged C57BL/6 and Balb/c mice, we observed an age-related reduction in the proportion of GC B cells in 2 year old animals compared to 3 months old mice. Further, 16S-seq data from our ageing mouse colony confirmed changes in the gut microbiome of 2-year-old mice when compared to 3-month-old mice. While bacterial diversity was not affected, we observed a higher prevalence of *Bifidobacterales* in young mice, while the old microbiome was enriched for *Enterboacteriales*. Taken together, there is a correlation between a poor GC response and changes in the microbiome in ageing. Future work aims to determine if this is a causal relationship.

P.D1.02.20
The effect of *E. coli* O83:K24:H34 on human and murine dendritic cells

***L. Súkeníková**, P. Petrásková, J. Hrdý;*
Institute of Immunology and Microbiology, Prague, Czech Republic.

A balanced microbiome is greatly beneficial for a host. Any disturbance is associated with various problems and diseases, therefore, a number of experiments focus on correction for dysbiosis by probiotic supplementation. One of the promising probiotics appears to be *Escherichia coli* O83:K24:H31 (*E. coli* O83) but the exact mechanism of its positive effect has not yet described. To uncover it, we focused on differences between human and murine dendritic cells (DCs) after *E. coli* O83 stimulation.
Both human and murine DC-like cells were obtained by *in vitro* differentiation from progenitor cells and then stimulated with probiotics and LPS for 24 hours. The appearance of DC surface markers was analysed by flow cytometry and the relative gene expression (qPCR) and secretion (ELISA) of various cytokines and enzymes were tested.
The expression of DC activation markers CD80, CD86 and MHCII was significantly increased after stimulation by *E. coli* O83, indicating that DC-like cells are able to engulf and process probiotic antigens and reflecting their maturation state. Besides that, primed human DC-like cells produce higher amounts of IL-10 cytokine and express indole 2,3-dioxygenase enzyme. A slightly different mechanism occurs in the murine cells expressing also inducible nitric oxide synthase, typical for activated macrophages.
Together, results suggest that the positive effect of *E. coli* O83 is mediated by the reinforcement of tolerogenic DCs, thus supporting T regulatory cells which play a critical role in the induction of tolerance to self antigens and also to components of the microbiome.

P.D1.02.21

Proinflammatory microbial profiles associate with respiratory infections in older adults

*S. Fuentes[1], J. Ferreira[1], J. Pennings[1], G. den Hartog[1], J. van Beek[1], **D. van Baarle**[1,2];*
[1]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [2]University medical Center Utrecht, Utrecht, Netherlands.

There is increasing evidence that interactions between the gut microbiome and the immune system can shape immune responses. With ageing, the immune response deteriorates leading to increased susceptibility to respiratory infections, posing a major health threat.
We studied the impact of gut microbiota composition on the development of respiratory infections using a cohort of older adults (=60 years) followed for influenza-like illness (ILI). Participants were sampled within 48-72hours of reporting an ILI (n 223), 7-9 weeks after ILI (n= 201) and compared to individuals without any ILI event (n=189).
Significant differences were found in the phyla Proteobacteria, Bacteroidetes and Firmicutes. Prediction analyses by Random Forest indicated the species *Ruminococcus torques* as top predictor for ILI. Stratification of groups by presence (Rt+) or absence (Rt-) of *R.torques* revealed higher abundance of pathogens from the *E.coli/Shigella* group. Furthermore, individuals from the Rt+ group showed significant lower diversity, a biomarker for gut microbiota resilience. Although levels of *R.torques* decrease after ILI recovery, levels of *E.coli/Shigella* remain elevated and beneficial bacterial groups (f.e.*Akkermansia*) remain reduced. As *R.torques* has been associated with a proinflammatory state, we measured inflammatory mediators including CRP, cytokines and chemokines. Redundancy analysis showed a proinflammatory profile in the ILI+Rt+ group both locally and systemically.
In conclusion, we reveal a proinflammatory microbiome profile in individuals presenting with ILI and identify potential microbial biomarkers for severity of disease. Understanding how gut microbiota influence onset and severity of respiratory infections can provide new leads for interventions targeted at microbiota modulation in the aging population.

P.D1.02.22

ROLE OF MICROBES IN HUMAN HEALTH, EFFECT ON INFECTIOUS DISEASE DYNAMICS

***M. A. YUSUF**;*
Osun State Polytechnic, Iree, Nigeria.

The outbreak infectious disease in human health can now be investigated to identify microbes or pathogen and carriers for control of infections. The process of this microbiome outbreak can be in stages which can be blocked by different defense mechanisms: host is exposed to infectious particle by an infected individual, the mode of transmission and stability of an infectious person outside the host determine its infectivity.some pathogens such human immunodeficiency virus {HIV} are spread only by the exchange of bodily fluids,early contact of the microbes with a new host occur through an epithelia surface,the skin or the internal mucosal surface of the respiratory,gastrointestinal and urogenital tracts.The gut microbes in disease-inflamation:microbial resident of the human gut are a major attributes in the development and maintenance of health but it differs from patient to patient.The causative agent fall into these: viruses,bacteria, fungi and protozoa.These approaches are also transforming our understanding of how interaction and focus between the human microbiota and the host in order to provide an overview of the microbial role in basic biological processes and in the development and progression of major human diseases such as infectious disease, gastrointestinal cancer.The purpose of this study is to check the role of microbes in health and disease and how the research can be applied to medicine and therapeutic target in clinical practice.

The effector phenotype of human mucosal-associated invariant T (MAIT) cells in age-associated *Clostridium difficile* infections

***I. Bernal**[1,2], B. Bulitta[2], L. Gröbe[2], M. Neumann-Schaal[3,4], J. Hofmann[4], D. Jahn[4], A. Canbay[1], D. Bruder[1,2], L. Jänsch[2];*
[1]Otto-von-Guericke University of Magdeburg, Magdeburg, Germany, [2]Helmholtz Centre for Infection Research, Braunschweig, Germany, [3]Leibniz Institute DSMZ-German Collection of Microorganisms and Cell Cultures, Braunschweig, Germany, [4]Technical University Braunschweig, Braunschweig, Germany.

Clostridium difficile infection (CDI) can cause life-threating inflammatory responses in the intestinal mucosa and has become the nosocomial infection with the highest medical and economical relevance in Germany. However, our knowledge about host immunity in human CDI is fragmentary, and especially the role of memory effector T cells, like mucosal-associated invariant T (MAIT) cells, remains elusive. MAIT cells are innately pathogen-reactive and restricted by MHC class 1-related protein 1 (MR1), which presents antigenic bacterial metabolites of the riboflavin pathway. Presently the role of MAIT cells in CDI is unknown but interestingly their blood frequency decreases in age whereby the incidence of CDI increases. Thus, MAIT cells might mediate underscored protection against CDI infection and their functional impairment might increase susceptibility to CDI. We have recently reported the molecular effector phenotype of MAIT cells in healthy individuals (Bulitta et al., 2018) and here now elucidate their status und responsiveness in age-matched donor- and CDI-patient cohorts. As part of two consortia (ABINEP, CDIFF) and in cooperation with our clinicians we established an analytical pipeline allowing detailed molecular phenotyping with the support of proteomics. We will present results on the age-dependent alteration of MAIT cell effector functions, thereby complementing knowledge on the development and immunosenescence of the MAIT cell compartment. Beyond this we will present data characterizing the responsiveness of MAIT cells towards *C. difficile*. We defined the riboflavin synthesis of selected clinical isolates and using *ex vivo* isolated MAIT cells characterized which effector functions are activated dose- and MR1-dependently by *C. difficile*.

P.D1.03.02

Transcriptome profiling of Staphylococci-infected keratinocytes provides insight into the commensal-induced protective effect against *S. aureus*

***K. Bitschar**[1], L. Klink[1], B. Krismer[2], A. Peschel[2], B. Schittek[1];*
[1]Department of Dermatology, University Hospital Tübingen, Tübingen, Germany, [2]Interfaculty Institute of Microbiology and Infection Medicine, Infection Biology, University of Tübingen, Tübingen, Germany.

Introduction: Our skin is constantly exposed to a large number of pathogens while at the same time undergoing selective colonization by harmless commensal microorganisms such as *S. epidermidis*. We previously showed that secreted factors of *S. epidermidis* protect human and mouse skin against *S. aureus* infection. This work aims at elucidating the mechanism of this commensal-induced protective effect as well as providing a deeper understanding of how keratinocytes discriminate commensals from pathogens.
Materials and Methods: In order to identify the differential innate immune response triggered by commensals or pathogens we compared the transcriptomes of *S. epidermidis* and *S. aureus*-infected primary human keratinocytes by applying RNAseq. Furthermore, an *in vitro* skin infection model with keratinocytes and human skin explants as well as an *in vivo* epicutaneous mouse skin infection model were used to analyze the innate immune response induced by Staphylococci.
Results: We show that *S. epidermidis* is able to alarm keratinocytes by inducing the expression of Nf-κB target genes while at the same time preventing excessive inflammation. Hereby, the alarmin Interleukin-1α, which itself is sufficient to induce the protective effect, seems to play a key role. Consequently, the *S. epidermidis*- mediated protection is lost in IL-1R-deficient mice.
Conclusion: In healthy skin *S. epidermidis*, as part of the skin microbiota, alarms keratinocytes and thus creates a protective environment which prevents *S. aureus* from colonizing the skin. Further studies will provide deeper insight into the mechanisms of the IL-1R-mediated modulation of the innate immune response, which reduces *S. aureus* skin infection.

P.D1.03.03

Synergistic action of soluble-pattern recognition molecule pentraxin 3 (PTX3) with myeloperoxidase (MPO)-mediated bacteria killing

***K. Daigo**[1,2,3], D. Morone[2], S. Valentino[2], M. Sironi[2], F. Petroni[2], A. Doni[2], A. Inforzato[2], B. Bottazzi[2], A. Mantovani[2];*
[1]Nippon Medical School, Kanagawa, Japan, [2]IRCCS Humanitas Research Hospital, Milan, Italy, [3]The University of Tokyo, Tokyo, Japan.

Introduction: PTX3 is a soluble-pattern recognition molecule that plays non-redundant protective roles against infections through pathogens recognition, complement regulation and opsonization. PTX3 comprises eight-identical protomers, each consisting of a conserved C-terminal pentraxin domain and an N-terminal domain unrelated to other proteins. We previously reported that PTX3 interacts with MPO, a bactericidal enzyme in neutrophils. Both PTX3 and MPO have been reported as protective molecules against *Aspergillus fumigatus* infection. Aim of our study is to investigate the role of PTX-MPO interaction on *A. fumigatus* conidia killing. Results: Characterizing structural features of PTX3-MPO interaction, we found that PTX3 N-terminal domain was responsible for MPO binding. Surprisingly, MPO enzymatic activity was increased in the presence of PTX3, an effect recapitulated by the PTX3 N-terminal domain. Consistent with the effect, PTX3 enhanced MPO-mediated conidia killing and this action was mainly exerted by PTX3 N-terminal domain. In contrast, when we evaluate the influence of PTX3 to conidia-bound MPO, we observed that full-length of PTX3 had no effect, while PTX3 N-terminal domain maintains the capacity to enhance both enzymatic and conidia killing activity of MPO. Finally, preliminary data indicated that exogenous PTX3 can amplify MPO-mediated conidia killing in neutrophil extracellular traps (NETs) from human neutrophils. Conclusions: Our data show that PTX3, through its interaction with MPO, can amplify MPO-mediated conidia killing mainly through the N-terminal domain. This could represent a novel antimicrobial mechanism of PTX3. Further studies will be needed to define the impact of our observations on the anti-microbial effects exerted by PTX3 in neutrophils.

P.D1.03.04

Effects of silicon-rich water intake during chronic ingestion of aluminum on the systemic and peritoneal inflammation

T. Dzopalic[1], *Z. Radovanovic*[1], *B. Djindjic*[1], *A. Veljkovic*[1], *M. Dunjic*[2], *D. Krstic*[3], *N. Djindjic*[1], *B. Bozic Nedeljkovic*[4];
[1]*University of Nis, Medical Faculty, Nis, Serbia,* [2]*European University, Novi Sad, Serbia,* [3]*University of Nis, Faculty of Occupational Safety, Nis, Serbia,* [4]*University of Belgrade, Faculty of Biology, Belgrade, Serbia.*

Introduction: Ingestion of the aluminum by nutrients lead to its accumulation in human tissues, inducing various disorders. Silicon-rich water is a great source of bioavailable silicic acid, a natural antagonist of aluminum. The aim of study was to evaluate the role of silicon-rich water intake on the systemic inflammation and functional characteristics of peritoneal macrophages (PMs) of rats chronically exposed to low levels of aluminum. Materials and Methods: One month-old female Wistar Albino rats were administered aluminum chloride dissolved in distilled water (1.6 mg/kg body weight in 0.5 mL) by gavage for 90 days. The rats were then given standard (6 mg/L) or silicon-rich (19 mg/L silicon) water (n=7/group). Control rats underwent sham gavage and received standard or silicon-rich water (n=7/group). Blood was assessed for cytokine levels by ELISA. Unstimulated and lipopolysaccharide (LPS)-stimulated PMs were examined in terms of phagocytic activity and cytokine secretion. Results: Treatment with silicon-rich water did not change serum TNF-α levels in aluminum-treated animals compared to non-treated animals. Aluminum-intoxication increased serum IL-2 and this was reversed by silicon-rich water ingestion. LPS-stimulated PMs from aluminum-intoxicated rats exhibited low phagocytic activity and release of TNF-α, this was significantly improved by silicon-rich water intake. The presence of silicon-rich water induced significant production of IL-10 by LPS-stimulated and unstimulated PMs of aluminum-exposed rats. Conclusions: Chronic ingestion of aluminum initiated systemic and peritoneal inflammation, while silicon-rich water restored levels of IL-10 and TNF-α produced by PMs thus preventing prolonged inflammation. Finally, silicon intake can decrease the immunotoxicity of aluminum.

P.D1.03.05

High protein diet influneces the severity of colitis in mice

A. Fajstova*, K. Klimesova, N. Galanova, S. Coufal, Z. Stehlikova, M. Kostovcik, M. Buganova, H. Tlaskalova-Hogenova, M. Kverka;*
Institute of Microbiology of the CAS, Prague, Czech Republic.

Introduction: Gut microbiome composition is strongly influenced by our diet, which also influences immune response. The aim of our experiments was to examine the association of diet, microbiome and immune response with Inflamatory bowel diseases development. Methods: We kept conventionaly (CV) reared and germ-free (GF) BALB/c mice and RAG2-/- mice on BALB/c background on High protein diet (HPD) or Control diet (CTRL) for 2-3 weeks. Then, we used 3% Dextrane Sodium Sulfate in drinking water to induce acute colitis. After 5 days, we terminated the experiment, evaluated the severity of colitis and collected samples. Results: We found that acute colitis was more severe in HPD fed CV mice compared to CTRL. HPD fed mice had shorter colon, higher disease activity index (calculated from weight loss, bleeding and diarrhea), greater weight loss and histological evaluation of colon samples showed more damage of the tissue. Similarly, in immunodeficient RAG2-/-mice, colitis was more severe in mice fed with HPD. Although there were no significant differences in general microbiome composition between mice on HPD versus CTRL diet, gut microbiota could have a role in the colitis development. Interestingly, in GF mice, acute colitis was equally severe on both diets. As expected, we found significant differences in metabolites pattern in feces of CV versus GF mice which may suggest that the effect of microbiota is probably mediated through metabolite production which can influence immune system activity. This work has been supported by grant 16-06326S from Czech Science Foundation.

Introduction: Inflammatory bowel disease is an immune-mediated disorder triggered by environmental factors affecting the mucosal barrier and the gut microbiota balance. While analyzing DSS-induced colitis in genetically similar C57BL/6 mice housed in two different animal facilities, we serendipitously observed a group of animals with a remarkable resistance to disease development. We aim to identify the microbial organisms/metabolites responsible for the protective phenotype.
Methods: C57BL/6 mice were administered with 3% DSS and disease activity index was scored. Colonic histological evaluation was performed by Hematoxylin-Eosin. Stool samples were analyzed by metagenomics while colon/serum metabolites were screened by NMR. Intestinal epithelial barrier function and permeability were evaluated by qPCR and FITC-dextran translocation.
Results: The two groups of mice display distinct microbiome and metabolic profiles, clustering separately in multivariate data analysis. We identified 2 bacterial species that are statistically enriched in resistant mice. These can be at the genesis of the protective phenotype, since fecal microbiota transplant from resistant to susceptible mice was able to reverse the susceptibility to colitis. From the 37 metabolites quantified by NMR, 12 are significantly increased in resistant mice. Moreover, our data shows significantly increased levels of IL-10, IL-17 and IL-22, as well as increased expression of claudin- and mucin-encoding genes in resistant mice prior to colitis induction.
Conclusions: Our results suggest that resistant mice display an intestinal epithelial barrier more prone to sustain an inflammatory insult. We are currently modulating the microbiome with putative microbiota/metabolic candidates to explore which mechanisms are contributing for protection to intestinal inflammation.

L-Threonine supplementation during colitis induction impairs goblet cell number and delays disease recovery

J. Gaifem[1,2], *L. Gonçalves*[3], *R. Dinis-Oliveira*[4,5,6], *C. Cunha*[1,2], *A. Carvalho*[1,2], *E. Torrado*[1,2], *F. Rodrigues*[1,2], *M. Saraiva*[7,8], *A. Castro*[1,2], *R. Silvestre*[1,2];

Introduction: Dietary nutrients have emerged as potential therapeutic adjuncts for inflammatory bowel disease (IBD) given their impact on intestinal homeostasis through the modulation of immune response, gut microbiota composition and epithelial barrier stability. Several nutrients have already been associated with a protective phenotype. Yet, there is a lack of knowledge towards the most promising ones as well as the most adequate phase of action.
Methods: C57BL/6 mice were administered with 2% DSS. The colon metabolic profile was assessed by NMR. Alcian Blue/PAS was performed for goblet cell counting. Cytokine levels were measured by ELISA.
Results: We have observed a 2-fold decrease in threonine levels in mice subjected to colitis. We assessed the effect of threonine supplementation in the beginning of the inflammatory process (DSS+Thr) or when inflammation is already established (DSS+Thr D8). Colitis progression was similar between treated groups and control colitic mice, yet threonine had a surprisingly detrimental effect when administered in the beginning of the disease, with mice displaying a delayed recovery when compared to control mice and DSS+Thr D8 mice. Although no major changes were found in their metabolic profile, DSS+Thr mice displayed altered expression in mucin-encoding genes and in goblet cell counts, unveiling an impaired ability to produce mucus. Moreover, IL-22 secretion was decreased in DSS+Thr mice when compared to DSS+Thr D8 mice.
Conclusion: These results suggest that supplementation with threonine during colitis induction impact goblet cell number and delays the recovery period. This reinforces the importance of a deeper understanding regarding threonine supplementation in IBD.

Comparative genomics and *in silico* epitope prediction for the development of specific monoclonal antibodies for microorganisms in drinking water

M. Göthel[1], *S. Hoppe*[2], *M. von Nickisch-Rosenegk*[2], *K. Hanack*[1];
[1]*University Potsdam, Department of Biochemistry and Biology, Immunotechnology group, Potsdam, Germany,* [2]*Fraunhofer Institute for Cell Therapy and Immunology, Branch Bioanalytics and Bioprocesses (IZI-BB), Department of Bioanalytics and Biosensorics, Potsdam, Germany.*

Introduction: Contamination of drinking water by pathogenic microorganisms is a great concern worldwide and leads to severe infections in humans. So far, the diagnostic detection of these pathogens is mainly performed by microbiological methods such as cultivating the sample on agar plates and counting of the colonies. Flow cytometry and cell enzyme-linked immunosorbent assay (ELISA) are alternative methods to improve the monitoring of water quality. Therefore, specific monoclonal antibodies are indispensable for these techniques.

Methods: In this study, we performed a comparative genomics analysis based on next generation sequencing data of 50 microbial genomes to identify *E.coli* specific antigens useful as potential antibody targets. The genes presented in 30 different pathogenic *E.coli* strains but absent in 20 nonpathogenic *E. coli*/non-*E.coli* strains were subjected to an *in silico* analysis to identify secreted or surface-expressed proteins.
Results: From 226.735 genes we obtained a total of 10 genes which encode potential protein candidates. We analyzed the resulting proteins for linear epitope prediction as well as epitope surface accessibility and antigenicity. The epitopes with the highest scores to harbor specific epitopes have been cloned into a viral carrier protein used for immunization. With this approach we generated monoclonal antibodies specific to pathogenic *E.coli,* which could be part of a diagnostic tool for the detection of drinking water contaminations.
Conclusions: The described bioinformatic approach is able to identify novel epitope candidates for the generation of specific monoclonal antibodies specific to pathogenic microorganisms.

P.D1.03.09
Innate Recognition and Inflammasome Activation in Human Myeloid Immune Cells by Methanogenic Archaea

*T. Vierbuchen[1], C. Bang[2], R. Schmitz[3], **H. Heine**[1];*
[1]Research Center Borstel, Div. of Innate Immunity, Borstel, Germany, [2]University Hospital Schleswig-Holstein, Institute of Clinical Molecular Biology (IKMB), Kiel, Germany, [3]Kiel University, Institute for General Microbiology, Kiel, Germany.

The importance of the microbiota on health and immune homeostasis is widely accepted and the interaction between the microbiota and our body is currently investigated. However, most of these studies are focusing on bacteria alone, although viruses, fungi and archaea are also part of this microbial community. Recent studies showed that archaea are present at nearly every part of the body but their contribution to health and disease is not understood. It is known that the gut-associated methanogenic archaeon *Methanosphaera stadtmanae* induces inflammatory responses, however, the mechanism how this archaeon is sensed by the immune system has not been evaluated until now. This study aims to elucidate the receptors, archaeal structures and signaling pathways that are engaged upon activation of human immune cells by *M. stadtmanae*.
We show that *M. stadtmanae* induces secretion of pro-inflammatory cytokines as well as expression of type I and III interferons in primary human myeloid cells as well as in the monocytic cell line BLaER1. CRISPR/Cas9 generated KO cells were used to identify TLR7 and TLR8 as main receptors for recognition of *M. stadtmanae*. Furthermore, the archaeon induces a TLR8-dependent activation of the NLRP3 inflammasome sharing features with the LPS-induced alternative pathway.
For the first time, our results describe specific recognition of an archaeon by human immune cells in detail. As some studies indicate a potential connection of *M. stadtmanae* to inflammatory bowel disease and lung hypersensitivity, our findings might help to understand how archaea are involved in inflammatory diseases.

P.D1.03.10
The antigen specificity of resident memory T cells in the human lungs

*A. Oja[1], F. Morgana[1], B. Bardoel[2], D. van der Zwan[1], J. Mok[3], M. Maas[3], G. Brasser[3], R. van Lier[1], W. van Esch[3], **P. Hombrink**[1];*
[1]Department of Hematopoiesis, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands, [2]Bacterial Infections and Immunity, University Medical Center Utrecht, Utrecht, Netherlands, [3]Department of Reagents, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands.

Resident memory T-cells (TRM) are critical for local adaptive immune responses. In the lungs TRM are elementary for protection against airborne pathogens. This protection is superior relative to that provided by circulating T-cells and is modulated by the release of cytotoxic molecules. As TRM are in disequilibrium with circulation and most antigen discovery studies rely on peripheral blood for readout, little is known about the magnitude, phenotype and specificity of protective T-cell populations in the lungs. In this study we simultaneously dissect the phenotype and function of CD4+ and CD8+ T-cells in human lung tissue and compare these to the blood compartment. By using extensive HLA-tetramer combinatorial coding screens we analyzed the phenotype and frequency of lung CD8+ T-cells specific for respiratory and systemic viruses in donors with no recent history of infection. We demonstrate an enrichment of respiratory specific T-cells in the lung CD8+ T-cell compartment. While *Influenza* and *RSV* reactive CD8+ T-cells are biased to a CD103+ TRM phenotype, those specific for *CMV* and *EBV* are phenotypically identical to circulating cells. In contrast, influenza reactive CD4+ T-cells in the lungs lack expression of CD103, suggesting a strict spatial regulation. In addition we mapped the lung CD4+ T-cell response to the human pathogens *Staphylococcus aureus* and *pneumonia* using libraries of recombinant proteins and discovered novel immunodominant responses. The ability to monitor antigen-specific T-cell responses in human lungs, will facilitate subsequent translation into vaccination strategies that aim to boost local protection to airborne pathogens.

P.D1.03.11
MAIT cells are recruited to the intervillous space of the placenta by placenta-derived chemokines

*M. Solders[1], L. Gorchs[1], E. Tiblad[2,3], S. Gidlöf[2,3,4], E. Leeansyah[5,6], J. Dias[5], J. K. Sandberg[5], I. Magalhaes[7], A. Lundell[8], **H. Kaipe**[1,9];*
[1]Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of CLINTEC, Karolinska Institutet, Stockholm, Sweden, [3]Center for Fetal Medicine, Karolinska University Hospital, Stockholm, Sweden, [4]Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, [5]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden, [6]Program in Emerging Infectious Diseases, Duke-National University of Singapore Medical School, Singapore, Singapore, [7]Department of Oncology/Pathology, Karolinska Institutet, Stockholm, Sweden, [8]Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [9]Clinical Immunology and Transfusion Medicine, Karolinska University Hospital, Stockholm, Sweden.

The intervillous space of the placenta is a part of the fetal-maternal interface, where maternal blood enters to provide nutrients and gas exchange. Little is known about the maternal immune cells at this site, which are in direct contact with fetal tissues. We have characterized the immune cell composition and chemokine profile in paired intervillous and peripheral blood from healthy mothers giving birth at term. We found that mucosal-associated invariant T (MAIT) cells were enriched in the intervillous blood compared to peripheral blood. Pregnant women had lower proportions of peripheral MAIT cells compared to non-pregnant women, further indicating that MAIT cells home to the placenta during pregnancy. We observed that the levels of several chemokines were dramatically higher in intervillous compared to peripheral blood, including MIF, CXCL10, and CCL25, whereas others were lower. Migration assays showed that MAIT cells migrate towards conditioned medium from placental explants. A multivariate discriminant analysis indicated that high levels of MIF and CCL25 were associated with high proportions of MAIT cells in intervillous blood. A positive correlation was observed between MAIT cell proportions and MIF levels in intervillous, but not in peripheral blood. Blocking of MIF or a combination of MIF, CCL25, and CCL20 in migration assays decreased the number of migrating MAIT cells. Finally, MAIT cells showed migratory capacities towards recombinant MIF. Together, these findings indicate that term placental tissues attract MAIT cells, and that this is partly mediated by MIF. The importance of MAIT cells in pregnancy remains to be determined.

P.D1.03.12
Experimental high-fat diet consumption leads to intestinal barrier damage and severe colitis

***K. Klimesova**, N. Galanova, A. Fajstova, S. Coufal, M. Kostovcik, M. Buganova, H. Tlaskalova-Hogenova, M. Kverka;*
Institute of Microbiology CAS, Prague, Czech Republic.

Diet is important environmental factor influencing gut homeostasis. Increased fat intake has been related to higher risk of inflammatory bowel disease development. Here, we focused on effects of high-fat diet consumption on colitis development in mouse model. Fourteen days before colitis induction, we transferred mice to diet with increased or normal fat content - high-fat diet (HFD, 22% fat) or control diet (CD, 5% fat), respectively. Then, we induced colitis with 3% dextran sodium sulfate (DSS) in drinking water for 7 days. Before DSS treatment, mice consuming HFD gained approximately twice more weight than CD mice and they have also significantly longer colon and bigger spleen. Moreover, HFD mice showed increased permeability of intestine measured by fluorescein isothiocyanate-conjugated dextran and mild inflammatory changes observed by microscopical analysis of hematoxylin/eosin stained sections. DSS treatment in HFD mice led to significant reduction of their body weight, diarrhea and rectal bleeding. The length of colon did not change significantly but spleen weight doubled compared to CD mice. In spleen of HFD mice, we found significant increase in Th17 cells - CD4+RorgT + population measured by flow cytometry, and higher production of IL-17 after CD3/CD28 stimulation. In conclusion, we confirmed that HFD significantly increased the sensitivity of mice to DSS colitis. Mice consuming HFD developed low local and systemic inflammation which could lead to mucosal immune system exhaustion and induction of systemic Th17 response. The study has been supported by Czech Science Foundation grants no. 16-06326S and 17-06632Y.

P.D1.03.13
Polyunsaturated fatty acids (PUFAs) dampen the inflammatory antiviral immune response by diminishing two dimensional (2D) antigen recognition by T cells

***E. M. Kolawole**, B. D. Evavold;*
University of Utah, Salt Lake City, United States.

Polyunsaturated fatty acids (PUFAs) have been shown to dramatically influence inflammatory responses. Although omega-3 fatty acids lead to the production of less inflammatory metabolites, little is known about how PUFAs change surface protein interactions and T cell activation. To probe the protein interactions, we utilized novel 2D based technologies for single cell and single molecule analyses of T cell receptor (TCR) engagement with peptide-MHC (pMHC) antigen. We found that dietary fish oil decreased 2D affinity of T cell receptor transgenic and polyclonal T cell responses in both CD8 and CD4 T cells at peak anti-viral immunity to lymphocytic choriomeningitis (LCMV) infection. In addition, an omega-3 based diet manipulated structural lipid content in plasma membranes leading to a reduced T cell frequency and changes in the prevalence of immunodominant epitopes. This reduced affinity led to decreased markers of activation and effector function. These data indicate that a major effect of dietary omega-3 fatty acids on T cells is the modification of the cell membrane to dampen the initial recognition of antigen.

P.D1.03.14

the dietary food additive maltodextrin promotes endoplasmic stress-driven mucus depletion and exacerbates intestinal inflammation

F. Laudisi[1], *D. Di Fusco*[1], *V. Dinallo*[1], *C. Stolfi*[1], *A. Di Grazia*[1], *I. Marafini*[1], *A. Colantoni*[1], *A. Ortenzi*[1], *C. Alteri*[1], *F. Guerrieri*[2], *F. Ceccherini-Silberstein*[1], *M. Federici*[1], *T. T. MacDonald*[3], *I. Monteleone*[1], *G. Monteleone*[1];
[1]*University of Rome Tor Vergata, Rome, Italy,* [2]*Istituto Italiano di Tecnologia, Rome, Italy,* [3]*Queen Mary University of London, London, United Kingdom.*

Food additives, such as emulsifiers, stabilizers or bulking agents, are present in the western diet and their consumption is increasing. However little is known about their potential effects on intestinal homeostasis. In this study we examined the effect of some of these food additives on gut inflammation. Maltodextrin (MDX)-enriched diet exacerbated intestinal inflammation in experimental models of colitis and ileitis. Analysis of the mechanisms underlying the detrimental effect of MDX revealed up-regulation of the inositol-requiring enzyme (IRE)1β, a sensor of endoplasmic reticulum (ER) stress, in goblet cells and reduction of mucin-2 expression with no significant change in mucosa-associated microbiota composition. Stimulation of murine intestinal crypts and the human mucus-secreting cells with MDX induced IRE1β via a p38 MAP kinase-dependent mechanism. Treatment of mice with the ER stress inhibitor Tauroursodeoxycholic acid prevented mucin-2 depletion and attenuated colitis in MDX-fed mice. Interestingly, mice receiving a prolonged MDX-enriched diet exhibited low-grade intestinal inflammation, which was characterized by focal inflammatory infiltrates, distortion of gland architecture and edema. In conclusion, this study shows, for the first time, that MDX-enriched diet triggers ER stress in goblet cells with consequent reduction of the intestinal content of mucin-2, thus making the host more sensitive to colitogenic stimuli. Our data supports the hypothesis that western diet rich in the food additive MDX can contribute to gut disease susceptibility.

P.D1.03.15

Identification of perturbed immune responses at the transcriptional and metabolic levels during Tuberculosis disease

A. Llibre[1,2], *E. Nemes*[3], *V. Rouilly*[1], *C. Posseme*[1,2], *S. Mabwe*[3], *B. Charbit*[4], *H. Mulenga*[3], *M. Musvosvi*[3], *S. Thomas*[1,2], *N. Bilek*[3], *T. J. Scriba*[3], *M. L. Albert*[2,4,5], *D. Duffy*[1,2,4], *Milieu Intérieur Consortium;*
[1]*Immunobiology of Dendritic Cells, Institut Pasteur, Paris, France,* [2]*Inserm U1223, Institut Pasteur, Paris, France,* [3]*South African Tuberculosis Vaccine Initiative, Division of Immunology, University of Cape Town, Cape Town, South Africa,* [4]*Centre for Translational Research, Paris, France,* [5]*Genentech Inc, San Francisco, United States.*

One quarter of the world's population is estimated to be latently infected with tuberculosis (TB). Adherence to treatment and emergence of multidrug resistance strains are key challenges for achieving TB eradication. Thus, new treatments are urgently needed and host targeted therapies offer great potential.
IFN-g (type II IFN) plays an essential role in the immune control of TB, however, the role of type I IFNs in M. tuberculosis (M. tb) infection remains controversial. It has also been reported that a shift from oxidative phosphorylation to aerobic glycolysis occurs in M. tb infected macrophages. We wish to understand the dynamics between IFN and cellular metabolism; bringing new insights into TB pathogenesis that may lead to the development of novel immunotherapies, targeting both immune and/or metabolic host cell pathways. Using M. tb antigens, we stimulated whole blood using the TruCulture system from 25 active TB patients (pre and post treatment) and 25 asymptomatic individuals with M. tb infection. Protein, metabolomic and gene expression analysis of more than 600 genes was performed using Luminex multi-analyte profiling, Mass Spectroscopy and Nanostring technologies, respectively.
We observed at baseline a high type I IFN transcriptional signature, a perturbed glycolysis pathway and diminished expression of MHC-II related genes in active TB patients as compared to controls. We detected stimuli-specific differences between asymptomatic controls and active cases, both at gene expression and metabolomic levels. Many of these perturbed phenotypes were restored to control levels after successful treatment suggesting that they may serve as on treatment prognostic biomarkers.

P.D1.03.16

Immunoglobulin G coating shows earlier microbiota-host interaction in MCJ-deficient model during murine experimental colitis

A. Peña Cearra[1], *M. A. Pascual-Itoiz*[2], *A. Fullaondo*[3], *J. Anguita*[2], *L. Abecia*[2];
[1]*CIC bioGUNE and University of the Basque Country, Derio, Spain,* [2]*CIC bioGUNE, Derio, Spain,* [3]*University of the Basque Country, Leioa, Spain.*

Introduction: Ulcerative Colitis (UC) is a relapsing disorder of the gastrointestinal tract characterized by intestinal inflammation and epithelial injury. Although, the precise cause of UC remains unknown, microbial-host interactions and mitochondrial dysfunction play a critical function. Therefore, it is needed to know the role that a natural negative regulator of mitochondrial respiration such as Methylation-controlled J protein (MCJ) exerts in the disease.
Materials and Methods: To analyze host-microbiota interaction in a Dextran Sodium Sulfate (DSS)-mediated colitis and antibiotic-mediated dysbiosis model, wild type and MCJ-deficient mice were used. Dysbiosis was promoted administrating orally a broad spectrum antibiotic, twice per day during 7 days. Later, colitis was induced by adding 3% (w/v) DSS (36-50 KDa) in the drinking water for 6 days followed by a 2 day recovery period. Flow cytometry was used to quantify IgG coated fecal bacteria. GraphPad software was used for statistical analysis.
Results: After 7 days of antibiotic administration, dysbiotic mice presented higher percentage of IgG coated bacteria compared to non dysbiotic groups. At day 6, dysbiotic non colitis mice reached basal IgG levels. However, after 6 days of DSS administration, colitis mice showed higher IgG levels except for non dysbiotic control mice that took until day 8.
Conclusion: Antibiotic administration affected IgG coating bacteria. Basal levels were recovered in 6 days, indicating the period that hosts immune system needs to achieve bacterial tolerance. However, higher IgG coating in MCJ deficient non dysbiotic colitis group indicated earlier microbial-host cross-talk due to the lack of MCJ.

P.D1.03.17

Lifelong asymptomatic infections: The role of the microbiota

R. Romero[1], *A. Zarzycka*[1], *A. Visekruna*[1], *F. Fischer*[1], *G. Frankel*[2], *B. Stecher*[3], *U. Steinhoff*[1];
[1]*Institute for medical microbiology and clinical hygiene, Marburg, Germany,* [2]*Imperial College London, London, United Kingdom,* [3]*Max von Pettenkofer-Institut, Munich, Germany.*

Introduction: *Citrobacter rodentium* is an enteric murine pathogen that is suitable to model lifelong asymptomatic infections of humans with the enteropathogenic *E. coli* (EPEC). It is still unknown why some individuals become lifelong asymptomatic carries of EPEC and unknowingly spread the disease, while others can develop an acute, in some cases life-threatening, clinical manifestation. This immunological situation can be mimiked in germ-free (GF) mice, as these animals are unable to eliminate *C. rodentium* and become lifelong asymptomatic carriers of the bacterium.
Material and methods: Bacterial communities essential for the elimination of *C. rodentium* were assessed by analysis of the microbiota composition. 16S rDNA sequencing, MALDI and FACS analysis were performed to analyze microbial populations. Immunological analyses of *C. rodentium* infected mice were performed by FACS, qPCR and histology.
Results: Conventionalization of GF-mice reverses the asymptomatic carrier state by mediating activation and migration of neutrophils into the intestine. Interestingly, colonization of GF mice with 12 bacteria representing the five most prevalent phyla of the intestinal microbiome is insufficient to induce clearance. This shows that distinct bacterial species are able to trigger a proper immune response that results in sterile clearance of the pathogen. Conclusions: Eradication of asymptomatic infections with enteropathogens is mediated by the activation of immune cells through specific commensals. Surprisingly, dominant bacteria representing the microbial phyla can not compensate for the lack of these specifc bacteria. These results may explain why humans despite harbouring a complex microflora may become aysmptomatic carriers.

P.D1.03.18

Inflammatory monocytes promote bacterial resistance to antibiotic killing during influenza and*Staphylococcus aureus* coinfection

K. J. Fischer, V. Kumar Yajjala, C. Bauer, S. Bansal, R. Chen, ***K. Sun****;*
University of Nebraska Medical Center, Omaha, United States.

Methicillin-resistant *Staphylococcus aureus* (MRSA) has emerged as a significant contributor to morbidity and mortality during recent influenza pandemics and epidemics. The mechanism responsible for this influenza-induced susceptibility to secondary bacterial infection is incompletely understood. We have previously shown in a clinical-relevant mouse model that preceding influenza infection suppresses the effectiveness of antibiotics for treatment of secondary *S. aureus* infection. This suppression coincides with influenza-induced accumulation of inflammatory monocytes. C-C chemokine receptor type 2 (CCR2) is responsible for pulmonary monocyte recruitment after influenza infection. Here we demonstrate that compared with wild-type animals, CCR2-deficient ($Ccr2^{-/-}$) mice are more resistant to post-influenza *S. aureus* infection, despite a delay in viral clearance. In agreement with their increased survival rate, influenza/MRSA co-infected $Ccr2^{-/-}$ mice exhibit a significantly improved ability in lung bacterial clearance, with or without antibiotic treatment. Mechanistically, our results suggest that influenza-induced inflammatory monocytes serve as reservoirs to protect bacteria from killing by antibiotics and more potent neutrophils, thereby promoting lung bacterial persistence during secondary *S. aureus* infection. Collectively, we demonstrate in this study that inflammatory monocytes constitute an important and hitherto underappreciated mechanism of the conflicting immune requirements for viral and bacterial control in the lung, which subsequently leads to exacerbated outcomes of influenza and *S. aureus* coinfection. (This work was supported by National Institutes of Health/National Heart, Lung, and Blood Institute R01 HL118408 to K.S.)

P.D1.03.19

Vgamma9Vdelta2 T cells proliferate in response to phosphoantigens released from erythrocytes infected with asexual and gametocyte stage *Plasmodium falciparum*

C. Liu[1], *N. Emami*[2], *J. Pettersson*[3], *L. Ranford-Cartwright*[4], *I. Faye*[2], *I. Parmryd*[1];
[1]*Medical cell biology Uppsala univerisity, Uppsala, Sweden,* [2]*Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm University, Stockholm, Sweden,* [3]*Department of Chemistry, Uppsala University, Uppsala, Sweden,* [4]*Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom.*

Introduction:Vγ9Vδ2 T cells are the dominant γδ T cell subset in human peripheral blood. Vγ9Vδ2 T cells are activated by phosphoantigens, primarily isoprenoid pyrophosphates. It has long been known that phosphoantigens that stimulate Vγ9Vδ2 T cells are released from *Plasmodium falciparum*-infected erythrocytes upon schizont rupture, but recently it was reported that release also occurs at the ring stage of the parasite life cycle. We therefore set out to investigate whether phosphoantigens are released at any other of the blood stages. **Basic Method:** Pure cultures of *Plasmodium falciparum*-infected erythrocytes at all asexual stages were obtained using a combination of a plasmion and sorbitol synchronization and of sexual gametocytes by using heparin. Sterile-filtered media from the cultures was assessed for its ability to cause proliferation of Vδ2 T cells from human PBMCs. **Results**:Vγ9Vδ2 T cells were proliferated by addition of the media from erythrocytes infected with parasites at all blood stages (ring, trophozoite, schizont, rupturing schizont and gametocytes). The proliferation was caused by phosphoantigens, verified by phosphatase-treatment. The iron-levels in the media from infected cultures were not elevated indicating that erythrocyte rupture was minimal. **Conclusion**: Phosphoantigens in sufficient quantities to stimulate Vδ2 T proliferation are released by intact parasite-infected erythrocytes at all blood-stages of the parasite life cycle. **Grants**: This work was supported by grants from INFRAVEC (EU/FP7) to IF and the Swedish Research Council, AFA Insurance and Claes Groschinsky's Foundation to IP.

Assessment of multivalent viral vectored vaccines against outbreak pathogens: Ebola, Marburg & Lassa

A. Flaxman[1], *S. Sebastian*[1], *C. Gilbride*[1], *H. Sharpe*[1], *S. Dowall*[2], *S. Charlton*[2], *J. Purushotham*[1], *A. Hill*[1], *S. Gilbert*[1], *T. Lambe*[1];
[1]*Jenner Institute, University of Oxford, Oxford, United Kingdom,* [2]*Public Health England, Salisbury, United Kingdom.*

Since the 2013-2016 Ebolavirus outbreak, there have been a number of other documented outbreaks of lethal haemorrhagic fever caused by filoviruses and arenaviruses. Filovirus family members including Ebolavirus and Marburg virus and arenaviruses such as Lassa virus cause haemorrhagic fevers with high mortality rates in humans. As yet, no specific treatment or prophylactic multivalent vaccine against filoviruses or arenaviruses has been licensed. It is generally accepted that either a mixture of monovalent vaccines or, preferably, a multivalent vaccine, will be required to confer protective immunity against viral haemorrhagic fever. The costs of developing individual vaccines against filoviruses and an arenavirus (Lassa virus (LASV)) may be prohibitively high. Considering the geographical overlap between Ebola, Marburg and Lassa virus endemic areas, a multivalent vaccine would be of significant benefit. Our pre-developed core vaccine platforms (adenoviral vectors and MVA) can express multiple antigens and have demonstrated capability for the induction of durable immune responses in other infectious disease settings e.g. influenza/malaria.
We have now used this technology to develop multivalent vaccines against several lethal haemorrhagic fever- causing viruses, including Filoviruses (Ebolaviruses & Marburg virus) and Arenaviruses (Lassa virus). These vectors elicited antigen expression *in vitro* and were immunogenic *in vivo*. We assessed different vaccination regimes in mice and tested efficacy by challenging guinea pigs with Ebola Zaire post-vaccination. Our viral vectored vaccines showed protection from disease in this model. Therefore, we have successfully developed preclinical vaccine candidates against three outbreak pathogens (Ebola, Marburg and Lassa) using a multivalent platform.

P.D1.03.21

omplex and unusual antigen-specific activation ofVδ2+ gamma-delta T-cells by the BTN3A-receptor complex.

D. A. Rhodes[1], *S. Smith*[1], *J. Trowsdale*[1], *N. McCarthy*[2], *M. Eberl*[3];
[1]*University of Cambridge, Cambridge, United Kingdom,* [2]*Centre for Immunobiology, Blizard Institute, London, United Kingdom,* [3]*Systems Immunity Research Institute, Cardiff University, Cardiff, United Kingdom.*

The gamma delta T-cell pool in human blood is dominated by Vγ9/Vδ2 (Vδ2+) T-cells, which are specialised to detect phosphoantigens (pAg) produced by microbes and tumours. Activation of Vδ2+ T-cells by pAg HMB-PP and IPP requires expression of BTN3A molecules by presenting cells. At present it is not clear what conformation of the three BTN3A isoforms transmits activation signals nor how they are regulated. To investigate this, we used BTN3A knockout HeLa cells (HeLa/sgBTN3A), generated by CRISPR/cas9 gene editing, together with stable re-expression of BTN3A isoforms in all combinations. BTN3A1 and BTN3A3 proteins were subject to cell intrinsic suppression, whereas BTN3A2 was expressed constitutively. In co-culture experiments with expanded Vδ2+ T-cells, we confirmed that BTN3A1 was necessary but not sufficient to transmit activation signals, with BTN3A2 and/or BTN3A3 also being required. There were differences in responses induced by activating stimuli, HMB-PP, IPP and agonist antibody CD277 20.1. The combination of BTN3A1 with BTN3A3 induced more potent cytotoxicity and cytokine production as measured by lactate dehydrogenase release and IFN-γ secretion into co-culture medium, whereas the BTN3A2/BTN3A3 combination was non-functional by these stimuli. A critical role for the BTN3A1 and BTN3A2 juxta-membrane domains, pivotal in shaping the BTN3A-dependent activating epitope required for γδ T cell receptor engagement, was shown. Our results reveal additional complexity and highlight the unusual nature of the antigen-specific activation of human Vδ2+ T-cells, which is regulated by cell intrinsic mechanisms linked to infection and cell transformation by pAg sensing and control of BTN3A protein stability.

P.D1.04 Microbiome, metabolites and the immune system - Part 4

P.D1.04.01

***Anaeroplasma* of the phylum *Tenericutes* induce mucosal TGF-â and promote IgA production**

A. Beller[1], *A. Kruglov*[1,2], *P. Durek*[1], *K. Werner*[1], *V. von Goetze*[1], *J. Ninnemann*[1], *K. Lehmann*[1], *B. Siegmund*[3], *U. Hoffmann*[1], *G. A. Heinz*[1], *M. F. Mashreghi*[1], *A. Radbruch*[1], *H. D. Chang*[1];

In humans and mice, mucosal immune responses are dominated by IgA antibodies and the cytokine transforming growth factor beta (TGF-β), suppressing unwanted immune reactions but also targeting immunoglobulin class switching to IgA. IgA plays a central role in the interplay between the host cells and microbiota at the mucosal surfaces. The production of IgA as such is controlled by microbiota and requires the cytokine "transforming growth factor beta" (TGF-β), which induces IgA switch transcripts. However it has not been clear which bacteria direct production of IgA and how they do it. It had been suggested that eosinophils promote the generation and maintenance of mucosal IgA-expressing plasma cells. Here we demonstrate that not eosinophils, but specific bacteria enhance mucosal IgA production. We also now show that not the colonization of the intestinal tract and the stimulation of the intestinal immune with bacteria as such, but rather distinct microbial species lead to the preferential induction of intestinal IgA. Our data indicate that the bacteria of the genus *Anaeroplasma* increase numbers of IgA secreting plasma cells in the lamina propria of the small intestine, and significantly enhance mucosal IgA levels. *Anaeroplasma* controls IgA expression by inducing expression of the IgA class switch-inducing cytokine TGF-β in T follicular helper cells of Peyer´s patches. *Anaeroplasma* is also a part of the human microbiota. Its anti-inflammatory properties of inducing the immune regulatory cytokine TGF-β, strengthening the intestinal barrier by enhancing mucosal IgA, make it an interesting probiotic for the prevention and treatment of intestinal inflammation.

P.D1.04.02

Immune dysregulation in common variable immunodeficiency disorder: a role for *Enterococci*?

R. Berbers[1], *P. Ellerbroek*[1], *J. van Montfrans*[1], *M. Rogers*[1], *M. Viveen*[1], *F. Paganelli*[1], *V. Dalm*[2], *M. van Hagen*[1], *A. van de Ven*[3], *J. van Laar*[1], *R. Willems*[1], *H. Leavis*[1];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Erasmus Medical Center, Rotterdam, Netherlands,* [3]*University Medical Center Groningen, Groningen, Netherlands.*

Common variable immunodeficiency disorder (CVID) is the most common primary immunodeficiency, but its etiology is not well understood. Currently, only 10% of cases can be explained by genetic variants. This humoral immunodeficiency is often accompanied by immune dysregulation phenomena, including autoimmunity, granulomas and lymphoproliferation. Better understanding of the cause of CVID and the immune dysregulation phenotype is key to improving care for these patients. Given the limited genetic contribution to CVID and prevalence of gastrointestinal symptoms in these patients, a role for the gut microbiome has been hypothesized.We aimed to characterise the composition of the fecal microbiota of 106 CVID patients and 49 healthy controls (HC) cross-sectionally. 16S rRNA profiling revealed decreased diversity in CVID patients compared to HC. Interestingly, IgA deficiency did not change alpha diversity within CVID patients. Although patients did not cluster separately from controls in unsupervised analyses, in unsupervised analyses distinct groups of bacteria were significantly associated with CVID. *Escherichia coli* was more abundant in CVID patients as compared to HC. *Enterococcus* spp were increased in patients with immune dysregulation (n=50) as compared to those without (n=56), regardless of use of medication. *Veillonella dispar* was associated with enteritis, while bacteria belonging to the *Clostridiaceae* and *Bifidobacteriaceae* families were more abundant in relatively healthier patients. To conclude, immune dysregulation in CVID was associated with low bacterial diversity and increased abundance of *Enterococci*, a group of bacteria that has recently been implicated in autoimmunity.

P.D1.04.03

Understanding the interaction between vaginal microbiota and immunity; the role of immunoglobulin A

***A. Breedveld**, H. Schuster, L. Pedró-Cos, R. Mebius, D. Budding, M. van Egmond;*
VUmc, Amsterdam, Netherlands.

Immunoglobulin (Ig) A is the most prevalent antibody at mucosal surfaces and alterations in IgA coating of gut-resident bacteria have been associated with inflammatory bowel disease. An unbalanced vaginal microbiota was recently linked to preterm birth, raising the question whether IgA is involved in this process. Still, much less is known about the interaction between IgA, bacteria and the immune system of the female genital tract.
We determined the vaginal microbial composition of healthy women using IS-pro. IgA coating of the vaginal microbiota from healthy donors was measured with flow cytometry. Additionally, the presence of specific IgA against common vaginal bacterial strains in serum was examined. Neutrophils, monocytes and monocyte-derived dendritic cells (moDCs) were stimulated with IgA-opsonized vaginal bacteria for 30min to measure phagocytic capacity. Cytokine production after 24h stimulation of cells with IgA-opsonized vaginal bacteria will be measured using ELISA.
Healthy vaginal microbial composition was predominated with *Lactobacillus spp*. Vaginal swabs contained a high proportion of IgA-coated bacteria. Neutrophils, monocytes and moDCs showed increased phagocytic capacity for IgA-opsonized vaginal bacteria. These results demonstrate a mucosal and systemic IgA response against vaginal bacteria. Cytokine profile of innate immune cells after stimulation with IgA-coated bacteria will be established and bacterial cell sorting as well as molecular microbiota analysis will be performed to study taxa-specific IgA coating. We aim to use IgA coating of vaginal bacteria as predictor for preterm birth.

P.D1.04.04

BCG vaccination in the childhood of women influences their placenobiomeduring pregnancy: vertical transmission of mycobacterial L forms

***T. Dimova**[1], A. Terzieva[1], L. Djerov[2], A. Nikolov[2], V. Dimitrova[2], P. Grozdanov[3], N. Markova[3];*
[1]Institute of Biology and Immunology of Reproduction "acad. K. Bratanov", Bulgarian Academy of Sciences, Sofia, Bulgaria, [2]Medical University, University Obstetrics and Gynecology Hospital "Mother House", Sofia, Bulgaria, [3]Institute of Microbiology "Acad. St. Angelov", Bulgarian Academy of Sciences, Sofia, Bulgaria.

Introduction: It has been shown that maternal microbiota drives early postnatal innate immune development and prepares the newborn for host-microbial mutualism by vertical transfer of microbial molecules. Recent studies with human placenta found the presence of dynamic placental microbiome with specific metabolic functions, which effects on the developing fetus and neonate is still unknown. Since live mycobacterial L-forms could be found in the blood of BCG-vaccinated people, we aimed to investigate a possible trans-placental transfer of BCG L-forms from the blood of healthy BCG-vaccinated pregnant women to their neonates as well as the presence of specific gamma/delta T-cell response in the placentobiome. Materials and methods: Sterile obtained samples from early pregnancy deciduas, term placentas, maternal blood and cord blood were examined by isolation and appropriate cultivation, electron microscopy, qPCR and FACS. Results: We proved that the majority of the samples of maternal blood, gestational tissues and cord blood of healthy newborns delivered by healthy BCG-vaccinated pregnant women were colonized with mycobacterial L-forms. The transfer of L-forms occurs early in gestation and the maternal decidua mediates the process of placenta colonization. No specific expansion of pathogen-reactive Vdelta2 gamma/delta T cells was detected. Conclusions: Novel data about mother-to-newborn transmission of mycobacterial L forms suggests that BCG vaccination in the childhood of the woman may affect her placentobiome during pregnancy.

P.D1.04.05

Effects of obesity on Tick-borne encephalitis (TBE) booster vaccination

E. Pöllabauer[*1], **E. Garner-Spitzer***[*1], A. Wagner[1], A. Guzek[1], I. Zwazl[1], C. Seidl-Friedrich[1], S. Schulz[1], C. Binder[2], K. Stiasny[3], M. Kundi[4], U. Wiedermann[1];*
[1]Medical University of Vienna, Institute of Specific Prophylaxis and Tropical Medicine, Vienna, Austria, [2]Dept. for Laboratory Medicine, Medical University Vienna, Austria, Vienna, Austria, [3]Center of Virology, Medical University Vienna, Austria, Vienna, Austria, [4]Center for Public Health, Medical University Vienna, Vienna, Austria.

Obesity has significantly increased worldwide and has, apart from related co-morbidities, direct effects on the immune system leading to immune dysfunction and increased susceptibility to infectious diseases. Thus prophylaxis against vaccine preventable diseases is particularly important in obese individuals. In order to assess vaccine efficacy, we performed an open-label phase IV clinical trial with 37 obese individuals and 36 normal-weight controls, which were booster-vaccinated against tick-borne encephalitis (TBE). The general immunologic and metabolic profile along with vaccine-specific humoral and cellular immune responses were evaluated in sera and PBMC. Obese adults showed significantly increased metabolic (leptin, insulin, triglycerides, cholesterol) and pro-inflammatory (CRP) markers. Total immunoglobulin levels (IgM, IgA) were increased in obese vaccinees, while natural IgM against pathogens (PC) were significantly reduced, possibly indicating higher infection susceptibility. Obese individuals showed a stronger fold-increase of TBE-specific Ab titers 4 weeks after booster, which was positively correlated with metabolic parameters. However, Ab levels declined significantly faster within 6 months in this group. At cellular level, TBE-specific cytokines (IL-2, IFN-γ) were increased in obese vaccinees before vaccination and distributions of B- and T-cell subsets differed between obese and control group. Vaccine reactogenicity (local and systemic) was higher in obese subjects. Our results indicate that TBE booster vaccination was effective at humoral and cellular level in obese individuals; however, the higher decline rate in obese might lead to shorter long-term protection. Whether the effects of obesity on primary TBE vaccination are similar remains to be investigated. *contributed equally Supported by investigator initiated industrial funding (Pfizer)

P.D1.04.06

Study on the effect of metformin and succinate on the differentiation and functions of mesenchymal stem cell

***H. Ho**[1], B. Chiang[2];*
[1]Graduate Institute of Oral Biology, School of Dentistry, Taipei, Taiwan, [2]Graduate Institute of Clinical Medicine College of Medicine of National Taiwan University, Taipei, Taiwan.

Introduction: Mesenchymal stem cells (MSCs) have been used for a variety of diseases due to their unique properties. Metabolic regulation including metabolic modulators treatment and glucose supplementation has indicated to enhance MSCs properties. But the metabolic regulation to immunomodulatory function of MSCs remains unclear. Hyperglycemia induces inflammation and impairs TCA cycle, causing immunity-related succinate accumulated in T2D, which can treat by MSCs and metformin. Combined metformin and MSCs could be a possible choice for T2D. Hence, we investigated the immunomodulation of metformin on the MSCs, including clarifying the role of succinate in the mechanisms.
Materials and Methods: MSCs are derived from the bone marrow of the 4-5 week old female BALB/c mice. Isolated-MSCs are treated by metformin or succinate to assay the immunosuppressive function and differentiation capacity. The gene expression of immunoregulatory factors and metabolic change are detected by Q-PCR.
Results: we found that metformin and succinate could enhance suppressive function to T cell and also the differentiation capacity. The mRNA level of iNOS increases in treated-MSCs but decreased after treating with INF-γ, which is required for MSC-mediated immunosuppression activation. Treated-MSCs change the metabolic genes including glycolysis, oxidative metabolism and mitochondrial biogenesis. The supernatant of treated-MSCs also demonstrated enhanced suppressive function, indicating the potential mechanism of treated-MSCs.
Conclusions: Metformin- or succinate-treated MSCs demonstrated enhanced suppressive function and different metabolism. We believe further clarification on the metabolic mechanisms involved in the development and functions of MSCs might shed light on future application of MSCs for immune modulation.

P.D1.04.07

Metronidazol changes the susceptibility to imiquimod-induced skin inflammation

***Z. Jiraskova Zakostelska**[1], Z. Stehlikova[1], F. Rob[2], K. Klimesova[1], P. Rossmann[1], I. Novosadova[1], D. Srutkova[3], M. Kostovcik[1,4], T. Hudcovic[3], P. Bohač[2], K. Juzlova[2], J. Hercogova[2], H. Tlaskalova Hogenova[1], M. Kverka[1,5];*
[1]Institute of Microbiology of the CAS, Prague, Czech Republic, [2]2nd Medical Faculty, Charles University in Prague and Bulovka Hospital, Prague, Czech Republic, [3]Institute of Microbiology of the CAS, Novy Hradek, Czech Republic, [4]BIOCEV, MBU-BIOCEV, Vestec, Czech Republic, [5]Institute of Experimental Medicine of the CAS, Prague, Czech Republic.

Introduction: Alteration of microbiota influences the immune response of the host. Overall changes in microbiota composition are also involved in the psoriasis incidence and maintenance. The aim was to reveal whether peroral antibiotic treatment has the potential to mitigate experimental skin inflammation and to describe in detail subsequent changes in microbiota composition on the skin and in the intestine. **Methods:** To alter the microbiota, we gavaged BALB/c mice with antibiotics, specifically metronidazole (MET), vancomycin, colistin and streptomycin, and their mixture (ATBs) or water (W) in controls consecutively for 21 days. To induce the imiquimod-induced skin inflammation (IISI), we applied imiquimod on the shaved back skin for last 6 days. Then, we evaluated the severity of IISI. We used Illumina approach to assess the changes in microbiota. **Results:** Compared to W control mice, we found that MET and ATBs mitigated the severity of IISI in all clinical parameters. This effect was associated with downregulation of Th17 response. Next, we found that treatment with MET and ATBs significantly decreased the intestinal microbial diversity but microbial diversity on skin was significantly changed only after treatment with MET. Although, ATBs increased the proportion of phylum Firmicutes in the intestine, particularly order *Lactobacilales*, other members, such as *Clostridiales* and *Bacillales*, were decreased. **Conclusions:** Our findings suggest that differences in microbiota composition can influence experimental skin inflammation development and can lead to identification of specific microbial patterns associated with the disease. This study was supported by Ministry of Health of the Czech Republic grant nr. 15-30782A

P.D1.04.08

Impact of Foxp3$^+$ Regulatory T cell depletion on the murine gut microbiome

C. Wilk, D. Schoemer, A. Adamczyk, E. Pastille, A. Westendorf, J. Buer, ***J. Kehrmann****;*
Institute of Medical Microbiology, Essen, Germany.

Introduction: Besides the impact of the gut microbiota to shape the immune system in the intestine, the immune system itself is considered to shape the gut microbiota composition. The relevance of regulatory T cells (Tregs) in this context is unclear so far. We analyzed the gut microbiome in DEREG mice over a period of twenty days after depletion of Tregs by Diphtheria Toxin (DT).
Methods: We extracted DNA from stool samples of twenty-four mice (19 DEREG and 5 wild-type mice) at 5 different time points (day -7 [seven days before first DT application], day 0, 5, 10 and 20), derived from 3 independent experiments. Sequencing of the V3/V4 region of the 16S rRNA gene was performed using the Illumina MiSeq 2 x 301 paired ends reads cartridge (Illumina). Data processing and analysis was performed using the QIIME pipeline.
Results: Variation of the gut microbiome´s alpha and beta diversity was clearly higher between individual mice compared to the different time points of stool sampling within mice of this study. Principle Coordinate Analysis (PCoA) of weighted and unweighted UniFrac distance matrices did not separate DEREG and wildtype mice gut microbiomes. PCoA clustered samples according to their sample identifier and age rather than according to the different time points before and after Treg depletion.
Conclusions: In this work we analysed the gut microbiome variation associated with Treg depletion in mice over time. Intra-mice variability of the gut microbiome over time was less pronounced compared to inter-mice variability before Treg depletion.

P.D1.04.09

Expression of Toll-like receptors in PBMCs of schizophrenic patients

E. Kozlowska*[1], J. Agier[1], K. Sobierajska[2], E. Brzezińska-Blaszczyk[1], A. Wysokinski[3];*
[1]Department of Experimental Immunology, Medical University of Lodz, Lodz, Poland, [2]Department of Molecular Cell Mechanisms, Medical University of Lodz, Lodz, Poland, [3]Department of Old Age Psychiatry and Psychotic Disorders, Lodz, Poland.

Background. Schizophrenia is a severe mental disorder characterized by firmly impaired thinking, emotions, and behaviors, affecting approximately 1% of the population worldwide. Increasing evidence suggests that, apart from neurochemical abnormalities, various immunological alterations are related to the pathogenesis of schizophrenia. Given a fact that Toll-like receptors (TLRs) play pivotal role in the initiation of innate immunity and inflammatory mechanisms in this study we determine the TLR expression in peripheral blood mononuclear cells (PBMCs) in schizophrenic patients.
Materials and methods. Twenty-seven adult European Caucasian patients with paranoid schizophrenia were included in this prospective study. Twenty-nine healthy volunteers were also randomly selected as a control group. PBMCs were isolated from whole blood by density gradient centrifugation. Total RNA was isolated from PBMCs by acid guanidinium thiocyanate-phenol-chloroform extraction. TLRs expression was evaluated using quantitative real-time polymerase chain reaction (qRT-PCR).
Results. We demonstrated that TLR1, TLR2, TLR4, TLR6, and TLR9 mRNAs expression were down-regulated in patients with schizophrenia in opposite to TLR3 and TLR7 mRNAs which manifested higher expression. TLR5 and TLR8 mRNAs demonstrated non-statistically significant alterations.
Conclusion. Altered expression of TLRs in PBMCs of schizophrenic patients may reflect an important interplay between TLRs and development of schizophrenia.
Supported by the Medical University of Lodz (grant no 502-03/6-164-01/502-64-106).

Roles of IRF-1 in negative cross-talk between Liver X Receptors (LXRs) and IFN-γ signalling

N. A. Letelier*[1], L. Apetoh[2], A. M. Planas[3], A. F. Valledor[1];*
[1]Nuclear Receptor Group, Department of Cell Biology, Physiology and Immunology, School of Biology, University of Barcelona, Barcelona, Spain, [2]Centre de Recherche INSERM LNC-UMR1231, F-21000, Dijon, France, [3]Department of Brain Ischemia and Neurodegeneration, Institute for Biomedical Research of Barcelona (IIBB), Consejo Superior de Investigaciones Clentíficas (CSIC), Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain.

Liver X Receptors (LXRs) are members of the nuclear receptor family of transcription factors that regulate lipid and glucose homeostasis and exert several roles at the interface between metabolism and the immune system. Pharmacological LXR activation induces the expression of genes involved in cholesterol efflux (e.g. *Abca1* and *Abcg1*) and inhibition of cholesterol uptake (*Idol*). Recent work from our group has revealed that LXR activation also induces the expression of the enzyme CD38 in macrophages, a transmembrane glycoprotein that controls NAD+ levels in tissues. Further, we have previously reported reciprocal cross-talk between IFN-γ signalling and the LXR pathway in macrophages. IFN-γ involves activation of the JAK-STAT1 pathway to promote the expression of primary IFN response genes, including the transcriptional regulator IFN regulatory factor-1 (IRF-1). To characterize the roles of IRF-1 in the cross-talk between IFN-γ and LXR activation, we compared the effects of IFN-γ stimulation on the expression of LXR target genes in macrophages from wild type and IRF-1 or STAT1-deficient mice. IFN-γ signalling resulted in reduced induction of *Abca1* and *Aim* by LXR, effects that were STAT1-dependent but IRF-1-independent. In contrast, IFN-γ signalling and LXR cooperated in transcriptional induction of *Cd38* in a STAT1-dependent manner and this synergistic induction was drastically enhanced in IRF-1-deficient macrophages. These results suggest that IRF-1 serves to fine-tune the expression of CD38 during the macrophage response to IFN-γ.
This work was supported by grant 201605.31 from Fundació La Marató de TV3 to A.F.Valledor; Nicole Letelier is a CONICYT fellowship awarded.

Short-chain fatty acids regulate systemic bone mass and protect from pathological bone loss

S. Lucas*[1], Y. Omata[1], J. Hofmann[2], M. Böttcher[3], A. Iljazovic[4], K. Sarter[1], O. Albrecht[1], O. Schulz[1], B. Krishnacoumar[1], G. Krönke[1], M. Herrmann[1], D. Mougiakakos[3], T. Strowig[4], G. Schett[1], M. M. Zaiss[1];*
[1]Department of Internal Medicine 3, Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany, [2]Division of Biochemistry, Department of Biology, Friedrich-Alexander University Erlangen-Nürnberg (FAU), Erlangen, Germany, [3]Department of Internal Medicine 5, Hematology and Oncology, Translational Research Center, University Hospital Erlangen, Erlangen, Germany, [4]Helmholtz Centre for Infection Research, Braunschweig, Germany.

Host-microbe interactions are considered being a fundamental component influencing health and disease. Especially the gut microbiota and their metabolites are known to modulate immune responses of the host. The main metabolites derived from microbial fermentation of dietary fibers are short chain fatty acids (SCFA). SCFA have been recognized as potential mediators involved in the effects of the gut microbiota on local and systemic immune function.
Because immune activation is intimately linked to bone homeostasis, we analyzed the effect of SCFA on bone.
Therefore, we characterized different mouse models addressing physiological bone homeostasis in naïve C57BL/6 and Rag1$^{-/-}$ mice as well as models for post-menopausal and inflammation driven pathological bone loss during SCFA supplementation or fiber rich diets.
The analysis of tibial bone revealed that SCFA increased bone mass during physiological conditions by directly impacting on the metabolic status of osteoclast precursors, shifting it at early time points towards enhanced glycolysis. Moreover, propionate and butyrate attenuated ovariectomy-induced bone loss as well as the severity of inflammation during collagen induced arthritis, and subsequently preserved local and systemic bone mass.
SCFA appear to be potent regulators of bone homeostasis, and are also able to prevent pathological bone loss. These data suggest that microbial homeostasis in the gut associated with adequate production of SCFA is an important regulatory element in determining bone composition in mice. Therapeutic supplementation of SCFA or diets increasing the endogenous production of SCFA may therefore provide a powerful instrument to balance osteoclast activity and prevent enhanced bone resorption.

P.D1.04.12

Gut microbiota-derived metabolite pentanoate restrains T cell-mediated immunopathology through metabolic and epigenetic reprogramming of B and T lymphocytes

M. Luu*[1], R. Romero[1], R. Singh[2], M. Lauth[2], U. Steinhoff[1], A. Visekruna[1];*
[1]Institute for Medical Microbiology and Hygiene, Philipps-University Marburg, Marburg, Germany, [2]Institute of Molecular Biology and Tumor Research, Philipps-University Marburg, Marburg, Germany.

Short-chain fatty acids (SCFAs) are able to induce differentiation of regulatory T cells (Tregs), which is one of the crucial mechanisms by which commensal bacteria contribute to the maintenance of mucosal homeostasis. SCFAs are able to exert protective effects in the host cells through both G-protein-coupled receptor (GPCR)-dependent and -independent mechanisms. While a potent immunomodulatory activity for acetate, propionate and butyrate has been described in various experimental models, the role for the SCFA pentanoate (valerate) in regulation of immune cell function is still unknown. Here, we show that pentanoate is abundantly present in the gut lumen of conventional but not of germ-free (GF) mice. Interestingly, pentanoate was not able to expand regulatory T cells (Tregs) *in vitro* or *in vivo*. In CD4$^+$ T lymphocytes, pentanoate acted as epigenetic regulator of gene expression by exhibiting strong histone deacetylase (HDAC)-inhibitory activity, thereby reducing IL-17A production and suppressing pathogenic Th17 responses *in vivo*. Furthermore, pentanoate strongly enhanced IL-10 production in regulatory B cells (Bregs) and Th17 cells by reprogramming their metabolic activity. This effect was dependent on pentanoate-triggered metabolic switch towards high aerobic glycolysis via enhancement of mTOR activity. Pentanoate-induced IL-10$^+$ Bregs mediated protection in the mouse model of colitis and multiple sclerosis. Taken together, our study reveals that the microbiota-derived metabolite pentanoate regulates the fate of lymphocytes by initiating metabolic reprogramming in these cells.

P.D1.04.13

Microbiome composition of air samples from livestock farms and their effect on innate immune receptors and cells

***R. Mariman**, D. Liu, M. Gerlofs-Nijland, B. John, F. Cassee, E. Pinelli;*
RIVM, Bilthoven, Netherlands.

Patients with respiratory diseases in rural areas have been reported to have enhanced responsiveness to ambient particulate matter (PM). In addition to the physical and chemical components, ambient PM can contain microorganisms or parts thereof which is referred here as BioPM. The aim of this study is to characterize the microbial composition of BioPM originating from livestock, and to investigate whether these BioPM can trigger the activation of innate receptors and cells. Size-resolved BioPM samples (<2.5 and 2.5-10 micrometer) were collected from chicken, pig and goat farms using the versatile aerosol concentration enrichment system (VACES) connected to a Biosampler. The fungal and bacterial community was assessed with an amplicon based approach using Next Generation Sequencing. In parallel, HEK-Blue cells expressing different pattern recognition receptors (Toll like receptors (TLR) 2,3,4,5,7,8,9 and NOD1,2) and a human monocytic cell line (MM6) were exposed to BioPM from these sites. Results indicate distinct airborne microbiota profiles associated with the corresponding animal farm. Moreover, the various BioPM contained mainly ligands for TLR2 and TLR4 resulting in a concentration-dependent increase of pro-inflammatory cytokines secreted by MM6 cells. In addition to TLR2 and TLR4 only the pig-derived BioPM induced TLR5 activation. These findings indicate that BioPM from livestock can activate innate cells and therefore, trigger inflammatory responses. Knowledge on the microbial composition of BioPM derived from different farms and understanding what type of inflammatory responses they induce is crucial for future studies on the effect of that exposure to BioPM may have on respiratory symptoms.

P.D1.04.14

Lactobacilli secreted factors dampen human IFN-γ responses through a monocyte-dependent mechanism

***M. Mata Forsberg**, S. Björkander, E. Sverremark-Ekström;*
The Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm, Sweden.

Lactobacilli are common members of the human microbiome known for their immunomodulatory function. We have previously shown that lactobacilli cell free supernatants (CFS) dampen T cell and NK cell pro-inflammatory cytokine production, proliferation and cytotoxicity, *in vitro*. However, the mechanisms involved remain elusive. Here, we aimed to investigate how soluble factors present in the lactobacilli-CFS mediate the dampening activity. We stimulated whole human PBMC or PBMC depleted of antigen presenting cells in the presence or absence of size fractionated lactobacilli-CFS. Furthermore, conditioned cell culture media from isolated monocytes pre-treated with lactobacilli-CFS was used in subsequent PBMC stimulations. Cytokine production was analyzed with ELISA and flow cytometry. We show that lactobacilli-CFS contains multiple soluble factors of different molecular size capable of reducing IFN-γ expression in NK cells and several T cell subsets. Moreover, the dampening activity is lost when monocytes, but not B cells, are depleted from the PBMC cultures prior to stimulation. Conditioned cell culture media from isolated monocytes pre-treated with lactobacilli-CFS also resulted in reduced IFN-γ secretion from PBMC. In summary, we show that lactobacilli-CFS dampen pro-inflammatory immune responses via a mechanism that involves soluble factors produced by monocytes.

P.D1.04.15

Metabolic reprogramming towards aerobic glycolysis might control the antigen presentation capacity of CD4+ T cells

***J. Osuna Pérez**, R. García-Ferreras, A. Cruz-Adalia, M. Torres Torresano, E. Veiga Chacón;*
Spanish National Center for Biotechnology, 28049, Spain.

Conventional $CD4^+$ T cells have recently been identified as potent inductors of cytotoxic memory $CD8^+$ T cells responses. By a process termed transphagocytosis T $CD4^+$ T cells capture bacteria from infected dendritic cells and degrade it to present bacterial antigens to $CD8^+$ T naive T cells, which proliferate and become cytotoxic in responses. This T $CD4^+$ T cell-mediated antigen presentation generates central memory T $CD8^+$ cells with low PD-1 expression and provide anti tumor protection, highlighting the potential of $CD4^+$ T cells a tool for cancer immunotherapy. Among the complex field of immunometabolism, the present study aims to determine the association between the metabolic state of transphagocytic $CD4^+$ T cells and their ability to present bacterial antigens to $CD8^+$ T cells. A higher rate of glycolysis was found in tp$CD4^+$ T cells when compared with activated $CD4^+$ T cells and disruption of the glycolytic pathway with 2-Deoxyglucose impaired T $CD8^+$ cells proliferation induced by $CD4^+$. Thus, we provide mechanistic insights into the metabolic reprogramming that gover the generation of central memory and antitumor response induced by T $CD4^+$ cells.

P.D1.04.16

X-linked Chronic Granulomatosis: molecular and cellular mechanisms underlying intestinal inflammation

***M. Pellicciotta**[1], M. Chiriaco[2], S. Di Cesare[3], E. Fontana[1], S. Guglielmetti[4], R. Rigoni[1], F. Rea[5], V. Marrella[6], A. Finocchi[3], B. Cassani[7];*
[1]Humanitas Clinical and Research Hospital, ROZZANO (MILANO), Italy, [2]University Department of Pediatrics, Childrens' Hospital Bambino Gesù, Rome, Italy, roma, Italy, [3]University Department of Pediatrics, Childrens' Hospital Bambino Gesù, Rome, Italy, Roma, Italy, [4]Department of Food, Environmental, and Nutritional Sciences (DeFENS), University of Milan, Italy, MILANO, Italy, [5]Digestive Endoscopy and Surgery Unit, Bambino Gesù Children Hospital, Roma, Italy, [6]Istituto di Ricerca Genetica e Biomedica, Milan Unit, CNR, Milan, Italy, MILANO, Italy, [7]Istituto di Ricerca Genetica e Biomedica, Milan Unit, CNR, Milan, Italy, ROZZANO (MILANO), Italy.

X-linked Chronic Granulomatous Disease is immunodeficiency disorder of phagocytes, due to defect in the CYBB gene, encoding the gp91phox subunit of the NADPH enzyme, resulting in impaired killing of bacteria and fungi. The enzyme is expressed also in lymphocytes but its functional implication is poorly characterized. Affected individuals develop life-threatening infections and unexplained autoinflammatory/autoimmune conditions, involving particularly the intestine. Increased tissue expression of pro-inflammatory cytokines (IL-17, IL-6, IL-1beta) underlined the intestinal inflammation in the gp91phox-/- mice. Treg cell frequency in the mesenteric lymph nodes was reduced in mutants as well as the percentage of CD103+ dendritic cells, endowed with tolerogenic functions. Consistently, OVA-specific Treg conversion, analyzed in vivo upon adoptive transfer of CD4+ OTII cells and oral antigen delivery, was affected in gp91phox-/- mice. Interestingly, IgA compartment, crucial to contain gut microbes, was similarly defective in the knock-out mice. PBMC of 13 CGD patients and of 10 age-matched HD were evaluated by flow cytometry. Eight out of 13 patients suffered from IBD with predominant colonic involvement. Analysis at the enrollment showed diminished naïve CD4 and CD8 subsets and increased effector memory (CD45RA-CD27- and CD45RA-CCR7-) cells as well as a slight increase in the NKT subset. Despite normal B cell frequencies, the memory subsets (CD19+CD27+ unswitched and switched memory CD19+CD27+IgD-), were all below the normal range values. Studies are underway to investigate the presence of rare genetic variants associated with IBD. Furthermore, gene and protein expression from intestinal biopsies will be correlated with microbiota composition and fecal IgA content.

P.D1.04.17

The influence of sex chromosome-specific gut microbiomes on a sexually dimorphic immune response

*A. Pettit[1], J. Franko[1], E. Onga[2], K. Blethen[1], C. Cuff[1], **R. Schafer**[1];*
[1]West Virginia University, Morgantown, United States, [2]Universidade Federal De Vicosa, Vicosa, Brazil.

Despite being less susceptible to infectious disease, females are 10X more likely to develop autoimmune diseases than males. Immune-related sexual dimorphisms have primarily been attributed to sex hormones, however, XX vs. XY sex chromosome complements and sex-specific gut microbiomes may play a role. To identify mechanisms contributing to distinct male vs. female immune responses, the gut microbiome composition of four-core genotype (4CG) mice and its influence on a sexually dimorphic immune response was evaluated. FCG mice exhibit one of 4 genotypes: XX or XY females (ovaries) and XX or XY males (testes). 4CG mice have been used to identify differences in phenotypes caused by sex chromosome complements, sex hormones, and interactions between the two. 16s rDNA sequencing and metagenomics analysis was performed on DNA isolated from the fecal pellets of 6-8 week old 4CG mice and again 4 weeks post-gonadectomy. Distinct populations of bacteria were identified between XX females and XY males, and also between XX and XY males, suggesting a role for sex chromosome complements in the regulation of gut microbiome composition. Elimination of gut bacteria by antibiotic administration demonstrated a potential role for sex chromosome-specific gut microbiomes on the XX-dependent enhancement of heat-killed *Streptococcus pneumoniae* immune responses after exposure to the herbicide, propanil. Future experiments will determine the metabolic by-products produced by the microbiome of 4CG mice and determine if these metabolites influence immune responsiveness in a sex chromosome-dependent manner. Funded by the Department of Microbiology, Immunology, and Cell Biology Research Internship and NIH Grant P20GM103434, WVINBRE.

Psoriasis related changes in skin microbiota composition

***Z. Stehlikova**[1], K. Juzlova[2], F. Rob[2], J. Hercogova[2], A. Uzan[3], O. Koren[3], M. Kostovčik[1,4], H. Tlaskalova Hogenova[1], Z. Jiraskova Zakostelska[1];*
[1]Institute of Microbiology of the CAS, v.v.i., Prague, Czech Republic, [2]Bulovka Hospital, 2nd Faculty of Medicine, Prague, Czech Republic, [3]Bar-Ilan University, The Azrieli Faculty of Medicine, Safed, Israel, [4]BIOCEV, Institute of Microbiology of the CAS, v.v.i., Vestec, Czech Republic.

Introduction: Psoriasis is an immune mediated, chronic, inflammatory skin disease of unknown etiology affecting 2-3% of the worldwide population. It is widely accepted that it develops from a combination of genetic and environmental triggers, such as stress, bacterial infection, antibiotics, and diet. However, the role of microbiota in its pathogenesis remains still unclear. The aim of this study was to describe microbiota composition in psoriatic patients and compare it to healthy controls.
Methods: We collected samples from the human back skin using two sampling techniques: swabbing, and scraping. Subsequently, we compared microbiota composition of affected psoriatic skin with unaffected contralateral skin from the same patient and with healthy controls after sequencing V1V2 region of 16S rRNA on Illumina MiSeq platform. Data were analyzed using QIIME.

Results: Intergroup β-diversity showed significantly higher microbiome variability among controls in contrast to higher similarity between psoriatic patients including both affected and unaffected skin. Intergroup α-diversity revealed increasing bacterial diversity from controls to affected psoriatic lesions, with a decrease of *Staphylococcus epidermidis*, increase of *Corynebacterium* species and appearance of pathogenic *Staphylococcus haemolyticus* in psoriatic patients. Moreover, we observed proportional changes in the bacterial distribution in between the sampling techniques used.
Conclusions: Our results confirmed that psoriasis is associated with changes in skin microbiota. However, whether it is of its primary etiological significance or secondary to the disease remains to be established.
This study was supported by Ministry of Health of the Czech Republic, grant No.15-30782A, RVO: 61388971 and by European Regional Development Fund BIOCEV CZ.1.05/1.1.00/02.0109.

P.D1.04.19
Human gut microbes are highly susceptible to antimicrobial food additives *in vitro*

L. Hrncirova[1,2]*, E. Sukova*[1]*, T. Hudcovic*[1]*, J. Krejsek*[2]*, T. Hrncir*[1]*;*
[1]*Institute of Microbiology, Czech Academy of Sciences, Novy Hradek, Czech Republic,* [2]*Faculty of Medicine in Hradec Kralove, Charles University in Prague, Hradec Kralove, Czech Republic.*

The aim of this project was to test the hypothesis that antimicrobial food additives may alter the composition of human gut microbiota by selectively suppressing the growth of susceptible gut microbes. To explore the influence of antimicrobial food additives on the composition of the human gut microbiota, we examined the susceptibility of both aerobic and anaerobic gut bacteria to sodium benzoate, sodium nitrite, and potassium sorbate, and their combinations, using a broth microdilution method. The tested bacteria showed a range of susceptibilities to the different food additives, with *Bacteroides coprocola* and *Clostridium tyrobutyricum* being particularly sensitive. However, most importantly, we found that gut microbes with known anti-inflammatory properties were mostly susceptible to the antimicrobial food additives, while microbes with known pro-inflammatory or colitogenic properties were mostly resistant. Our data show that some human gut microbes are highly susceptible to antimicrobial food additives. We speculate that permanent exposure of human gut microbiota to even low levels of additives may modify the composition and function of gut microbiota and thus influence the host's immune system. Whether the effect of additive-modified gut microbiota on the human immune system could explain, at least in part, the increasing incidence of allergies and autoimmune diseases remains to be shown.

P.D1.04.20
Food preservatives induce *Proteobacteria* dysbiosis of the human gut microbiota

T. Hrncir[1]*, L. Hrncirova*[1,2]*, E. Trckova*[1]*, V. Machova*[1]*, J. Krejsek*[2]*;*
[1]*Institute of Microbiology, Czech Academy of Sciences, Novy Hradek, Czech Republic,* [2]*Faculty of Medicine in Hradec Kralove, Charles University in Prague, Hradec Kralove, Czech Republic.*

The incidence of allergies and autoimmune diseases is increasing worldwide. Recent data suggest that gut microbiota can modulate not only local but also systemic immune responses. In this study, we focus on environmental factors, specifically food preservatives, which may modify the composition of gut microbiota and thus influence host's immune responses. To address this issue, we have administered either sterile water or water supplemented with additives to wild-type and Nod2-deficient C57BL/6 mice colonized with human microbiota. The daily intake of additives was calculated to match the maximum daily intake reached in human populations in Europe. We have analyzed the effect of additives on microbial composition and diversity by amplification and high-throughput sequencing of the hypervariable regions of the 16S rDNA genes. The resulting sequences were processed using QIIME2 software package. Our results indicate that commonly used food preservatives can decrease the diversity of the human gut microbiota and also trigger *Proteobacteria* dysbiosis.

A cell-autonomous role of DOCK8 in development of type3 innate lymphoid cells

R. Aihara[1]*, M. Watanabe*[1]*, Y. Fukui*[1,2]*;*
[1]*Medical Institute of Bioregulation. Kyushu University, Fukuoka, Japan,* [2]*Reseach Center for Advanced Immunology, Kyushu University, Fukuoka, Japan.*

Introduction: RORgt-expressing ILC3s play an important role in the defense against intestinal pathogens and promotion of epithelial homeostasis via production of IL-22. However, the mechanism controlling ILC3 development is not fully understood. In this study, we examined the role of DOCK8, an atypical guanine nucleotide exchange factor for Cdc42, in ILC3 development. Material and methods: Conventional DOCK8 KO mice and control mice were used for FACS analyses and immunohistochemical analyses to examine ILC3 development and intestinal fucosylation. The conditional KO mice lacking DOCK8 in RORgt-positive cell lineage were developed and used to examine its effect on ILC3 development. Results: DOCK8 KO mice exhibited a severe reduction of RORgt+ c-Kit+ Sca1- ILC3s in intestinal lamina propria. Consistent with this, lineage-negative cells producing IL-22 were also reduced in the KO mice under the both steady state and IL-23-treated condition. IL-22 is known to mediate the epithelial fucosylation. Although the epithelial fucosylation was severely impaired in the KO mice, IL-22 administration completely restored the fucosylation response. To examine whether DOCK8 regulates ILC3 development in a cell-autonomous manner, we generated the conditional DOCK8 KO mice. When the conditional KO mice were crossed with RORgt-Cre mice, ILC3 development was impaired, as was observed in conventional KO mice. In contrast, genetic deletion of DOCK8 in CD11c-positive cell lineage did not affect ILC3 development. Conclusion: DOCK8 regulates ILC3 development in a cell-autonomous manner.

Introduction: Innate lymphoid cells (ILCs) are lymphocytes that act as the first line of immunological defence at mucosal surfaces such as the gut, lungs and the skin. Here, we provide a detailed appraisal of the whole ILC population (group 1, 2 and 3 subsets) in the murine gingivae and the regional lymph nodes (dLNs) draining the oral cavity.
Methods: Oral dLNs and gingivae were harvested from mice and processed/digested to obtain single cell suspensions, which were subsequently stained with antibodies for identification of ILCs by flow cytometry. For cytokine profiling of ILCs, cells were stimulated prior to staining.
Results: We show that ILCs made up a greater percentage of the whole CD45+ lymphocyte population in the murine gingivae than in the oral dLNs (0.356 ± 0.039% vs. 0.158 ± 0.005%, $p<0.001$). The gingivae-resident ILCs were more diverse than the oral dLNs, with a significantly greater proportion of CD117+, NKp46- ILCs (35.19 ± 3.84 compared to 5.03 ± 0.69%, $p<0.0001$). The cytokine profile of ILCs in the gingivae also differed from the oral dLNs; there was a relatively similar proportion of IFN-γ+ and IL-5+ ILCs in the murine gingivae, whereas IL-5+ ILCs predominately populated the oral dLNs.
Conclusion: The function of ILCs in the oral cavity is currently unknown; here, we demonstrate that the ILC compartment is enriched, more diverse, and has a different cytokine profile at the gingival surface compared to the oral dLNs. Future work investigating inflammatory oral diseases using mouse models may merit consideration of these ILC populations.

P.D2.01.03
CD62L marks circulating ILC precursors

*Y. E. Bar-Ephraim, **E. Burniol Ruiz**, J. Koning, T. Konijn, V. P. Mourits, K. Lakeman, L. Boon, M. Bögels, J. van Maanen, J. J. Den Haan, M. Van Egmond, G. Bouma, R. M. Reijmers, R. Mebius;*
VUmc, Amsterdam, Netherlands.

Innate lymphoid cells (ILCs) guard epithelial tissue integrity during homeostasis, but can be potent immune effector cells during inflammation. Precursors to all ILC subsets (ILC precursors, ILCP) have been identified in human peripheral blood (PB). We found that during homeostasis, ILCP in PB of mouse and man expressed homing receptors for secondary lymphoid organs, mainly CD62L. These ILCP entered mouse lymph nodes (LNs) in a CD62L-dependent way and relied on S1P receptors for their exit. Importantly, CD62L expression was absent on human ILCs expressing NKp44 in tonsils and PB of Crohn's disease (CD) patients, and reduced number of CD62L$^+$ ILCP were present in PB of CD patients. These data are in agreement with selective expression of CD62L on non-activated ILCP. As such, we conclude that CD62L not only serves as a functional marker of ILCP but has potential to be used in the clinic as a diagnostic marker in inflammatory disorders.

P.D2.01.04
Dynamics of innate lymphoid cells (ILCs) during *Mycobacterium tuberculosis*infection

***D. Corral**, F. Levillain, O. Neyrolles, D. Hudrisier;*
Institut de Pharmacologie et de Biologie Structurale, Toulouse, France.

Understanding the immune response to *Mycobacterium tuberculosis* (*Mtb*), the etiological agent of tuberculosis (TB) may help propose innovative therapeutic approaches. In this context, the role of innate lymphoid cells (ILCs), which form a recently identified group of innate lymphocytes, remains unexplored. ILCs are preferentially located at mucosal surfaces where they contribute to controlling immunity. The aim of our project is to analyze the dynamics of ILCs upon *Mtb* infection in the murine model and to understand their contribution to the balance between immune-driven protection and pathology, key parameters in ensuring *Mtb* elimination while preserving functional integrity of the lung tissue during TB. Our data show that, during *Mtb* infection, ILC subsets are differentially recruited to the lungs where they are activated and produce various subset-specific cytokines that may contribute to both pathogen clearance and tissue repair. Moreover, we found that cells of the ILC2 subset progressively display common features with ILC1 during the infection time course, suggesting cell plasticity. We now wish to characterize the mechanisms controlling ILC2 dynamics and plasticity in the lungs, as well as their role in modulating TB pathology and anti-mycobacterial immunity.

P.D2.01.05
Dasatinib skews in vitro human CD56$^+$ innate lymphoid cells differentiation towards ILC3

***L. Damele**[1], E. Montaldo[2], L. Moretta[3], M. Mingari[4], C. Vitale[5];*
[1]CEBR-(Centre of Excellence for Biomedical Research), Italy, Genova, Italy, [2]IRCCS G. Gaslini, Genova Italy, present adress: San Raffaele Telethon Institute for Gene Therapy, IRCCS-San Raffaele Scientific Institute, Milano, Italy, [3]Immunology Area, Pediatric Hospital Bambino Gesù, Roma, Italy, [4]Dimes (Dipartimento Medicina Sperimentale), Università degli Studi di Genova, CEBR (Centre of Excellence for Biomedical Research), Università degli Studi di Genova, Policlinico San Martino, IRCCS indirizzo Oncologico, Genova, Italy, [5]Dimes (Dipartimento Medicina Sperimentale), Università degli Studi di Genova, Policlinico San Martino, IRCCS indirizzo Oncologico, Genova, Italy.

Tyrosine kinase inhibitors (TKI) improved the prognosis of Chronic Myeloid Leukemia and of Philadelphia$^+$ Acute Lymphoblastic Leukemia patients. However, TKI can develop of resistance and lack of complete molecular remission in the majority of patients. Clinical evidences suggest that the terminally differentiated CD56+CD16+CD57+ NK cells, may be associated with successful Imatinib therapy discontinuation or with a deep molecular response in Dasatinib-treated patients. Therefore, is important study how the chronic exposure to TKI may influence NK cell development and repertoire. CD34$^+$ Hematopoietic Stem Cells were cultured with appropriate cytokines to induce in vitro NK cell differentiation, in the absence or in the presence of Imatinib, Nilotinib, Dasatinib, or KX2-391 Src kinase inhibitor. At different time intervals, cells were counted and analyzed for the expression of lineage-specific markers, cytokines production and cytolytic activity. Our results show that Dasatinib sharply skewed the repertoire of CD56$^+$ cells, leading to a reduced recovery of CD56$^+$CD117$^-$CD16$^+$CD94/NKG2A$^+$EOMES$^+$ NK cells, to an impaired cytotoxicity, while IFN-γ production was increased. On the other hand, the development of CD56$^+$CD117$^+$CD94/NKG2A$^-$RORγt$^+$IL-22-producing ILC3 was not affected. This effect appears to involve the Dasatinib-mediated inhibition of Src kinases, as suggested by experiments with a KX2-391. Our experiments, revealed a possible mechanism by which Dasatinib may interfere with the maturation of competent NK cells, affecting signaling pathways required for differentiation and survival NK cell but not for of ILC3. Moreover, could identify new tools to design patients-individualized timing and dosing of Dasatinib to favor an NK-mediated immune response against leukemia.

P.D2.01.06
Characterization of CD56^{bright} NK cells which inversely correlate with survival of melanoma patients

***K. de Jonge**[1], A. Ebering[1], S. Nassiri[1,2], P. Baumgärtner[1], D. E. Speiser[1,3];*
[1]Dept. of Fundamental Oncology and Ludwig Cancer Center, Epalinges, Switzerland, [2]Swiss Institute of Bioinformatics (SIB), Lausanne, Switzerland, [3]Dept. of Oncology, University Hospital Center (CHUV), Lausanne, Switzerland.

The roles of NK cells in human melanoma remain only partially understood. We characterized NK cells from PBMC and found that their frequencies were similar between stage III/IV melanoma patients and healthy donors. Interestingly, overall survival was significantly reduced in the patients who had high frequencies of CD56^{bright} NK cells. The production of IFNγ, granzyme B, perforin and CCL4 by the CD56^{bright} NK cells from patients was equal to healthy controls. In contrast, we found lower production of TNFα, GMCSF and CCL3, suggesting that the CD56^{bright} NK cells might be less capable to fight against tumors. Furthermore, the increased expression of CD11a and CD38 may be associated with enhanced inhibition of T cells. Thus, the activation status of CD56^{bright} NK cells may contribute to poor clinical outcome by both reduced anti-tumor activity and increased T cell inhibition. Our results highlight the significance of CD56^{bright} NK cells in patient prognosis, emphasizing the potential of NK cells for biomarker discovery and future therapeutic targeting.

P.D2.01.07
Innate lymphocytes (ILCs) respond to crystal-deposition and promote local inflammation and fibrosis

***T. Frasconi**[1], S. Schwab[1,2], C. Kurts[1], I. Ludwig-Portugall[1];*
[1]Institute od Experimental Immunology, Bonn, Germany, [2]University Clinic, Department of Internal Medicine, Bonn, Germany.

Crystal-induced inflammation is a common manifestation of a variety of genetic and acquired metabolic disturbances. DCs or macrophages sense the crystals, activate the NLRP3-inflammasome and produce cytokines like IL18 and IL1β. These, together with others like IL23, promote local inflammation and induce the development of kidney fibrosis.
Our preliminary data suggested that a Roryt+ and RAG-independent population play an important role in the development of kidney fibrosis. Based on this,we aim to understand the mechanism by which ILCs sense and respond to crystal deposition and influence the development kidney fibrosis.
We use a mouse model of crystal nephropathy induced by adenine-enriched chow to analyze the cytokines profile of Rorγt+ and Rorγt- ILCs. We established an intra-renal injection of IL18, IL1β and IL23 to evaluate their effect on ILCs by analysis of cytokine production and cell proliferation. IL18, IL1β and IL23 are produced in crystal nephropathies by resident DCs and macrophages.
ILCs can sense this inflammatory environment and respond to these stimuli by releasing pro-inflammatory cytokines, such as IL17 and IFNγ, which promote the development of kidney fibrosis. The IFNγ production seems to be sustained not only by T-bet+ILC1, but also by ILC3.
Our data suggest that the pro-inflammatory environment promoted by crystal deposition has an effect on ILCs, which play a role in IFNγ and IL17 production suggesting plasticity within ILCs groups.
As a consequence, ILCs can be considered as early responders in a context of crystal nephropathies and might serve as a key player in kidney fibrosis.

P.D2.01.08
Type 3 Innate Lymphoid Cells might have an impact in active Behçet's Disease

***M. GELMEZ**[1], G. Ozcit[1], E. Cetin[1], S. Cinar[1], M. Erdugan[2], G. Babuna[3], A. Gul[2], A. Akdag-Kose[3], G. Deniz[1];*
[1]Aziz Sancar Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Rheumatology,, Istanbul, Turkey, [3]Istanbul University, Istanbul Faculty of Medicine, Department of Dermatology, Istanbul, Turkey.

Innate lymphoid cells (ILCs) are lymphoid cells that do not express rearranged receptors and have important effectors and regulatory functions in innate immunity and tissue remodeling. Uncontrolled activation and proliferation of ILCs can contribute to inflammatory autoimmune diseases. Behcet's disease (BD) is a complex systemic inflammatory disorder and the role of ILCs is still unknown in BD. In this study, the quantity and effect of ILCs in the pathogenesis of BD were investigated. PBMC were isolated from whole blood from eleven BD patients (7 active and 4 inactive stage) and five healthy controls. ILCs were analyzed by using anti-Lineage, -CD45, -CD161, -CRTH2, -NKp44, -c-kit and -CD127 monoclonal antibodies by flow cytometry. Total ILC, ILC3 and NKp44$^-$ ILC3 cells were increased in all patients compared to healthy subjects (p= 0.05, p= 0.05, and p= 0.0066, respectively), whereas ILC1 and NKp44$^+$ ILC3 cells were decreased (p= 0.05, and p= 0.0066, respectively).

Similarly, CD161$^+$ cells (total ILC), ILC3 and NKp44$^-$ ILC3 cells were increased (p= 0.05, p= 0.0002, and p= 0.0002, respectively); ILC1 and NKp44$^+$ ILC3 cells were decreased (p= 0.01, and p= 0.0002, respectively) in active patients compared to healthy subjects, not in inactive patients. Increased neutrophilic infiltration and IL-17 secreting Th17 cells in BD were shown. It is known that ILC3$^+$ cells are similar to Th17 subset as cytokine variety and transcription factors, regarding our preliminary data showed that inflammatory status in BD might direct ILC cells to ILC3$^+$ subset.

P.D2.01.09
Innate lymphoid cells interact with fibroblastic reticular cells in lymphoid organs

***B. A. Heesters**, L. Krabbendam, S. M. Bal, H. Spits;*
AMC, Amsterdam, Netherlands.

Fibroblastic Reticular Cells (FRCs) together with other lymph node stromal cells (LNSCs), regulate immunity and self-tolerance, yet key aspects of their biology remain ill defined. FRCs are located within lymphoid organs and organize the T cell zone. They are strategically localized to respond quickly to dangerous stimuli. FRC are well equipped to detect danger signals and are able to respond by secretion of cytokines long before the onset of adaptive immunity. Innate lymphoid cells (ILCs) readily respond to cytokines early during inflammation. FRCs could be a source of these activating cytokines. However, ILCs also require cytokines to survive and to retain the phenotype required in lymphoid tissues. Here we show that FRCs are responsible for ILC survival and differentiation within lymphoid organs. FRCs are a source of interleukin (IL)-7, IL-4 and various other cytokines and chemokines. Besides secretion of cytokines vital for ILC survival, FRCs express a plethora of cytokine and chemokine receptors. These discoveries led to the development of an FRC cell line that supports ILC survival and differentiation in vitro. This culture system allows for in vitro ILC experiments that more closely resemble the situation in vivo. Together our data describe the reciprocal relationship between FRC and ILC in lymphoid organs.

P.D2.01.10
Type 2 Innate lymphoid cells are increased cells in acute dengue infections

***A. I. Kamaladasa**[1], Y. Perera[1], L. Gomes[1], D. Jayathilake[1], C. Hardman[2], A. Wijewickrama[3], G. Ogg[2], N. Malagive[1,2];*
[1]Centre for Dengue Research,, Nugegoda, Sri Lanka, [2]MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Oxford NIHR Biomedical Research Centre and University of Oxford, Oxford, United Kingdom, [3]Infectious Disease Hospital, Angoda, Sri Lanka.

Objective: Type 2 Innate lymphoid cells (ILC2s) are known to produce type 2 cytokines during viral infections in the mice models. During acute dengue viral (DENV) infections type 2 cytokines are elevated in individuals with severe disease. Therefore, we set out to investigate the possible role of ILC2s in the pathogenesis of acute dengue. **Methods:** The frequency of ILC2s were determined in adult patients with dengue fever (DF) (n=40) and dengue haemorrhagic fever (DHF) (n=26) and in and 15 healthy individuals. Serum IL-4, IL-5 and IL-13 were measured in serum samples taken daily throughout the course of illness in some of these patients (n=20). **Results:** The frequency of ILC2 in patients with DHF (median 0.6%, IQR 0.33 to 1.03%) were significantly higher (p=0.02) compared to healthy individuals (median 0.36% IQR 0.17 to 0.48%).
Further the absolute ILC2 count was significantly higher (P=0.03) individuals with DHF (median 8.52, IQR 5.74 to 14.54 cells/mm^3) compared to DF (median 0.52 , IQR 1.41 to11.14 cells/mm^3). However, there was no difference in the proportion of ILC2s in patients with DF compared to those with DHF. Serum IL-13 and IL-5 was not detected in any of the patients, while IL-4 was detected in 7 patients. **Conclusion:** As the proportion and absolute count of ILC2 in DHF is significantly increased these cells could be playing a role in DENV infections. But this role may not be related to Th2 cytokine production as we could not detect these cytokines in acute dengue patients.

P.D2.01.11
ILC2s regulate early anti-cryptococcal immunity

***M. Kindermann**[1], L. Knipfer[1], S. Obermeyer[2], U. Schleicher[2], C. Bogdan[2], G. Alber[3], M. Neurath[1], S. Wirtz[1];*
[1]Medical Department 1, Erlangen, Germany, [2]Microbiology, Erlangen, Germany, [3]Immunology, Leipzig, Germany.

Infections with the opportunistic pulmonary pathogen *Cryptococcus neoformans* are a leading cause of co-morbidity and mortality of immunocompromised individuals. Initially, pulmonary infection originates from inhaled spores or desiccated fungi. Clinical signs manifest ranging from mild asymptomatic nodular disease to severe acute respiratory distress syndrome (ARDS) cumulating in fungal dissemination to the CNS, which triggers fatal meningitis or meningoencephalitis.
The host immune status as well as the prominent type of immune response is decisive for the course of disease. Here, a type-2 biased immune response is rather linked to a poor prognosis whereas type-1/3 immunity is related to fungal control and clearance.
Despite knowing that type-2 immunity is detrimental during late stages of pulmonary cryptococcosis, little is known about early events directing subsequent immunomodulatory pathways.
In order to address this issue, we investigated ILC2-deficient mice during onset of infection since ILC2s play crucial roles in mediating early type-2 responses. Noteworthy, ILC2 deficient mice evolve a less prominent detrimental type-2 immunity indicated by reduced amounts of classical markers of type-2 immunity such as IL-4, IL-13 and AAM-markers. Contrary, type-1/3 immune response is increased in these mice indicated by elevated levels of type-1/3 signature cytokines. Consequently, this phenotypic shift results in more efficient fungal control accompanied by less severe lung pathology and prolonged survival.
In conclusion, we provide evidence that ILC2s function as early immune regulators during pulmonary cryptococcosis by favoring detrimental type-2 immunity. Further, intervening with this regulatory checkpoint may be a potential approach for anti-mycotic treatments in human patients.

P.D2.01.12
Identification of a human KLRG1$^+$ CRTH2$^{\pm}$ ILC2 precursor

***M. Nagasawa**, B. A. Heesters, C. M. Kradolfer, H. Spits, S. M. Bal;*
AMC, Amsterdam, Netherlands.

Group 2 Innate lymphoid cells (ILC2s) produce type 2 cytokines in response to epithelial cell derived cytokines such as thymic stromal lymphopoietin (TSLP) and interleukin 33 (IL-33). These cells are important in immune responses to helminths, but they can also be involved in the pathogenesis of inflammatory airway and skin diseases. Human ILC2s depend on the transcription factor GATA3 and express prostaglandin D2 receptor 2 (PTGDR2, also known as CRTH2). However, little is known about their development. To characterize human ILC2s in detail, we analyzed the phenotype and transcriptome of adult peripheral blood (PB) ILCs. In addition, ILC subsets isolated from PB were co-cultured with an OP9 mouse bone marrow stromal cell line to evaluate their developmental capacity and functionality. Here we identified a pre-ILC2 population that lacks CRTH2 expression, but does express the ILC2 associated molecule Killer cell lectin-like receptor subfamily G member 1 (KLRG1). Transcriptome analysis of KLRG1$^+$ CRTH2$^{\pm}$ ILCs suggested that these cells are ILC2 precursors. This notion is supported by the observation that KLRG1$^+$ CRTH2$^{\pm}$ ILCs could differentiate towards conventional CRTH2$^+$ ILC2s *in vitro*. In contrast to conventional ILC2s, pre-ILC2s also produce type 1 (IFN-γ) and type 3 (IL-17 and IL-22) cytokines upon stimulation with IL-1β and IL-23. This suggests these cells are of a developmentally immature stage and have more functional flexibility than conventional ILC2s.

P.D2.01.13
MESENCHYMAL STROMAL CELLS STIMULATE THE PROLIFERATION AND INTERLEUKIN-22 PRODUCTION OF GROUP 3 INNATE LYMPHOID CELLS

***S. Z. Omar**[1,2,3], V. v. Hoeven[1,2,3], M. Munneke[1,2,3], A. S. Cornelissen[4], M. J. Spruit[1], M. Kleijer[4], J. H. Bernink[2,3], B. Blom[2,3], C. Voermans[4], M. D. Hazenberg[1,2,3];*
[1]Department of Hematology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Department of Experimental Immunology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Cancer Center Amsterdam and Amsterdam Infection and Immunity Institute, Amsterdam, Netherlands, [4]Department of Hematopoiesis, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands.

Infusion of mesenchymal stromal cells (MSCs) is a promising and increasingly applied therapy for patients who suffer from a variety of inflammatory diseases, including graft-versus-host disease (GvHD), a common and life-threatening complication after allogeneic hematopoetic stem cell transplantation (aHSCT). The therapeutic effect of MSCs is mainly ascribed to their ability to suppress the activity of (alloreactive) T cells and to support tissue-repair. However, clinical response rates in patients with GvHD are limited to 50%, and the determinants for MSC responsiveness are unknown. We demonstrated that high frequencies of activated group 3 innate lymphoid cells (ILC3s) before and after aHSCT were associated with a lower risk of GvHD. This may be related to interleukin (IL)-22 production by ILC3s, a cytokine important for intestinal epithelial cell homeostasis. To Study whether ILC3s may contribute to the therapeutic effect of MSCs, we co-cultured human tonsil-derived ILC3s with human bone-marrow derived MSCs in standard or transwell culture plates. In co-cultures, MSCs stimulated the proliferation and IL-22 production of ILC3s and reciprocally, ILC enhanced MSC expression of VCAM-1 and ICAM-1. In both directions the stimulatory effect was mainly mediated by cell-cell contact. Experiments with various blocking agents revealed that MSC derived soluble factors, namely IL-7 and aryl hydrocarbon receptor ligands, also stimulate ILC3 proliferation and function. Thus, in addition to inhibiting the proliferation of alloreactive T cells, MSCs also promote the expansion and IL-22 production of ILC3s which may be important for the treatment of various inflammatory conditions in the intestine, including GvHD.

From birth onward, the lungs are exposed to the external environment and therefore harbor a complex immunological milieu to protect this organ from damage and infection. We investigated the homeostatic role of the epithelium-derived alarmin interleukin-33 (IL-33) in newborn mice and discovered the immediate upregulation of IL-33 from the first day of life, closely followed by a wave of IL-13- producing type 2 innate lymphoid cells (ILC2s), which coincided with the appearance of alveolar macrophages (AMs) and their early polarization to an IL-13-dependent anti-inflammatory M2 phenotype. ILC2s contributed to lung quiescence in homeostasis by polarizing tissue resident AMs and induced an M2 phenotype in transplanted macrophage progenitors. ILC2s continued to maintain the M2 AM phenotype during adult life at the cost of a delayed response to Streptococcus pneumoniae infection in mice. These data highlight the homeostatic role of ILC2s in setting the activation threshold in the lung and underline their implications in anti-bacterial defenses.

P.D2.01.17

Transcriptional regulation of human natural killer cell and ILC3 development and function by ETS-1

S. Taveirne[1], *S. Wahlen*[1], *L. Kiekens*[1], *E. Van Ammel*[1], *K. De Mulder*[1], *J. Roels*[1], *L. Tilleman*[1], *M. Aumercier*[2], *F. Van Nieuwerburgh*[1], *T. Kerre*[1], *T. Taghon*[1], *B. Vandekerckhove*[1], *G. Leclercq*[1];
[1]*Ghent University, Ghent, Belgium,* [2]*Université de Lille, Lille, France.*

Introduction: Natural killer (NK) cells and innate lymphoid type 3 cells (ILC3s) are innate lymphoid cells that play a critical role in the immune response against tumor cells and pathogens, and also have important immune regulatory functions. The transcription factor Ets-1 is an important factor in murine NK cell biology as Ets-1-deficient mice show severely reduced NK cell numbers and residual NK cells display decreased functionality. No data regarding the function of ETS-1 in the development of human NK cells is available. In addition, the role of ETS-1 in neither murine nor human ILC3 biology has been investigated.
Methods: In this study, we generated ETS-1-deficient human embryonic stem cell (hESC) clones using the CRISPR/Cas9 technology. In a complementary approach, we generated ETS-1 loss-of-function cord blood hematopoietic stem cells (HSCs) by retroviral transduction of the dominant-negative ETS-1 p27 isoform.
Results: Each ETS-1-deficient human ESC clone displayed defective NK cell differentiation capacity. ETS-1 p27-transduced HSCs had a lower potential to differentiate into NK cells and NKp44$^+$ ILC3, which correlated with increased apoptosis. Residual NK cells showed reduced cytokine secretion and cytotoxic activity. Transcriptome analysis showed that ETS-1 had a dual role in NK cells and NKp44$^+$ ILC3, as it both induces and inhibits expression of NK cell- and ILC3-specific genes, respectively.
Conclusion: Our data show that ETS-1 is a critical regulator of human NK cell and ILC3 development and function and provide important insights in the molecular mechanisms of their biology.

P.D2.01.18

ILC3 NCR$^+$ regulate endothelial cell activation through NF-kB

G. Vanoni, *P. Romero, S. Trabanelli, C. Jandus;*
University of Lausanne, Lausanne, Switzerland.

Innate lymphoid cells (ILCs) represent the most recently identified subset of lymphocytes. Despite their established involvement in inflammatory immune responses, the role of ILCs in cancer remains poorly defined.
Our aim is to assess whether ILCs might exert an active role in controlling or promoting tumor growth through the interaction with the endothelium.
Therefore, short-term in vitro expanded ILC subsets isolated from the peripheral blood of healthy donors were used in 3h co-culture experiments with an endothelial cell line (HUVEC, human umbilical vascular endothelial cell line) at 1:1 ratio. The activation state of endothelial cells (ECs) was assessed by flow cytometry, by evaluating the level of surface expression of the adhesion molecules E-Selectin, ICAM-1 and VCAM-1.
Among all ILC subsets, ILC3 NCR$^+$ elicited the strongest upregulation of adhesion molecules in ECs, in a contact-dependent manner. By specifically blocking the NF-kB pathway in ECs, the level of expression of adhesion molecules was reverted to basal levels. Pre-exposure of ILC3 NCR$^+$ to human bladder carcinoma cell lines strongly impaired this capacity. ILC3 NCR$^+$ induce the expression of adhesion molecules in ECs via NF-kB pathway. The in vitro ECs-ILCs interaction will be further evaluated to assess its functionality and to identify the molecular players. With the use of tumor-bearing mice, the in vivo relevance of the in vitro findings will be tested to unravel if this capacity of ILC3 NCR$^+$ could represent a way for facilitating the immune cell infiltration in the tumor and, therefore, impact tumor progression and/or growth.

P.D2.01.19

Relationship between group 3 innate lymphoid cells (ILC3) and Th17 in human nasopharynx-associated lymphoid tissue and their association with pneumococcal carriage in humans

L. Zaki[1], *R. Xu*[1], *M. S. Ahmed*[1], *R. Sharma*[2], *S. Leong*[3], *N. French*[1], ***Q. Zhang***[1];
[1]*University of Liverpool, Liverpool, United Kingdom,* [2]*Alder Hey Children's Hospital, Liverpool, United Kingdom,* [3]*Aintree University Hospital, Liverpool, United Kingdom.*

Innate lymphoid cells including ILC3 are increasingly appreciated as being critical in local immune homeostasis and inflammation. Similar to Th17 cells, ILC3 express IL17A and/or IL22. Recent data from animal models suggest there is a reciprocal interaction between ILC3 and T cell responses. It is not known whether any relationship between ILC3 and Th17 cells in human nasopharynx and whether ILC3 contributes to the regulation of pneumococcal carriage in humans. Methods: We have studied the ILC3 and Th17 populations in the nasopharynx-associated lymphoid tissue (NALT) from children and adults following stimulation by PMA or a Staphylococcal extract, and analysed their association n with pneumococcal carriage. ILC3 and Th17 frequencies and responses following stimulation were examined by flow-cytometry following staining for linage markers, CD127, NKP44, c-kit, RORgt, IL17A and IL-22. Results: We showed the ILC3 frequency in NALT was higher in children and mainly express IL22 which was in contrast to the markedly higher Th17 frequency in adults. Further analysis revealed that there was an inverse relationship between the IL22-expressing ILC3 and IL17A- producing Th17 cells, and a higher frequency of ILC3 was shown with pneumococcal carriage positive than in negative children. *S.aureus* stimulation reduced ILC3 number and HLA-DR expression but markedly increased Th17 response. *S.aureus* induced Th17 response was inhibited by RORgt-blocker which correlated to an increase in ILC3. Our results suggest there is significant interactions between ILC3 and pathogen-induced Th17 response, and ILC3 may critically regulate Th17 response in human nasopharynx through which mediate bacterial carriage in children.

P.D2.01.20

HIV-1 Infects and depletes innate lymphoid cells via type I interferon pathway

J. Zhao[1], *L. Cheng*[2], *L. Su*[2], ***Z. Zhang***[1];
[1]*Beijing 302 hospital, Beijing, China,* [2]*University of North Carolina, Chapel Hill, United States.*

Innate lymphoid cells (ILCs), including ILC1, ILC2 and ILC3 subsets, have emerged as central players in homeostatic and inflammatory conditions, and correlated with the pathogenesis of multiple human diseases. Our recent studies found that ILC3s were severely depleted from gut mucosal of patients with chronic HIV-1 infection via Fas/FasL-mediated pathway. Blockade of type I interferon (IFN-I) pathway significantly restored ILC3 loss in humanized mice with HIV-1 infection. However, it is not clear whether HIV-1 can infect ILCs. Here, we found that human ILC1s comprising of CD4+ and CD4- subpopulations were present in various human lymphoid organs but with different transcription programs and functions. CD4+ ILC1s expressed HIV-1 co-receptors and were productively infected by HIV-1 *in vitro* and *in vivo*. HIV-1 infection leads to activation, depletion and functional impairment of ILC1sin humans and in humanized mice*in vivo*. Highly active antiretroviral therapy (HAART) efficiently rescued the ILC1 numbers and reduced their activation, but failed to restore their functionality in HIV-1 patients. Blocking IFN-I signaling also prevented HIV-1 induced depletion or apoptosis of ILC1 cellsin vitro and in humanized mice in vivoduring HIV-1 infection. Our study identified the CD4+ ILC1 cells as a new target population for HIV-1 infection, and revealed that IFN-I contributes to the depletion of ILC1s during HIV-1 infection.

CARMIL2 splice site mutation in a patient with warts

F. Atschekzei[1], *R. Jacobs*[1], *G. Ahrenstorf*[1], *A. Dhingra*[2], *R. Schmidt*[1];
[1]*MHH, Department of Clinical Immunology and Rheumatology, Hannover, Germany,* [2]*MHH, Department of Virology, Hannover, Germany.*

We report a novel homozygous spice site mutation in *CARMIL2* (*RLTPR*) gene underlying a primary immunodeficiency with warts.Molecular genetic testing was composed of targeted next-generation sequencing of a panel of PID related genes. A now 29-year-old male patient, born of consanguineous parents, presented since childhood with a history of eczema, recurrent bacterial infections such as pyoderma and pneumonia. Since the age of 22 he suffers from disseminated and persistent warts (verruca vulgaris palmaris) particularly in the hands and sole of the feet. Targeted next generation sequencing identified a novel homozygous splice-acceptor site mutation [c.795-1 G>A] in *CARMIL2* gene, which co-segregated with the disease phenotype. This is one of few reports of cutaneous warts associated with a homozygous mutation in *CARMIL2* which underlines the role of CARMIL2 in primary immunodeficiency. Therefore, it might be considered in the molecular differential diagnosis of patients with disseminated and/or persistent warts. Supported by DZIF TTU 07.801

P.D2.02.02
Tumor necrosis factor superfamily member induces Ig synthesis against PAMP stimulation by activatingNF-κB pathway in freshwater carp, *Catla catla*

R. Banerjee[1], *M. Samanta*[2], *S. Das*[1];
[1]*National Institute of Technology, Rourkela, India,* [2]*ICAR- Central Institute of Freshwater Aquaculture, Bhubaneswar, India.*

Introduction: Tumor necrosis factor superfamily (TNFSF) members consist of different cytokines amongst which, B cell activating factor (BAFF) and a-proliferation-inducing ligand (APRIL) are involved in B-cell development playing a crucial role in adaptive immunity. These two similar homology domain ligands have three common receptors: BAFF receptor, BCMA and TACI which binds to enhance the immune system in wide range of vertebrates. Therefore, to gain insights into the efficacy of Ig synthesis in the Indian Major Carp *Catla catla*, the binding of BAFF/APRIL to the receptors were studied which may trigger the immune system in downstream signaling cascade orchestrating the Ig synthesis.
Materials and Methods: The immune response of BAFF and APRIL along with downstream signaling molecules involved in NF-κB pathway have been analysed by performing qRT-PCR, immunoblotting and flow cytometry. Further, NF-κB inhibitor was also used to inhibit the NF-κB complex to investigate the transcriptomic analysis of the signaling molecules along with Ig synthesis.
Results: The qRT-PCR analysis elucidated their role in PAMPs stimulated tissues leading to the upregulation and activation of downstream signaling molecules. The leukocyte isolated from the blood was treated with r-BAFF which showed an enhancement in the Ig synthesis.
Conclusion: The study can therefore prove the insight of BAFF and APRIL during PAMPs stimulation in carps augmenting the Ig synthesis by NF-κB dependent pathway. Expressions of r-BAFF also showed the critical role in adaptive defence mechanism in *C. catla*.

P.D2.02.03
Long term effects of chronic HCV infection on Natural Killer cells

W. Bi[1], *M. Heyner*[1], *J. Hengst*[2], *L. Nilse*[3], *B. Bulitta*[1], *F. Klawonn*[1,4], *H. Wedemeyer*[2], *L. Jänsch*[1];
[1]*Helmholtz Center for Infection Research, Braunschweig, Germany,* [2]*Hannover Medical School, Hannover, Germany,* [3]*University of Freiburg, Freiburg, Germany,* [4]*Ostfalia University of Applied Sciences, Wolfenbüttel, Germany.*

Natural killer (NK) cells play a pivotal role in the direct defense against tumors and viral infections. Basically, NK cells have the capacity to counteract hepatitis C virus (HCV) infections. However, NK immune responses are apparently impaired in chronically infected HCV patients, which contribute to HCV-related diseases including hepatocellular-carcinoma (HCC). Since 2014, direct acting antivirals (DAAs) such as Harvoni®, were approved for therapy of HCV patients. While DAA application results in complete viral clearance, it was tempting to speculate that HCV-mediated immune evasion mechanism in NK cells are rescued in parallel. This project aims to decipher mechanisms of how HCV infections cause NK cell dysfunctions. We collected primary NK cells from Harvoni®-treated HCV patients before, along and after therapy, and then performed a comprehensive molecular phenotyping by means of quantitative proteomics. We found important NK cell functions from cured patients still de-regulated after virus clearance suggesting long-term effects on human NK cell immunity. Among those functions, we selected ADAP to complement information about its importance for human NK cell responses. We newly generated ADAP knock out NK cells and performed *in vitro* assays that determined its role in cytotoxicity, degranulation and cytokine production. This project is supported by China Scholarship Council.

P.D2.02.04
Persistent replication of HIV, HCV and HBV results in distinct gene expression profiles by human NK cells

L. Boeijen, *J. Hou, R. de Groen, A. Verbon, A. Boonstra;*
Erasmus MC, Rotterdam, Netherlands.

Background: NK cells during chronic viral infection have been well studied over the last decade. We performed an unbiased next-generation RNA-sequencing approach to identify commonalities or differences of the effect of HIV, HCV and HBV viremia on NK cell transcriptomes.
Methods: Using cell sorting, we obtained CD3-CD56+ NK cells from blood of 6 HIV, 11 HCV, and 32 HBV infected patients without treatment. After library preparation and sequencing, we used an in-house analytic pipeline to compare expression levels with matched healthy controls.
Results: In NK cells from HIV, HCV and HBV patients, transcriptome analysis identified 272, 53, and 56 differentially expressed genes, respectively (fold change >1.5, q-value 0.2). Interferon stimulated genes were induced in NK cells from HIV/HCV patients, but not during HBV infection. HIV viremia downregulated ribosome assembly genes in NK cells. In HBV, viral load and ALT variation had little effect on genes related to NK effector function.
Conclusion: We compare, for the first time, NK cell transcripts of viremic HIV, HCV and HBV patients. We clearly demonstrate distinctive NK cell gene signatures in 3 different populations, suggestive for a different degree of functional alterations of the NK cell compartment as compared to healthy individuals.

P.D2.02.05
Mature NKG2C$^+$ NK cells demonstrate increased HLA-DR expression

S. A. Erokhina, *P. A. Kobyzeva, M. A. Streltsova, E. I. Kovalenko;*
Institute of Bioorganic Chemistry of RAS, Moscow, Russian Federation.

A common reaction of human NK cells to CMV infection is appearance of highly differentiated CD56^{dim}NKG2C$^+$NKG2A$^-$CD57$^+$ subset, often described as a variation of “adaptive” NK cells. The activating receptor NKG2C can be also found on the surface of less differentiated CD56^{dim}CD57$^-$ and CD56^{bright} cells. In order to investigate similarities and distinctions of the different NKG2C-positive subsets we have analyzed by flow cytometry the surface expression of HLA-DR, known as a marker of NK cell activation, in NK cells at certain differentiation stages.
In *ex vivo* studies, we observed significant proportion of HLA-DR-expressing cells among all NKG2C-positive NK cells. In CD56^{dim}CD57$^+$ and CD56^{dim}CD57$^-$ subsets, NKG2C$^+$ NK cells demonstrated higher level of HLA-DR-positive cells, along with higher HLA-DR expression intensity, than respective NKG2C$^-$ cells, whereas in CD56^{bright} subset HLA-DR expression level in NKG2C$^+$ and NKG2C$^-$ NK cells were similar. After in vitro stimulation of bulk cultures with IL-2 and K562 feeder cells expressing membrane-bound IL-21, the proportion of HLA-DR$^+$ cells increased in all NK cells, but especially in NKG2C-positive. Besides, among clonally expanded NK cell populations, acquired in the same stimulating conditions, HLA-DR expression intensity was higher in clones from NKG2C$^+$CD56^{dim}CD57$^-$/ NKG2C$^+$CD56^{dim}CD57$^+$ subsets compared to clones from their NKG2C$^-$ counterparts.
Thus, *in vivo* part of NKG2C$^+$ NK cells, but not NKG2C$^-$ NK cells, from more differentiated CD56^{dim} subset maintain HLA-DR expression, demonstrating more activated status than NKG2C$^-$ cells, and the same NK cells respond more effectively to cytokine/feeder cells stimulation.
The work was supported by Russian Science Foundation, grant #16-15-00309.

P.D2.02.06
Endometrial natural killer cells reveal a tissue-specific receptor repertoire

D. Feyaerts[1], *T. Kuret*[1], *B. van Cranenbroek*[1], *S. van der Zeeuw-Hingrez*[1], *O. W. van der Heijden*[2], *A. van der Meer*[1], *I. Joosten*[1], *R. G. van der Molen*[1];
[1]*Department of Laboratory Medicine, Laboratory for Medical Immunology, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Department of Obstetrics and Gynaecology, Radboud University Medical Center, Nijmegen, Netherlands.*

Natural killer cells (NK) discriminate foreign and malignant cells from healthy ‘self’ cells. However, during pregnancy local uterine NK cells play a different and more regulatory role by creating an immunologically privileged niche, and promoting trophoblast invasion and correct placenta formation. NK receptors (NKRs) are central regulators of NK activity, however, little is known about NKR expression on pre-pregnancy endometrial NK cells (eNKs). In order to bridge this knowledge gap, we analyzed NKR expression on pre-implantation eNKs to examine their potential role in successful pregnancy and questioned whether the NKR repertoire of eNK cells is different from peripheral blood NK cells (pbNKs).
eNK cells, obtained from menstrual blood, were immunophenotyped for NKR expression using flow cytometry, and compared to pbNKs of the same female.

Results showed that the NKR repertoire of eNKs is distinct from pbNKs, with eNKs co-expressing more than 3 NKR simultaneously. In contrast to the pbNKs, expansions of NK subpopulations present in the eNKs were independent of prior cytomegalovirus (CMV) infection and *HLA-C* genotype, suggesting rapid local turnover of eNKs and/or a distinct licensing process. Taken together, our data reveals that eNKs have a unique tissue-specific signature, suggesting they are finely tuned to accept the semi-allogenic fetus. These findings pave the way for the evaluation of eNK function during pregnancy complications, and may yield insight into their pathogenesis, thereby setting the stage for the discovery of pregnancy-success related biomarkers.

P.D2.02.07

Early Extracellular Followed by a Late Surge in Intracellular Release of Oxygen Radicals in Rat Neutrophils Following Acute Burn Injury With Sepsis

*N. Fazal, **M. Ibrahim**;*
Chicago State University, Chicago, United States.

Background: This is a study of neutrophil host defense and neutrophil oxidant production in burn-injured rats with a superimposed E. faecalis infection; it will enhance our understanding of pathogenic mechanisms by which infections exacerbate host defense dysfunction occurring with burn injury alone.
Methods: Our studies focus on alterations in neutrophils' oxidative in burn rats inoculated with Enterococcus faecalis. Blood and peritoneal PMN were obtained from different experimental and control groups of animals. O2- production both extracellular and intracellular was measured in PMN before and after their stimulation with PMA (100ng/mL) using Isoluminol-enhanced luminometry.
Results: We found that there is an early extracellular followed by a late surge in intracellular release of oxygen radicals in rat neutrophils following acute burn injury with sepsis. Blood PMN O2- remained upregulated after infection of rats with E. faecalis superimposed with the burn injury. E. faecalis alone did not cause an increase in blood PMN O2- to the level caused by burn alone. E. faecalis plus burn cause a much greater increase in peritoneal PMN O2- than in blood PMN O2- compared to the increase with burn alone.
Conclusions: These data show tissue PMNs exiting into the peritoneal cavity are activated to extracellularly release greater quantities of O2- than PMNs in blood with the combined burn and E. faecalis injury. Thus there was a likely exacerbation of extracellular O2- release by tissue PMNs in the combined injury. We conclude a differential kinetics of ROS release in circulatory and tissue neutrophils following burn and sepsis.

P.D2.02.08

CD127+ Innate Lymphoid Cells (ILCs) with NK cell features accumulate in Inflammatory Bowel Disease (IBD)

***L. Krabbendam**[1], C. Kradolfer[1], C. Buskens[1], W. Bemelman[1], J. H. Bernink[2,1], H. Spits[1];*
[1]Academic Medical Center, Amsterdam, Netherlands, [2]Hubrecht Institute, Utrecht, Netherlands.

Crohn's disease and Ulcerative Colitis are intestinal inflammatory disorders characterized by dysregulated immune responses. Innate Lymphoid Cells (ILCs), including helper ILCs and NK cells, are important for intestinal homeostasis and protective immune responses, but can contribute to inflammatory diseases when not properly balanced. Three helper ILC subsets are distinguished by their cytokine profile but each subset adapts its phenotype and cytokine profile in response to environmental cues. This plasticity is extensively described between helper ILC subsets, but the distinction and plasticity between helper ILCs and NK cells requires further investigation.
In human intestinal tissue, we identified an IFN-γ-producing cell type that expresses the ILC markers CD127 (IL-7R) and the NK cell marker CD94. Based on phenotype, transcription profile and cytokine secretion this cell type resembles both ILCs and NK cells. *In vitro* experiments demonstrated that conventional helper ILCs acquire a cytotoxic, IFN-γ-producing CD94$^+$ phenotype when exposed to IL-12 that can kill K562 target cells. Since these cytotoxic ILCs retain expression of a number of ILC markers and lack some NK markers they remain distinct from NK cells. This indicates that helper ILCs can acquire NK cell features, which may be reversible. Thus, like CD4+ T cells, helper ILCs can acquire features of cytotoxic cells. These cytotoxic CD127+CD94+ ILCs are more prominent in human adult inflamed intestine compared to non-inflamed resection specimen and virtually absent in human fetal intestine, suggesting that an inflammatory environment favors accumulation of this cell type. Therefore, these novel cytotoxic CD127+CD94+ ILC may contribute to IBD pathology.

P.D2.02.09

Murine gamma delta T cells display distinct subpopulations based on their ability to phagocytose unopsonised bacteria

***J. C. Lenzo**, S. Fong, J. Holden, N. M. O'Brien-Simpson, E. C. Reynolds;*
Oral Health Cooperative Research Centre, Melbourne Dental School, Bio21 Institute, The University of Melbourne, Melbourne, Victoria, Australia., Melbourne, Australia.

In humans and mice, gamma-delta (γδ) T cells constitute approximately 1-5% of the total circulating T cells. Despite being a minority in circulation, murine γδ T cells exist as a large proportion in skin and mucosal sites. Given that mucosal epithelium serves as the initial barrier against invading pathogens, roles in immune regulation and infection surveillance are proposed for γδ T cells. Chronic periodontitis, an inflammatory disease of the supportive tissues of the teeth, leads to resorption of alveolar bone and eventual tooth loss. Although chronic periodontits is associated with a polymicobial biofilm, specific bacterial species such as *Porphyromonas gingivalis* are closely associated with clinical measures of disease. Using *in vivo* mouse models, we show that γδ T cells respond rapidly upon *P. gingivalis* infection and are able to phagocytose unopsonised *P. gingivalis*, confirming their role in innate immune responses. We have also identified novel murine γδ T cell subpopulations based on cell surface marker expression and ability to phagocytose bacteria, CD27$^-$ γδ T cells are efficient phagocytes while CD27$^+$ γδ T cells are less phagocytic and express higher levels of expressed antigen presentation markers. We have also found that human blood γδ T cells can phagocytose unopsonised *P. gingivalis*, indicating that they may also play a role in the immune response observed in human periodontitis. Based on our findings, we propose that the slower phagocytic CD27$^+$ γδ T cells have a more antigen presentation role, whereas the rapid phagocytic CD27$^-$ γδ T have a more microbial clearance role.

P.D2.02.10

Molecular functional characterisation of neutrophil granulocytes during *Aspergillus fumigatus* infection

***F. Neumann**[1], J. Weski[1], P. Seddigh[1], T. Bracht[2], M. Gunzer[1];*
[1]University Hospital Essen, Institute for Experimental Immunology and Imaging, Essen, Germany, [2]Ruhr-Universität Bochum, Medizinisches Proteom-Center, Bochum, Germany.

Invasive Aspergillosis is common condition in individuals suffering from one of various forms of immune suppression. The cause of this ailment are inhaled conidia of the mould fungus *Aspergillus fumigatus*, normally cleared from the airways predominantly by neutrophil granulocytes. If the clearing fails, the conidia start to germinate and the hyphal network can spread and invade every mayor organ. However, the underlying mechanisms making or breaking a successful clearance are still to be identified. By analysing the proteome of neutrophils from mice challenged with conidia, we could identify proteins which are highly regulated in the activated cell, like PAD4 or MPO. The majority of proteins we identified remain as of yet uncharacterised in an infectious context and are now investigated utilizing immortalised HoxB8 progenitor cells. We knock out the correlating genes via CRISPR/Cas and the *in vitro* differentiated HoxB8 neutrophils will be examined in an array of methods designed to assess neutrophil functionality, e.g. NET formation or ROS production. We created HoxB8 cells which express tdTomato only when differentiated into neutrophils. This specific fluorescence permits us to confirm gene function of promising candidates even under near physiological conditions by transferring knockout cells into mice and tracking them to verify their role in an *in vivo* model of pulmonary aspergillosis. In researching the basic mechanisms of the mostly unnoticed conidia clearing process we will be able to bring more understanding to *A. fumigatus* infection cases and possibly aid in curing, perchance even preventing this life-threatening condition in immunocompromised patients.

P.D2.02.11

NKG2D sets activation threshold for NCR1 early in NK cell-development and controls sensitivity of cancer immune-surveillance

*V. Jelenčić[1], M. Lenartić[1], T. Holmes[2], M. Prchal[3], V. Sexl[3], Y. T. Bryceson[4], F. M. Wensveen[1], **B. Polic**[1];*
[1]Faculty of Medicine, University of Rijeka, Rijeka, Croatia, [2]Broegelmann Laboratory, Department of Clinical Sciences, University of Bergen, Bergen, Norway, [3]Institute of Pharmacology and Toxicology, Department for Biomedical Sciences, University of Veterinary Medicine Vienna, Vienna, Austria, [4]Center for Hematology and Regenerative Medicine, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden.

Introduction: NKG2D and NCR1 (NKp46) are both activating receptors expressed on all NK cells during NK cell development and have important role in the stress-surveillance. 'Stressed' cells up-regulate NKG2D and/or NCR1 ligands which can engage their receptors and activate NK cells. Previously, our group has shown that NKG2D-deficiency affects NK cell development (Zafirova et al. Immunity 2009). Klrk1$^{-/-}$ mice showed an enhanced NK cell-mediated resistance to MCMV infection, while they kept impaired ability to kill NKG2D-expressing tumor targets. **Aim**: Here we investigated molecular mechanism underlaying the NK hyperreactivity and how it influences control of tumors which do not express NKG2D ligands. **Materials and Methods:** In our research we used two tumor models: γ irradiation-induced thymoma and B16 melanoma. We also used different functional assays, flow cytometry and various genetically modified mice to investigate roles of specific receptors and signaling molecules. **Results**: NKG2D-deficiency results in specific NCR1-medicated NK cell hyperreactivity. The hyperreactivity occurs during the NK cell development and is due to the lack of signaling through NKG2D-DAP12 axis. It is correlated with reduced expression of CD3ζ and Zap70. The hyperreactivity results in better control of the investigated tumors and MCMV infection in Klrk1$^{-/-}$ and DAP12$^{-/-}$ mice. **Conclusion**: This research shows for the first time that an activating NK receptor controls activity of another one. Early during NK cell development NKG2D/DAP12 axis sets threshold for NCR1 which leads to NK cell hyperreactivity and better control of MCMV infection and tumors expressing NCR1 ligands.

P.D2.02.12

Peptide-specific recognition of human cytomegalovirus strains controls adaptive natural killer cells

*Q. Hammer[1], **T. Rückert**[1], C. Romagnani[1,2];*
[1]Innate Immunity, German Rheumatism Research Center (DRFZ), Leibniz Association, Berlin, Germany, [2]Charité Universitätsmedizin, Berlin, Germany.

Natural killer (NK) cells are innate lymphocytes that lack antigen-specific rearranged receptors, a hallmark of adaptive lymphocytes. In some people infected with human cytomegalovirus (HCMV), an NK cell subset expressing the activating receptor NKG2C undergoes clonal-like expansion that partially resembles anti-viral adaptive responses. However, the viral ligand that drives the activation and differentiation of adaptive NKG2C$^+$ NK cells has remained unclear. Here we found that adaptive NKG2C$^+$ NK cells differentially recognized distinct HCMV strains encoding variable UL40 peptides that, in combination with pro-inflammatory signals, controlled the population expansion and differentiation of adaptive NKG2C$^+$ NK cells. Thus, we propose that polymorphic HCMV peptides contribute to shaping of the heterogeneity of adaptive NKG2C$^+$ NK cell populations among HCMV-seropositive people.

P.D2.02.13

Neutrophils suppress mucosal associated invariant T cells

***M. Schneider**, J. E. Ussher;*
Department of Microbiology and Immunology, University of Otago, Dunedin, New Zealand.

Mucosal associated invariant T (MAIT) cells are abundant innatelike lymphocytes which are rapidly activated in response to bacterial and fungal infections. Upon activation MAIT cells produce cytokines, including INFγ and TNFα, and upregulate cell surface markers CD69 and CD137 (4-1BB). Neutrophils are crucial for the early immune response and have been shown to suppress the activation of innatelike lymphocytes, such as γδ T cells and iNKT cells. Here, we investigated the influence of neutrophils on MAIT cell activation. MAIT cells, monocytes, and neutrophils were isolated from the blood of healthy donors. Cells were stimulated with fixed bacteria, and their activation assessed by flow cytometry. We show that neutrophils supressed the activation of MAIT cells, both in cocultures with monocytes and in PBMCs after stimulation with fixed bacteria. The production of effector cytokines INFγ and TNFα, as well as the upregulation of cell surface markers CD69 and CD137 (4-1BB), was inhibited. Therefore, neutrophils suppress the activation of MAIT cells and may play an important role in the regulation of the innate immune response to extracellular bacteria through the inhibition of innatelike lymphocytes. Investigations into the mechanism of suppression are ongoing with results to be presented at the conference.

P.D2.02.14

***In vivo* depletion of T-bet in intestinal innate lymphoid cells**

***J. Schroeder**[1], J. Lo[1], L. Roberts[1], H. Helmby[2], G. Lord[1];*
[1]King's College London, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom.

Introduction: Innate lymphoid cells (ILCs) have been suggested to play important roles at mucosal surfaces primarily by the expression of subset-specific cytokines regulated by lineage-defining transcription factors. However, due to the lack of appropriate mouse models the functional redundancy of ILC in certain models cannot be excluded. Method: We generated T-bet fl/fl x Cre-Ert2 mice allowing the tamoxifen-induced depletion of T-bet *in vivo*. Breeding pairs were set up in order to generate Cre-Ert2 positive and negative litters. Tamoxifen was administered via the intraperitoneal route on 5 consecutive days. Mice were rested until 3 weeks post the initial injection of tamoxifen. Afterwards cells were harvested without further treatment or upon exposure to dextran sulfate sodium (DSS)-containing drinking water or intestinal infection with *N. brasiliensis* or *H. polygyrus*. Results/ conclusion: Here we show that T-bet is crucially important to maintain NKp46$^+$ NK1.1$^+$ CD127$^+$ ILC in the colonic and small intestinal lamina propria. In contrast to CD127$^+$ ILC, T-bet expression in CD4$^+$ T cells was only partially diminished. Strikingly, upon tamoxifen-induced depletion of T-bet$^+$ CD127$^+$ ILC mice showed significantly less weight loss upon DSS challenge. This observation stands in contrast to models of intestinal infection with *N. brasiliensis* or *H. polygyrus* as depletion of T-bet - expressing CD127$^+$ ILC did not result in accelerated parasite depletion. Furthermore there was minimal evidence of ILC plasticity following temporally defined T-bet deletion. Hence, our novel model of specific depletion of T-bet in CD127$^+$ ILC points to the crucial role of this transcription factor in mucosal inflammation.

P.D2.02.15

Galectin-3 deficiency promotes liver inflammation and facilitates TNF-α-dependent hepatocyte death in MCMV infection

***B. S. Stojanovic**[1], I. Strazic Geljic[2], A. Arsenijevic[1], J. Milovanovic[1], N. Arsenijevic[1], S. Jonjic[1], M. L. Lukic[1], M. Milovanovic[1];*
[1]Faculty of medical science, Kragujevac, Serbia, [2]Faculty of Medicine, Rijeka, Croatia.

Galectin-3 (Gal-3) is a lectin that plays various roles in the pathogenesis of malignant, inflammatory, autoimmune and infectious diseases including liver diseases. In this study, using C57BL/6 mice with target deletion Lgals3 gene (Gal-3-/-) for the first time was demonstrated that the absence of Gal-3 enhanced liver damage in hepatitis induced by intraperitoneal application of murine cytomegalovirus (MCMV). Livers of MCMV infected Gal-3-/- mice contained more inflammatory and necrotic foci, necrotic hepatocytes, and significantly higher level of ALT in the sera compared with the group of C57BL/6 (WT) infected mice, 36 and 72 hours after infection. Significant increase in viral titres was detected in the liver of Gal-3-/- mice compared to WT mice, 72 hours after infection. TNF-α expression was detected in hepatocytes of MCMV infected mice and it was higher in the livers of Gal-3 KO mice compared with the group of WT mice. The number of TNF-α-positive hepatocytes isolated from the livers of infected mice and and concentration of TNF-α liver tissue homogenate was significantly higher in the group of Gal-3 KO mice. TNF-α blockade with monoclonal antibodies before MCMV infection significantly reduced hepatocyte necrosis only in Gal-3 KO mice. MCMV infection increased the expression of Gal-3 on hepatocytes of WT mice. Treatment with Gal-3 inhibitor (TD139) enhanced liver necrosis in WT mice and administration of recombinant Gal-3 reduced inflammation and liver damage in Gal-3 KO mice. This study demonstrated that Gal-3 plays a protective role in hepatitis induced with murine cytomegalovirus infection by reducing TNF-α-induced hepatocyte death.

P.D2.02.16

The role of IFNγ in patients with ulcerative colitis

***A. Valeeva**[1], O. Skorokhodkina[1], R. Abdulkhakov[1], S. Abdulkhakov[2], A. Rizvanov[2];*
[1]Kazan State Medical University, Kazan, Russian Federation, [2]Kazan Federal University, Kazan, Russian Federation.

Ulcerative colitis (UC) is a clinical form of inflammatory bowel diseases (IBD) and considered as a chronic disorder of the gastrointestinal tract characterized by intestinal inflammation and epithelial injury. The pathogenesis of UC remains unclear. Disease has been considered to be associated with a non-conventional Th2 response. Besides the role of Th17 in the pathogenesis of autoimmune inflammation in UC is being discussed. Nowadays results from numerous studies indicate a role for innate lymphoid cells (ILC) in the pathogenesis of chronic intestinal inflammation in IBD.Objective: To analyze the serum levels of IFNγ in patients both in the acute stage and remission of UC. Methods: Forty eight patients in the acute stage and twenty patients in remission of UC were included into the study. Serum cytokine levels were analyzed using multiplex immunoassay. Statistical analysis was performed using STATISTICA 6.0 Software Package. 11 healthy volunteers were included into the control group.Results: Statistically significant increase of IFNγ in serum of patients both in acute stage (176,15 pg/ml [65,15;359,84]) and remission (42,6 pg/ml [29,4;64,45]) compared to controls (16,5 pg/ml [12,3;23,2], p=0,00107; 0,0118) respectively) was revealed. ILC type 1 are defined by production of proinflammatory IFNγ , which is discussed nowadays to play a substantial role in chronic inflammation in IBD. Therefore increase of IFNγ might be a marker for functional overactivity of ILC.Conclusions: Increased levels of IFNγ might suggest overactivity of innate lymphoid cells. Innate lymphoid cells may contribute to chronic immune inflammation in the pathogenesis of ulcerative colitis.

P.D2.02.17

Innate lymphoid cells in paediatric inflammatory bowel disease

***A. Van Acker**[1], E. Kvedaraite[1,2], M. Lourda[1,2], M. Ideström[3], J. Henter[2], M. Svensson[1], J. Mjösberg[1];*
[1]Center for Infectious Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Childhood Cancer Research Unit, Department of Women's and Children's Health, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [3]Paediatric Gastroenterology, Hepatology and Nutrition Unit, Department of Women's and Children's Health, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Background: The underlying etiology of paediatric inflammatory bowel disease (PIBD) remains largely unknown, indicating the dire need for more knowledge on the mechanisms driving this disease. Recent publications have highlighted the importance of ILCs in murine and adult IBD development and progression. In this project, we aim to study ILC heterogeneity and function specifically in PIBD. **Methods:** Peripheral blood mononuclear cells (PBMCs) and single-cell suspensions were isolated from blood and colon biopsies, respectively, of 20 PIBD and 5 non-PIBD patients admitted to the Paediatric Gastroenterology, Hepatology and Nutrition Unit at Karolinska University Hospital, Sweden. ILC population frequency and phenotype was examined by 18-colour flow cytometry and correlated to children's IBD physician global assessment (PGA) scores. **Results:** Preliminary results from our flow cytometry data show a statistically significant decrease in the frequency of ILC3 cells ($p<0.05$) and a statistical tendency towards an increase in the frequency of ILC1 ($p=0.06$) in the gut of PIBD as compared with non-PIBD control patients. In PBMC, we detected a slight decrease in the frequency of ILC1 ($p=0.06$). **Conclusions:** Our data suggests a skewing of the ILC balance in the intestinal mucosa of PIBD patients, with an increase of IFN-γ producing ILC1, and a decrease of IL-22 producing ILC3. However, our results are based on a small patient cohort and as yet lack sufficient power for our intended statistical analysis. Extensive further research will now be conducted to continue this analysis as well as examine additional phenotypical and functional differences in ILCs from PIBD patients and non-PIBD controls.

P.D3.01 Novel approaches to vaccinology - Part 1

P.D3.01.01

Investigation of immunogenic properties of Hemolin from *Bombyx mori* as carrier protein: an Immunoinformatic approach.

S. Aathmanathan[1], *V. K. Prajapathi*[2], *M. Krishnan*[1,2];
[1]*Bharathidasan University, Trichy, India,* [2]*Central University of Rajasthan, Ajmer, India.*

Encapsulated bacteria are pathogens which causes disease among elderly, infants and immune-compromised individuals. Since polysaccharides (haptens) are less immunogenic, carrier proteins are conjugated with haptens to elicit a stronger immune response and prolonged T-cell memory. Dendritic cells are the most potent antigen presenting cells (APC's). Toll like receptors (TLR's) present on APC's plays a major role in identification of antigen and activation of cell mediated immunity. Hence TLR agonists are potential immunostimulants. Carrier protein which enhances the cell mediated immunity through TLR activation is a potent candidate for conjugate vaccine. Hemolin,48 kDa protein which is present in major lepidopteran insects, that is similar to mammalian immunoglobulin. It has also a natural affinity towards the bacterial lipopolysaccharides. In the present study, Hemolin was modelled using RaptorX server. The model was validated using RAMPAGE and ProsaWeb servers. LPS of *E.coli*, TLR3 and TLR4 of *Homo sapiens* were docked with Hemolin using Patchdock and interaction was visualized using Chimera 1.11. Docked complexes were subjected to molecular dynamics for 20ns using GROMACS standalone tool. B and T-cell epitopes were identified using tools in IEDB server. IFN-γ activation epitopes were identified using IFN epitope server. The allergenicity was predicted using Allertop and AllerFP servers. This makes hemolin a suitable candidate as a carrier protein in conjugate vaccine because of its high immunogenicity and TLR activation.

P.D3.01.02

In silico designing of a novel multi-epitope peptide vaccine against *Leishmania infantum*: Analysis of its immunogenic potential *in vitro* and *in vivo*

M. Agallou, *E. Athanasiou, M. Margaroni, E. Karagouni;*
Laboratory of Cellular Immunology, Department of Microbiology, Hellenic Pasteur Institute, Athens, Greece.

In the present study, we have designed a multi-epitope peptide vaccine referred as LiChimera, containing several Helper (HTL) and Cytotoxic (CTL) T lymphocyte epitopes obtained from different *Leishmania infantum* proteins through computational vaccinology approaches. The selected epitopes were fused together by using appropriate linkers, while the N-terminal domain of Heparin-Binding Hemagglutinin (HBHA) from *Mycobacterium tuberculosis* was also linked as a TLR4 agonist. LiChimera was effectively expressed in *E. coli* system and its immunogenicity was determined by injecting it intramuscularly alone or in the presence of Addavax - a squalene-based adjuvant - twice at 2 weeks intervals in BALB/c mice.
Results indicated that LiChimera was highly immunogenic and elicited antigen-specific adaptive immune responses, as shown by the high level of serum IgG production and splenocyte proliferation, which were further enhanced in the presence of Addavax. In addition, bone-marrow derived macrophages obtained from mice that received LiChimera and Addavax demonstrated increased leishmanicidal activity confirmed by reduced parasite load in comparison to macrophages obtained from control mice. Overall, we described a new multi-epitope peptide vaccine and its immunogenic properties as a candidate vaccine against leishmaniasis. Further experimentation will be conducted in order to determine its protective efficacy against infectious challenge of *Leishmania*. *This research was made possible through the grant from the Stavros Niarchos Foundation to the Hellenic Pasteur Institute, as part of the Foundation's initiative to support the Greek research center ecosystem.*

Adjuvants enhance induction of germinal center and antibody secreting cellsin spleen of neonatal mice and their persistence in bone marrow

A. A. Aradottir Pind[1,2], *M. Dubik*[1,2], *S. S. Thorsdottir*[1,3], *J. Holmgren*[4], *A. Meinke*[5], *G. Del Giudice*[6], *S. P. Bjarnarson*[1,2], *I. Jonsdottir*[1,2];
[1]*Department of Immunology, Landspitali, the National University Hospital of Iceland, Reykjavík, Iceland,* [2]*Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavík, Iceland,* [3]*Karolinska Institute, Stockholm, Sweden,* [4]*University of Gothenburg Vaccine Research Institute (GUVAX), Department of Microbiology and Immunology, University of Gothenburg, Gothenburg, Sweden,* [5]*Valneva Austria GmbH, Vienna, Austria,* [6]*GSK Vaccines, Siena, Italy.*

Introduction: Immaturity of the immune system contributes to poor vaccine responses in early life. Germinal center (GC) activation is limited due to poorly developed follicular dendritic cells (FDC), causing generation of few antibody-secreting cells (AbSCs) with limited survival and transient antibody responses. The potential of five adjuvants to overcome limitations of the neonatal immune system to induce more robust and prolonged vaccine responses was explored.
Materials and methods: Neonatal mice were immunized with a pneumococcal conjugate vaccine Pnc1-TT w/wo adjuvants LT-K63, mmCT, MF59, IC31 or alum. Spleen, bone marrow (BM) and blood were collected at various time points after immunization. Spleen sections were stained for FDC maturation and GC activation, vaccine-specific AbSCs were enumerated in spleen and BM with ELISPOT and vaccine-specific serum-antibodies measured with ELISA.
Results: Mice immunized with Pnc1-TT with LT-K63, mmCT, MF59 or IC31 had significantly enhanced maturation of FDCs compared to mice immunized with vaccine alone. LT-K63, MF59 and IC31 significantly enhanced GC formation and mmCT and MF59 significantly enhanced vaccine-specific AbSCs in spleen 14 days after immunization. Neonatal mice immunized with Pnc1-TT with LT-K63, mmCT, MF59 or IC31 had significantly enhanced numbers of vaccine-specific AbSCs in BM 9 weeks after immunization and significantly enhanced vaccine-specific serum antibodies persisting above protective levels against pneumococcal bacteremia and pneumonia.
Conclusion: LT-K63, mmCT, MF59 and IC31 overcame limitations of the neonatal immune system and enhanced both induction and persistence of protective immune response when administered with Pnc1-TT. They are therefore promising candidates for further research on neonatal immune responses.

P.D3.01.04

Immunogenicity of DNA vaccines delivered by patches &lt electroporation in pig skin

C. Bernelin-Cottet[1], *C. Urien*[1], *F. Blanc*[2], *J. Leplat*[2], *J. McCaffrey*[3], *D. Collins*[3], *V. Jakob*[4], *E. Bordet*[1], *C. Barc*[5], *V. Contreras*[6], *N. Bertho*[1], *N. Collin*[3], *C. Barnier-Quer*[4], *A. Moore*[7], *I. Schwartz-Cornil*[1];
[1]*VIM-INRA-Université Paris-Saclay, Jouy-en-Josas, France,* [2]*GABI-INRA-AgroParisTech-Université Paris-Saclay, Jouy-en-Josas, France,* [3]*School of Pharmacy, University College Cork, Xeolas, Cork, Ireland,* [4]*Vaccine Formulation Laboratory, Department of Biochemistry, University of Lausanne, Epalinges, Switzerland,* [5]*INRA, UE1277, Plate-Forme d'Infectiologie Expérimentale, PFIE, Nouzilly, France,* [6]*CEA-Université Paris Sud-INSERM, U1184 « Immunology of viral infections and auto immune diseases », IDMIT department, IBFJ, Fontenay-aux-Roses et Kremlin-Bicêtre, France,* [7]*School of Pharmacy, University College Cork, Xeolas, Cork, France.*

DNA vaccines show suboptimal efficacy in humans and domestic species. The delivery of DNA vaccine is key to improve immunogenicity. As skin is a readily accessible tissue rich in antigen presenting cells and pig skin is a relevant models for humans, we evaluated different modes of DNA delivery in pig skin, i.e. surface electroporation (EP) and dissolvable microneedle patches (DMN), and we assessed the benefit of DNA adsorbtion on cationic poly(lactic-co-glycolic acid) nanoparticles (NP). We used plasmids encoding for luciferase and vaccine plasmid encoding for weak antigens derived from the Porcine Reproductive and Respiratory Syndrome Virus (PRRSV), an arterivirus responsible of reproductive disorders in sows and respiratory illnesses in piglets. All methods were successful at inducing luciferase expression in skin. At 24 hours post administration, EP, and not DMN, induced a strong recruitment of granulocytes in skin, with the reduction of conventional dendritic cell subsets (cDC1 and cDC2) and of Langerhans cell, in association to a high production of IL1b and IL8. Substantial T cell responses against the PRRSV antigens were induced upon delivery with EP and DMN. Notably we obtained the broadest IFNg T response against a large panel of PRRSV antigenic regions with DNA adsorbed on NP and delivered by EP. Good systemic and mucosal IgG responses were induced by EP and not by DMN delivery. Altogether, delivery of DNA vaccines with electroporation and patches can be achieved in pig skin with variable degrees of transduction efficacy and local inflammation and can induce immune responses against weak antigens.

P.D3.01.05

Bipolymer based Novel Nanoparticles in Microsphere System as Vaccine Adjuvant

S. Bhargava[1], *V. Bhargava*[2];
[1]*Himalayan University, Kanpur, India,* [2]*GTB Hospital, Kanpur, India.*

Novel strategies are required for the achievement of safe and effective immunization beyond conventional strategies.Frequent booster dosing can be avoided by development of mucosal/adjuvant vaccine delivery system, which can produce both humoral and cell-mediated responses. The work envisaged uses combined hydrophilic(gelatin nanoparticles, GN) with a hydrophobic polymeric system(PLGA microspheres) which creates a biodegradable system for HBsAg delivery. GN & PLGA microspheres were prepared by double emulsification method and composite system by phase separation method.Composites were optimized and characterized *in-vitro* for their shape, size by Scanning & Transmission Electron Microscopy, %antigen entrapment and stability. Fluorescence microscopy was carried out to confirm the uptake. *In-vivo* study comprised of estimation of IgG response in serum and sIgA in various body secretions using specific ELISA. The *in-vitro* studies exhibited an initial burst release from gelatin nanoparticles, degradation of antigen from PLGA microspheres & a continuous release from composite system. This supports the hypothesis to formulate single shot vaccine with such system (to mimic booster dosing). The fluorescence studies showed the selective uptake of composites by NALT. Humoral response generated by single dose of composites was comparative to marketed formulation receiving booster dose. Further, composite system generated effective sIgA antibody which was not elicited by marketed formulation.Thus, it could be concluded from present study that bipolymer based composite system are capable to provide sufficient protein stability and can be a promising candidate for development of single shot vaccine, not only against Hepatitis but against all those diseases that invade host by mucosal surfaces.

P.D3.01.06
Oral combination vaccine against Anthrax & Hepatitis B: Development & Characterization

M. Bhargava[1], *S. Bhargava*[2];
[1]*GTB Hospital, Kanpur, India,* [2]*Himalayan University, Kanpur, India.*

Infections are still leading cause of morbidity and mortality and most of which can be prevented by vaccination. However, there are too many vaccines to be administered, increasing cost of immunization. Combination vaccines can answer these problems by development of single vaccine containing all possible antigens. The goal of present study was to see the effect of 2 antigens when given in combination. Bilosomes can provide needle free, painless approach for immunization. Recombinant hepatitis-B surface antigen(HBsAg) and recombinant protective antigen(rPA) were candidate antigens.
Bilosomes containing rPA and HBsAg were prepared by lipid cast film method. Antigen loaded bilosomes were characterized *in-vitro* for shape, size, antigen entrapment and stability in various body fluids. Fluorescence microscopy was done to confirm the uptake of bilosomes. The *in-vivo*study comprised of immunization of Balb/c mice and estimation of IgG response in serum and sIgA in various body secretions using specific ELISA.
Bilosomes formed were multilamellar and stable in gastric and intestinal fluids. Fluorescence microscopy suggested that bilosomes were taken up by gut associated lymphoid tissues. *In-vivo*data demonstrates that combination produced both systemic as well as mucosal antibody responses upon oral administration at higher dose levels as compared to intramuscular immunization but fail to produce any synergistic effect.
When rPA and HBsAg given in combination, HBsAg(high dose) potentiates the production of anti-rPA antibody. Also they elicited measurable sIgA in mucosal secretions, while alum adsorbed antigens failed to elicit such responses. The combination produced both systemic as well as mucosal antibody responses upon oral administration.

P.D3.01.07
***Mycobacterium indicus pranii (Mw)* in combination with heat induced promastigotes persuade host protection against drug- sensitive and - resistant *Leishmania donovani* infection: Activation of Flt3+ preDC leading to IL-6 producing CD11c+ cDC**

S. Dey[1], *D. Mukherjee*[2], *S. S. Sultana*[2], *S. Mallick*[2], *S. Mandal*[2], *A. Dutta*[2], *P. Patra*[3], *B. Saha*[4], *C. Pal*[5];
[1]*West Bengal State University (work station address) Barasat Govt College (Present address) Dept of Zoology, Kolkata, India,* [2]*West Bengal State University Dept of Zoology, Kolkata, India,* [3]*Canning Subdivisional Hospital, Kolkata, India,* [4]*National Centre for Cell Sciences, Pune, India,* [5]*West Bengal State University Dept of Zoology (Corresponding Author), Kolkata, India.*

Introduction: The major concerns of currently available chemotherapeutics against VL are severe toxicity & resistance. The aim of this work is to design a successful adjuvant in combination with *Mw* & HIP against experimental murine VL.
Methods: 5 Balb/c mice, per group, were administered with s.c. injection of *Mw* (10^8 cells/ kg b.w.) & HIP (50 µg/ kg b.w.) for 7 days after establishing infection. Organs were harvested for flow cytometric & RT-PCR analysis.
Results*: Mw+HIP* effectively reduced the hepatic & splenic parasite burden of infected animals by inducing CD4+IFN-γ+ T cells, along with the upregulation of Th1 promoting cytokines, chemokines & TLR2. We demonstrated that this therapy requires the cooperation of an integrated TLR~Cytokine~Chemokine loop. We established the roles of IL-6 & IL-12p40 as critical cytokines that mediate anti-*Ld* host protection. *Mw+HIP* induced the expansions of CD11c+CD11b+, CD11c+CD8α+ splenic cDCs & $CD11c^{interim}$ B220+PDCA1+ splenic pDCs along with the up regulated expressions of IL-6 & IL-12p40. *Mw+HIP* restored the depleted bone marrow system, *in vivo* & could direct bone marrow CDP cells to preDCs, ultimately repopulating the DCs. It also induced collateral host protective responses by diminishing the CD4+ CD25+ FoxP3+ IL-10+TGF-β+ regulatory T cells, and increasing the CD4+ IL17+ Th17 cells *in vivo*. Interestingly, *Mw+HIP* were found effective against Miltefosine resistant-*L. donovani* (HePC-R) *in vitro & in vivo* as evidenced by the concomitant surge in iNOS level & limited expression of amastigote specific *Ld-kDNA*.
Conclusion: This novel combinational therapy cures murine VL by the pro-inflammatory host protective immune responses.

P.D3.01.08
How to improve diphtheria vaccination for the elderly

M. Grasse*, A. Meryk, C. Miggitsch, B. Grubeck-Loebenstein;*
Institute for Biomedical aging research, University of Innsbruck, Innsbruck, Austria.

We previously demonstrated booster vaccinations with multivalent tetanus/diphtheria vaccines provided long-term protection to tetanus, while long-lasting immunity against diphtheria was insufficient in humans, particularly in the elderly. To investigate the reason for that, we set up a mouse model with different vaccination regimes, consisting of varying numbers of primary and booster vaccinations. Furthermore, we targeted dendritic cells(DCs) by application of GMCSF, and measured humoral & cellular immune responses by ELISA and flow cytometry. For tetanus we can show, that animals who received a primary immunization with three shots of Infanrix® and additionally three booster shots with Boosterix® had the same antibody titers than animals which received only three booster shots with Boosterix®. The diphtheria-specific antibodies were much lower of the mice that received only booster shots, compared to the mice with primary and booster shots. By applying GM-CSF next to the vaccine, young and old mice had significantly better diphtheria-specific antibody responses. GM-CSF treated mice had more diphtheria-specific CD4+ T-cells producing IL-2, IL-6 and TNF-a. GM-CSF was leading to a higher number of DCs at the injection-site 24h after vaccination and also to more splenic DCs with upregulated MHC-II expression. Our findings demonstrate, that the imbalanced level of protection against tetanus and diphtheria provided by multivalent tetanus/diphtheria vaccines is most likely due to the vaccine composition and not because of the vaccination regimes. Moreover, targeting DCs with GM-CSF improves the diphtheria-specific immune response and this might be a useful strategy to improve the vaccination situation for the elderly.

P.D3.01.09
Novel RNA adjuvant transcribed from viral internal ribosome entry site improves vaccine efficacy enabling immune-stimulatory capacities

H. Kwak*, H. Ko, H. Park, H. Park, R. Kim, J. Nam;*
Catholic University of Korea, Seoul, Korea, Republic of.

Most of the vaccines use aluminum compounds (alum) as an adjuvant to increase adaptive immune response to antigens. However, alum-based adjuvant strongly induce Th2 immune response rather than Th1 response. Here, we developed a novel single-stranded RNA adjuvant to induce balanced Th1 and Th2 responses. The plasmid containing the gene of interest under the internal ribosome entry site of the cricket paralysis virus intergenic region was transcribed by T7 RNA polymerase. The RNA adjuvant treated bone marrow derived dendritic cells (BMDCs) showed higher expression of activation marker. Furthermore, the RNA adjuvant stimulated immune-related genes in BMDCs. In addition, the RNA adjuvant injected mice showed higher antigen specific IgG1 (indicative of Th2 response) and IgG2a (indicative of Th1 response), as well as neutralizing antibody against antigen, compared to those in alum adjuvant injected group. Furthermore, the RNA adjuvant injected group showed higher antigen specific T cells secreting IFN-γ than alum adjuvant injected group. Taken together, the RNA adjuvant can increase humoral and cellular immune responses to vaccine antigen and act as a promising immunoenhancer.

P.D3.01.10
Human milk oligosaccharide improves innate and adaptive immunity and alters gut microbiota composition in an influenza-specific murine vaccination model

X. Ling*;*
Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.

Human milk is uniquely suited to provide optimal nutrition and immune protection to infants. 2'-Fucosyllactose (2'FL) is one of the most predominant oligosaccharides present in and associated with the immune benefits of human milk. The effect of 2'FL on vaccination responsiveness and mechanisms involved was determined.
A dose range of 0.25-5% (w/w) dietary 2'FL was provided to a murine influenza vaccination model. Vaccine-specific delayed-type hypersensitivity (DTH), antigen-specific antibody levels in serum, and immune cell populations within several organs were evaluated. The effects of 2'FL on vaccine-specific T-cell proliferation and cytokine secretions, and the direct immunomodulatory effects of 2'FL were assessed using *ex vivo* bone marrow-derived dendritic cells (BMDCs) T-cell co-culture. Finally, the impact of 2'FL on the gut microbiota composition was evaluated.
Dietary 2'FL effectively enhanced vaccine specific DTH responses and serum vaccine-specific IgG1 and IgG2a levels in a dose-dependent manner. Consistently, higher frequency of B-cells was detected in mice receiving 2'FL. Moreover, proliferation of vaccine-specific CD4+ and CD8+ T-cells, and IFN-γ production after *ex vivo* restimulation were significantly increased in spleen cells of mice receiving 2'FL, which were in line with changes detected within DC populations. Direct effect of 2'FL on the maturation status and antigen presenting capacity of BMDCs was confirmed *in vitro*. And the microbiota profile was significantly changed by 2'FL.
Dietary intervention with 2'FL improves both humoral and cellular immune responses to vaccination in mice, which might be attributed both direct immunomodulatory effects and microbiota modification of 2'FL.

P.D3.01.11

Inflammatory monocytes differentiate into mature antigen presenting cells *ex vivo* by oligomannose-coated liposomes

Y. Matsuoka[1], *Y. Kawauchi*[1], *Y. Kuroda*[1], *K. Kawauchi*[2], *A. Takiyama*[1], *N. Kojima*[1];
[1]*Tokai university, Hiratsuka, Japan,* [2]*Tokyo Women's Medical University, Tokyo, Japan.*

Oligomannose-coated liposomes (OMLs), in which the antigens are entrapped, have been shown to serve as effective antigen delivery vehicles and as a novel adjuvant to induce antigen-specific cellular immune response. Here, we demonstrate that inflammatory monocytes in PBMC can differentiate into mature professional antigen presenting cells *ex vivo* in response to uptake of OMLs.
When PBMC from C57BL/6 was co-cultured with OMLs in the presence mouse serum, OMLs rapidly was incorporated to $CD11b^+/Ly6C^+$ mouse inflammatory monocyte. In addition CD86, CCR7, CD83, and MHC class II significantly was upregulated within 24 h after OML uptake. OVA-encasing OML-ingesting monocytes can activate $CD8^+$ T cells from OT-1 mice, suggesting that antigens encapsulated in OMLs were cross-presented in inflammatory monocytes. Adoptive transfer of the monocytes that engulf OVA-encasing OMLs led to induction of an antigen-specific Th1 immune response in mice. We also observed that OMLs was preferentially incorporated into human $CD14^+$ monocyte in vitro. In response to in vitro OML uptake, CD14+ monocytes matured accompanied with enhanced expression of HLA-DR and CD86, and with secretion of IL-12. Furthermore, CD209, CD123, and CD169 were expressed on $CD14^+$ monocytes in response to OML treatment. Taken together, mature antigen presenting cells, which can activate CD8 T cells, is generated from inflammatory monocytes in peripheral blood by *ex vivo* treatment of the cells with OMLs without any additional stimuli.

Introduction: Great progress has been made in understanding the mechanisms of HIV-1 infection, but no effective vaccine worthy of clinical development has been developed to date. In recent years, numerous studies have demonstrated that mRNA-based vaccines could elicit potent immune responses against various infectious pathogens. We have generated a vaccine platform where nucleoside-modified mRNAs were encapsulated into lipid nanoparticles (LNPs), which have recently proved to be safe and efficient tools for *in vivo* nucleic acid delivery. Materials and Methods: Rhesus macaques were intradermally immunized five times with clade C HIV-1 1086C envelope (Env) gp160-encoding nucleoside-modified mRNA-LNPs and antibody responses were assessed by ELISA and virus neutralization assays (standard TZM-bl luciferase reporter system).
Results: Animals generated anti-gp120-specific antibodies, as measured by ELISA. Potent neutralization activity against a highly neutralization sensitive clade C Tier 1 virus (MW965.26) was detected in all animals after four immunizations. Importantly, 3 out of 6 animals developed neutralizing antibodies against the autologous Tier-2 virus (Ce1086_B2). Interestingly, one animal generated antibodies with low neutralizing activity against heterologous clade C Tier-2 strains (25710-2.43 and Ce1176_A3).
Conclusions: Our results demonstrate that antigen-encoding nucleoside-modified mRNA complexed in LNPs induces Tier-2 neutralizing antibody responses in non-human primates. Further characterization of anti-HIV immune responses in this study is underway.

Zika virus DNA vaccine construction and evaluation of its immunogenicity in mice

E. Prompetchara[1], *P. Bamrungchaokasem*[1], *B. Sukchawalit*[1], *C. Ketloy*[2], *K. Ruxrungtham*[2];
[1]*Department of Biochemistry and Microbiology and Vaccines and Therapeutic Protein Research Group (STAR), Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand,* [2]*Chula Vaccine Research Center (ChulaVRC), Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*

Major ZIKV outbreak occurred during 2015-2016 worldwide. Although most of the ZIKV infections are asymptomatic, unfortunately, there are several reports on severe complications such as microcephaly in newborns and Guillain Barre Syndrome in adults. Currently, either specific treatment or approved ZIKV preventive vaccine are not available. This research, therefore, emphasizes on the study and development of the DNA vaccine against ZIKV as it is easy and fast to produce, thermostable and efficient in immune induction especially when administered with the effective delivery systems.
ZIKV pre-membrane and envelope prM/E consensus proteins were analyzed from ZIKV isolates deposited in the GenBank database. The humanized codons of the consensus ZIKV *prM/E* were subcloned into the mammalian expression vector (pCMVkan). The protein expression in mammalian (Vero) cell transformed with pCMVkan encoding ZIKV *prM/E* was investigated. ZIKV envelope proteins weredetected extra- and intracellularly when analyzed by western blot and indirect immunofluorescence, respectively. The vaccine was then immunized 3 doses, two-week interval in ICR using intramuscular electroporation as a delivery method. The results demonstrated that neutralizing antibodies (NAb) against ZIKV were detected since week 4 (Geometric mean titer, GMT = 10). NAb levels gradually increased at week 6 and week 8 (GMT = 40 and 80, respectively) andare significantly different from those inthe control group (p<0.05). Collectively, this vaccine prototype is immunogenic in mice and warrant further studies foruse as an effective ZIKV vaccine.

Química Orgánica, Facultad de Bioquímica y Ciencias Biológicas, Universidad Nacional del Litoral, Santa Fe, Argentina,* [5]*Laboratoire Inflammation, Tissus Epithéliaux et Cytokines (LITEC), EA 4331, Université de Poitiers, Poitiers, France,* [6]*CHU de Poitiers, Poitiers, France.*

Introduction: Liposomes are vaccine adjuvant systems able to transport hydro- and liposoluble molecules, allowing the co-incorporation of antigen and different immunostimulants. Our aim was to evaluate the adjuvanticity of a cationic liposomal formulation (Lip) with the addition of a CpG oligodeoxynucleotide (CpG-ODN) and/or an aminoacidic amphiphile (Gem) as immunostimulants, in the immunization against recombinant clumping factor of *Staphylococcus aureus* (rClf).
Materials and Methods: Balb/c mice were immunized with: Lip+CpG-ODN+rClf, Lip+Gem+rClf, or Lip+Gem+CpG-ODN+rClf. Mice received three intradermal doses and were sacrificed three days after the last injection. Anti-rClf IgG was evaluated by indirect ELISA in plasma. Lymph nodes cells were analysed by flow cytometry to assess IL-4, IL-17 and IFN-γ production in CD4+ and CD8+ T cells.
Results: Lip+CpG-ODN+rClf, Lip+Gem+rClf and Lip+Gem+CpG-ODN+rClf all led to high IgG levels. Formulations containing Gem or CpG-ODN increased the number of CD4+ lymphocytes. Lip+Gem+CpG-ODN+rClf significantly enhanced CD4+ cells compared to Lip+CpG-ODN+rClf. A similar trend was found for CD8+ lymphocytes. Gem and CpG-ODN were able to induce the production of IL-4 and IFN-γ by CD4+ cells and IFN-γ by CD8+ cells. Only Gem increased the production of IL-17 by CD4+ cells. Lip+Gem+CpG-ODN+rClf induced the highest number of CD4+ and CD8+ cells producing the three cytokines compared to Lip+CpG-ODN+rClf.
Conclusions: Both Gem and CpG-ODN act as immunostimulants when introduced in liposomes, but their combination enhances the stimulant effect. It should be noted the cytotoxic cells stimulation by the Lip+Gem+CpG-ODN+rClf formulation, considering the impact of this profile in the design of viral or cancer preventive vaccines.

P.D3.01.16

Immunogenic properties of single component adjuvants for vaccine formulations

L. Rossmann[1], *A. Ulrich*[1], *K. Lindt*[1], *S. Shorte*[2], *M. Hasan*[2], *B. David-Watine*[2], *M. Bastian*[3], *G. van Zandbergen*[1,4];

An appropriate adjuvant is of pivotal importance for vaccine efficacy and thus should be selected on the basis of the adjuvant's immunogenic modes of action. We hypothesize that adjuvant properties can be correlated to specific innate cellular responses influencing the resulting adaptive immune response.
Here, we aim to investigate the immunogenic properties of ten different single component adjuvants *in vitro*, comprising TLR agonists, aluminium salts, oil-in-water emulsions and saponins. We focus on side-by-side comparison of the adjuvants using human primary immune cells of 30 donors which are evenly distributed in sex and age.
In a first step, all adjuvants were tested for their pyrogenicity using an *in vitro* monocyte activation test. Except for MPLA, all tested adjuvants were non-pyrogenic.
The capacity of the adjuvants to induce lymphocyte proliferation was examined in a co-culture based assay composed of human monocyte-derived dendritic cells and autologous peripheral blood lymphocytes (PBLs). We observed that Pam3CSK4, Gardiquimod, R848, synthetic MPLA, natural-derived MPLA and TDB induced antigen-independent proliferation of PBLs to varying degrees, with R848 being the strongest stimulator. More detailed examination of B-, NK-, NKT-, $CD4^+$ and $CD8^+$ T cells within the proliferated PBL population revealed that each adjuvant promoted the proliferation of different cell types. An ongoing Luminex multiplex analysis will uncover the cytokine profile within the co-culture in the first 24h of adjuvant stimulation.
In summary, this work will help to identify immunological properties of adjuvants and will facilitate the rational design of adjuvant-based vaccines.

P.D3.01.17

Development and immunogenicity in mice of a novel chimeric Virus Like Particles (cVLPs) of MERS-CoV

***W. TAN**, Y. Deng, J. Lan;*
National Institute for Viral Disease Control and Prevention, China CDC, BEIJING, China.

The newly found Middle East respiratory syndrome coronavirus (MERS-CoV) was belonged to the coronavirus genus. It resulted a very high case-fatality rate. While there is no specific prophylactic or therapeutic measures to control its spread. In this study we aimed to acquire a chimeric Virus Like Particles (cVLPs) of MERS-CoV in baculovirus expression system by co-expression of M1 and S. Among them, M1 ,which come from the H5N1 ,was the core of the cVLPs and S which come from the MERS-CoV existed the surface of the cVLPs. The results by the electron microscope showed the spheroid cVLPs with a diameter of 80 to 100 nm, which was similar to the MERS-CoV. It was enveloped and looked like a crown. We immunized intramuscularly the mice with the acquired cVLPs and detected the IgG and neutralizing antibodies in the serm of the immunized mice. Above all, we acquired the immunogenic cVLPs of MERS-CoV by co-expression of M1 (H5N1) and S(MERS-CoV) in a baculovirus expression system.Next, the cVLPs will be developed as an effective vaccine against the MERS-CoV infection.

P.D3.01.18

Proteomic analysis of cholera toxin adjuvant-stimulated human monocytes identifies Thrombospondin 1 and Integrin beta 1 as strongly upregulated molecules involved in the adjuvant action

***M. Terrinoni**[1], J. Holmgren[1], M. Lebens[1], M. Larena[1,2];*
[1]Microbiology and Immunology, Biomedicine, Gothenburg, Sweden, [2]Organismal Biology, Uppsala, Sweden.

Background. Cholera Toxin (CT) and its non-toxic derivatives, mmCT and dmLT, have been shown to be potent adjuvants for mucosally administered vaccines. Their adjuvant activity is mediated via antigen presenting cells (APC), and involves cAMP/proteinkinase A (PKA) pathway and inflammasome-dependent IL1β signaling. We extended our investigation to further elucidate the molecular signal transduction mechanisms activated in APCs by this group of adjuvants.
Methods. First, we employed high-throughput proteomic analysis to investigate differential expression of proteins in CT-treated human monocytes at various time points. Next, bioinformatics analyses allowed us to identify protein abundance and major signaling pathways involved. The expression of selected protein after specific treatments was confirmed by *in vitro* assays. Th17responses, measured by ELISA, were evaluated following co-culture of adjuvants-treated human monocytes and dendritic cells with purified CD4+Tcells. Lastly, siRNAs were used to investigate the effect of knocking down expression of selected genes on adjuvant-treated human monocytes.
Results. We report activation of three main biological pathways among upregulated proteins: cellular organization, metabolism, and immune response. Specifically, amongst proteins classified under immune response category, we note a strong upregulation of thrombospondin-1(THBS1) and integrin beta-1(ITGB1). Th17responses were significantly reduced when THSB1 and ITGB1 in APCs were blocked by siRNAtreatment. Furthermore, blocking of cAMP production or inhibition of PKA activity in APCs were found to abrogate the increased expression of THSB1 and ITGB1 along with the Th17 promoting activity induced by the adjuvants.
Conclusions. Our data demonstrate the importance of THSB1 and ITGB1 in the cAMP/PKA-dependent adjuvant action of CT/mmCT/dmLT on APCs.

P.D3.01.19

Live attenuated influenza vaccines are superior in evoking cross-reactive T cell responses against H7N9 in ferrets compared to other traditional vaccines

***K. van de Ven**, H. van Dijken, F. de Heij, J. de Jonge;*
National Institute of Public Health and the Environment, Bilthoven, Netherlands.

Traditional influenza vaccines primarily invoke a humoral immune response against the viral HA and NA proteins. However, as most elicited antibodies do not possess broad cross-reacting properties, immune escape by the virus is a serious problem. T-cell responses against conserved epitopes of internal influenza proteins could potentially offer protection against a broader spectrum of influenza viruses, including viruses that have the potential to cause pandemics. Current vaccines and adjuvanted formulations hereof, have extensively been researched in mice for their capacity of inducing cross-reactive cellular responses. However, since the ferret is a more suitable model for investigation of vaccine efficacy and more tools are becoming available for analysis of cellular responses, we wondered how the cellular immune response differed between traditional vaccine formulations in ferrets. In order to test this, we thawed PBMCs and spleen lymphocytes from previously vaccinated and challenged ferrets and performed ELISPOTs with influenza NP and M1 peptides and H7N9 viruses. Results indicate that a strong cross-reactive T cell response was evoked by the live attenuated influenza vaccine (LAIV), and to some extend by whole inactivated virus (WIV). The T cell response was marginal in animals vaccinated with split-vaccine. These results argue for the use of influenza vaccine formulations that also evoke cellular immunity in order to offer protection against the continuously antigenic-drifting and potential pandemic influenza viruses.

P.D3.01.20

Induction of virus-specific T cell responses via R848 functionalised calcium phosphate nanoparticles

***C. Wenzek**[1], A. Westendorf[1], J. Buer[1], S. Kollenda[2], M. Epple[2], T. Knuschke[1];*
[1]University Hospital Essen, Essen, Germany, [2]University Duisburg-Essen, Essen, Germany.

Calcium phosphate (CaP) nanoparticles are new promising agents for vaccination as they promote virus-specific immune responses which can protect the organism against infection. The aim of this study was to assess the immunomodulatory effects of a new type of CaP nanoparticles, which are functionalised with toll-like receptor 7 ligand resiquimod (R848), viral antigens and the polymer polyethylenimine (PEI), compared to previously used CpG nanoparticles to induce and reactivate Friend retrovirus (FV) specific T cell responses.
Stimulation of immune cells revealed that R848 loaded CaP nanoparticles are able to effectively activate dendritic cell (DC) subsets *in vitro* and *in vivo*, which in turn triggered effector T cell responses. Here, R848 functionalised nanoparticles were most efficient among the tested particles to induce virus-specific $CD8^+$ T cell responses whereas the induction of $CD4^+$ T cells was impaired. The cause might be a negative effect of PEI on MHC II antigen processing. Despite the activation of innate and adaptive immune cells, immunisation of mice with R848 and viral peptide functionalised CaP nanoparticles provided minor protective immunity against acute and chronic retroviral infection as they display inferior $CD4^+$ and $CD8^+$ T cell responses in comparison with CpG functionalised nanoparticles. Therefore, this study defines the potential advantages of R848 functionalised CaP nanoparticles to induce virus-specific $CD8^+$ T cell responses and illustrates the necessity for $CD4^+$ T cell induction for a protective immunity.

P.D3.01.21

Similar antibody responses elicited in SHIV infected and HIV-1 envelope glycoprotein immunized non-human primates

***J. van Schooten**[1], M. van Haaren[1], C. Cottrell[2], D. Sok[2], D. R. Burton[2], A. Ward[2], G. Shaw[3], R. Sanders[1], M. J. van Gils[1];*
[1]Academic Medical Center, Amsterdam, Netherlands, [2]The Scripps Research Institute, San Diego, United States, [3]Perelman School of Medicine, Philadelphia, United States.

The human immunodeficiency virus (HIV-1) remains a global health threat and the development of an effective vaccine is highly desirable to eradicate the HIV/AIDS pandemic completely. Experimental vaccines against HIV-1 have not yet been able to induce protective immune responses. Recently, soluble native-like HIV-1 envelope glycoproteins, termed BG505 SOSIP.664 trimers, were developed which induced neutralizing serum responses against the homologous virus in both non-human primates (NHP) and rabbits. However, it is still unclear whether these native-like trimers elicit similar responses compared to natural infection. Therefore, NHP were immunized with BG505 SOSIP.664 trimers or infected with the homologous BG505 SHIV. Immunogen-specific IgG+ B cells from BG505 SOSIP immunized and BG505 SHIV infected NHP were single cell sorted to obtain monoclonal antibodies (mAbs). The viral population from the BG505 SHIV infected NHP was sequenced over time to study HIV-1 escape from antibody responses. Both neutralizing and non-neutralizing mAbs were isolated and these mAbs targeted distinct epitopes on the HIV-1 trimer, such as the fusion peptide and strain-specific holes in the glycan shield of BG505 SOSIP trimer. mAbs elicited by the BG505 SOSIP trimer showed similar phenotypic characteristics compared to mAbs isolated from the BG505 SHIV infected NHP, however mAbs from the SHIV infected NHP neutralized the homologous virus more frequently and substantial more B-cell clonal expansion was observed during SHIV infection. In conclusion, the results suggest that immunizing with the BG505 SOSIP trimer mimics infection correctly by the induction of mAbs with similar target epitopes. The knowledge obtained in this study will help design immunization strategies to broaden the response after vaccination.

P.D3.01.22

Antibodies from vaccinated rabbits reveal an immunodominant epitope at the bottom of soluble HIV-1 envelope trimers

***M. M. van haaren**[1], C. Cottrell[2], L. E. McCoy[3], P. van der Woude[1], A. Yasmeen[3], S. W. de Taeye[1], A. Torrents de la pena[1], P. Klasse[4], D. R. Burton[2], A. B. Ward[2], R. W. Sanders[1], M. J. van Gils[1];*
[1]Amsterdam university medical centers, Amsterdam, Netherlands, [2]The Scripps Research Institute, San Diego, United States, [3]Weill Medical College of Cornell University, New york, United States, [4]Weill Medical College of Cornell University, New York, United States.

High viral diversity of HIV-1 worldwide requires the development of broadly neutralizing antibodies (bNAbs) through vaccination. Although current vaccine candidates elicit neutralizing antibodies, only limited neutralization coverage is observed. Characterizing antibody responses elicited by current immunogens should provide insight on which epitopes are targeted and what causes the limited breadth. Rabbits were immunized with soluble antigenic mimics of a subtype B HIV-1 envelope glycoprotein (AMC008 Env trimer). Monoclonal antibodies (mAbs) were isolated by single-cell sorting of B cells and subsequent amplification and cloning of the heavy and light chain variable regions of the antibody. We isolated 21 AMC008-specific mAbs, four of which could cross-bind various subtypes.

The complementary determining region three (CDR3) of the light chain of these mAbs were longer than average in rabbits, resembling characteristics of previously isolated bNAbs. Negative stain-electron microscopy and ELISA revealed an epitope at the bottom of the Env trimer targeted by the majority of the isolated mAbs, indicating the immunodominant site of the AMC008 Env trimer. However, the observed approach angle of these mAbs would lead to a clash of the Fc portion with the viral membrane. Nevertheless, homologous AMC008 neutralization, and neutralization of another subtype B virus was observed for four antibodies, potentially achieved by destabilization of the Env trimer on the viral surface. In conclusion, mAbs elicited by AMC008 Env trimer immunizations target the immunodominant bottom of the Env trimer. Viral variability and the suboptimal angle of approach provide an insight in the poor neutralization breadth and should guide future vaccine design.

Riboflavin supplementation enhances antigen specific humoral and cellular immune responses to oral vaccines

A. S. Albutti[1,2], *C. McEntee*[3], *S. Longet*[1], *A. Svennerholm*[4], *J. Holmgren*[4], *E. Lavelle*[1];
[1]*University of Dublin, Trinity college, Dublin, Ireland,* [2]*Qassim University, Al Qassim, Saudi Arabia,* [3]*University of Manchester, Manchester, United Kingdom,* [4]*University of Gothenburg, Gothenburg, Sweden.*

In contrast to injectable vaccines, effective mucosal vaccines can provide protective local and systemic immunity. Oral vaccination in particular has the potential to offer a safer and more efficacious approach than injection-based approaches, especially in developing countries. Nevertheless, in general, antigen delivery via the oral route triggers weak immune responses or immunological tolerance. The effectiveness of oral vaccination can be improved by co-administering adjuvants. However, a major challenge is the absence of potent and safe oral adjuvants for clinical application. A second obstacle is that responses to oral vaccines vary between developed Western countries and developing countries where they are often less effective. This may be attributed in part to nutritional deficiencies including a limited intake of factors including vitamins, impacting on the microbiome and the generation of specific metabolites. Here, the immunomodulatory potential of oral supplementation with riboflavin (Vitamin B2) was investigated. It was found that oral delivery of the vitamin enhanced antigen-specific Th1 and Th17 responses in draining lymph nodes in addition to antigen specific antibody responses in mice orally vaccinated with the heat killed oral vaccines against enteric bacterial infections. Supplementation with riboflavin prior to and during vaccination with oral cholera vaccine enhanced antigen-specific intestinal and serum humoral immunity. These findings suggest the potential of riboflavin supplementation to enhance the capacity of oral vaccines to trigger mucosal and systemic immunity.

P.D3.02.02

Sensitivity of the bovine BCG challenge model

L. Biffar[1,2], *M. Vordermeier*[2], *H. McShane*[1], *B. Villarreal-Ramos*[2];
[1]*University of Oxford, Oxford, United Kingdom,* [2]*Animal and Plant Health Agency, Weybridge, United Kingdom.*

Bovine tuberculosis is a zoonotic disease affecting cattle and causing economic loss to farmers worldwide. Protection induced, by the currently only experimentally used BCG vaccine, varies between 0 to 80%. Lacking a correlate of protection every new vaccine candidate has to be tested in lengthy and expensive *M. bovis* challenge experiments. Methods that would allow for a faster and cheaper pre-selection of vaccine candidates and additionally improve welfare of experimental animals are needed. We have previously developed a bovine BCG challenge model in which animals are challenged intranodally with a non-pathogenic BCG strain. Improved protection results in reduced bacterial burden in the injected lymph nodes of protected cows compared to unprotected animals three weeks after challenge. The aim of this work was to analyse the sensitivity of the BCG challenge model and thus its ability to differentiate between different vaccine regimens resulting in varying degrees of protection. In order to do so we compared vaccination with BCG only to a heterologous Adenovirus Antigen 85A prime boost vaccine regimen which has previously been demonstrated to improve protection over BCG alone in pathogenic *M. bovis* challenge experiments. We show, that the BCG challenge model is able to measure improved protection of both vaccine regimens over unvaccinated control animals. However, the model is currently not sensitive enough to distinguish between the two different vaccine regimens. Nevertheless, it allows us to determine the ability of new vaccine candidates to induce protection at least as good as BCG.

Presentation of Hepatitis B virus antigens on human dendritic cells; hunting for novel immune therapy targets by Mass spectrometry

R. Bouzid[1], *K. Bezstarosti*[2], *M. de Beijer*[1], *P. Biesta*[1], *A. Woltman*[1], *J. Demmers*[2], *S. Buschow*[1];
[1]*Erasmus MC Dept. of Gastroenterology and Hepatology, Rotterdam, Netherlands,* [2]*Erasmus MC Dept. of Biochemistry, Rotterdam, Netherlands.*

Approximately 350 million individuals worldwide have a chronic hepatitis B infection and as a consequence are at risk for developing hepatocellular carcinoma (HCC). In addition, 50% of all HCC cases arise in individuals infected with HBV, highlighting the contribution of chronic HBV infection to the high prevalence of HCC. Conventional therapies are not curative, are expensive and need to be taken life-long. We aim to design a therapeutic vaccine for the treatment of chronic HBV, that should boost or initiate immunological responses to critical Human leukocyte antigen (HLA) epitopes. To identify target epitopes we here loaded human monocyte derived dendritic cells with HBV antigens from different sources, isolated HLA I complexes and performed sensitive Mass spectrometry on eluted HLA-peptides. We thereby identify therapeutically relevant HBV-epitopes presented on professional antigen presentation cells. Currently we are expanding our methodology to HLA II and primary DCs.

P.D3.02.04

Mixed mucosal-parenteral immunizations with the broadly conserved pathogenic *Escherichia coli* antigen SslE induce a robust mucosal and systemic immunity without affecting the murine intestinal microbiota

I. Naili[1,2], *J. Vinot*[1], *B. C. Baudner*[1], *A. Bernalier-Donadille*[2], *M. Pizza*[1], *M. Desvaux*[2], *G. Jubelin*[2], *U. D'Oro*[1], ***C. Buonsanti***[1];
[1]*GSK, Siena, Italy,* [2]*Université Clermont Auvergne, INRA, Clermont-Ferrand, France.*

E. coli can cause a vast range of intestinal (InPEC) and extraintestinal (ExPEC) diseases but only a very limited number of antibiotics still remains effective against this pathogen. A broad spectrum *E. coli* vaccine could be a promising alternative to prevent the burden of such diseases, while offering the potential for covering against several InPEC and ExPEC at once. SslE, Secreted and Surface-associated Lipoprotein of *E. coli*, is a widely distributed protein among InPEC and ExPEC. SslE functions *ex vivo* as a mucinase capable of degrading mucins and reaching the surface of mucus-producing epithelial cells. SslE was identified by reverse vaccinology as a protective vaccine candidate against an ExPEC murine model of sepsis, and further shown to be cross-effective against other ExPEC and InPEC models of infection. In this study, we aimed to gain insight into the immune response to antigen SslE and identify an immunization strategy suited to generate robust mucosal and systemic immune responses. We showed, by analyzing T-cell and antibodies responses, that mice immunized with SslE via an intranasal prime followed by two intramuscular boosts developed an enhanced overall immune response compared to either intranasal-only or intramuscular-only protocols. Importantly, we also report that this regimen of immunization did not impact the richness of the murine gut microbiota. Mice had a comparable cecal microbial composition, whether immunized with SslE or PBS. Collectively, our findings further support the use of SslE in future vaccination strategies to effectively target both InPEC and ExPEC while not perturbing the resident gut microbiota

P.D3.02.05

Intranasal delivery of inactivated enterovirus D68 induces robust virus-specific humoral and cellular responses and confers protection against lethal viral challenge in mice

C. Chin[1], *Y. Lin*[2], *P. Cheng*[2], *B. Chiang*[1,2,3];
[1]*Graduate Institute of Immunology, National Taiwan University, Taipei, Taiwan,* [2]*Department of Medical Research, National Taiwan University Hospital, Taipei, Taiwan,* [3]*Graduate Institute of Clinical Medicine College of Medicine, National Taiwan University, Taipei, Taiwan.*

Introduction: Enterovirus D68 (EV-D68) has been recognized as a significant respiratory pathogen in children since its infections have remarkably increased worldwide during the past decade. In addition to severe respiratory tract infection, EV-D68 has been reported to associate with acute flaccid myelitis (AFM) in recent years. However, neither effective vaccines nor antiviral drugs are currently available to prevent its infections. Given that its infections have been demonstrated to depend on mucosal invasion, we sought to develop a potential mucosal vaccine against EV-D68.
Materials and Methods: C57BL/6 mice were intranasally immunized with the inactivated virus, and both humoral and cellular immune responses were assessed after the immunization. Sera collected from the vaccinated mice were further used in neutralization tests and passive protection assays.
Results: We found enhanced EV-D68-specific responses in C57BL/6 mice after the intranasal challenge, including the elevated antibody titers in nasal wash, saliva, bronchoalveolar fluid, feces, and sera, as well as the increased proliferative and IgG-producing ability of the restimulated splenocytes. We also confirmed the sera to have neutralizing and cross-neutralizing capability in human Rhabdomyosarcoma (RD) cells. Furthermore, we found that anti-EV-D68 sera transfer before the intracerebral challenge lowered the incidence of paralysis and prolonged the survival of neonatal Institute of Cancer Research (ICR) mice. Tissue load analysis showed decreased viral levels in the spinal cord and limb muscles of the sera recipients, and the histopathologic examination revealed reduced necrosis of hindlimb muscles of the recipients.
Conclusion: Our data demonstrated the proof-of-concept for effective intranasal vaccination with inactivated EV-D68.

P.D3.02.06

Modulation of primary immune response by different adjuvants to design heterologous prime-boost combinations

A. Ciabattini[1], *E. Pettini*[1], *F. Fiorino*[1], *S. Lucchesi*[1], *G. Pastore*[1], *F. Santoro*[1], *P. Andersen*[2], *G. Pozzi*[1], *D. Medaglini*[1];
[1]*University of Siena, Siena, Italy,* [2]*Statens Serum Institute, Copenhagen, Denmark.*

Adjuvants contribute to enhancing and shaping the vaccine immune response through different modes of action. Here, we profiled early biomarkers of adjuvanticity after priming and investigated the impact of heterologous prime-boost approaches on the vaccine-specific immune responses. The modulation of primary T and B cell responses was characterized in mice primed with the mycobacterial antigen H56 and different adjuvants. Combinations of adjuvanted-H56 priming with homologous or heterologous boosting, were also analysed. Vaccine formulations containing the liposome system CAF01 or a squalene-based adjuvant elicited a primary CD4+ T cell response skewed to Th1/Th17 and Th1/Th2, respectively. Induction of short-lived plasma cells and early H56-specific IgG were observed mainly in mice immunized with CpG or the squalene-based adjuvant, while all tested adjuvants promoted the germinal centre reaction but with different magnitude. Mice primed with CAF01, but not antigen alone, and boosted with homologous or heterologous formulations, showed a strong secondary CD4+ T cell response.
Computational analysis performed with the FlowSOM software (R package) allowed clustering of antigen-specific T helper cells in different polyfunctional subsets producing combinations of TNF-α, IL-2 and IFN-γ, that were observed only in mice primed with the adjuvanted-formulation, regardless of the booster formulation used. These results show that the immunological activity of different adjuvants can be characterised profiling early biomarkers after immunization and highlight the crucial role of the adjuvant in generating primary immune responses that can be recalled by boosting. These data could give an important contribution to the rational development of heterologous prime-boost vaccine immunization protocols.

P.D3.02.09

Immunogenicity of Leishmania extracellular vesicles in combination with CpG ODN as a vaccine against cutaneous Leishmaniasis

B. Geçkin[1], *I. C. Ayanoğlu*[1], *I. C. Yılmaz*[1], *E. M. İpekoğlu*[1], *I. Gürsel*[2], *M. Gürsel*[1];
[1]*Department of Biological Sciences, Middle East Technical University, Ankara, Turkey,* [2]*Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey.*

Introduction: Cutaneous Leishmaniasis (CL), also known as Aleppo sore is a neglected parasitic disease that presents as self-healing skin lesions or cause debilitating large chronic or recurring lesions. During 1990-2010, >46.000 new CL cases caused by 3 different Leishmania species have been identified in Turkey. Considering the vast number of refugees immigrating to Turkey from Syria where CL is highly endemic, a substantial increase in CL cases is anticipated in the near future. The absence of an available licensed vaccine coupled with the cost, toxicity and drug resistance associated with the pentavalent antimonials used for treatment, necessitates the development of an effective preventive vaccine. Herein, we explored the immune protective vaccine potential of Leishmania antigen-rich small vesicles (exosomes) secreted from parasites in combination with CpG ODN based vaccine adjuvants.
Materials & Methods: Soluble leishmania antigen (SLA) or parasite exosomes were isolated from *L. major* species. For vaccination, Balb/c mice were immunized twice with: heat-killed parasites, SLA or exosomes as such or in combination with CpG ODN based vaccine adjuvants. Leishmania antigen specific IgG levels were quantified from sera by ELISA. Th1/Th2/Th17 responses elicited by vaccine formulations were measured antigen stimulated splenocytes using cytometric bead array (CBA).
Results: The results suggest that SLA and exosomes are promising anti-Leishmania protective antigens and D-type CpG ODN is the most promising adjuvant.
Conclusion: The preliminary work indicates that parasite exosomes are promising antigen carriers but methods to inactivate vesicle-associated proteases may increase their immunogenicity.

Pigs as translational model: vaccination by tattoo with DNA in nanoparticles

A. Hoek[1], *A. van Nes*[1], *V. P. Rutten*[1], *G. G. Kenter*[2], *J. F. Engbersen*[3], *C. A. Jansen*[1], *A. D. Bins*[4];
[1]*Faculty of Veterinary Medicine, Utrecht, Netherlands,* [2]*Netherlands Cancer Institute, Amsterdam, Netherlands,* [3]*MIRA institute for Biomedical Technology & Technical Medicine, Enschede, Netherlands,* [4]*Academic Medical Center, Amsterdam, Netherlands.*

DNA vaccination in the skin is an established vaccination method in small laboratory animals. Historically, mice have been used as a preclinical model for dermal vaccine delivery, but extrapolation to humans may be difficult. Since the resemblance between pig and human skin, we investigated whether pigs may be used as preclinical model for dermal vaccination. Nanoparticle pDNA formulations were selected based on transfection efficiency of *ex vivo* pig skin. A selection of nanoparticle pDNA formulations in combination with the naked pDNA vaccine was subsequently applied *in vivo* by tattooing. Uptake of vaccine encoded antigen by cells in the draining lymph node (dLN) was determined by flowcytometry. Finally, HA37 formulated Human Papilloma Virus (HPV) 16 E6E7 DNA vaccine, currently used in a human trial, and unformulated DNA vaccine were assessed for their ability to stimulate T cells. Formulation of pDNA in polyplex HA37 resulted in the highest dermal transfection efficiency in pigs *in vivo*. Although cells in the dLN were able to take up the antigen, high background in some of the sham vaccinated pigs complicated this analysis. Tattoo with either HA37 DNA or naked DNA increased the number of IFNγ+ cells in the blood which was observed from the second vaccination onwards. In conclusion, DNA vaccination in the skin of pigs results in local production of antigen, its uptake by cells in the dLN and the induction of IFNγ+ cells. This suggest that DNA vaccination in the skin of pigs is an efficient way to induce vaccine-specific T cell responses.

P.D3.02.11

Corpuscular carrier enhances immune response after conjunctival immunization with chlamydial outer membrane proteins

A. Inic-Kanada[1], *M. Stojanovic*[2], *E. Stein*[1], *I. Lukic*[2], *E. Ghasemian*[1], *A. Filipovic*[2], *R. Miljkovic*[2], *T. Barisani-Asenbauer*[1];
[1]*Medical University of Vienna, Vienna, Austria,* [2]*Institute of Virology, Vaccines and Sera, Belgrade, Serbia.*

Trachoma, caused by the intracellular bacterium *Chlamydia trachomatis* (Ct), remains the world's leading preventable infectious cause of blindness. Recent attempts to develop effective vaccines rely on modified chlamydial antigen delivery platforms. We therefore characterized immune responses after conjunctival immunization with a N-terminal portion (amino acid 1-893) of the chlamydial polymorphic membrane protein C (PmpC) and a major outer membrane protein (MOMP) expressed in *Escherichia coli* bacterial ghosts (BGs) in a guinea pig model of ocular infection animals. Three immunizations were performed at two-week intervals, and the IgG immune responses were evaluated. Animals were further infected with *C. caviae* ($1x10^4$ IFU/animal) two weeks after the last immunization and ocular pathology and chlamydial clearance were investigated. Antigen-specific IgG levels in sera yielded significantly increased levels in the group immunized with MOMP BGs compared to animals immunized with PmpC BGs. Furthermore, a decrease in intensity of the transitional inflammatory reaction in conjunctiva of challenged guinea pigs immunized with MOMP-BGs compared with PmpC-BGs-immunized animals was observed. Analysis of changes in chlamydial load during the post-infection period revealed significantly lower absolute numbers of *C. caviae* in MOMP-BGs immunized guinea pigs on day 4 post-infection ($P < 0.05$) compared to the corresponding PmpC-BGs-immunized animals. Although neither immunization scheme provided full protection, MOMP-BGs merit further investigations as chlamydial protein carriers with intrinsic adjuvant properties in conjunctival vaccine against Chlamydia.

P.D3.02.12

Variance and dynamism of humoral responses in humans against a novel intranasal RSV subunit vaccine

M. S. Kalyan[1,2], *S. Ascough*[1,2], *I. Vlachantoni*[2], *B. Jan Haijema*[3], *S. Wallin*[3], *M. Dijkstra*[3], *M. S. Ahmed*[4], *Q. Zhang*[4], *K. Leenhouts*[3], *P. Openshaw*[2], *C. Chiu*[1];
[1]*Section of Infectious Diseases & Immunity, Imperial College London, London, United Kingdom,* [2]*National Heart and Lung Division, Imperial College London, London, United Kingdom,* [3]*Mucosis B.V. , represented by trustee Mr. Holtz LLM, Bout Advocaten, Groningen and Virtuvax B.V., Odijk, Netherlands,* [4]*Department of Clinical Infection, Microbiology and Immunology, Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom.*

Respiratory syncytial virus (RSV) is a major cause of respiratory illness in both infants and the elderly but despite decades of research, no effective vaccine exists. We recently showed in human RSV infection challenges that mucosal IgA associated more closely with protection from infection than any other recognised correlate. Intranasal vaccination to induce both mucosal and systemic immunity could therefore offer preferential protection against RSV and other respiratory pathogens.
Here, we report humoral and cellular immunity data from a randomised controlled Phase 1 trial of an intranasal subunit vaccine comprised of the RSV F protein linked to a bacterium-like particle (BLP). The vaccine was well tolerated and significantly induced antibody-secreting cells, which were associated with consistent increments in anti-F protein serum IgG. Nasal IgA responses displayed heterogeneity in timing and magnitude, but very large increments seen in those with lower pre-existing titres. However, serum antibodies were preferentially non-neutralising and antibodies directed against the pre-fusion F protein conformation were not detectable. *In vitro* culture of tonsillar mononuclear cells from adults and children with the vaccine induced anti-F protein antibodies in a dose-dependent manner and was associated with marked CD4+ and CD8+ T cell proliferation with production of IFN-γ, IL-21 and IL-22.
Thus, this novel intranasal BLP platform can stimulate both mucosal and systemic responses, with serum antibody and plasmablast response comparable to live attenuated virus vaccines. The added advantages of subunit vaccine manufacturing and stability suggest that this vaccine can be a candidate for further optimisation.

P.D3.02.13

Innate immune responses to improve anti-carbohydrate vaccines against bacterial pneumonia

P. Kaplonek[1,2]*, L. E. Sander*[3]*, P. H. Seeberger*[1,2]*;*
[1]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany, [2]Freie Universität Berlin, Institute of Chemistry and Biochemistry, Berlin, Germany, [3]Medizinische Klinik m.S. Infektiologie und Pneumologie, Charité Universitätsmedizin, Berlin, Germany.

High mortality rates of bacterial pneumonia and increase of antibiotic resistance is the major reason to develop novel vaccine strategies against *Streptococcus pneumoniae.* Ideal vaccines should be affordable, broadly available, easy to administer and induce long-lived protective immunity which requires activation of both innate and adaptive immune responses. Efficiency of vaccine depends on the quality and way of recognition of antigens as well as on proper adjuvants.
Preliminary results from our group showed protective effects of a SP3-tetra (the synthetic repeating unit tetrasaccharide of the *S. pneumoniae* serotype 3 (SP3) capsular polysaccharide) CRM_{197} conjugate vaccine *in vivo*, but long-term protection was limited. New adjuvants, such as prokaryotic mRNA and other vita-PAMPs (viability-associated pathogen-associated molecular patterns), have been shown to promote long-lasting humoral immunity in mice. Innate recognition of bacterial viability efficiently promotes human T_H1 and T_{FH} immunity. Thus, microbial signals (e.g. vita-PAMPs) that mimic live bacteria would represent ideal adjuvants for carbohydrate-conjugate vaccines directed against capsulated extracellular pathogens.
We design PRR (pattern recognition receptor)-ligand based adjuvant formulations to selectively induce innate signals that promote Th_1 and T_{FH} differentiation and humoral immunity. Encapsulated purified PAMPs (e.g. bacterial mRNA), or synthetic ligands (e.g. Imiquimod) in poly(lactic-co-glycolic acid particles (PLGA) are used to improve the immunoprotective effect of SP3-tetra in conjugation to both CRM_{197} and conserved pneumoccocal proteins (single amino acid substitution mutants, L469E, of pneumolysin). We use an *in vivo* mouse model (C57BL/6 mice) immunized with SP3-tetra conjugate microparticles.

P.D3.02.14

A reverse vaccinology approach in *Leishmania infantum* genome for the identification of surface-exposed/secreted antigens and selection of antigenic T cell epitopes for application in a multi-epitope peptide vaccine against leishmaniasis

M. Agallou[1]*, D. Zisis*[2]*, A. G. Hatzigeorgiou*[2,3]*,* ***E. Karagouni***[1]*;*
[1]Laboratory of Cellular Immunology, Department of Microbiology, Hellenic Pasteur Institute, Athens, Greece, [2]Bioinformatics-lab, Hellenic Pasteur Institute, Athens, Greece, [3]DIANA-Lab, Department of Electrical and Chemical Engineering, University of Thessaly, Volos, Greece.

Reverse vaccinology is a promising approach for direct screening of genome sequence assemblies for designing of new vaccine candidate proteins against different pathogens. The aim of the present study was to combine robust *in silico* approaches in the search for potential immunogenic T cell epitopes, based on the proteome of *Leishmania infantum*, for the development of an anti-*Leishmania* vaccine. Thus, the predicted proteome of *Leishmania infantum* was compared with other *Leishmania* species through BLAST protein alignment tool in order to select highly conserved protein sequences (>90%) resulting to a stringent set of 10 proteins. Then, subcellular and extracellular localization predictions were performed using Vacceed tool in order to select only the secreted and transmembrane proteins. Seven proteins were selected among which were 4 hypothetical proteins, 1 protein of unknown function and 1 protein namely vacuolar ATPase, subunit H. IEDB consensus tool was used to predict epitopes from the above proteins able to bind to MHCI and MHCII for the most prevalent allele supertypes of human and mice, whereas epitopes showing conservancy with human and murine proteome were excluded so as to avoid autoimmune responses. The resulting epitopes were then clustered to avoid redundancies and were used for molecular modelling and docking with MHCI and MHCII in order to select the most promising ones. *This research was funded by the grant from the Stavros Niarchos Foundation to the Hellenic Pasteur Institute and by EPAnEK Operational Programme (NSRF 2014-2020) co-financed by Greece and the European Union (T1EDK-03902).*

P.D3.02.15

Development of vaccine against fowl adenovirus 4

G. Ke[1]*, H. Chaung*[2]*, Y. Lien*[2]*, M. Wu*[3]*, T. Tsai*[1]*;*
[1]Graduate Institute of Animal Vaccine Technology, College of Veterinary Medicine/ Center of Animal Biologics, Pingtung, Taiwan, [2]Department of Veterinary Medicine, College of Veterinary Medicine/ Center of Animal Biologics, Pingtung, Taiwan, [3]Department of Food Science/ Research Center of Animal Biologics, Pingtung, Taiwan.

Fowl adenovirus-4 (FAdV4) belongs to avian adenovirus group I and is a double-stranded DNA virus without envelope. The diameter is about 70-90 nm. Clinical symptoms of FAdV4 infection is mainly Hydropericardium Syndrome (HPS) and Inclusion Body Hepatitis (IBH). HPS and IBH have a short incubation period and acute onset. The virus quickly spreads through the whole organism, resulting in a large number of deaths and huge economic losses. In this study, the FAdV4 virus was cultured with chicken liver cells and was successfully passaged in LMH cells. Titer of the virus gradually increased, reaching $10^{7.6}$ TCID50/mL at passage 10. The Hexon protein gene of FAdV4 was selected and expressed using the E. coli expression system, in which the protein expression reached 180 μg/mL. The inactivated 10^5 TCID50 FAdV4 virus along with 50 μg/mL recombination Hexon protein and adjuvant were prepared as a vaccine and used to immunize chickens. The neutralizing antibody titer reached over 2048x dilution 14 days after immunization. When immunized chickens were challenged, complete protection was observed and no virus was detected 14 days after challenge. The present results revealed that FAdV4 virus and Hexon protein retains high antigencity and can elicit high neutralizing antibody titers Therefore, it suggests that Hexon protein of FAdV4 could be a good candidate to be developed as a vaccine in the future.

P.D3.02.16

Virus like particles for the characterization of flavivirus cross-reactive antibody responses

E. Montoya-Diaz, *V. von Messling;*
Veterinary Medicine Division, Paul-Ehrlich-Institut, Langen, Germany.

The flavivirus family includes several important human pathogens. Due to the considerable structural and functional similarities, antibody responses induced by one virus frequently cross-react with other flaviviruses. Such cross-reactive antibodies are often beneficial but may also result in enhanced disease. A better understanding of the underlying mechanisms is thus essential for the development of safe vaccines in areas where several flaviviruses coexist. Since virus-like particles (VLPs) retain the morphology of the viral particle but are no longer infectious, they are a promising platform for flavivirus vaccine development. To assess the extent of flavivirus cross-reactive VLP-induced antibody responses and the associated risk for antibody-dependent enhancement of disease, we expressed the structural genes of Zika virus, Japanese Encephalitis virus, and Yellow Fever virus in mammalian cells and established a purification and concentration process, which reliably yields VLPs at concentrations around 1mg/ml. Immunization studies in mice to determine the kinetics of total and functional antibody responses against the homologous, as well as heterologous viruses with differing phylogenetic distance, are currently ongoing, and *in vitro* assays for the analysis of antibody-dependent enhancement activity are under development. We expect that these studies will provide new insights into the beneficial and adverse effects of cross-reactive flavivirus antibodies and contribute to the development of safe vaccines for these viruses.

P.D3.02.17

Intranasal immunization with outer membrane vesicle pertussis vaccine results in optimal protection

R. Raeven, ***D. Rockx-Brouwer****, L. van der Maas, T. Bindels, E. van Riet, B. Metz, G. Kersten;*
Intravacc, Bilthoven, Netherlands.

Immunization against *Bordetella pertussis* has led to a dramatic decrease of pertussis cases worldwide. Unfortunately, the world is currently facing a resurgence of whooping cough. This situation has led to the initiation of the development of improved pertussis vaccines. Our vaccine based on *B. pertussis* outer membrane vesicles (omvPV) is one of them. Subcutaneous immunization with omvPV leads to a broad antibody response against multiple antigens and a mixed Th1/Th2/Th17 response. While this systemic immunity is protective, we found that additional induction of mucosal immunity upon pulmonary administration of the vaccine improves protection against *B. pertussis* in mice. To explore alternative mucosal routes, we compared intranasal and subcutaneous omvPV immunization in mice to investigate the changes in protection and immunity. Intranasal immunization led to improved protection, and, in contrast to subcutaneous vaccination, induced strong mucosal responses of both IgA and Th17, while maintaining a similar degree of systemic IgG antibody levels, IgG-producing plasma cells, memory B-cells, and Th1/Th2/Th17 response. This study demonstrates that the development of mucosal pertussis immunity can be achieved by intranasal immunization and that this leads to enhanced protection against *Bordetella pertussis*.

P.D3.02.18

Identification of human Rhinovirus virus (HRV) CD8 T cell epitopes

M. Gomez Perosanz*, J. Sanchez-Trincado, M. Moreno Abraham, E. M. Lafuente, P. A. Reche Gallardo;*
Laboratory of Immunomedicine. Faculty of Medicine. Complutense University of Madrid, Madrid, Spain.

Adaptive immunity is based on the ability of T- and B-lymphocytes to recognize and remember antigens. More specifically, T- and B-lymphocytes recognize regions of the antigens known as epitopes. The knowledge of the epitopes that focus the attention of the immune system has a great practical relevance, as it allows to develop vaccines with a selective and controlled specificity. However, the development of this type of vaccine is not yet possible for certain pathogens whose epitopes are not described, as is the case of the human Rhinovirus (HRV). Here, we used a computational approach to select possible HRV epitopes from species A and C, the most frequent subtypes in the clinic of various pulmonary diseases. This approach is based on the identification of peptides within the conserved regions that show high HLA I-binding promiscuity.

Experimental identification of conserved CD8 T epitopes, was studied by IFNγ-ELISPOT assays using peripheral mononuclear cells (PBMC) from typed subjects exposed to synthetic peptides, consisting of predicted HRV-specific CD8 T epitopes. We have characterized 39 candidate epitopes derived from the computational analysis (25 of RVH A and 14 of HRV C) and 20 of them obtained a positive result in the analysis of release of IFNγ by ELISPOT. We verified peptide-binding to HLA-A0201 of ELISPOT positive responses using TAP-deficient T2 cell line binding-assays, which has led to the experimental identification of two Rhinovirus epitopes (VLEKGIPTL and GLEPLDLNTSAGFPYV) restricted by this allele that could potentially serve for the development of a vaccine.

P.D3.02.19

Optimization of HIV-1 DNA vaccine by comparing Minicircle and conventional vectors

***H. Huang**, W. Yikchun, C. Zhiwei, C. Samantha, C. Meisum;*
AIDS institute, Hong Kong, China.

DNA-based vaccine has become a promising vaccine vector because of its good safety profile and high immunogenicity. However, many current DNA vaccines only support short-term antigen expression and have low protective efficacy. Part of the reason is due to their large sizes and the presence of bacterial backbone sequences. Minicircle DNA vector is a next generation circular DNA vector that mostly consists of a small expression cassette, without the unnecessary bacterial backbone. Several studies have reported that minicircle vector enhances expression level and duration of inserted transgenes.
In this study, we examined the efficacy of minicircle vector in comparison to conventional pVAX plasmid as a vaccine against a HIV antigen in mouse models. The recombinant antigen focused in this study consisted of a soluble program death 1 (PD-1) molecule fused to a mosaic HIV-Gag-p41 antigen that was designed *in silico* based on the major circulating HIV sequences in China. The soluble PD-1 molecule allows effective antigen targeting to dendritic cells for antigen presentation.
We firstly confirmed the long-term antigen expression in mice treated with minicircle DNA vaccine intramuscularly with electroporation. Mice immunized with the minicircle vaccine induced a trend of higher $CD8^+$ in the spleen, lung and genital tract than those injected with an equal mass of the full-length pVAX vaccine during both acute and memory phases.
More importantly, the minicircle vaccine conferred a better protection in mice against intercostal challenge with malignant mesothelioma AB1 cells expressing HIV-Gag antigen. Collectively, our results demonstrate that minicircle vaccine is a favorable vaccine vector for inducing strong protective T cell immunity.

P.D3.02.20

Autoreactive potential of universal influenza vaccines

*M. R. Pillai[1], T. Chang[1], J. Crawford[1], R. Keating[1], C. Lewis[1], J. Labombarde[1], Q. Li[2], P. G. Thomas[1], **M. A. McGargill**[1];*
[1]St. Jude Children's Research Hospital, Memphis, United States, [2]UT Southwestern, Dallas, United States.

A universal influenza vaccine could save millions of lives in the event of a deadly pandemic. It is not clear why antibodies specific for conserved regions of influenza viruses are so rare. One possibility is that these antibodies have a higher potential to cross-react to self-proteins, and therefore B cells that generate these antibodies are deleted through tolerance mechanisms. In support of this, infections and vaccinations with the 2009 H1N1 pandemic strain induced more antibodies that were cross-reactive against multiple influenza strains than were induced by previous seasonal strains. However, they were also associated with a higher risk of autoimmune disorders, including narcolepsy and Guillain-Barré syndrome. Therefore, we examined whether cross-reactive influenza antibodies had a higher potential to be autoreactive than antibodies specific for one subtype of influenza. We previously demonstrated that H3N2-vaccinated mice treated with a low dose of rapamycin had more cross-reactive influenza antibodies and were better protected against subsequent lethal infections of multiple subtypes. Thus, we utilized rapamycin to increase the frequency of influenza cross-reactive antibodies, and tested whether these antibodies were more reactive to self-proteins than strain-specific antibodies. We found that mice with increased levels of cross-reactive influenza antibodies also had more IgM antibodies specific for self-antigens. Although the increase in autoreactive IgM antibodies was transient, it correlated with increased susceptibility to disease in mouse models of multiple sclerosis and Guillian-Barre Syndrome. Together, our results suggest that influenza cross-reactive antibodies have the potential to be autoreactive. These data have important implications for developing universal influenza vaccines designed to generate durable influenza cross-reactive antibodies.

P.D3.02.21

PHASE I, DOUBLE-BLIND, PLACEBO-CONTROLLED, RANDOMIZED SAFETY AND IMMUNOGENICITY TRIAL OF REACTIVATION OF PERTUSSIS TOXIN IMMUNITY WITH AN INVESTIGATIONAL EPICUTANEOUS PATCH IN HEALTHY ADULTS.

***O. Chatzis**[1], G. Blanchard-Rohner[1,2], L. Mondoulet[3], B. Pelletier[3], A. de Gea-Hominal[1], M. Roux[3], A. Huttner[4,1], P. L. Hervé[3], M. Rohr[2], A. Matthey[5], G. Gutknecht[5], B. Lemaître[6], C. Hayem[3], H. T. Pham[7], W. Wijagkanalan[7], P. H. Lambert[1], P. H. Benhamou[3], C. A. Siegrist[1,2];*
[1]Center for Vaccinology, University Hospitals of Geneva, Geneva, Switzerland, [2]Division of General Pediatrics, Department of Pediatrics, University Hospitals of Geneva, Geneva, Switzerland, [3]DBV Technologies, 177-181, avenue Pierre Brossolette, 92120, Montrouge, France, [4]Division of Infectious Diseases, University Hospitals of Geneva, Geneva, Switzerland, [5]Center for Clinical Research, University Hospitals of Geneva, Geneva, Switzerland, [6]Laboratory of Vaccinology, University Hospitals of Geneva, Geneva, Switzerland, [7]BioNet-Asia Co., Ltd., Bangkok, Thailand.

Background: Novel immunization strategies against pertussis are needed as immunity induced by acellular vaccines can be short-lived. Additionally, vaccination with needle-less and adjuvant-free patches could expand the target population benefiting from immunization. Methods: A Phase I, double-blind placebo-controlled randomized trial assessed safety and immunogenicity of an epicutaneous patch, Viaskin, administering recombinant pertussis toxin (rPT), in healthy adult (last PT-vaccination>10 years). Viaskin patches of PT 25µg, 50µg or placebo were administered at day 0 and 42, applied directly on the skin (n=25, 25, 10) or after controlled epidermal laser-based skin preparation (n=5, 25, 12). The primary outcome was safety of Viaskin PT. Antibody responses were assessed at day 14, 28, 42 and after administration of Boostrix®dTpa on day 70. Results: Baseline characteristics were similar among groups. Safety and tolerability profiles were favorable. Application directly on skin generated no detectable immunogenicity signal.In the group treated with Viaskin following skin preparation, D42 PT-IgG Geometric Mean Concentrations (GMCs) were significantly higher compared to placebo ($p<0.001$): Viaskin PT25 (33.24 IU/ml (95% CI, 9.59; 115.23), Viaskin PT50 (57.00 IU/ml (95% CI, 41.39; 78.51), placebo (4.03 IU/ml (95% CI, 2.56; 6.37). D42 seroconversion rates were significantly higher with Viaskin PT25 and PT50 vs. placebo (80% and 88% vs. 0%, $p=0.002$ and $p<0.001$, respectively). One-month after Boostrix®dTpa, PT-IgG antibody levels were similar in all groups.Conclusions: Viaskin PT applied after epidermal skin preparation resulted in favorable safety and immunogenicity: anti-PT booster responses were comparable to those elicited by Boostrix®dTpa.Clinical Trial Registration: NCT 03035370

A replication-incompetent adenoviral vector-based HSV-2 vaccine induces strong humoral responses and protects mice against lethal HSV-2 challenge

***E. Rossetti**, M. Vujadinovic, E. van Huizen, M. Mulders, L. Tettero, J. Drijver, S. Damman, H. Schuitemaker, E. Saeland, R. Zahn;*
Janssen Vaccines and Prevention BV, Leiden, Netherlands.

Herpes Simplex Virus-2 (HSV-2) is the leading cause of genital herpes and a major global health problem. HSV-2 resides in nerve cells and can reactivate sub-clinically or cause genital blisters. Several prophylactic vaccines against this lifelong disease have been studied and failed in the clinic to show efficacy against the infection. Therefore, the development of an effective HSV-2 vaccine is urgently needed. Replication-incompetent adenoviral vectors are a very promising vaccine platform and they have shown to be safe and capable of inducing both humoral and cellular immune responses in animal models and in humans.
We have generated an adenoviral vector-based HSV-2 vaccine. Immunogenicity and efficacy of the vaccine were evaluated in an HSV-2 challenge model in mice. Virus neutralization and ELISA titers were measured in serum before challenge. Viral titers, clinical scoring and survival rate were monitored after intravaginal challenge with 200 LD50 HSV-2 G strain virus.
The HSV-2 vaccine candidate induced comparable high virus neutralizing antibody titers, both after prime and prime-boost immunization. Both vaccine regimens induced complete protection against lethal challenge with the wild type HSV-2 G strain virus. We are currently investigating HSV-2 latency in dorsal root ganglia isolated from the infected mice. Additionally, experiments are being conducted to further characterize the humoral response by measuring IgG subclasses and antibody dependent cellular cytotoxicity. Cellular responses will be measured by IFNγ-ELISpot and intracellular cytokine staining.
The results from this study strongly encourage us to investigate more thoroughly this promising vaccine platform against HSV-2.

P.D3.02.23

Education of Stem Cells by BCG: An innovative Approach in TB Vaccine Development

E. Kaufmann[1], *J. Sanz*[2], *J. L. Dunn*[1], *N. Khan*[1], *L. E. Mendonca*[1], *A. Pacis*[2], *F. Tzelepis*[1], *E. Pernet*[1], *A. Dumaine*[3], *J. Grenier*[3], *F. Mailhot-Léonard*[3], *E. Ahmed*[1], *J. Belle*[4], *R. Besla*[5], *B. Mazer*[1], *I. L. King*[1], *A. Nijnik*[4], *C. S. Robbins*[5], *L. B. Barreiro*[3], *M. Divangahi*[1];
[1]*McGill University Health Centre, Montreal, Canada,* [2]*Université de Montréal, Canada, Montreal, Canada,* [3]*Université de Montréal, Montreal, Canada,* [4]*McGill University, Montreal, Canada,* [5]*University of Toronto, Toronto, Canada.*

Introduction BCG is still the only available vaccine against TB, but prevents only the disseminated forms of the disease in early childhood. The efficacy of BCG against pulmonary TB in adults ranges from 0-80%. While control of TB requires T-cells to prevent disease progression, clinical trials of T-cell-targeting vaccines have failed to demonstrate protection against *Mycobacterium tuberculosis* (*Mtb*) infection. We therefore hypothesize that a protective mechanism afforded by BCG in adults is mainly dependent on monocytes/macrophages which are one of the first immune cells to encounter *Mtb* upon infection. However, considering the nature of monocyte/macrophage differentiation and their relatively short lifespan, we hypothesize that the access of BCG to the bone marrow (BM) will educate the hematopoietic stem cells (HSCs) to subsequently generate protective innate immunity.
Methods&Results Using mouse models, we demonstrated that following intravenous but not subcutaneous BCG vaccination, the bacteria access the BM. The presence of BCG in the BM significantly increased the numbers of lineage$^-$c-Kit$^+$Sca1$^+$ HSCs as well as multi-potent progenitors, and led to the generation of epigenetically modified monocytes/macrophages. By using parabiosis and chimeric mice as well as adoptive transfer approaches, we demonstrate that these educated monocytes/macrophages provide sustainable protection against *Mtb* infection *in vivo*.
Conclusions Our findings demonstrate that access of BCG into the BM is critical for generating a unique set of educated monocytes/macrophages that are protective against virulent *Mtb* infection. Reprogramming of HSCs thus may provide an innovative approach in vaccine development.
This work was supported by CIHR, DFG and FRQS.

Despite decades of vaccine prevention, pertussis continues to occur and its prevalence is increasing. Clinical trials have demonstrated the efficacy of the current acellular vaccines (aP), however primo-infection still confers a better and more sustained protection. In humans, vaccine-induced antibodies rapidly wane after immunization, suggesting the failure to induce long-lived plasma cells. This contrast with murine data, in which antibody titres only slowly decline, in correlation with the persistence of plasma cells in the bone marrow. To circumvent the issue of antibody persistence in mice, we developed an adoptive transfer model in which memory immune cells induced by primo-infection or aP vaccination are transferred to naïve recipients prior to booster immunization or intranasal challenge with *Bordetella pertussis* (BP). This allows us to asses recall responses in the absence of circulating serum antibodies, mimicking the situation in humans.
Using this model, we found, that BP challenge recalls both vaccine-and pre-exposure-induced B cell memory much slower than a vaccine booster. As in humans, pre-exposure to BP provides a better protection than vaccine priming, efficiently initiating bacterial clearance in the first week post-challenge. This implies (1) that the delayed reactivation of memory B cells by BP contributes to the lack of protection against BP, and (2) that other key protective memory cells are induced by primo-infection but not aP vaccines.

The Porcine Reproductive and Respiratory Syndrome Virus (PRRSV) induces reproductive disorders in sows and respiratory illnesses in growing piglets and is considered as the main pathogenic agent responsible for economic losses in the porcine industry worldwide. Modified live PRRSV vaccines (MLV) are by far the most efficient vaccine types but they are mainly protective against homologous strains and they may reverse to pathogenicity upon residual replication. We aimed at evaluating DNA vaccine strategies as stand-alone vaccines or used as priming to improve the MLV efficacy and safety. Our DNA PRRSV vaccines encode B and T antigens from a European subtype 1 strain which are relatively conserved across strains and which are expressed in a native form or in the form of vaccibodies targeted to the endocytic receptor XCR1 and CD11C expressed by dendritic cells. When delivered in skin with surface electroporation, the DNA vaccines induced antibody and T cell responses which were not promoted by antigen targeting to dendritic cells. Interestingly when delivered with surface electroporation or with needle-free jet fluid, a DNA prime enhanced the antibody response and broaden the T cell response induced by MLV. Furthermore, the DNA prime resulted in lower MLV replication in blood at day 20 after inoculation. The protective immunity against a heterologous strain is currently being evaluated.

P.D3.03.03

Development of a robust and standardized immunoserological assay for detection of anti-measles IgG antibodies in human serum

K. Böröcz*;*
Department of Immunology and Biotechnology, Clinical Centre, University of Pécs, Pécs, Hungary, Pécs, Hungary.

Introduction. Recent measles outbreaks face epidemiologists, diagnostic laboratories and health authorities with new challenges. High age-specific attack rates of the 1980-81 and 1988-89 epidemics suggest the existence of immunization gaps in the Hungarian population. Consequently, there is a need for continuous and large-scale monitoring of immunological protection against infection. For such monitoring to be feasible, a cost-effective, reliable and high-throughput assay is necessary. We developed a new ELISA protocol for assessment of anti-measles antibody levels in human serum.
Materials and Methods. A serum bank of anonymous patient sera was established (N >3000 samples). Sera were grouped based on measles immunization schedules and/or changes in vaccine components since the introduction of the first measles vaccine in Hungary in 1969. Our automated indirect ELISA was compared to indirect immunofluoresence and to anti-measles nucleocapsid (N) monoclonal antibody-based sandwich ELISA.
Results. Our results are in high agreement with the confirmatory methods (p-value< 0.0001). Based on measurement of 2057 sera, the highest ratio of low/questionable antibody level samples was detected in cluster '1978-1987' (~25.4%), followed by cluster '1969-1977' (~15.4%). Between age-groups of the new vaccination era, no statistical difference was found.
Conclusion. The identified potentially susceptible cohorts confirm our initial presumption of vaccine failure of the initial period of anti-measles immunization. Our new assay is cost-effective, allows high-throughput screening and has a better signal-to-noise ratio
compared to many commercial kits. This assay can serve as a first step in assessment of the effectiveness of all three components of the MMR vaccine.

P.D3.03.04

Development of vaccines against listeriosis

R. Calderón González*, E. Frande Cabanes, H. Terán Navarro, D. Salcines Cuevas, C. Álvarez Domínguez;*
Instituto de Investigación Marqués de Valdecilla (IDIVAL), Santander, Spain.

Introduction: Despite its increase in Europe during the last years, there is no vaccine approved against listeriosis. The goal of our laboratory has been the development of a prophylactic therapy that may be not only effective against the disease, but also easy and cheap to implement in healthcare systems.
Materials and Methods: While several *in silico* and *in vitro* experiments were made to search for peptides to be used in vaccination and to study its capacity to develop an immune response and its safety, the most useful tool in our research was the use of animal models. They allowed us to study the effectivity of our vaccines in models of different susceptibility to develop the disease, as well as listeriosis infection during pregnancy.
Results: The use of a cellular vector like dendritic cells allowed us to see that two peptides of *L. monocytogenes* LLO and GAPDH virulence factors have a great effectivity in the prevention of listeriosis, providing an effective Th1 immune response. As cellular therapy may be too expensive and difficult to apply on clinical practice, we use another vector: gold glyconanoparticles. These nanovaccines, used with adjuvants, proof to be as effective as dendritic vaccines, providing great protection levels in all the murine models we used.
Conclusions: Our laboratory has developed two different kinds of vaccines against listeriosis. While dendritic vaccines could be used in some specific cases like oncological patients, the use of nanovaccines may be a more convenient preventive therapy for the vaccination of global population.

P.D3.03.05

Increased adaptive immune responses and proper feedback regulation protect against clinical dengue

*E. Simon-Lorière[1], V. Duong[2], A. Tawfik[1], S. Ung[2], S. Ly[2], I. Casademont[1], M. Prot[1], N. Courtejoie[1], K. Bleakley[3], P. Buchy[2], A. Tarantola[2], P. Dussart[2], A. Sakuntabhai[1], **T. Cantaert**[2];*
[1]Institut Pasteur, Paris, France, [2]Institut Pasteur Cambodia/Institut Pasteur International Network, Phnom Penh, Cambodia, [3]INRIA Saclay, Palaiseau, France.

Clinical symptoms of dengue virus (DENV) infection, the most prevalent arthropod-borne viral disease, range from classical mild dengue fever to severe, life-threatening dengue shock syndrome. However, most DENV infections cause few or no symptoms. Asymptomatic DENV-infected patients provide a unique opportunity to decipher the host immune responses leading to virus elimination without negative impact on an individual's health. We used an integrated approach of transcriptional profiling and immunological analysis to compare a Cambodian population of strictly asymptomatic viremic individuals with clinical dengue patients. Whereas inflammatory pathways and innate immune response pathways were similar between asymptomatic individuals and clinical dengue patients, expression of proteins related to antigen presentation and subsequent T cell and B cell activation pathways was differentially regulated, independent of viral load and previous DENV infection history. Feedback mechanisms controlled the immune response in asymptomatic viremic individuals, as demonstrated by increased activation of T cell apoptosis-related pathways and FcgRIIB (Fcg receptor IIB) signaling associated with decreased anti-DENV-specific antibody concentrations. Together, our data illustrate that symptom-free DENV infection in children is associated with increased activation of the adaptive immune compartment and proper control mechanisms, leading to elimination of viral infection without excessive immune activation, with implications for novel vaccine development strategies.

P.D3.03.06

Age-dependent pre-vaccination immunity affects the immunogenicity of Varicella Zoster vaccination in middle-aged adults

*M. van der Heiden[1,2,3], **L. G. H. de Rond**[1], M. C. van Zelm[4,5], G. A. Berbers[1], A. M. Boots[2], A. Buisman[1];*
[1]National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands, [2]University of Groningen, Groningen, Netherlands, [3]The Wenner-Gren Institute, Stockholm University, Stockholm, Sweden, [4]Erasmus MC, Rotterdam, Netherlands, [5]Central Clinical School, Monash University and Alfred Hospital, Melbourne, Australia.

Background The incidence of Herpes Zoster disease increases with age. Unfortunately, vaccine strategies to harness VZV-specific cell mediated immunity (CMI) demonstrate low effectiveness in the elderly, due to immune ageing. Timely vaccination of middle-aged adults might improve VZV-specific CMI at higher age. Therefore, we investigated immune responses after VZV vaccination (Zostavax) in Dutch middle-aged adults (N=53, 50-65 years of age). *Methods* Blood samples were taken pre-, 14 days, 28 days, and 1 year post-vaccination. VZV-specific IFNγ-producing cells were measured by Elispot, activated T-cells by flow cytometry, IgG and IgA antibody levels by fluorescent bead-based multiplex immunoassays, and whole blood cellular kinetics by TruCOUNT analysis. *Results* Robust short-term VZV-specific immune responses were observed post-vaccination. Remarkably, long-term enhancement of VZV-specific IFNγ producing cell numbers was induced only in participants with low pre-vaccination numbers of these cells, who were significantly older. These participants also showed enhancement of VZV-specific IgA 14 days post-vaccination. Finally, a high CD4/CD8 T-cell ratio was positively related to vaccine responsiveness. *Conclusion* These results suggest that adults in their early sixties, who showed a high CD4/CD8 T-cell ratio and low VZV-specific CMI, benefit from VZV vaccination, also shown by a VZV-specific IgA response at day 14 post-vaccination. This provides important knowledge for strategies to strengthen VZV-specific immunity before reaching old age.

Vaccine-induced immune responses in Gabonese infants

***M. Esen**[1,2,3], J. Flügge[1,3], J. Honkpehedji[2], E. Askani[1,2], M. Massinga Loembe[1,2,4], S. Brückner[1], M. Duali[2], J. Strunk[1], B. Mordmüller[1,2,3], S. T. Agnandji[1,2], B. Lell[1,2], P. G. Kremsner[1,2,3], A. A. Adegnika[1,2,3];*
[1]Institut für Tropenmedizin, Tübingen, Germany, [2]Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon, [3]German Center for Infection Research (DZIF), Tübingen, Germany, [4]Université des Sciences de la Santé, Libreville, Gabon.

Helminth infections are common in Sub-Saharan Africa. It is generally recognized that infected individuals show a bias towards a Th2 immune response. Most vulnerable to helminth infection are children and pregnant women. The consequences of parasite infection during pregnancy for the mother and particularly for the fetus and the newborn can be severe and may include late effects on immune response during acute infection and vaccination. From February 2014 until September 2016 we conducted a study to investigate the influence of maternal parasite infection during pregnancy on the immune system of their infants in Lambaréné, Gabon and surroundings (ClinicalTrials.gov Identifier: NCT02714348). Here we present data on the immune responses to vaccines given within the expanded program on immunization (EPI) in 123 infants born to helminth infected and non-infected mothers. Helminth infection was diagnosed microscopically by the Kato-Katz method. Antibody titers to different vaccines (diphtheria, whooping cough, tetanus, poliomyelitis, hepatitis B and *Haemophilus influenza* A) were measured using commercial and validated ELISA kits. Our data show that infection with helminths is still common in pregnant women in Gabon but has only subtle effects on infants' immune responses to vaccines given as part of the EPI. Funding: This work was supported by the German Federal Ministry of Education and Research [01 KA 1009].

P.D3.03.08

SapM mutation to improve BCG vaccine efficacy: impact on vaccine clearance and quality of adaptive immune response

***N. Festjens**, K. Vandewalle, E. Houthuys, E. Plets, D. Vanderschaeghe, K. Borgers, A. Van Hecke, P. Tiels, N. Callewaert;*
VIB-UGent, Zwijnaarde, Belgium.

The *M. bovis* Bacille Calmette Guérin (BCG) vaccine shows variable efficacy in protection against adult tuberculosis (TB). Earlier, we have described a BCG mutant with a transposon insertion in the gene coding for the secreted acid phosphatase SapM, which led to enhanced long-term survival of vaccinated mice challenged with TB infection. We have now further characterized the genome and transcriptome of this *sapM*::Tn mutant versus parental BCG Pasteur. Moreover, we investigated the clearance of this improved vaccine strain from the immunization site, and the evoked immune response upon vaccination. Our findings strongly suggest that a more effective innate immune control over the vaccine bacteria leads to a more modest primary expansion of IFNγ Th1 and Tc1 cells. This correlates with an improved control of BCG *sapM*::Tn bacterial loads compared to WT BCG load following vaccination.

P.D3.03.09

DNA vaccination with APC-targeted hemagglutinin for prevention of influenza pandemics

***G. Grodeland**[1], T. Andersen[1], A. B. Fredriksen[2], B. Bogen[1];*
[1]University of Oslo and Oslo University Hospital, Oslo, Norway, [2]Vaccibody AS, Oslo, Norway.

Pandemic influenza represents a threat to society, and novel vaccine strategies are needed to counter an unexpected emergence. DNA vaccines can be rapidly manufactured, but it has been difficult to translate promising results from DNA vaccination in mice to larger animals and humans. Immunogenicity of DNA vaccination can be greatly increased by targeting of antigen to antigen presenting cells (APC). Further, by careful selection of receptor targets on APC, the induced immune responses can be polarized to different types of immunity. Thus, targeting of influenza hemagglutinin (HA) towards MHC class II (MHCII) molecules is particularly efficient for induction of rapid, enhanced and long-lasting antigen-specific antibody titers in both mice and larger animals. Correspondingly, targeting of HA to chemokine receptors particularly raise cellular immunity. In the context of influenza prevention, antibodies represent an important correlate of protection. Thus, we have developed novel HLA class II-targeted DNA vaccines that could be rapidly produced to counter a pandemic emergence. Importantly, the HLAII-specific targeting unit binds most of the polymorphic HLA class II molecules pan-specifically in humans. A single HLAII-targeted DNA vaccination induced neutralizing antibodies in larger animals such as ferrets, pigs and rhesus macaques. As an indication that the vaccines could also be useful for human application, HLA class II-targeted vaccine proteins were found to increase human $CD4^+$ T cell responses by a factor of $x10^3$ *in vitro*.

Characterization of early responses in blood skin and lymph node compartment induced by intradermal injection of Modified Vaccinia Ankara

*P. Rosenbaum[1], N. Tchitchek[1], **C. Joly**[1], L. Stimmer[2,3], H. Hocini[4,5], N. Dereuddre-Bosquet[1], A. Beignon[1,4], C. Chapon[1,4], Y. Lévy[4,5], R. Le Grand[1,4], F. Martinon[1,4];*
[1]Immunology of Viral Infections and Autoimmune Diseases, IDMIT Department, CEA – Université Paris Sud 11 – INSERM U1184, Fontenay-aux-Roses, France, Fontenay-aux-Roses, France, [2]CEA – INSERM, MIRCen, UMS27, Fontenay-aux-Roses, France, Fontenay-aux-Roses, France, [3]INSERM U1169, Kremlin-Bicêtre, France, Kremlin-Bicêtre, France, [4]Vaccine Research Institute, Henri Mondor Hospital, Créteil, France, Créteil, France, [5]INSERM U955, Henri Mondor Hospital, University of Paris East, Créteil, France, Créteil, France.

Vaccine design approaches would be greatly facilitated by a better understanding of the early immune changes, and those that occur at the site of injection, inducing a durable and oriented protective response. We characterized in details very early infection and host response events after the intradermal administration of the modified vaccinia virus Ankara as a live attenuated vaccine model in non-human primates. We performed *in vivo* imaging, histology, flow cytometry, multiplex cytokine, and transcriptomic and analyzed data using tools derived from systems biology, such as co-expression networks.
We showed a strong early local and systemic inflammatory response that peaked at 24 h, which was then progressively replaced by an adaptive response during the installation of the host response to the vaccine. Granulocytes, macrophages, and monocytoid cells were massively recruited during the local innate response in association with local productions of GM-CSF, IL-1β, MIP1α, MIP1β, and TNFα. We also observed a rapid and transient granulocyte recruitment and the release of IL-6 and IL-1RA, followed by a persistent phase involving inflammatory monocytes. This systemic inflammation was confirmed by molecular signatures, such as up-regulations of IL-6 and TNF pathways and acute phase response signaling. Such comprehensive approaches improve our understanding of the spatio-temporal orchestration of vaccine-elicited immune response, in a live attenuated vaccine model, and thus contribute to rational vaccine development.

P.D3.03.12

Tannic acid-modified silver nanoparticles as novel adjuvants in herpes virus infection

*P. Orlowski[1], E. Tomaszewska[2], K. Ranoszek-Soliwoda[2], G. Celichowski[2], J. Grobelny[2], **M. Krzyzowska**[1];*
[1]Military Institute of Hygiene and Epidemiology, Warsaw, Poland, [2]Faculty of Chemistry, University of Lodz, Lodz, Poland.

Silver nanoparticles (AgNPs) are promising new antimicrobial agents against a wide range of skin and mucosal pathogens. We have previously shown that tannic acid modified silver nanoparticles (TA-AgNPs) consist a promising microbicide against genital herpes. The aim of this study was to study the ability of TA-AgNPs to induce DCs activation in the presence of HSV-2 antigens when used at non-toxic doses. Additionally, we tested ability of TA-AgNPs to induce efficient anti-viral immunity in vivo using mouse genital herpes model. Preparations of HSV-2 treated with nanoparticles (TA-AgNPs-HSV-2) were used to investigate HSV-2 antigen uptake, activation markers and cytokine production by JAWS II dendritic cell line. We also accessed proliferation and activation of HSV-2 specific T cells by DCs treated with TA-AgNP-HSV-2. Our results showed that TA-AgNPs were potent stimulators of DCs maturation and helped to internalise viral antigens. TA-AgNPs-HSV-2 also helped to overcome inhibition of DCs maturation by live or inactivated virus through up-regulation of activation markers and cytokine production. HSV-2 treated with TA-AgNPs stimulated activation of memory CD8+ T cells, and induction of IFN-γ producing CD4+ and CD8+ T cells. HSV-2 infected mice treated intravaginally with TA-AgNPs showed better recovery, lower viral titers in spinal cords, higher levels of seroneutralising antibodies upon viral challenge and development of effective B and T cell memory compartment. We conclude that TA-AgNPs consist a novel class of nano-adjuvants, which can help to overcome virus-induced suppression of DCs activation. This work was supported by DEC- 2012/05/N/NZ6/01757 grant.

Circulating T follicular helper cells and immune response induced by influenza vaccine in children with acute lymphoblastic leukemia during maintenance therapy

***N. Le Corre**[1,2], C. P. Martinez-Valdebenito[1,2], F. Barriga[3], M. Contreras[3], M. Vidal[3], R. Moreno[4], X. Claverie[4], P. Contreras[4], L. Huneman[4], R. Alarcón[2], T. García[1], R. Rathnasinghe[1], R. Medina[1], M. Ferrés[1,2];*
[1]Dpto Enfermedades Infecciosas e Inmunología Pediátrica, Pontificia Universidad Católica de Chile, Santiago, Chile, [2]Laboratorio de Infectología y Virología Molecular, Red Salud UC-Christus, Santiago, Chile, [3]Unidad Oncología División Pediatría, Pontificia Universidad Católica de Chile, Santiago, Chile, [4]Unidad Hemato-Oncología Pediátrica Complejo Asistencial Dr. Sótero del Río, Santiago, Chile.

Vaccine immune response is impaired in immunocompromised patients. Follicular helper-T-lymphocytes (cTfh) are essential for high-affinity and long-lasting humoral response. We evaluate the role of cTfh in immune response induced by influenza vaccine in children with acute linfloblastic leukemia (ALL). Children with ALL in maintenance therapy and a control group of healthy children were included. Blood samples were taken on the day of vaccination (D0), and on day 28 (D28). The humoral response and frequency of cTfh were evaluated. Twenty-four children with ALL and 8 healthy children were included: 66,7 and 38% were women, median age of 5 years old in both. A 33,3%(8/24) of patients and 63%(5/8) of controls were seroprotected at D28. Seroprotected children were significantly older (10 years) than non-protected children at D28 (3.6 years),(p=0,004). During follow-up, three children had influenza infection. An increase of percentage of cTfh cells from D0 to D28 was observed in both groups, but only significantly in ALL (mean-ALL, D0-D28:18-23% (p=0.003) and mean-controls, D0-D28:22-26%).
Comparing seroprotected versus non-seroprotected children no differences were found in cTfh cell at D0 or D28. The increase of percentage of cTfh cells from D0 to D28 observed in both groups, was significant only non-seroprotected subject (mean-seroprotected, D0-D28:21-24%and mean-non-seroprotected, D0-D28:18-24% p=0.004).Children with ALL achieved a lower seroprotection than healthy children. After vaccination, all children had a increase of cTfh cells. We did not found association between percentage of cTfh cells and seroprotection at D28. It should be evaluated if the lack of humoral response is associated to cTfh disfunction. Fondecyt-11150970

<META NAME="author" CONTENT="Microsoft Office 用户">
To construct and express a chimeric protein of immunogenic epitopes from five types of human adenoviruses(HAdV), type 3, 7, 11, 14 and 55, and identify its immunoactivity. The amino acid sequences of hexons from the five types of HAdV were analyzed respectively by using software, and the immunogenic epitopes with strong antigenicity were screened. The selected immunogenic epitopes were linked together with Gly-Gly-Ser for constructing a chimeric protein of immunogenic epitopes. The DNA of the chimeric protein was synthesized chemically, and cloned into plasmid pET-28a(+) for expressing the chimeric protein. The chimeric protein was purified by Ni-NTA resin and used as an antigen to immune Balb/c mice, the antisera were prepared. The antigenicity and immunogenicity of the chimeric protein were detected by ELISA. The chimeric protein was expressed and purified successfully. The titers of antiserum from the mice immunized four times with the chimeric protein reached to 1:320,000, and the ELISA results confirmed that the chimeric protein has strong antigenicity and immunogenicity. The expressed chimeric protein of immunogenic epitopes from the five types of HAdV laid foundation for developing vaccine and diagnostic reagents.

Repeated mycobacteria vaccination in mice induces myeloid-derived suppressor cell killing of splenic dendritic cells via iNOS-dependent NO production

*E. Ribechini[1], I. Eckert[1], A. Beilhack[1], N. Du Plessis[2], G. Walzl[2], U. Schleicher[3], U. Ritter[4], **M. B. Lutz**[1];*
[1]University of Würzburg, Würzburg, Germany, [2]Stellenbosch University, Cape Town, South Africa, [3]University of Erlangen, Erlangen, Germany, [4]University of Regensburg, Regensburg, Germany.

Myeloid-derived suppressor cells (MDSCs) accumulate in patients with tuberculosis (TB) and a vaccine based on *Mycobacterium tuberculosis* (Mtb) is lacking. From this, we hypothesized that Mtb-based vaccines may induce MDSCs impairing vaccination success. Our data indicate that *in vitro*, bone marrow-derived resting MDSC (R-MDSC) stimulation with heat-killed Mtb resulted in the production of NO, directly suppressing T cells and inducing bone marrow-derived dendritic cell (BM-DC) apoptosis. The killing was NO dependent since blocking of iNOS reverted the effect. *In vivo*, repeated immunization of mice with Complete Freund´s Adjuvant (CFA) containing Mtb but not Incomplete Freund's Adjuvant (IFA) lacking the Mtb component induced activated MDSCs (A-MDSCs) in the spleen. Myeloid cells isolated from spleens of CFA/CFA injected mice but not single CFA or CFA/IFA injected mice suppressed $CD4^+$ and $CD8^+$ T cell proliferation in a nitric oxide (NO) dependent manner. The accumulation of $Gr\text{-}1^+$ $CD11b^+$ $iNOS^+$ myeloid cells was restricted to the splenic red pulp and bridging channels. Short term microbial challenge of mice *in vivo* induced infiltration of $iNOS^+$ A-MDSCs after 6h into the white pulp resulting in conventional DCs (cDCs) and plasmacytoid DCs (pDCs) apoptosis in the T cell areas of the white pulp after 24h. DC apoptosis was not observed after microbial challenge alone and was reduced in $NOS2^{-/-}$ mice. In contrast, apoptosis of T cells was not observed and macrophage killing occurred but was independent of NO. Together, our data indicate that Mtb vaccines induced and activated MDSCs in spleens of mice leading to NO-dependent DC killing.

Immune profile driven by a novel tuberculosis nanovaccine correlates with protection against *Mycobacterium tuberculosis* infection

***A. Martínez-Pérez**[1], A. Igea[1], O. Estévez-Martínez[1], C. M. Ferreira[2], A. G. Castro[2], E. Torrado[2], Á. González-Fernández[1];*
[1]Immunology. Biomedical Research Centre (CINBIO) (Singular Centre of Research), Galicia Sur Health Research Institute (IISGS), University of Vigo, Vigo, Spain, [2]Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal, and PT Government Associate Laboratory ICVS/3B's, Braga, Portugal.

Introduction: The mechanisms underlying protection against *Mycobacterium tuberculosis* (Mtb) infection remain unclear. Prime vaccination with BCG following by boosting actions with novel vaccines has emerged as a promising strategy. In this regard, a new vaccine composed by a nanoparticle and a fusion protein containing three Mtb antigens and administered intranasaly, has been shown to enhance protection against Mtb when compared to BCG alone. In this study, we aimed at defining the immune cellular and molecular profile generated by this vaccine with the ultimate goal of identifying correlates of protections against Mtb infection.
Materials and methods: Mice were vaccinated with BCG following by two boosts two weeks apart with two different nano-vaccines. Two weeks after the last boost, mice were sacrificed and lung and spleen cells analyzed by flow cytometry and RNA-Sequencing.
Results: We found different protection levels induced by the tested nanovaccines. Interestingly, the level of protection correlated with the polyfunctionality of the Ag-specific CD4 T cell response and composition of the lung immune infiltrates. Crucially, gene expression analysis revealed a unique profile of differentially expressed genes in protected mice.
Conclusions: The results obtained in this study offer new insights that may be useful in the design of novel and more efficient vaccines to tuberculosis.

Introduction: Anti-viral DNA vaccines are a novel strategy in the vaccine-development field, which consists in the administration of expression vectors coding viral antigen sequences into the host's cells. It has been shown that FcγRI on human monocytes enhances antigen presentation *in vivo*. Targeting of conserved viral epitopes by antibody fragments specific to activating cell surface co-receptor molecules on antigen-presenting cells could be an alternative approach for inducing protective immunity. Materials and Methods: Genetic engineering, signal transduction, cell transfection, flow cytometry, generation of humanized NOD/SCID model, ELISpot, ELISA and cytotoxicity assays; Results: Various DNA constructs, encoding a scFv fragment from mouse anti-human FcγRI monoclonal antibody, coupled to a sequence, encoding a T- and B-cell epitope-containing influenza A virus hemagglutinin intersubunit peptide were inserted into the eukaryotic expression vector pTriEx-3 Neo. The constructed chimeric DNA molecules were expressed by transfected CHO cells and the ability of the engineered proteins to interact with FcγRI-expressing cells was confirmed by flow cytometry. The fusion protein induced a strong signal transduction on human monocytes via FcγRI. The expression vector pTriEx-3 Neo containing the described construct was used as a naked DNA vaccine and introduced directly to experimental humanized NOD/SCID mice with or without boosting with the expressed fusion protein. Immunization with the generated DNA chimeric molecules, and prime-boost with the expressed recombinant proteins induced significant serum levels of anti-influenza IgG antibodies and strong CTL activity against influenza virus-infected cells in humanized animals. Conclusions: Genetically engineered molecules elicit an efficient anti-influenza immune response in the humanized mice.

T-CELL AND B-CELL MEMORY IMMUNITY AFTER A SINGLE DOSE BIVALENT HPV VACCINATION COMPARED TO TWO- OR THREE DOSE VACCINATED GIRLS TO 6 YEARS POST-VACCINATION

H. Pasmans[1], *T. Schurink- van ,t Klooster*[1], *M. Welters*[2], *S. van der Burg*[2], *F. van der Klis*[1], *A. Buisman*[1];
[1]*RIVM, Bilthoven, Netherlands,* [2]*LUMC, Leiden, Netherlands.*

Vaccines consisting of virus-like particles (VLPs) against Human Papillomavirus (HPV) are currently administered in subsequently two- or three injections. However, it has been shown that just one-dose of the bivalent HPV16/18 vaccine results in the seroconversion of all women in a 7 years follow-up vaccination study. The seroconversion is associated with a low prevalence of HPV-16/-18 infections suggesting that the induced protection after one-dose of vaccine may be long lived. Since T- and B-cell responses are important in the immunity against HPV, we evaluated these responses in subjects vaccinated with different schedules. Blood was cross-sectional collected and PBMCs were isolated from girls vaccinated at 12 years of age according to a one-, two- or three-dose schedule. T-cells producing IFN-γ were determined by ELISPOT after stimulation of PBMCs by VLPs for HPV-16, HPV-18, HPV-31 and HPV-45. HPV-type-specific memory B-cell responses were determined by specific ELISPOT assays after polyclonal stimulation of isolated (CD19+) B-cells. Even after 6 years following vaccination HPV-type-specific interferon-gamma producing T cells were detectable .
However, these numbers are lower compared to two- and three-dose vaccinated individuals. Memory B-cell responses are detected at least 2 years post vaccination against type 16, 18, 31 and 45. The one-dose schedule is highly immunogenic and induces long-term HPV-specific T- and B-cell memory, although further studies will evaluate T-cell responses in more detail. The results suggests that a booster immunization might not be necessary to induce long-lived HPV-specific immunity.

Identification of candidate *Coxiella burnetii* T-cell epitopes for a novel human Q-fever vaccine

A. Scholzen[1], *L. Moise*[2], *G. Richard*[2], *P. M. Reeves*[3], *S. Raju Paul*[3], *T. A. Brauns*[3], *L. A. Baeten*[4], *R. A. Bowen*[4], *R. Bucala*[5], *C. M. Boyle*[2], *W. D. Martin*[2], *A. E. Sluder*[3], *A. Garritsen*[1], *A. S. De Groot*[2], *M. C. Poznansky*[3];
[1]*Innatoss Laboratories, Oss, Netherlands,* [2]*EpiVax, Providence, United States,* [3]*Massachusetts General Hospital, Boston, United States,* [4]*Colorado State University, Fort Collins, United States,* [5]*Yale University School of Medicine, New Haven, United States.*

Coxiella burnetii (Cb), the causative agent of Q-fever, is a Gram-negative intracellular bacterium transmitted via aerosol. Regulatory approval of the Australian whole-cell vaccine Q-Vax in the US and Europe is hindered by reactogenicity in previously exposed individuals. The aim of this study was to identify and rationally select Cb epitopes for a safe, effective and less reactogenic T-cell targeted human Q-fever vaccine. Immunoinformatic methods were used to predict 65 HLA class I and 50 class II Cb epitopes. HLA binding assays confirmed 89% of class I and 75% of class II predictions, and 11 class II epitopes elicited IFNγ responses following heterologous DNA/peptide prime-boost immunizations of tgHLA-DR3 mice. Individuals naturally exposed to Cb during the 2007-2010 Dutch Q-fever outbreak were divided into three groups: controls without immunological evidence for previous infection and individuals with responses to heat-killed Cb in a whole blood IFNγ release assay (IGRA) which remained asymptomatic or experienced clinical Q-fever. Recall responses to Cb epitopes were assessed by cultured IFNγ ELISpot. While class I epitope responses were sparse, we identified 21 class II epitopes that re-called T-cell IFNγ responses in 10-28% of IGRA+ subjects. Past asymptomatic and symptomatic IGRA+ individuals showed a comparable response pattern and cumulative peptide response which correlated with IGRA responses. These data demonstrate that a substantial proportion of immunoinformatically-identified class II epitopes show long-lived immunoreactivity in naturally infected individuals, making them desirable candidates for a novel epitope-based Q-fever vaccine. This work was supported by contract HDTRA1-15-C-0020 from the US Defense Threat Reduction Agency.

P.D3.03.20

Improving the vaccine efficacy of recombinant BCG utilizing the major membrane protein-II (MMPII) antigen against tuberculosis

Y. Tsukamoto[1], *Y. Maeda*[1], *T. Tamura*[1], *T. Mukai*[1], *S. Mitarai*[2], *S. Yamamoto*[3], *M. Makino*[1];
[1]*Department of Mycobacteriology, Leprosy Research Center, National Institute of Infectious Diseases, Tokyo, Japan,* [2]*Department of Mycobacterium Reference and Research, The Research Institute of Tuberculosis, Tokyo, Japan,* [3]*Japan BCG Laboratory, Tokyo, Japan.*

Mycobacterium bovis BCG (BCG) has been used as a vaccine against tuberculosis. However, its efficacy against adult pulmonary tuberculosis is limited. To improve the efficacy of BCG vaccination against tuberculosis, we utilized Major Membrane Protein-II (MMPII) antigen (Ag) from *M. tuberculosis* (MTB). MMP-II Ag is highly immunogenic in terms of activating T cells in vitro. We developed a new recombinant BCG vaccine against MTB with MMP-II Ag from MTB, termed as BCG-DHTM. BCG-DHTM has two characteristics; (1) expresses HSP70-MMPII fusion Ag and (2) induces phagosome-lysosome fusion in cells infected with BCG-DHTM due to depletion of *UreC* gene in host BCG. BCG-DHTM secreted the fusion Ag and efficiently stimulated immune cells. To improve the vaccine efficacy of BCG-DHTM, we added proteolysis-inducing signal (PEST sequence) on both ends of HSP70-MMPII fusion gene and introduced into *ureC*-gene depleted BCG, and termed this BCG as BCG-PEST. BCG-PEST secreted the PEST-HSP70-MMPII-PEST fusion Ag and more efficiently induced cytokine production from human APCs than control BCG. DCs infected by BCG-PEST effectively activated naive T cells and promoted IFN-γ production. Furthermore, a single inoculation of BCG-PEST more effectively reduced the multiplication of MTB in murine lungs than control BCG. These results suggest that vaccination with BCG-PEST may efficiently control the growth of MTB in human.

Cellular immune responses to influenza vaccination in a Dutch cohort of healthy individuals

S. Rosendahl Huber[1], *A. Turksma*[2], *M. Hendriks*[1], *R. H. Jacobi*[1], *R. A. van Boxtel*[1], *N. Y. Rots*[1], *A. ten Brinke*[2], *W. Luytjes*[1], ***J. van Beek***[1];
[1]*National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands,* [2]*Sanquin Research, Amsterdam, Netherlands.*

Introduction: Influenza virus-specific T cells are able to limit influenza virus infection and reduce clinical symptoms. However, the induction of T cells by current influenza vaccines remains under debate. **Materials and Methods:** We performed a vaccine trial in adults and collected PBMCs before, after vaccination, and after 2nd and 3rd vaccinations in two consecutive seasons (2009 - 2011). We analyzed the T cell responses by IFN-γ ELISPOT. PBMCs were stimulated for 18 hours with live influenza A virus or the vaccine components HA or NA. The data was analyzed in a mixed effects negative binomial regression statistical model to correct for pre-existing immunity, sex and age. In depth analyses was performed by FluoroSpot and flow cytometry for CD40L in combination with different cytokines. **Results:** We showed that a single dose of unadjuvanted or adjuvanted vaccine resulted in a significant induction of the response. Interestingly, the revaccination with an unadjuvanted vaccine 1 year after a adjuvanted vaccination induced a significant additional increase in cellular levels compared to the post-vaccinations level, whereas, a 2nd vaccination, three weeks after the first dose, did not result in a further increase.
In depth analysis by flow cytometry and FluoroSpot using the vaccine antigens HA and NA confirmed vaccine specificity, activation status and Th1 cytokine profile of the T cell response. **Conclusion:** We show the induction of T cells by both adjuvanted and unadjuvanted subunit influenza vaccination. Research was funded by the Dutch government

The cAMP CHO reporter cell line to replace the *in vivo* safety test for acellular pertussis vaccines

*M. E. Hoonakker, L. M. Verhagen, **J. van der Cruijsen**, L. de Brouwer, L. van der Maas, A. Sloots, C. F. Hendriksen;*
Intravacc, Bilthoven, Netherlands.

Pertussis toxin (PTx) is one of the major virulence proteins of *Bordetella pertussis*. Since pertussis toxoid (PTd), the detoxified form of PTx, contributes to protection, this toxoid is the key component of all acellular pertussis vaccines. To examine possible toxin content in vaccine batches, each batch is subjected to the *in vivo* Histamine Sensitization test (HIST). In the last decades the intrinsic limitations of this test - including a lack of mechanistic understanding and animal welfare concerns - have pushed the search for alternative methods. A promising alternative method is based on PTx-induced clustered growth of CHO cells, though the subjective read-out and the limited capacity to discriminate between levels of clustering hamper quantitative detection of PTx levels. On a cellular level, PTx primarily interferes with intracellular pathways that involve cAMP. Based on this phenomenon, we generated a CHO reporter cell line that stably expresses a reporter construct responsive to changes in intracellular cAMP levels. This cell line enables the detection of PTx in a concentration-dependent manner up to a concentration well below the levels detected with the *in vivo* HIST. More importantly, the cell line detects PTx in the context of an aluminium phosphate adjuvated aP multivalent vaccine, with a sensitivity equal to the HIST. These results demonstrate that the CHO reporter cell line enables simple, quantitative and concentration-dependent detection of PTx. The cell line therefore offer a promising *in vitro* method to replace the suboptimal *in vivo* HIST and *in vitro* CHO clustering tests.

Chitosan mediated co-delivery of SN38 and Snail-specific siRNA as a useful anticancer approach against prostate cancer

***V. Younesi**[1], A. Afkham[2], L. Aghebati-Maleki[2], H. Siahmansouri[3], M. Ahmadi[4], M. Yousefi[5];*
[1]Tabriz University Medical Of Sciences, Tabriz, Iran, Islamic Republic of, [2]Immunology Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, Tabriz, Iran, Islamic Republic of, [3]Department of Immunology, Tabriz University Medical Of Sciences, Tabriz, Iran, Islamic Republic of, [4]Drug Applied Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, Tabriz, Iran, Islamic Republic of, [5]Department of Immunology, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Iran, Tabriz, Iran, Islamic Republic of.

Background: Prostate cancer is known as the most common malignancy in men. Chitosan has generated great interest as a useful biopolymer for the encapsulation of small interfering RNA (siRNA). Due to cationic nature, chitosan is able to efficiently encapsulate siRNA molecules and form nanoparticles. Furthermore, the biocompatible and biodegradable attributes of chitosan have paved the way for its potential application in the in vivo delivery of therapeutic siRNAs. In this study, we aimed to design chitosan/CMD nanoparticles for the efficient encapsulation of the anti-cancer drugs SN38 and Snail-specific siRNA.
Methods: Physicochemical characteristics of the synthesized chitosan nanoparticles were analyzed using Scanning Electron Microscopy. Down regulation of targeted genes were confirmed using real time PCR assays. Growth inhibitory properties of the Dual delivery of SN38-Snail siRNA CMD-chitosan nanoparticles were investigated by MTT assay in metastatic prostate cancer cells. Results: Our findings revealed that in ChNP-CMD-SN38-siRNA treated cells the mRNA level of snail decreased from 1.00 to 0.30 (±0.14) and 0.09 (±0.04) after 24 h and 48 h, respectively. Moreover, co-delivery of SN38and Snail specific siRNA in an appropriate nanocerrier (chitosan nanoparticles) significantly reduced the viability and proliferation rate of the PC-3 cells. Conclusion: In conclusion, ChNPs encapsulating SN38 and Snail-specific siRNA may represent huge Potential as an effective anti-cancer drug delivery system for the treatment of metastatic prostate cancer.

Introduction: As the hepatitis B virus is widely spread and responsible for considerable morbidity and mortality, WHO recommends vaccination from infancy to reduce acute infection and chronic carriers. However, current subunit vaccines are not 100% efficacious and leave 5-10% of recipients unprotected.
Methods: To evaluate immune responses after Engerix-B vaccination, we determined, using 3' mRNA-sequencing, whole blood early gene expression signatures before, at day 3 and day 7 after the first dose and correlated this with the resulting antibody titer after two vaccine doses.
Results: Our results indicate that immune related genes are differentially expressed in the responders mostly at day 3 and in the non-responders mostly at day 7. The most remarkable difference between responders and non-responders were the differentially expressed genes at day 0 before vaccination. The granulin precursor gene (GRN) was significantly downregulated in responders while upregulated in non-responders at day 0. Furthermore, absolute granulocytes numbers were significantly higher in non-responders at day 0.
Conclusion: The non-responders already showed an activated state of the immune system before vaccination. Furthermore, after vaccination, they exhibited a delayed and partial immune response in comparison to the responders. Our data may indicate that the baseline and untriggered immune system can influence the response upon hepatitis B vaccination.

P.D3.04.02

An APC-targeted PfRH5-containing DNA vaccine induce protective immune responses against *Plasmodium falciparum*

***L. Bjerkan**[1], R. Braathen[1], G. Ram Visweswaran[1], G. Grødeland[1], A. Gudjonsson[1], G. Labbe[2], S. Draper[2], B. Bogen[1];*
[1]Institute of Clinical Medicine, Oslo, Norway, [2]Jenner Institute, Oxford, United Kingdom.

The development of an effective, safe and deployable malaria vaccine remains an urgent priority for improving global public health. Targeted delivery of antigen to antigen presenting cells (APC) is an efficient way to increase specific immune responses. Here, we present a DNA vaccine that targets *Plasmodium falciparum* RH5 (PfRH5) antigen to major histocompatibility complex (MHC) class II molecules expressing APC.
The PfRH5 antigen was cloned into bivalent homodimeric Ig-based molecules (vaccibodies) bearing anti MHC class II scFv. We showed that this vaccine strategy induced high titers of PfRH5-specific antibodies in BALB/c mice that efficiently inhibited the growth of the *Plasmodium falciparum* 3D7 clone *in vitro*. Furthermore, the APC-targeted PfRH5 vaccine efficiently induced rapid peptide specific IFN-γ T cell responses in mice. To prepare for translation into human vaccination, we constructed a DNA vaccine that targeted HLA class II (HLA-II) molecules which cross-react with MHC- class II molecules in several species of larger mammals, including humans. We demonstrated induction of PfRH5-specific antibody responses in vaccinated pigs and that this APC targeted DNA vaccine showed no toxicity.
In conclusion, these results reveal a novel vaccination strategy for development of future vaccines against malaria.

P.D3.04.03

Cross-reactivity of anti-dengue human monoclonal antibodies with zika virus (ZIKV)

***K. Boonha**[1], S. Benjathummarak[1], P. Pitaksajjakul[1,2], P. Ramasoota[1,2];*
[1]Center of Excellence for Antibody Research (CEAR), Faculty of Tropical Medicine, Mahidol University, BANGKOK, Thailand, [2]Department of Social and Environmental Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand.

ZIKV is a mosquito-borne belonging to similar flavivirus family with Dengue virus (DENV). ZIKV and DENV serotype 2 share 54% sequence identity of full envelope protein and 100% identity of fusion loop protein. The correlation and homology of ZIKV and DENV may play a role in the pre-existing immunity to DENV. Eventhough, anti-fusion loop antibodies was considered as the major populations found in human immune response, and showed protective activity, the information of antibodies that found in ZIKV infected patients is still limited.

We firstly screened the binding of our 20 human monoclonal antibodies (huMAbs) that showed strong neutralizing activity against all 4 DENV serotypes with ZIKV by IFA. These huMAbs were characterized their binding regions on domain II of E protein and showed cross-reactivity with other flavivirus like Japanese encephalitis virus (JEV) and some showed strong neutralizing activity against JEV. It was shown that 19 of 20 huMAbs shown strong binding activity with ZIKV, as expected by their highly conserved of fusion loop region among the two species. Cross-reactive anti-DENV huMAbs with ZIKV were tested for neutralizing activity using focus reduction neutralization test in Vero cell. It was shown that most of huMAbs that targeted to envelop DII showed low neutralizing activity. Different with DENV, it was hypothesized that our anti-fusion loop huMAbs might not be the target epitope of ZIKV neutralization and protective activity in ZIKA infected patients. Further study of antibody inhibition ELISA using ZIKV infected serum with several kind antibodies specific to different epitope might showed the real situation of the antibody response of ZIKV infection.

P.D3.04.04

Measles vaccination before 9 months of age results in reduced antibody functionality long-term

I. Brinkman[1], *A. Butler*[2], *J. de Wit*[1], *G. Smits*[1], *H. ten Hulscher*[1], *R. Jongerius*[1], *F. van der Klis*[1], *N. Rots*[1], *D. van Baarle*[1], *G. Alter*[2], *R. van Binnendijk*[1];
[1]*National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands,* [2]*Ragon Institute of MGH, MIT and Harvard, Cambridge, United States.*

Background Measles is one of the most infectious viruses, but effective vaccination significantly reduces the amount of measles cases. However, as maternal antibodies are no longer present around 6 months of age, young infants are at risk until they receive their primary vaccination between 12-15 months of age. This provides a strong incentive to reduce the age of measles vaccination, but the long-term immunological consequences are largely unknown.
Methods Children who received first measles vaccination between 6-8 months or 9-12 months and a second dose at 14 months of age were compared with a control group who only received one dose at 14 months of age. Effectiveness of measles-specific antibodies was determined at 14 months and 1 and 3 years later by systems serology.
Results The majority of children that received a first measles vaccination between 6-12 months induced a significant measles-specific antibody response. However, when vaccinated before 9 months of age measles-neutralizing antibody concentrations were lower, and induction of phagocytosis by monocytes and neutrophils as well as complement deposition were affected compared with children who received a first dose after 9 months of age. The reduced effectiveness of antibodies increased over time after vaccination.
Conclusions Early measles vaccination provides short-term protection in the majority of children, but children vaccinated before 9 months of age have a less functional antibodies compared with children vaccinated at a later age. Eventually, this may result in an increasing number of children susceptible to measles long-term.

P.D3.04.05

Transcriptomic analysis of the blood immune response to the rVSV-ZEBOV Ebola vaccine

F. Santoro[1], ***A. Donato***[1], *A. Gerlini*[2], *S. Lucchesi*[1], *S. Sorgi*[1], *M. C. Haks*[3], *A. Huttner*[4], *A. M. Harandi*[5], *T. P. Monath*[6], *T. H. Ottenhoff*[3], *C. Siegrist*[4], *G. Pozzi*[1], *D. Medaglini*[1], *the VSV-EBOVAC consortium, the VSV-EBOPLUS consortium;*

rVSV-ZEBOV is a live-attenuated recombinant vesicular stomatitis virus vaccine expressing Ebolavirus glycoprotein G and is the only Ebola vaccine with demonstrated clinical efficacy. Here we studied the blood transcriptomic response upon injection of a single dose of vaccine. Whole blood RNA from 64 healthy volunteers, 51 injected either with 10^7 or $5x10^7$ PFU of rVSV-ZEBOV and 13 with placebo, collected at different time points after vaccination, was analyzed by targeted transcriptome sequencing. At each time point, differentially expressed genes (DEGs) were identified with edgeR, ranked by FDR, and used to find biological signatures assessing the activation of 346 blood transcription modules. Between baseline and day 1 after vaccination, 5,469 DEGs were detected. This number decreased over time: at day 35 only 10 DEGs were detected. Functional analysis identified 135 different modules affected by vaccination. Innate immunity pathways were activated from day 1 to day 14. At days 2 and 3, neutrophil modules were downregulated and complement-related modules upregulated. T-cell and cell-cycle associated modules were upregulated at days 7 and 14, while at day 28 no modules remained activated. Correlation analyses of gene expression with ZEBOV glycoprotein-specific antibody titers identified 15 strongly correlated genes at day 14 after vaccination (absolute Spearman's Rho>0.5, p<0.001).Vaccination with rVSV-ZEBOV induced a strong and durable modulation of innate response associated genes. An algorithm correlating with antibody titers one year after vaccination was developed based on the expression levels of 15 genes. Study supported by IMI2-JU Ebola+ program under VSV-EBOVAC [grant 115842] and VSV-EBOPLUS [grant 116068] projects.

P.D3.04.06

Potential impact of maternal vaccination on life-threatening respiratory syncytial virus infection during infancy

N. M. Scheltema[1], *X. M. Kavelaars*[2], *K. Thorburn*[3], *M. P. Hennus*[4], *J. B. van Woensel*[5], *C. K. van der Ent*[6], *J. A. Borghans*[2], *L. L. Bont*[1], ***J. Drylewicz***[2];
[1]*University Medical Center Utrecht, Department of Paediatric infectious diseases and immunology, Utrecht, Netherlands,* [2]*University Medical Center Utrecht, Laboratory of Translational Immunology, Utrecht, Netherlands,* [3]*Department of Paediatric Intensive Care, Alder Hey Children's Hospital, Liverpool, United Kingdom,* [4]*University Medical Center Utrecht, Department of Paediatric Intensive Care, Utrecht, Netherlands,* [5]*Academic Medical Centre Amsterdam, Department of Paediatric Intensive Care, Amsterdam, Netherlands,* [6]*University Medical Center Utrecht, Department of Paediatric pulmonology, Utrecht, Netherlands.*

Respiratory syncytial virus (RSV) infection is an important cause of infant mortality. Here, we estimated the potential impact of maternal vaccination against RSV on life-threatening RSV infection in infants. We developed a mathematical model of maternal vaccine-induced antibody dynamics taking into account transplacental antibody transfer and antibody decline after birth. The model was applied to data from two cohorts of children younger than 12 months with RSV-related paediatric intensive care unit (PICU) admission in the United Kingdom (n = 370) and the Netherlands (n = 167), and a cohort of 211 children younger than 12 months with RSV-related in-hospital death from 20 countries worldwide. For each cohort, we predicted the percentage of children with life-threatening RSV infection potentially prevented by maternal vaccination. Our model predicted that, depending on vaccine efficiency, maternal vaccination at 30 weeks gestational age could have prevented 62-75% of RSV-related PICU admissions in the United Kingdom and 76-87% in the Netherlands. For the global mortality cohort, the model predicted that maternal vaccination could have prevented 29-48% of RSV-related deaths. Preterm children and children with comorbidities were predicted to benefit less than (healthy) term children. In conclusion, maternal vaccination against RSV may substantially decrease life-threatening RSV infections in infants.

P.D3.04.07

High-dimensional profiling of early immune events following acellular pertussis booster vaccination

J. Gillard[1,2], *P. Brazda*[3], *N. Atlasy*[3], *M. Suffiotti*[4], *M. I. de Jonge*[1,2], *E. Simonetti*[1,2], *E. M. Janssen-Megens*[3], *C. Teodosio*[5], *R. de Groot*[1,2], *G. Pantaleo*[4], *G. Berbers*[6], *C. Fenwick*[4], *H. Stunnenberg*[3], *D. Diavatopoulos*[1,2];
[1]*Section Pediatric Infectious Diseases, Laboratory of Medical Immunology, Radboud Institute for Molecular Life sciences, Nijmegen, Netherlands,* [2]*Radboud Center for Infectious Diseases, Radboudumc, Nijmegen, Netherlands,* [3]*Department of Molecular Biology, Radboud University, Faculty of Science, Nijmegen, Netherlands,* [4]*Swiss Vaccine Institute, Lausanne, Switzerland,* [5]*Leiden University Medical Center, Department of immunohematology and blood transfusion, Leiden, Netherlands,* [6]*National Institute for Public Health and Environment (RIVM), Center for Infectious Disease Control (Cib), Biltoven, Netherlands.*

Many countries continue to experience pertussis epidemics in spite of widespread vaccination. Moreover, increasing disease incidence has been observed in completely vaccinated children, adolescents and adults. It is thought that the first vaccine dose given during infancy programs long-term immunity to pertussis, with acellular (aP) and whole cell pertussis (wP) vaccines inducing distinct immune profiles. Thus the objective of this study is to apply systems vaccinology to study the early innate immune response to aP booster vaccination in young adolescents primed with either aP or wP vaccines during infancy. We characterized early immune events before, and 24 hours after booster vaccination using complementary tools. Deep phenotyping of circulating immune cells was performed with a specialized mass cytometry (CyTOF) panel for innate responses. In parallel, flow cytometry was used to further characterize the immune response and to obtain single innate immune cells by index sorting, thereby bridging our cytometry dataset and downstream gene expression analysis through single-cell RNA sequencing (scRNAseq). We found that both cytometry datasets display high concordance, including shifts in granulocyte and myeloid populations post-vaccination. scRNAseq and correlation analysis of early innate immunity with long-term pertussis-specific immunity is ongoing. This study provides novel insights into the molecular mechanisms underlying the immune response to aP booster vaccination and provides an important framework for the development of new pertussis booster vaccines.

P.D3.04.08

MHC class II targeted DNA vaccine is most efficient in the induction of protective antibodies against influenza

D. M. Hinke, *H. C. Spång, E. Fossum, G. Grødeland, B. Bogen, R. Braathen;*
K.G. Jebsen Centre for Influenza Vaccine Research, Oslo, Norway.

Most successful vaccines owe their efficacy to induction of protective antibodies. Vaccine formats that induce high and long-lasting antibody responses will be highly interesting. One approach, APC-targeted DNA vaccination, explores that transfected cells secrete fusion proteins with targeting units specific for surface molecules on APC. This targeting of antigen to the APC increases delivery of antigen, resulting in improved immune responses. We have benchmarked several different targeting units in their ability to influence the magnitude of antibody responses against hemagglutinin (HA) from influenza A virus.

We created DNA plasmid vaccines that encode bivalent homodimeric Ig-based molecules (vaccibodies) which express two HA antigens fused to two APC targeting units. The results showed that targeting of Xcr1$^+$ type 1 conventional dendritic cells, using Xcl1, MIP-1α, αCD40 and αDEC205 targeting units, preferentially induced IgG2a responses. Simultaneous targeting of several dendritic cell subtypes in addition induced IgG1 responses, as shown for αCD11c, αMHCII, Flt-3L and FliC targeting units. IgG1 responses occurred early after immunization but declined relatively rapid over time. IgG2a responses appeared later but lasted longer (>252 days). The overall antibody induction in BALB/c mice depended on the targeting units in the following order: αMHCII>αCD11c>αCD40>Xcl-1=MIP-1α>FliC>GM-CSF>Flt-3L>αDEC205. MHC class II targeted DNA vaccines elicited complete short- and long-term protection against influenza virus. Other antigens and T cell assays will be included to confirm the role of the various targeting units in the magnitude of the responses.
In conclusion, targeting a wide range of APC with MHC class II targeting unit induces protective antibodies against influenza.

P.D3.04.09

Uncovering the epitopes underlying the induction of varying adaptive immune responses by different *Mycobacterium tuberculosis* lineages

C. Magalhães[1,2]*, I. Comas*[3,4]*, M. Saraiva*[5,6]*, N. S. Osório*[1,2]*;*
[1]*Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal,* [2]*ICVS/3B's - PT Government Associate Laboratory, Braga, Portugal,* [3]*CIBER en Epidemiología y Salud Pública, Valencia, Spain,* [4]*Instituto de Biomedicina, IBV-CSIC, Valencia, Spain,* [5]*i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal,* [6]*IBMC - Instituto de Biologia Molecular e Celular, Universidade do Porto, Porto, Portugal.*

Tuberculosis (TB) is the deadliest infectious disease in the history of humankind and remains vastly uncontrolled. Active TB results from infection with distinct genetic lineages of the *Mycobacterium tuberculosis* complex. Interestingly, a strong geographic association between TB cases and specific lineages exists, which is disrupted in the context of HIV-1 co-infection. This fact highlights the relevance of CD4$^+$ T cell-driven immune responses in the interaction between different human/pathogen populations and TB outcome. *M. tuberculosis* lineage-specific epitope diversity might thus alter the type and level of CD4$^+$ T cell responses generated during infection. Despite the importance of this topic, host-pathogen molecular characteristics influencing immune synapse in TB are not sufficiently studied.
We have developed a genome-wide immunoinformatics approach to identify T cell epitopes that are influenced by the presence of *M. tuberculosis* lineage-specific polymorphisms. Importantly, it was possible to find significant associations between HLA-binding predictions for a given lineage and the frequency of the HLAs in the human populations with more TB caused by that lineage. Some mutant epitopes were also inferred to have been selected over time by distinct computational molecular evolution methodologies.
Overall, this study suggests that specific *M. tuberculosis* lineage-restricted polymorphisms have been fixed during parallel evolution with the host due to CD4$^+$ T cell pressure. The identification and extensive characterization of varying *M. tuberculosis* epitopes might be of great relevance for the development of more effective TB vaccination and diagnostics strategies.

P.D3.04.10

Immunisation with a conserved rhinovirus capsid protein induces antibodies that bind a variable neutralising epitope

S. Narean[1]*, C. Nunn*[1]*, N. Glanville*[2]*, S. Johnston*[2]*,* ***G. McLean***[1,2]*;*
[1]*Cellular and Molecular Immunology Research Centre, London, United Kingdom,* [2]*National Heart and Lung Institute, Imperial College London, London, United Kingdom.*

Introduction: Human rhinovirus (RV) infections are the principle cause of common colds and precipitate asthma and chronic obstructive pulmonary disease exacerbations. Currently there is no vaccine for RV which is largely due to the existence of ~150 serotypes/strains. We demonstrated previously that immunising mice with highly conserved VP4 and VP2 regions of the RV polyprotein (RV16 VP0) generated broadly cross-reactive protective immunity to RV *in vivo*. This study investigated and mapped the epitopes of RV16 VP0 that are targets for neutralising polyclonal antibody responses. **Materials and Methods:** Serum samples from VP0 immunisation and RV challenge studies in mice were used to determine IgG recognition sites by ELISA and *in vitro* RV neutralisation assay. Peptide pools and individual peptides spanning the immunogen sequence (RV16 VP0) were assessed for IgG binding sites to identify neutralising epitopes. **Results:** Eight peptide pools containing 15-mer peptides spanning the RV16 VP0 sequence were assessed for binding by antisera obtained from RV16 VP0 immunised and RV challenged mice.
We found that peptide pools covering the C-terminus of VP4, N-terminus of VP2 and the neutralising NIm-II loop within VP2 were bound by serum IgG but not by serum IgA. The NIm-II loop peptide pool blocked IgG binding to the immunogen RV16 VP0 but was unable to inhibit IgG neutralisation of RV *in vitro*. **Conclusions:** We have identified immunodominant epitopes of RV vaccine candidate RV16 VP0. Strong polyclonal IgG binding antibodies were observed that target a key neutralising epitope that is highly variable amongst RV serotypes.

P.D3.04.11

Searching for novel vaccine candidates against *Echinococcus granulosus* combining proteomic and bioinformatic explorations of tegumental antigens.

S. Miles[1]*, M. Portela*[2]*, M. Cyrklaff*[3]*, M. Ancarola*[4]*, F. Frischknecht*[3]*, R. Durán*[2]*, S. Dematteis*[1]*, G. Mourglia-Ettlin*[1]*;*
[1]*Immunology Lab - DEPBIO - UdelaR, Montevideo, Uruguay,* [2]*Institut Pasteur de Montevideo, Montevideo, Uruguay,* [3]*Integrative Parasitology, Center for Infectious Diseases, Heidelberg University, Heidelberg, Germany,* [4]*Instituto de Investigaciones en Microbiología y Parasitología Médica (IMPaM, UBA-CONICET), Facultad de Medicina, Buenos Aires, Argentina.*

Echinococcus granulosus is the helminth parasite responsible for cystic echinococcosis (CE), an important worldwide-distributed zoonotic disease. Development of new vaccines against CE might have great health and economic benefits. Here, we described an innovative vaccine design scheme starting from a tegumental antigens-enriched fraction derived from protoscoleces -named PSEx- already known to induce protection against CE. First, we characterized by mass spectrometry its protein composition. Then, by means of Gene Ontology analyses, we studied the potential biological processes, molecular functions and cellular localizations associated with identified PSEx components. After that, antigenicity predictions and determination of conservancy degree against other organisms were determined. Thus, 10 proteins -identified here for the first time- were proposed as novel vaccine candidates. Furthermore, linear B-cell epitopes free of post-translational modifications were predicted in the whole PSEx proteome through co-localization of *in silico* predicted epitopes within peptide fragments identified by MALDI-TOF/TOF. Resulting peptides were termed "clean linear B-cell epitopes", and through BLASTp scanning against all non-helminth proteins, those with 100% identity against any other protein were discarded. Then, secondary structure was predicted for the peptides -free and within their parental proteins- and those showing highly similar secondary structure in both cases were selected. Potentially toxic and/or allergenic peptides were discarded. Finally, selected clean linear B-cell epitopes were mapped within their corresponding 3D-modelled parental protein to assess their possible antibody accessibilities, resulting in 14 putative peptide vaccine candidates. At the end, we proposed 10 novel proteins and 14 peptides that deserve further testing as vaccine candidates against CE.

P.D3.04.12

Characterization of the porcine MHC I in the Goettingen minipig

B. von Silva-Tarouca*, M. Wu, D. Zehn;*
School of Life Sciences Weihenstephan, Freising, Germany.

Mice are widely used as an experimental system to explore all aspects of immunity. However, mice and humans have fundamental differences, as demonstrated by the many cases of unsuccessful translation of results from mice to human. Given the strong need to better evaluate therapeutic interventions that are based on biological substances, there is a high demand for well-characterized and robust alternative testing systems.
We propose that large animal-based models, such as minipigs, constitute an important alternative or complementary test system. One key limitation is that the murine immune system is much better characterized than the immune system in pigs, especially antigen-specific T cell responses. Therefore, we aim to advance the studies of adoptive immunity in pigs using a two-step strategy, beginning with the identification of frequently occurring MHC-alleles and followed by establishing a test system to screen peptide-restricted antigens by these MHC-alleles.
Using pooled next generation sequencing we have subtyped the SLA I molecules of 53 minipigs. To further improve the significance of our investigation we also included 25 samples from Landrace pigs and 65 samples from pigs raised on conventional farms. Contrary to the expectations, a high number of animals were homozygous for one or more SLA I-chains. The obtained data enabled us to identify alleles that are more frequent and we are now developing a MHC-peptide binding and epitope-prediction-assay based on these findings, which will allow us to investigate different aspects of infections like the PRRS-virus with valuable insights for new vaccines, and mechanisms of anti-tumor immunity.

P.D3.04.13

Comparative Immunogenicity protective efficacy of equivalent bivalent Generalized Modules for Membrane Antigens (GMMA) glycoconjugate vaccines against nontyphoidal Salmonella

F. Necchi[1], *R. Alfini*[1], *L. Lanzilao*[1], *O. Rossi*[1], *A. Negrea*[2], *S. Clare*[3], *P. Mastroeni*[4], *A. Saul*[1], *C. A. MacLennan*[5], *S. Rondini*[1], *F. Micoli*[1];

Invasive nontyphoidal *Salmonella* (iNTS) disease is a leading cause of death and morbidity in Africa. The most common pathogens are *Salmonella enterica* serovars Typhimurium and Enteritidis. The O-antigen portion of their lipopolysaccharide is a target of protective immunity, but no vaccines are currently available, or in clinical trials. Here we investigate the use of Generalized Modules for Membrane Antigens (GMMA) as delivery system for *S.* Typhimurium and *S.* Enteritidis O-antigen, and compare this technology to the more traditional glycoconjugation approach. GMMA are outer membrane vesicles released from genetically engineered Gram-negative bacteria, carrying deletion of the *tolR* gene or analogue to enhance their production. *Salmonella tolR*$^-$ strains were generated for GMMA production. O-antigens were extracted from corresponding wild-type bacteria and conjugated to CRM_{197}. Purified GMMA and conjugates were characterized, showing similar O-antigen structural characteristics. When compared in mice, GMMA gave higher anti-O-antigen IgG titers compared to conjugate, in the absence of Alhydrogel. With Alhydrogel, antibody levels were similar. Antibody isotype profile was also investigated, showing a diverse Ig subclass repertoire induced by GMMA, with greater serum bactericidal activity compared to that induced by the glycoconjugate. In an *in vivo* mouse infection model, bacterial colonization was reduced upon infection with *Salmonella*, with *S*. Typhimurium counts lower with GMMA and with *S.* Enteritidis burden similar with both vaccines. Overall, simplicity of manufacturing process and low costs of production, coupled with encouraging immunogenicity data, make GMMA an attractive strategy for the development of a nontyphoidal *Salmonella* vaccine compared with established glycoconjugate technology.

Pertussis remains an important cause of infant mortality despite global infant vaccination programs. The recent resurgence of *Bordetella pertussis* infections worldwide is calling for new vaccines inducing longer-lasting protection. The magnitude and persistence of pertussis-specific immunity was explored during a clinical study[1] (ClinicalTrials.gov NCT01529645) evaluating the safety and immunogenicity of different doses of booster vaccines of acellular pertussis (aP) in combination with diphtheria and tetanus antigens (TdaP) in adults. Participants received TdaP formulations, containing either the genetically or chemically detoxified pertussis toxin (PT) in combination with the filamentous hemagglutinin (FHA) and pertactin (PRN) antigens. Frequencies of antigen-specific plasmablasts (PB, at day [D] 8 after vaccination), $CD4^+$ T cells (at baseline, D8 and D30 after vaccination) and Memory B Cells (MBC) (at baseline, on D30 and D365 after vaccination) were assessed. All vaccine formulations expanded antigen-specific IgG^+ MBC and PB against FHA, PRN and PT. Remarkably, genetically detoxified PT induced higher frequencies of MBC than chemically detoxified PT, that remained higher one year after vaccination. Lack of IgM^+ PB and low frequencies of IgM^+ MBC in any of the vaccination groups indicate pre-existing immunity to pertussis antigens. Frequencies of PRN, FHA and PT-specific $CD4^+$ T cells increased at D8 and one month post-vaccination without major differences between groups. Overall the data reported here support the evidence of a stronger propensity of genetically detoxified PT to induce immunological responses which might prove promising for next generation pertussis vaccines.

Antibodies have been implicated in both protection and pathology of dengue virus infections. However, much of this data is gathered from serum/plasma responses that is a cumulative of historical and ongoing infection. To precisely understand the role of antibodies with respect to the ongoing dengue virus infection, we employed the cutting edge approach of generating of human monoclonal antibodies from individual plasmablasts from peripheral blood of dengue patients that allows us to probe for answers at a single cell level. This method involves *ex vivo* single cell sorting of plasmablasts from peripheral blood of characterised dengue infected patient followed by single cell molecular cloning of immunoglobulin heavy- and light- variable regions into expression vectors containing the defined constant region followed by transient co-transfection of HEK 293A cells with the heavy and light chain expression vectors made from genes arising from the same cell. Thus far, using this powerful technology, for the first time in India, we have made 73 number of human monoclonals, of which 36 are specific to dengue and 12 neutralize dengue at various concentrations. Interestingly, all the dengue neutralizing antibodies were envelope specific and recognised the highly conserved fusion loop of the dengue virus envelope. Together, with the ongoing comprehensive analysis of the B cell repertoire and somatic hypermutations, these studies provide a detailed understanding of the dengue-specific plasmablast cell response at a single cell level and create a platform for testing these antibodies for basic research, diagnostic, prophylactic and as well as therapeutic applications.

P.D3.04.16

Salmonella enterica **serovar Typhimurium SiiE interferes with the persistence of IgG-secreting plasma cells in laminin â1$^+$ bone marrow survival niches and prevents efficient vaccination**

Y. Yamasaki[1], *C. Männe*[1], *M. Mursell*[1], *F. Hiepe*[1], *S. H. Kaufmann*[2], *A. Radbruch*[1], ***K. Tokoyoda***[1];
[1]*Deutsches Rheuma-Forschingszentrum Berlin, Berlin, Germany,* [2]*Max Planck Institute for Infection Biology, Berlin, Germany.*

Invasive non-typhoidal *Salmonella* (iNTS) disease induced commonly by *Salmonella enterica* serovar Typhimurium was estimated to cause 3.4 million illnesses and 680,000 deaths (the fatality rate at ~20%) per year. No vaccine against non-typhoidal *Salmonella* is currently available, albeit multiple drug-resistant non-typhoidal *Salmonella* is already highly prevalent. We here report that the protein SiiE of *S.* Typhimurium is required and sufficient to prevent an efficient humoral immune response, selectively reducing the numbers of IgG-secreting plasma cells in the bone marrow (BM). Attenuated SiiE-deficient *S.* Typhimurium induces high and lasting titers of specific and protective IgG, and qualifies as the first efficient vaccine for the serotype. An SiiE-derived peptide with homology to laminin β1 is sufficient to ablate IgG-secreting plasma cells from the BM, identifying laminin β1 as a novel and essential component of niches for IgG-secreting plasma cells in the BM, and furthermore qualifies as a unique therapeutic option to ablate selectively IgG-secreting plasma cells in autoimmune diseases and multiple myeloma.

P.D3.04.17

IgA targeting HIV-1 envelope gp41 triggers antibody-dependent cell cytotoxicity cross-clade and cooperates with gp41 specific IgG to increase cell lysis

D. Tudor[1,2,3], *M. Duchemin*[1,2], *M. Khamassi*[1], *L. Xu*[1], *M. Bomsel*[1];
[1]*Laboratory of Mucosal Entry of HIV-1 and Mucosal Immunity, Department of Infection, Immunity and Inflammation, Cochin Institute, CNRS UMR 8104, Paris, France,* [2]*INSERM U1016, Paris, France,* [3]*Université Paris Descartes, Sorbonne Paris Cité, Paris, France.*

Introduction: Although raising broadly neutralizing antibodies (bNAbs) are the main goal of vaccination against HIV-1, growing evidence show that protecting antibodies could also control viral infection by Fc-mediated antiviral activity, such as antibody dependent cellular cytotoxicity (ADCC). Until now, mainly gp120 and gp41 HIV-1 envelope-specific IgGs have been shown to mediate ADCC whereas the ADCC potential of HIV-1 envelope-specific IgA remains elusive, despite the prevalence of IgA at mucosal level, the main portal entry for HIV-1. **Methods:** The capacity of HIV-1 envelope-specific IgA to induce Fcα-mediated ADCC was evaluated by flow cytometry using 2F5-IgA genetically engineered from the broadly neutralizing gp41-specific 2F5-IgG we have previously reported to induce ADCC. Effector cells were primary monocytes and target cells were $CD4^+$T lymphocytes either infected with the main HIV-1 subtypes, namely A, B or C, or coated with the P1-A, -B, and -C peptides covering the MPR region of gp41 from subtype A, B and C, respectively. **Results:** We show here that 2F5-IgA, targeting subtype A and B, but not C gp41, engages FcαRI (CD89), expressed on human monocytes, to induce the lysis of subtype A and B, but not C, HIV-1-infected cells and of P1-A and -B, but not -C, coated cells by ADCC. Furthermore, the 2F5-IgA cooperates with 2F5-IgG as well as with the bNAb gp41-specific 10E8-IgG to enhance target-cells lysis by ADCC. **Conclusion:** These results indicate that inducing IgA by vaccination, especially those targeting gp41, together with IgG could strength HIV-1 mucosal protection or reservoir eradication worldwide by mediating ADCC.

P.D3.04.18

Incidence and serotype distribution of pneumococcal pneumonia in Bangladeshi children under 5 years of age

S. Vestjens[1], *T. Lalmahomed*[2], *B. Meek*[1], *B. de Jong*[1], *D. Goswami*[3], *S. van Mens*[4], *B. Vlaminckx*[1], *D. Ahmed*[3], *H. Endtz*[5], *A. Brooks*[3], *G. Rijkers*[1,2];
[1]*St Antonius hospital, Nieuwegein, Netherlands,* [2]*University College Roosevelt, Middelburg, Netherlands,* [3]*ICDDR,B, Dhaka, Bangladesh,* [4]*MUMC+, Maastricht, Netherlands,* [5]*Erasmus university, Rotterdam, Netherlands.*

Introduction. Pneumonia is the leading cause of mortality in children under 5 years of age in developing countries, most often caused by *Streptococcus pneumoniae*. Pneumococcal conjugate vaccines (PCVs) for infants have been introduced in many national immunisation programmes. This includes the 10-valent PCV in Bangladesh in 2015, even though no data is available regarding pneumococcal serotype incidence. Our aim was to identify pneumococcal serotypes causing pneumonia in children under 5 in Bangladesh. **Methods**. From 1533 children aged 0 to 59 months with upper respiratory infection or pneumonia, serum samples were obtained at diagnosis and another ≥14 days later. Pneumococcus serotype-specific antibody responses were measured using a multiplex immunoassay panel of 25 serotypes (1, 2, 3, 4, 5, 6A, 6B, 7F, 8, 9N, 9V, 10A, 11A, 12A, 12F, 14, 15B, 18C, 19A, 19F, 20, 22F, 23F, 33F and 45). Calculating the fold increase of the antibody response between the second and first serum sample allowed to determine prevalence of pneumococcus-mediated pneumonia and the causative serotype. **Results**. Serotype-specific pneumococcal antibody responses were detected in 31% of the children. The 10 most frequently identified serotypes were 11A, 22F, 3, 2, 19F, 45, 15B, 19A, 33F, and 9N. **Conclusions** Our findings demonstrate that the 10-valent PCV used in Bangladesh yields low coverage of the most prevalent disease-causing serotypes. Although the identified serotypes may not all cause invasive pneumococcal disease, vaccines will be more effective if the prevalence serotypes is taken into account. Future vaccine combinations may improve coverage for the India/Bangladesh region.

P.D3.04.19

Detection of YF-17D viral RNA in human antigen-presenting cells by RNA flow cytometry

E. Winheim[1], *L. Habenicht*[1,2], *K. Eisenaecher*[1], *M. K. Scheck*[3,4], *M. Pritsch*[1,5], *J. Ahlfeld*[3,4], *S. Rothenfusser*[3,4], *A. B. Krug*[1];
[1]*Institute for Immunology, Biomedical Centrum, Ludwig Maximilian University of Munich, Planegg-Martinsried, Germany,* [2]*Klinik und Poliklinik für Innere Medizin II, Klinikum rechts der Isar, Technische Universitaet Muenchen, Munich, Germany,* [3]*Division of Clinical Pharmacology, Department of Medicine IV, University Hospital, Ludwig Maximilian University of Munich, Munich, Germany,* [4]*Einheit fuer Klinische Pharmakologie (EKliP), Helmholtz Zentrum Munich, Neuherberg, Germany,* [5]*Division of Infectious Diseases and Tropical Medicine, Medical Center of the University of Munich, Munich, Germany.*

Flaviviruses, a family of positive-strand RNA viruses, including yellow fever (YF), zika and dengue viruses represent a major global health threat. Vaccination with the live-attenuated YF-17D strain leads to life-long protective humoral and cellular immunity. A hallmark of this vaccine is the infection of antigen-presenting cell (APC) subpopulations and their activation by multiple virus sensors. We investigated the composition and activation of APC subpopulations before and 1, 3, 7, and 14 days after vaccination with YF-17D and observed changes in the monocyte and dendritic cell (DC) subtype composition which were most pronounced on day 7 after vaccination correlating with peak expression of ISGs. To investigate which APC types in the blood are directly infected, PBMCs were infected with YF-17D in vitro and viral RNA content was measured in different APC subpopulations by RNA flow cytometry. YF-17D (+) strand RNA was detectable in DCs and monocytes and the percentage of infected cells increased with inhibition of type I IFN induction pathways. YF-17D infection induced upregulation of costimulatory molecules and MHC class II in infected and uninfected bystander cells, which was partially dependent on type I IFN induction. These results suggest that monocytes and DCs play a major role in the immune response to YF-17D infection. We propose that the success of the YF-17D vaccine is based on controlled viral replication within monocytes and DCs leading to activation and optimal presentation of viral antigens.

P.D3.04.20

Shingles vaccine works yet why are uptake rates declining in the UK?

C. M. Heffernan*, NHS England (London) Immunisation Commissioning Team;
Public Health England (London), London, United Kingdom.*

Background: In 2013, a herpes zoster (Shingles) vaccination programme was introduced in England for adults aged 70 years with a phased catch-up programme for those aged 71-79. Within 3 years, the programme had a population impact equivalent to 17000 fewer episodes of herpes zoster and 3300 fewer episodes of postherpetic neuralgia among 5.5 million eligible individuals. However, uptake rates are declining each year, particularly in London from 51.3% amongst 70 year olds in 2013/14 to 41.3% in 2016/17. NHS England (London) immunisation commissioning team have to embed the scientific evidence to improve coverage. This study reveals the barriers and facilitators to uptake of an adult vaccine that is given for individual protection rather than for herd immunity. Methods: Audit of summer 2017 and 2018 London Shingles Vaccine campaigns with London's 1301 general practices including mystery shop of 20 practices, evaluation of immunological outreach at #Shingles70 events and in-depth follow up interviews with service providers and users. Results: All 1301 received and used the campaign materials but this was not accompanied by patient invite/reminder systems. Declining vaccinating workforce and shortage of appointments were issues. Thematic analysis of interviews revealed that there was confusion around eligibility, clinicians believed that there were too many contra-indications and complexities to offer Shingles vaccine and the vaccine wasn't a priority. Patients wanted someone to talk to them about how the vaccine works. Conclusions: Improving uptake of shingles vaccine is multifaceted including targeting quality of service provision and public acceptability. Immunological outreach has an important role to play addressing vaccine hesitancy amongst healthcare professionals and patients.

P.D3.04.21

Immunogenicity of a vaccine against *Salmonella enterica* serovar Typhimurium based on Generalized Modules for Membrane Antigens (GMMA)

F. Fiorino[1], *O. Koeberling*[2], *E. Pettini*[1], *A. Ciabattini*[1], *F. Schiavo*[2], *F. Mancini*[2], *F. Necchi*[2], *L. B. Martin*[2], *D. Medaglini*[1];
[1]*University of Siena, Siena, Italy,* [2]*GSK Vaccines Institute for Global Health S.r.l., Siena, Italy.*

INTRODUCTION: Salmonella enterica serovar Typhimurium (STm) is one of the predominant causes of invasive nontyphoidal *Salmonella* (iNTS) disease. The O-antigen portion of STm lipopolysaccharide (O:4,5) has been recognized as an important target for vaccination. In this work, we characterized the murine immune response to a vaccine against STm based on the GMMA (Generalized Modules for Membrane Antigens) technology as a delivery system for O:4,5.
METHODS: C57BL/6 mice were immunized with Alhydrogel formulated STmGMMA using two doses of vaccine by subcutaneous (SC) or intranasal (IN) route. Systemic and local O:4,5-specific antibodies, serum bactericidal activity and cellular immune response were characterized.
RESULTS: Following primary immunization, high levels of O:4,5-specific serum IgG were observed with both doses of STmGMMA administered by SC route and with the higher dose by IN route. Boosting after 10 weeks induced, in all groups, an increase of O:4,5-specific serum IgG and bactericidal activity against the homologous strain. The analysis of IgG subclasses showed a balanced Th1/Th2 response following SC immunization and a Th1 response after IN. At intestinal level, the higher vaccine dose elicited O:4,5-specific IgG by SC administration, and O:4,5-specific IgA by IN route. A significant production of IL-2, IFN-γ, and IL-17A by $CD4^+$ T cells was observed in splenocytes of mice immunized with STmGMMA using both doses and administration routes.
DISCUSSION AND CONCLUSIONS: These data demonstrate the ability of the STmGMMA vaccine to induce local and systemic, humoral and cellular, immune responses and highlight the modulation of the immune response driven by different routes of immunization.

Host cells respond to encephalomyocarditis virus infection by releasing diverse populations of extracellular vesicles

S. van der Grein[1], ***K. Defourny***[1], *C. Galiveti*[1], *G. Arkesteijn*[2], *H. Rabouw*[2], *F. van Kuppeveld*[2], *E. Nolte-'t Hoen*[1];
[1]*Department of Biochemistry and Cell Biology, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands,* [2]*Department of Infectious Diseases and Immunology, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.*

The role of extracellular vesicles (EV) in modulating the immune response to viral infection is increasingly recognized. Recently, it was demonstrated that naked viruses can be released from infected cells enclosed in EV, thereby changing their interaction with the immune system. Remarkably, both pro- and anti-viral functions have been ascribed to infected-cell derived EV. It is unknown whether this functional diversification can be attributed to different EV subpopulations released by infected cells. Therefore, we analyzed heterogeneity in the phenotype, function, and release dynamics of EV populations produced by cells infected with encephalomyocarditis virus (EMCV).
EV released by EMCV-infected cells were separated into subpopulations by differential ultracentrifugation and density gradient purification. High-resolution flow cytometry was applied to functionally separate and quantify EV subsets. In addition, protein content and infectivity of EV were analyzed by western blotting and end-point titration.
We show that EMCV infection induced the release of several EV subpopulations with a distinct protein composition indicative of separate biogenesis routes. Multiple subsets of EV transmitted infectious virus to recipient cells. Yet infection also triggered release of EV that did not efficiently convey infection. Each of these EV subpopulations were produced at different time points after infection, suggesting their tightly regulated release. Taken together, our data demonstrates the active induction of EV of mixed origin and content upon EMCV-infection. Moreover, we obtained evidence for functional diversity in virus-induced EV, by showing that EV subpopulations differed in their efficiency to transmit infection.
Supported by ERC Starting Grant 337581 and NWO grant ALWOP.351.

Preventing type I IFN production by the aminopeptidase IRAP in neonatal alveolar macrophages in response to RSV

d. descamps[1], *C. Drajac*[1], *D. Laubreton*[1], *L. Saveanu*[2], *I. Schwartz*[1], *S. Riffault*[1];
[1]*INRA, Jouy-en-Josas, France,* [2]*INSERM, Paris, France.*

Introduction: Respiratory Syncytial Virus (RSV) is the major cause of neonatal lower respiratory tract infection. Neonatal mice have an important defect in the pulmonary production of type I interferons (IFN-I) during RSV infection compared to adults. Recently, it has been showed in adult mice that alveolar macrophages (AM) constitute the main source of IFN-I upon RSV infection. The ability of neonatal AM to produce IFN-I in response to RSV infection remains to be determined. IFN-I responses can be triggered following RSV recognition by innate immune receptors of the cell, whose their activation and intracellular trafficking are tightly controlled. Thus, Insulin-Responsive Aminopeptidase (IRAP), an protein necessary for anchoring the endosomes to the actin network, has been described to participate in regulating of IFN-I production in dendritic cells. Thus, we characterized the ability of neonatal AMs to mobilize IFN-I pathways upon RSV infection, and we determined the contribution of IRAP in this response.
Methods: Neonatal or adult AMs from IRAP-deficient ($IRAP^{KO}$) mice and wild-type (WT) were isolated and exposed ex vivo to RSV or different ligands of innate receptors to in order to compare IFN-I responses.
Results: RSV infection of adult WT AMs induced the production of IFN-I and the up-regulation of interferon-stimulated gene transcripts, while these responses are very low in neonatal AMs. However, IFN-I responses were significantly increased in neonatal $IRAP^{KO}$ AMs following RSV infection.
Conclusion: These data suggest that IRAP plays a key role in regulating responsiveness of AMs to produce IFN-I following RSV infection during the neonatal period.

P.D4.01.03

Evasion of NK cell responses by a cytomegalovirus-encoded soluble CD48 homolog

P. Engel, *P. Martínez-Vicente, D. Farré, A. Angulo;*
University of Barcelona, Barcelona, Spain.

Cytomegaloviruses (CMVs) have developed a wide range of mechanisms to subvert host immunity and establish successful long-term infections. To accomplish it, they encode a large repertoire of immune modulator genes, some of which derive from their host genomes after being captured at different points during host-virus co-evolution. CD48 is a GPI-anchored protein that contains an ectodomain composed by 2 immunoglobulin (Ig) domains. Via its N-terminal Ig domain, CD48 recognizes the cell surface receptor 2B4. Engagement of 2B4 by CD48 results in the regulation of cytotoxic T lymphocyte and NK cell functions. We have recently reported the presence of a number of CD48 homologs (vCD48) encoded by different CMVs. Here, we have characterized the three vCD48 of owl monkey CMV, showing that they are highly glycosylated transmembrane proteins which display very distinctive structural and biochemical properties. Among them, only A43, the viral CD48 that exhibits the highest amino acid identity with host CD48 is able to bind 2B4, with the two other vCD48s having diverged to perform 2B4-independent functions. Interestingly, A43 is a soluble protein, released from the cell after being proteolitically processed through its stalk region. Kinetic studies revealed that A43:2B4 interactions are of exceptional affinity and highly stable, resulting in a Koff drastically reduced as compared with that established between CD48 and 2B4. We demonstrate that purified soluble A43 is capable to efficiently abrogate CD48:2B4 interactions. Furthermore, this viral protein severely impairs 2B4 mediated-NK cell cytotoxicity. Thus, A43 acts as a functional virally-encoded CD48 decoy receptor.

TNFAIP3 negatively regulates Cutibacterium acnes-induced inflammatory events in human epidermal keratinocytes

L. Erdei[1], *B. S. Bolla*[1], *G. Tax*[1], *E. Urbán*[2], *L. Kemény*[1,3], *K. Szabó*[3];
[1]*Department of Dermatology and Allergology, University of Szeged, Szeged, Hungary,* [2]*Institute of Clinical Microbiology, University of Szeged, Hungary, Szeged, Hungary,* [3]*MTA-SZTE Dermatological Research Group, Szeged, Hungary, Szeged, Hungary.*

Human epidermal keratinocytes can recognize the skin microbiome, such as *Cutibacterium acnes* (*C. acnes*), through TLRs, and induce innate immune and inflammatory events. Little is known about endogenous regulators which can control these events and protect the host from the prolonged inflammation. For that, we aimed to analyze whether TNFAIP3, a negative regulator of NF-κB signaling has a role in TLR ligand and *C. acnes*-induced innate immune and inflammatory events. In our studies we used a human immortalized keratinocyte cell line (HPV-KER). We analyzed TNFAIP3 expression in response to different TLR ligands and *C. acnes*, and followed NF-κB activation using a luciferase reporter assay and by monitoring the expression changes of pro-inflammatory mediators upon TNFAIP3-silencing by real time RT-PCR, western blotting and ELISA analysis. Our results show that TNFAIP3 mRNA and protein expression significantly increased in response to different TLR ligands. By analyzing the *C. acnes*-induced signaling events in details, we found that bacterial treatment also induced a significant, transient and dose-dependent upregulation of TNFAIP3 expression, which were dependent on JNK and NF-κB pathways. Downregulation of TNFAIP3 levels by siRNA-mediated silencing increased the basal NF-κB promoter activities and the mRNA expression of selected pro-inflammatory cytokines and chemokines, such as TNFα, IL-1α, IL-6, CXCL8 and CCL5. Parallel to that, secreted IL-6, CXCL8 and CCL5 levels also increased. Based on our results, TNFAIP3 is one of the negative regulators in keratinocytes, which may control *P. acnes*-induced signaling events and play a role in the maintenance of epidermal homeostasis.

P.D4.01.05

CD8 T CELLS IN EXPERIMENTAL ZIKA VIRUS INFECTION

N. Ghabdan Zanluqui, *C. Manganeli Polonio, L. Gomes de Oliveira, C. Longo de Freitas, J. Schatzmman Peron;*
Biomedical Sciences Institute, São Paulo, Brazil.

Introduction. The relevance of Zika virus (ZIKV) infection study was highlighted by the large number of infants born with microcephaly and some adults exhibited cases of Guillain-Barré syndrome caused by ZIKV infection. It is known that ZIKV, like other flaviviruses, has the ability to modulate innate and adaptive immune response of the host. Thus, in this work we aim to evaluate the role of CD8 cells in controlling viral replication and disease progression in murine infection by ZIKV. Methods. ZIKV (BeH815744 strain) was used to infect C57BL/6 (WT) and CD8-/- mice (106 PFU). All analysis were performed at 1, 3 and 5 days post infection by PCR, flow cytometry and CBA. Results. Although high infection both WT and CD8-/- mice did not show any morbidity or clinical sign in the course of infection. Interestingly, in the peak of infection CD8-/- showed high viremia compared to WT while the opposite was observed in the spleen.
Analysis of spleen showed downregulation of type I Ifn expression and their signaling in CD8-/- mice. On the other hand, it was possible to observe in WT spleen mice an increase of CD4+ and CD8+ cells frequency, accompanied by CD8+Foxp3+ and CD4+Foxp3+ cells, while a decrease of IL-10 secretion in CD8-/- mice was detected. Conclusion. CD8 T cells could regulate type I Ifn expression which is one of the most important cytokines in controlling viral replication and T suppressors cells could be evolved in suppressing immune response against zika virus infection.

EBV-specific CD8+ T cells are exhausted and senescent in Multiple Sclerosis patients

G. Guerrera[1], *D. F. Angelini*[1], *S. Ruggieri*[2], *F. Gargano*[1], *C. Gasperini*[2], *R. Placido*[1], *G. Borsellino*[1], *L. Battistini*[1];
[1]*Neuroimmunology Unit, Santa Lucia Foundation, Rome, Italy,* [2]*Department of Neuroscience "Lancisi", San Camillo Hospital, Rome, Italy.*

Multiple sclerosis (MS), the most common chronic inflammatory disease of the central nervous system (CNS), is associated with an increased Epstein-Barr virus (EBV) sero-prevalence and high immune reactivity to EBV. While EBV infection alone cannot explain MS development, our hypothesis is that, in susceptible individuals, defects in the control of EBV facilitate the establishment of viral infection and of continuous cycles of inflammation in the CNS, due to the recruitment and activation of inflammatory cells in the brain.
To study the immune response to EBV, we characterized the CD8+ T cells response specific for EBV lytic and latent antigens using pentamers. We measured their frequency, activation and functional state in MS patients compared with healthy donors (HD).
In MS patients, CD8+ cells specific for EBV antigens show the phenotype of terminally differentiated and senescent cells compared to HD. When stimulated with the EBV peptides corresponding to the pentamers, CD8 lymphocytes display a functional and specific response in terms of release of interferon, granzyme and CD107a. By analyzing the phenotype of these CD8+ interferon+ cells we confirm that the CD8 cells of MS patients express high levels of PD-1, compared to HD.
Thus, in MS patients, EBV-specific cells progress through terminally differentiated and functionally impaired and senescent cells, likely due to chronic viral stimulation; secondly, we find that some EBV-specific T cells are exhausted and express PD-1.

γδ T-cells in murine Cytomegalovirus infection

A. M. Hahn[1], *S. Sell*[1], *A. Schneider*[1], *S. Brey*[1], *A. Donaubauer*[1], *M. Mach*[2], *T. H. Winkler*[1];
[1]*Nikolaus-Fiebiger Center for Molecular Medicine, Institute of Genetics, Department of Biology, University Erlangen-Nuremberg (FAU), Erlangen, Germany,* [2]*Institute for Clinical and Molecular Virology, University Hospital Erlangen, Erlangen, Germany.*

Introduction: Upon Cytomegalovirus (CMV) infection immunocompromised patients are at substantial risk for developing severe organ disease eventually leading to multi-organ failure. Existing virus escape mechanisms to anti-viral drugs plus missing approved vaccination currently designate CMV as major health issue. Previous findings showed that γδ T cells can effectively control murine CMV (mCMV), remarkably when conventional immune mechanisms (like αβT, B or Natural Killer cells) are insufficient or absent, corresponding to the immune-suppressed state in transplant recipients and neonates. In accordance with recently published data from the human system, these studies suggest adaptive features of γδ T cells.

However, recognition mechanisms, antigen specificity and the formation of a classical memory remain enigmatic. Material & Methods: To examine, to what extent the T cell receptor (TCR) participates in sensing mCMV presence, we monitored γδ TCR repertoires in TCR$\alpha^{-/-}$ mice for clonal diversity. In different organs RNA-based immune-profiling of V(D)J rearranged complementary-determining regions (CDR) from selected receptor chains (TRGV1, TRGV4, TRDV5, TRAV15/DV6) was performed in a time kinetic manner. Taking advantage of a fluorescent reporter system for TCR activation and hybridoma technology we identified γδ T cell clones which recognize mCMV infected target cells *in vitro*. Results & Conclusions: Alterations in clonality and focusing of the CDR3 length distribution after virus exposure implicate an antigen-driven response with TCR involvement. Ongoing experiments will have to define the TCR engagement in more detail via mutational studies and the exploitation of virus deletion mutants. CMV-reactive γδ T cells are a promising target for future cellular therapies.

P.D4.01.08

Association of autoantibody to rods, rings with hepatitis C virus load

Y. Lakhoua Gorgi[1], *J. Abdellatif*[1], *M. Jellouli*[1], *M. Majdoubi*[1], *L. Mouelhi*[2], *T. Ben Abdallah*[1], *I. Sfar*[1], *T. Dhaouadi*[1];
[1]*Research Laboratory in Immunology of Renal Transplantation and Immunopathology (LR03SP01), Tunis, Tunisia,* [2]*Department of Gastroenterology Charles Nicolle hospital, Tunis, Tunisia.*

INTRODUCTION: Chronic infection with hepatitis C virus (HCV) is an indication for treatment with Ribavirin, a nucleoside analogue of guanosine. The cellular targets of Ribavirin are 2 enzymes (CTPS1 and IMPDH2) which are essential for the CTP and GTP nucleosides' synthesis. It has been reported that in treated patients, the appearance of rare autoantibodies directed against these 2 enzymes and giving the appearance of Rods and Rings (RnR) is generally correlated with a viral escape to treatment with Ribavirin. **MATERIAL AND METHODS**: In this context, anti-RnR antibodies (Ab) were detected by IFI on HEp-2 cells in 142 HCV patients under Ribavirin: 74 patients with positive HCV-PCR(G1) and 68HCV-PCR negative patients (G2) matched in age and sex with G1 and served as controls. **RESULTS**: The frequency of anti-RnR Ab was significantly higher in HCV-PCR positive patients (25.7%) than in those with negative HCV-PCR (0%), p<10E-5. Furthermore, in G1, the viral load was significantly higher in patients with anti-RnR Ab (6105378.32 IU/ml vs 380527.38 IU/ml), p=3.13 10E-6. Nevertheless, the presence of anti-RnR Ab was not correlated neither to gender nor to age. **CONCLUSION**: Anti-RnR Ab seems to be associated with increased replication of HCV and would be predictive of viral escape under Ribavirin.

P.D4.01.09

Cyokine responses upon Bovine Respiratory Syncytial Virusand Bovine Viral Diarrhea Virus vaccination in dairy cows

S. Lee*, Y. Kim, S. Ryu, A. Prasad;*
Chonbuk National University, Iksan, Korea, Republic of.

Bovine respiratory disease (BRD) is defined as a "disease complex", which is usually caused by a variety of pathogens including Bovine Respiratory Syncytial Virus (BRSV), ParaInfluenza 3 (PI3), and Bovine Viral Diarrhea Virus (BVDV). The key to reduce BRD is to vaccinate against these viruses. Although vaccination is an effective measure in reducing the risk of BRD in cattle, BRD losses remain significant. Increasing the efficacy of vaccination depends on elucidating the protective immune response to different antigens included in vaccines and understanding the cytokine responses which reflect complicated immune responses against vaccinated antigens. This study evaluated the serum antibodies present in dairy cows following vaccination with BRSV, BVDV and PI3. Antibody titers and cytokines were measured in more than 100 cows at 0, 1, 4, 24 weeks post vaccination. Upon vaccination, the levels of antibodies against viral respiratory pathogens were significantly enhanced in serum and innate cytokines such as TNF-α and IL-6 were also increased at 1 wk. Cytokines related with helper T cells including IFN-γ, IL-4 and IL-17 were also modulated by vaccination and correlated with antibody levels in serum. The present study may provide better understanding of immune responses against viral pathogens related with BRD upon vaccination.

P.D4.01.10

Mast cells promote thrombocytopenia during dengue virus infection through the release of serotonin.

M. Masri*, C. Mantri, A. Rathore, A. St. John;*
Duke-NUS Medical School, Singapore, Singapore.

Introduction: Thrombocytopenia, a reduction in platelet counts, is a classical trait of dengue fever (DF), which is caused by infection by dengue virus (DENV). DENV can activate mast cells (MCs), which are innate immune sentinels. This results in the release of MC mediators that can influence the severity of dengue vascular leakage. We hypothesized that MC-derived products also contribute to thrombocytopenia during DENV infection.
Materials and methods: Wild type (WT) and MC-deficient (Sash) mice were infected with DENV. Blood and spleens were harvested post-infection for analysis of platelet activation and turnover by flow cytometry. WT mice were treated with MC stabilizer, ketotifen, or $5HT_{2A}$ antagonist, ketanserin. Sash mice were reconstituted with MCs or administered exogenous serotonin to determine the role of mast cell derived serotonin during DENV infection.
Results: DENV infection of WT mice induced thrombocytopenia, which was absent in Sash mice and reduced in mice treated with ketotifen. Reconstitution of the Sash mice with MCs restored the phenotype of thrombocytopenia. Pharmacological inhibition of serotonin with the $5HT_{2A}$ receptor antagonist, ketanserin, in DENV-infected WT mice reduced thrombocytopenia compared to vehicle treated mice. Conversely, treatment of DENV-infected Sash mice with exogenous serotonin restored the thrombocytopenic phenotype that is absent in Sash mice.
Conclusions: Our findings have demonstrated that MC release of serotonin contributes to thrombocytopenia during DENV infection, revealing a potential therapeutic target of disease.

P.D4.01.11

A new in vivo model to study protective immunity to Zika virus infection in mice with intact type I interferon signaling

L. Nazerai*, A. Skak Schøller, P. Overbeck Sharma Rasmussen, S. Buus, A. Stryhn, J. Pravsgaard Christensen, A. Randrup Thomsen;*
Department of Immunology and Microbiology, University of Copenhagen, Copenhagen, Denmark.

The association between recent Zika virus (ZIKV) infection and severe neurological complications, microcephaly in the fetus and Guillain-Barré syndrome in adults, underscores the necessity for a protective vaccine. Unlike the situation in humans, ZIKV can only replicate effectively in mice when type I IFN signaling is interrupted. As type I IFN also impacts the adaptive immune response, mice with such a defect are not optimal for a comprehensive immunological analysis.
In this report, we show that even in wild-type (WT) mice, (intracranial) i.c. infection with low doses of ZIKV causes marked local virus replication and lethal encephalitis in naïve mice. Furthermore, peripheral infection of WT mice with low doses of virus induces a significant immune response, which provides long-lasting protection of WT mice from a fatal outcome of subsequent i.c. challenge. Therefore, combining peripheral priming with later i.c. challenge represents a new approach for studying the adaptive immune response to ZIKV in mice with intact type I IFN response. Using a combination of adoptive transfer, antibody-based cell depletion, and gene targeting, we show that the key protective factor in type I IFN replete mice is humoral immunity. CD8 T cells are not essential in mice with preformed specific antibodies, but under conditions where initial antibody levels are low, effector CD8 T cells may play a role as a back-up system. These results have important implications for our understanding of natural immunity to ZIKV infection and for Zika vaccine design.

P.D4.01.12

Reactivity of the immune system in rabbits experimentally infected with antigenic variants of RHDV (rabbit haemorrhagic disease virus).

P. Niedzwiedzka-Rystwej[1], *B. Tokarz-Deptuła*[1], *W. Deptuła*[2];
[1]*University of Szczecin, Faculty of Biology, Department of Immunology, Szczecin, Poland,* [2]*University of Szczecin, Faculty of Biology, Department of Microbiology, Szczecin, Poland.*

The aim of the study was to evaluate the immunogenicity of 6 selected RHDVa (Vt97, Triptis, Hartmannsdorf, Pv97, 9905 and 72V/2003) obtained in 1996-2003, based on selected natural and acquired immunity parameters. Clinical symptoms and mortality were also recorded. The experiment was performed on 120 rabbits of Polish mixed breed rabbits. Blood and serum was collected at hour 0, followed by 4, 8, 12, 24, 36, 48, 52, 56 and 60 h p.i. Analyzing the picture of changes in natural immunity parameters, the RHDVa strains differ from each other enough to be divided into three groups: with the highest amount of changes - Vt97 and Pv97, the average number of changes - Triptis and 72V/2003 and a small amount of changes - Hartmannsdorf and 9905. In contrast, in case of acquired immunity, no differences were found. No clinical symptoms were recorded, as the infection was rapid and severe, causing mortality in 24 h p.i. (Hartmannsdorf, 72V/2003) and in 36 h p.i. (Vt97, Triptis, Pv97, 9905) at 90 -100%. The picture caused by RHDVa is different both between the analyzed RHDVa (mainly in natural immunity), but also from the image of previously tested classical RHDV. The reasons for these differences may lie in the dissimilarity of RHDVa from RHDV also in genetic terms, as nucleotide changes within the VP60 protein between RHDV and RHDVa have been confirmed. However, the time of receiving RHDVa strains does not confirm the observations with classical RHDV strains, where time of isolation significantly influenced their diversity.

P.D4.01.13

Upregulation of intestinal Tumor Growth Factor-beta1 is associated with increased intestinal epithelial cell apoptosis in pathogenic simian immunodeficiency virus infection

B. Pahar[1], *D. Pan*[1], *S. K. Srivastav*[2], *W. Lala*[1], *A. Das*[1];
[1]*Tulane National Primate Research Center, Covington, United States,* [2]*Tulane University, New Orleans, United States.*

Mucosal Transforming Growth Factor-β1 (TGF-β1), a pleiotropic, potent immunoregulatory cytokine, demonstrated to manage phosphorylated AKT and IFNγ expressions, are associated with intestinal epithelial cells (iECs) survival in macaque colon explants and suggest a potential role of mucosal TGF-β1 in regulating intestinal homeostasis and iEC integrity. It is important to monitor and further explore the role of mucosal TGF-β1 in HIV/SIV pathogenesis and HIV/SIV enteropathy, which may lead to the development of improved therapeutic strategies to prevent iEC damage and systemic immune activation during acute and chronic infection. Our data showed an increased production of intestinal TGF-β1 in T-, B- and non-T/B cell populations during acute and chronic SIV infection in rhesus macaques, without a change in the expression of TGF-βRII. The increased levels of immunosuppressing TGF-β1 were also associated with increased production of IFNγ, suggest the lack of TGF-β1 mediated anti-inflammatory responses in SIV infection. An appropriate balance between inflammatory and anti-inflammatory cytokine responses are crucial for maintenance of a successful immune responses in HIV infection. TGF-β1 induced immune defects contribute to intestinal inflammation, loss of tight junction protein, and apoptosis by overexpression of SMAD3, and downregulation of inhibitory SMAD7 transcription factors. Together, these results indicate that SMAD mediated pathway play a crucial role in regulating TGF-β1 expression and that was thought to be a key contributor to the dysfunction of CD4+ and CD8+ T-cells, iEC apoptosis and disease progression.

P.D4.01.14

Immune modulation in inflammatory bowel disease; the role of IgA-coated microbiota

L. Pedró-Cos*, A. Breedveld, H. Schuster, R. Mebius, D. Budding, M. van Egmond;*
VUmc, Amsterdam, Netherlands.

Immunoglobulin A (IgA) is the most abundant immunoglobulin in mucosal areas and fundamental in maintaining gastrointestinal (GI) tract homeostasis. IgA opsonizes pathogens thereby facilitating uptake by immune cells including neutrophils and dendritic cells (DCs) through FcαRI activation. Inflammatory bowel disease patients have a disturbed intestinal microbiota and their tissue is highly infiltrated with neutrophils. Unfortunately not much is known about the interaction of bacteria with neutrophils and different DC subsets in the GI tract. Here we evaluate the effect of IgA-coated bacteria on immune cells. In the future we aim to identify DC subsets in inflamed intestinal tissue and evaluate their relationship with neutrophils.
Specific IgA in pooled human serum against *E. coli*, *S. aureus*, *S. typhimurium*, *B. breve* and *B. longum* was measured using flow cytometry. Neutrophils, monocytes and monocyte derived (mo)DCs were stimulated with IgA-coated bacteria to measure their phagocytic capacity after 30min using flow cytometry. After 24h stimulation, supernatant was collected for cytokine production measurement using ELISA.
Serum IgA against *E. coli*, *S. aureus*, *S. typhimurium*, *B. breve* and *B. longum* was present. Neutrophil phagocytic capacity was enhanced when bacteria were IgA-coated while moDCs preferably phagocytose IgG-coated bacteria. Activation of monocytes was increased after 24h bacterial stimulation showing enhanced production of IL-6. *B. longum* induced higher IL-10 production by monocytes compared to *S. typhimurium*. Surprisingly, IgA-coated *B. longum* induced higher levels of IL-12p40 production by monocytes. These results suggest differential effector functions of (IgA-coated) bacteria on immune cells.

P.D4.01.15

Circadian rhythms control lung inflammation in influenza infection

S. Sengupta[1], *S. Y. Tang*[1], *C. B. Lopez*[2], *S. Nayak*[1], *J. Devine*[1], *G. Grant*[1], *E. Genoyer*[2], *G. A. FitzGerald*[1];
[1]*University of Pennsylvania, Philadelphia, United States,* [2]*University of Pennsylvania School of Veterinary Medicine, Philadelphia, United States.*

Influenza is a leading cause of respiratory mortality and morbidity. While inflammation is necessary for fighting infection, a fine balance of anti-viral defense and host tolerance is crucial to the successful outcome. Circadian rhythms form an anticipatory system wherein various aspects of cellular physiology and behaviors oscillate across a 24hrs period; these rhythms have been known to modulate the immune responses. However, the role of circadian rhythms in influenza infection is not well known. To elucidate this role, we infected C57bl6 littermates with influenza virus (PR8) either at the beginning of their active phase (ZT11) or at the beginning of their rest phase (ZT23). Mice infected at ZT11 had more than fourfold higher mortality, more weight loss and worse clinical scores than mice infected at ZT23. This was the result of exaggerated inflammation as evident in higher bronchoalveolar lavage cell counts (including more neutrophils on day 2 post-infection) and worse lung histology on day 6. Interestingly, NK cells were present in higher numbers in the ZT23 than in the ZT11 group at the early phase of infection. Further, pathway analyses of our transcriptomic data supported the role of higher inflammation in the ZT11 group. Thus, circadian regulatory networks, make the host at ZT11 mount an inefficient viral clearance response, wherein more inflammation is needed to achieve similar clearance of the pathogen, resulting in more host injury and death. These data suggest that the circadian regulation of host inflammation and tolerance, rather than viral burden determines the outcome of influenza infection.

P.D4.01.16

The evidence of hepatitis E virus in wild rats from Lithuania

M. Simanavicius[1], *K. Juskaite*[1], *A. Verbickaite*[1], *M. Jasiulionis*[2], *P. L. Tamosiunas*[1], *R. Petraityte-Burneikiene*[1], *A. Zvirbliene*[1], *R. G. Ulrich*[3,4], *I. Kucinskaite-Kodze*[1];
[1]*Vilnius University Life Sciences Center Institute of Biotechnology, Vilnius, Lithuania,* [2]*Nature Research Centre, Vilnius, Lithuania,* [3]*Friedrich-Loeffler-Institut, Federal Research Institute for Animal Health, Institute of Novel and Emerging Infectious Diseases, Greifswald - Insel Riems, Germany,* [4]*German Center for Infection Research (DZIF), Hamburg-Luebeck-Borstel-Insel Riems, Germany.*

Rat hepatitis E virus (HEV) is an orthohepevirus which is related to other HEV found in humans and other mammals. It was first identified in Norway rats (*Rattus norvegicus)* from Germany in 2010, and then it was detected in Black rats (*Rattus rattus)* and Norway rats from USA, China, Indonesia, Vietnam and many European countries. In this study, we describe molecular and serological investigations of Black and Norway rats trapped in Lithuania for infections with rat HEV and human HEV genotypes 1-4. Rat HEV-specific real-time reverse transcription PCR (RT-qPCR) analysis of rat liver samples revealed the presence of rat HEV. In contrast, a RT-qPCR specific for HEV genotypes 1–4 did not reveal any positive samples. A nested broad spectrum RT-PCR was used for a confirmation of rat HEV infection with a subsequent sequencing of the amplified rat HEV genomic fragment. Phylogenetic analysis revealed a clustering of all newly identified rat HEV sequences with Norway rat-derived rat HEV sequences from Germany and a Black rat-derived sequence from Indonesia within the species *Orthohepevirus C*. An indirect ELISA using a yeast-expressed truncated rat HEV capsid protein variant revealed even more seropositive than RT-qPCR positive samples indicating a high rate of rat HEV circulation in the rat population examined. In conclusion, the current investigation confirms rat HEV infections in Norway and Black rats in Lithuania and the non-persistent nature of infection. This research was funded by the Lithuanian Science Council, grant number MIP-039/2015.

P.D4.01.17

Evaluation of the carriage of hepatitis B surface antigen in hospital personnel

M. D. SYLLA NIANG[1,2], *B. Mbengue*[1], *M. Mbow*[1], *M. Thiam*[1,2], *R. Derwiche*[1], *N. N. Diouf*[2], *O. Boye*[2], *T. N. Dieye*[1], *A. Dieye*[1];
[1]*Cheikh Anta Diop University of Dakar - SENEGAL, Dakar, Senegal,* [2]*General Hospital of Grand-Yoff, Dakar, Senegal.*

Introduction: Hepatitis B virus (HBV) infection is the second most common carcinogen factor after tobacco. The high concentration of HBV in biological secretions and its resistance in the external environment promote its high transmission capacity. Such characteristics make hospital staff at risk to HBV infection. The objective of this study was to evaluate the immunological status to HBV of hospital staff from a public health institution in Senegal.
Material and methods: A retrospective, descriptive and analytical study was conducted from June to August, 2015 at General Hospital of Grand-Yoff in Senegal. Were included in this study 319 out of 654 hospital staff members who attended the 2015 annual company medical check-up. Determination of HBsAg was performed using qualitative immunochromatographic test. Data were analyzed using Excel 2011 and Statview 5.0 software.
Results: The participation rate was 48.77%. The average age of the staff was 45± 2 years. The prevalence of HBsAg in the study population was 13%. HBsAg carriers were mostly paramedics (60%) and most of them (70%) have been working at the hospital for more than 10 years. Statistical analysis revealed that there was no relationship between HBV infection and the work duration at the hospital. Among the infected staff, 92% were married and the most represented age group was between 39 and 45 years.
Conclusion: The prevalence of HBsAg among hospital staff remains high. Preventive measures such as vaccination of people unprotected from HBV and awareness of the risks associated with practice in the hospital environment are needed.

P.D4.01.18

Effect of latent cytomegalovirus (CMV)-infection on the immune response to influenza with age

S. P. H. van den Berg[1,2], *R. J. Jacobi*[1], *M. Hendriks*[1], *R. van Schuijlenburg*[1], *K. Warmink*[1], *L. Beckers*[1], *N. M. Nanlohy*[1], *A. Wong*[1], *M. Knol*[1], *J. A. Borghans*[2], *J. van Beek*[1], *D. van Baarle*[1,2];
[1]*National Institute for Public Health and the Environment, Bilthoven, Netherlands,* [2]*University Medical Center Utrecht, Utrecht, Netherlands.*

Older adults are at higher risk for influenza-virus infection and for influenza-related death compared to younger adults. Unfortunately, influenza-vaccine responses are impaired in older adults due to ageing of the immune system (immunosenescence). Latent infection with cytomegalovirus (CMV) is generally thought to aggravate this state of immunosenescence. We studied whether CMV-infection impairs the immune response to influenza-virus. The effect of CMV-infection on the influenza-vaccine antibody response has been investigated before, with very contradicting results. Meta-analysis of these studies revealed a trend towards a negative effect of CMV-seropositivity on the response to influenza vaccination. Funnel-plot analysis suggests, however, that this is due to publication bias. Differences between studies might be due to confounding effects of preexisting immunity, which influences immune responses to seasonal influenza vaccines. Therefore, we investigated the influence of CMV-infection on the antibody response to the pandemic influenza vaccine of 2009, to which pre-existing immunity was negligible. Despite a negative effect of age, no effect of CMV-infection on the influenza-vaccine response was observed. Finally, we investigated the effect of CMV-infection on influenza virus-specific T-cells in a cohort of influenza virus-infected elderly. Despite a clear effect of CMV-infection on the phenotype of the total T-cell pool, CMV-infection did not impair the T-cell response to influenza-virus infection. Unexpectedly, the height of the T-cell response to CMV and influenza virus correlated positively, showing that the CMV-host balance is still not fully understood. Altogether, we find no evidence in human for impairment of the immune response to influenza vaccination or infection by CMV.

P.D4.01.19

Prevalence of broadly neutralizing antibody responses in HIV-1 infected injecting drug users

Z. Euler[1,2,3], *T. van den Kerkhof*[1,3], *R. Kouyos*[4], *D. Tully*[2], *T. Allen*[2], *R. Sanders*[1], *A. Trkola*[4], *H. Schuitemaker*[1,3], ***M. J. van Gils***[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States,* [3]*Janssen Pharmaceuticals, Leiden, Netherlands,* [4]*Institute of Medical Virology, Zurich, Switzerland.*

Understanding the factors involved in the development of broadly neutralizing antibody (bNAb) responses in natural infection can guide vaccine design aiming to elicit protection against HIV-1 acquisition. Most of the studies to identify and study development of bNAb responses were performed in individuals who had become infected via homo- or heterosexual HIV-1 transmission, however the prevalence and characteristics of bNAb responses in injecting drug users (IDUs) remains to be established.
A retrospective cohort study on the prevalence of bNAb responses in HIV-1 infected individuals, who reported injecting drug use as the only risk factor (50 male and 35 female participants of the Amsterdam Cohort Studies) was conducted.
The study revealed a significantly lower prevalence of bNAb responses compared to MSM, which was no longer evident when women were excluded from the IDU group. Interestingly, more elite neutralizers were found in the IDUs with 6% of male IDUs being elite neutralizers as compared to only 0.3% amongst MSM and 0% of female IDUs. Gender, transmission route and CD4+ count at setpoint, were independently associated with bNAb responses but not viral load for the IDUs or HIV-1 envelope glycoprotein sequence diversity within the first year of infection. Similar observations were seen in the Swiss Cohort, indicating that injecting drug use may influence the development of potent humoral immune responses, with a stronger effect in females.
Our data reveal that the emergence of bNAbs may be dependent on multiple factors, not only host or viral but also behaviour.

P.D4.01.20

Identification of new biomarkers to distinguish between a bacterial or viral infection in children

J. Zandstra[1,2], *M. H. Jansen*[3,2], *S. Zeerleder*[1,4], *T. W. Kuijpers*[2,5];
[1]*Dept of Immunopathology, Sanquin Blood Supply, Division Research, Amsterdam, Netherlands,* [2]*Dept of Pediatric Hematology, Immunology & Infectious diseases, Emma Children's Hospital, AMC, Amsterdam, Netherlands,* [3]*Department of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands,* [4]*Department of Hematology, Academic Medical Center, Amsterdam, Netherlands,* [5]*Dept of Blood Cell Research, Sanquin Blood Supply, Division Research, Amsterdam, Netherlands.*

The biggest cause of death in children under 5 years consists of infection. The most common presenting symptom of infection is fever. Most of febrile illnesses are caused by viral infections at this age. However a small number are life-threatening bacterial infections, such as meningitis or pneumonia. In the clinic it may be difficult to distinguish between a bacterial or viral infection based on clinical grounds. This results in unnecessary treatment with antibiotics when they are suffering from a viral infection out of fear of missing a bacterial infection. There is an urgent need of the development of improved methods to distinguish between bacterial and viral infections. In a prospectively, we focused on identification of new discriminators of bacterial and viral infection. We performed a multiplex protein assay with 27 candidate markers and ELISA to validate known biomarkers. In our cohort of 150 bacterial and viral plasma samples we have confirmed by ELISA that C-reactive protein and neutrophil protein elastase is increased in bacterial infections compared to viral infections. We found several pro-inflammatory proteins elevated in plasma from children with meningococcal infection. Also, neutrophil-derived S100A12 was significantly increased in bacterial infections, compared to viral infection. Further analysis into these markers is needed to get insight in the predictive value of these parameters. Our data clearly indicate that a reliable diagnostic tool based on a multiplex protein test will lead to a more accurate diagnosis to reduce hospital admissions and avoid overtreatment with antibiotics in febrile disease in pediatrics.

β-defensin as mast cell phenotype and activity modulator

J. Agier[1], *S. Rożalska*[2], *M. Wiktorska*[3], *P. Żelechowska*[1], *E. Brzezińska-Blaszczyk*[1];
[1]*Department of Experimental Immunology, Medical University of Lodz, Lodz, Poland,* [2]*Department of Industrial Microbiology and Biotechnology, University of Lodz, Lodz, Poland,* [3]*Department of Molecular Cell Mechanisms, Medical University of Lodz, Lodz, Poland.*

Background. Defensins play a crucial role as components of the early host defense against bacterial, viral, and fungal invasion but new research has cast light on alternative functionalities, including immunomodulatory activities. Given that mast cells (MCs) are firmly efficient effector cells in microbial elimination and play an essential role in orchestrating inflammatory response during infection, this study analyzes hBD-2-induced expression of RIG-I, NOD1, and NOD2 receptors and evaluates the effect of this peptide on the pro-inflammatory response in *in vivo* differentiated mature tissue MCs. Materials and methods. All experiments were carried out *in vitro* on freshly isolated peritoneal MCs obtained from female albino Wistar rats. qRT-PCR, flow cytometry, and confocal microscopy were used to evaluate both constitutive and hBD-2-induced expression of receptors. ROS was determined using H_2DCFDA, and chemotaxis assay was used to define the MC migratory response. Standard procedure assessed histamine release. Results. hBD-2 enhances the expression and induces translocation of the studied receptors and directly activates the pro-inflammatory and migratory responses of native MCs. Conclusion. These data suggest that hBD-2 might augment MC capability and sensitivity to RLR and NLR ligands and strengthen the role of MCs in inflammation. Supported by the Medical University of Lodz (grant no 503/6-164-01/503-61-001).

P.D4.02.02

Investigating metabolic mechanisms regulating collagen breakdown in tuberculosis

R. M. Asher, *J. S. Friedland;*
Imperial College London, London, United Kingdom.

Introduction: Tuberculosis (TB) is a global pandemic. Morbidity and mortality in TB result from inflammatory tissue destruction, driven by matrix metalloproteinases (MMP). Patients also experience profound weight loss. TB-infected macrophages display the Warburg effect, a metabolic shift from oxidative phosphorylation to aerobic glycolysis. However, the relationship between innate inflammation and cellular metabolism in TB remains poorly defined.
Methods: Primary normal human bronchial epithelial cells (NHBE) or monocyte-derived macrophages (MDM) were incubated with specific metabolic inhibitors, or transfected with siRNA. Cells were then directly infected with live, virulent TB or stimulated with conditioned media from TB-infected monocytes (CoMTB). Protein secretion, gene expression and functional tissue damage were measured by ELISA, luminex, zymography, real-time PCR and DQ collagen assay.
Results: The glycolysis inhibitor, 2-deoxyglucose (2DG), reduced gene expression and secretion of the key collagenase, MMP-1, in a dose-dependent manner. There was a 7-fold drop in MMP-1 secretion in CoMTB-stimulated NHBE ($p<0.0001$) and a 5-fold drop in TB-infected MDM ($p<0.0001$). This was accompanied by a functional decrease in collagen breakdown. 2DG also decreased IL-1β ($p=0.0001$) and IL-10 ($p<0.0001$) and increased TNF-α ($p=0.0012$) in TB-infected MDM. Enhanced transcription factor HIF-1α expression in CoMTB-stimulated MDM was attenuated by 2DG. MMP-1 and IL-1β secretion were decreased by inhibiting the metabolic regulator AMPK and increased by Pi3-kinase pathway blockade.
Conclusion: Our data show that glycolysis is a key modulator of MMP-1, cytokines and HIF-1α in TB. AMPK and Pi3-kinase also have central regulatory roles.
Research was funded by Medical Research Council (UK) and Mason Medical Research Foundation.

P.D4.02.03

Plasma cytokines CXCL9, CXCL10 and IL1RA correlate with disease severity in a controlled typhoid human challenge model

A. J. Barton[1], *M. Gibani*[1], *E. Jones*[1], *S. Camara*[1], *Y. Rosenberg-Hasson*[2], *I. Mohorianu*[1], *G. Obermoser*[3], *J. Galan*[4], *A. J. Pollard*[1];
[1]*University of Oxford, Oxford, United Kingdom,* [2]*Human Immune Monitoring Center, Stanford University, Stanford, United Kingdom,* [3]*Human Immune Monitoring Center, Stanford University, Stanford, United States,* [4]*Yale University, New Haven, United States.*

Introduction: *Salmonella enterica* serovar Typhi (*S*. Typhi) is a human-restricted pathogen estimated to cause 20 million cases of typhoid fever each year. The contribution of the typhoid toxin, a virulence factor specific to typhoidal *Salmonella*, to host-pathogen interactions *in vivo* is not well characterised. Here we investigate the changes in cytokine profile induced by wild-type and toxin-deficient *S*. Typhi challenge, and their correlation with disease severity.
Methods: 40 healthy adult volunteers were randomised to receive oral challenge wild-type Quailes strain *S*. Typhi or an isogenic typhoid toxin-deficient mutant with an attack rate of 75% (30/40). Post-challenge changes in plasma cytokine profile over a two week time series were assayed using a 62-plex Luminex system. Raw intensities were normalised, and log fold changes relative to baseline were compared using linear modelling.
Results: 37% of cytokines were differentially regulated in acute disease. At time of diagnosis, IL-12 was significantly upregulated in the toxin-negative group but not in the wild-type group. CXCL10 and IL1RA were positively correlated with temperature (R = 0.9 and R = 0.8) and CXCL9, CXCL10 and IL1RA with aggregate self-reported symptom scores.
Conclusions: Based on this extensive cytokine study, absence of the toxin may affect Th1 differentiation through IL-12. The correlation between disease severity and CXCR3 ligands CXCL9 and CXCL10 could relate to their action on T cell migration, while endogenous antipyretic IL1RA may have been upregulated to counteract the inflammatory action of IL-1.

P.D4.02.04

Anti-Cytomegalovirus IgG Antibody Titer is Positively Associated with Advanced T Cell Differentiation and Coronary Artery Disease in End-Stage Renal Disease

Y. Chiu[1,2], *K. Shu*[1], *I. Chen*[1], *F. Lay*[1];
[1]*Far Eastern Memorial Hospital, New Taipei City, Taiwan,* [2]*National Taiwan University, Taipei, Taiwan.*

Background: Accumulating evidence indicates that persistent human cytomegalovirus (HCMV) infection is associated with several health-related adverse outcomes including atherosclerosis and premature mortality in individuals with normal renal function. Patients with end-stage renal disease (ESRD) exhibit impaired immune function and thus may face higher risk of HCMV-related adverse outcomes. Whether the level of anti-HCMV immune response may be associated with the prognosis of hemodialysis patients is unknown. Results: Among 412 of the immunity in ESRD study (iESRD study) participants, 408 were HCMV seropositive and were analyzed. Compared to 57 healthy individuals, ESRD patients had higher levels of anti-HCMV IgG. In a multivariate-adjusted logistic regression model, the log level of anti-HCMV IgG was independently associated with prevalent coronary artery disease (OR=1.93, 95% CI=1.2~3.2, p=0.01) after adjusting for age, sex, hemoglobin, diabetes, calcium phosphate product and high sensitivity C-reactive protein. Levels of anti-HCMV IgG also positively correlated with both the percentage and absolute number of terminally differentiated CD8+ and CD4+CD45RA+CCR7- TEMRA cells, indicating that immunosenescence may participate in the development of coronary artery disease. Conclusion: This is the first study showing that the magnitude of anti-HCMV humoral immune response positively correlates with T cell immunosenescence and coronary artery disease in ESRD patients. The impact of persistent HCMV infection should be further investigated in this special patient population.

P.D4.02.05

The potential role of Th17-like immune responses in Johne's disease positive cows

J. L. DeKuiper*, P. M. Coussens;*
Michigan State University, East Lansing, United States.

Johne's disease (JD) is a chronic gastrointestinal disorder of ruminants caused by *Mycobacterium avium* subspecies *paratuberculosis* (MAP). Later stages of JD coincide with a classical Th2-like immune response. Defining importance of a classical Th1-like response in JD has been more difficult. A possibility exists that non-classical responses, such as a Th17-like response, might be important in MAP immunity. Indeed, mRNAs encoding the cytokines IL-23 and IL-17a are significantly elevated in PBMCs from MAP test positive (JD+), MAP test negative (JD-) cows, and subclinical JD+ CD4+ T-cells (IL-17a only), after MAP antigen stimulation. IL-23 and IL-17a production have been associated with Th17-like responses. Th17 cells are also defined by expression of IL-23 receptor (IL-23R). Surface staining for T-cell type (CD4, CD8, TCR1 (Yδ T-cell)) and IL-23R was performed and analyzed via flow cytometry to determine the relative prevalence of potential Th17 cells in PBMCs from JD+/- cows. Fresh PBMCs from JD+ cows (*n=12*) contained a significantly higher proportion of IL23R+ cells than PBMCs from JD- (*n=12*) (*p<0.05*). However, ELISA results for IL-17a revealed higher concentrations of IL-17a secreted from PBMCs stimulated with MAP (*n=20*) than from PBMCs not stimulated with MAP (*n=20*), regardless of JD status (*p<0.0001*). Plasma from highly infected JD+ (*n=20*) cows revealed significantly less IL-17a circulating in the periphery than in JD- cows from two distinct sources (*n=18 and n=20*) (*p>0.05 and <0.013, respectively*). This data suggests that Th17 cells may indeed play a role in early immune responses to MAP infection and development or control of JD.

P.D4.02.06

Clustering of CD8 T cells around malaria-infected hepatocytes is rapid and is driven by antigen-specific T cells

V. V. Ganusov[1], *R. Kelemen*[2], *H. Rajakaruna*[1], *I. Cockburn*[3];
[1]*University of Tennessee, Knoxville, United States,* [2]*nstitute of Science and Technology, Vienna, Austria,* [3]*Australian National University, Canberra, Australia.*

Malaria begins when Plasmodium-infected mosquitoes inject malaria sporozoites while searching for blood. Sporozoites migrate from the skin via blood to the liver, infect hepatocytes, and form liver stages. In mice, vaccine-induced activated or memory CD8 T cells are capable of locating and eliminating all liver stages in 48 hours, thus preventing the blood-stage disease. However, rules of how CD8 T cells are able to locate all liver stages in a limited timeframe remains poorly understood. We recently reported formation of clusters consisting of variable numbers of activated CD8 T cells around Plasmodium yoelii (Py)-infected hepatocytes. Using a combination of experimental data and mathematical models we now provide additional insights into mechanisms of formation of these clusters. We show that a model in which cluster formation is driven exclusively by T-cell-extrinsic factors, such as variability in ``attractiveness'' of different Py-infected cells, cannot explain distribution of cluster sizes in different experimental conditions. In contrast, the model in which cluster formation is driven by the positive feedback loop (i.e., larger clusters attract more T cells) can accurately explain the available data. Mathematical modeling also suggested that formation of clusters occurs rapidly, within few hours after adoptive transfer of T cells, thus illustrating high efficiency of T cells in locating their targets in complex peripheral organs such as the liver. Taken together, our analysis provides novel information into the mechanisms driving the formation of clusters of antigen-specific CD8 T cells in the liver.

P.D4.02.07

Innate recognition of heat-stable ligands from *Orientia tsutsugamushi* by C-type lectins

V. Hefter[1,2], *Z. Orfanos*[1], *S. Mayer*[3], *B. Lepenies*[3], *C. Keller*[1,2];
[1]*Institute of Virology, Philipps University Marburg, Marburg, Germany,* [2]*German Centre for Infection Research at the Institute of Virology, Philipps University Marburg, Marburg, Germany,* [3]*Research Centre for Emerging Infections and Zoonosis, University of Veterinary Medicine, Hannover, Germany.*

Orientia tsutsugamushi, an obligate intracellular Gram-negative bacterium causing the neglected febrile disease scrub typhus, elicits chemokine and cytokine production by heat-stable ligands via NF-κB-dependent pathways in phagocytes. It has not been studied how recognition by receptors other than Toll-like (TLR) and NOD-like receptors shape the inflammatory response to *Orientia*. *Orientia* has an atypical cell wall composition with high amounts of neutral saccharides in its outer membrane, which could predispose for recognition by C-type lectin receptors (CLR).
In order to screen for potential CLR ligands, we used purified heat-inactivated *Orientia* in a FACS-based interaction assay involving a library of 12 mouse and 4 human CLRs. We identified four mouse candidate receptors binding to *Orientia*. Binding to mouse Mincle was EDTA-sensitive and thus shown to be specific. Mincle was therefore chosen for further investigations.
Bone marrow-derived dendritic cells (BMDC) from C57BL/6 mice stimulated with inactivated *Orientia* showed an increasing, dose-dependent induction of *mincle* mRNA over 24 hours. Furthermore, upon stimulation significantly higher levels of TNF-α were seen in Mincle-deficient BMDC compared to the C57BL/6 wildtype, suggesting an inhibitory effect of Mincle on NF-κB-mediated cytokine production.
Combined, these results point toward an initial upregulation of Mincle by another receptor, e.g. a TLR, before the former can mediate its inhibitory effect. We aim to provide further insight into the role of Mincle in the recognition of *Orientia tsutsugamushi*.

P.D4.02.08

The role of ISG15 in proteasomal degradation and MHC class I antigen presentation

***T. Held**, M. Groettrup;*
Division of Immunology, Konstanz, Germany.

Interferon stimulated gene 15 (ISG15) is an interferon (IFN)-α/β-induced ubiquitin-like protein. It exists as an intracellular and extracellular molecule, as well as conjugated to target proteins (ISGylation). Both free and conjugated ISG15 exhibit antiviral activities against a wide range of viruses. Evidence indicates that ISGylation mostly targets newly synthesized proteins, as its E3 ligase Herc5 is physically associated with polyribosomes. It is suggested that upon viral infection newly translated viral proteins are primary targets of ISG15. Ubiquitin and other ubiquitin-like proteins such as FAT10 have been shown to target their conjugated proteins for proteasomal degradation thereby feeding antigens into the major histocompatibility complex (MHC) class-I restricted pathway. We hypothesize that ISGylation of viral proteins might as well contribute to proteasomal degradation of these proteins into MHC class I antigen presentation. To elucidate the role of ISG15 conjugation and proteasomal degradation, we treated interferon-induced as well as ISG15 overexpressing cells with the protein synthesis inhibitor *cycloheximid* and were able to show that ISGylation does not target proteins for proteasomal degradation. Thus, the biochemical function of ISG15 conjugation still needs to be further elucidated.

P.D4.02.09

Mechanism of induction of the Toll/Interleukin-1 receptor protein C (TcpC) of uropathogenic *E. coli* (UPEC)

***J. Hemberger**, T. Miethke;*
Universitätsmedizin Mannheim, Mannheim, Germany.

Toll/Interleukin-1 receptor (TIR) proteins are present in many pathogens like uropathogenic *Escherichia coli* (UPEC). They interfere with the TLR-signaling chain, which is an essential part of the innate immune system. Toll/Interleukin-1 receptor protein C (TcpC) from the UPEC strain CFT073 is an essential virulence factor that impairs the innate immune system, i.e. TLRs and inflammasomes, increases the bacterial spread and causes severe organ damage. To find possible gene inductors we tested the native promotor of the operon that includes *tcpC*, a putative promotor directly in front of *tcpC*, and a segment that includes both promotors with *gfpmut2* as a reporter gene that was measured by its fluorescence. We first explored whether different cell culture media influenced the promoter activity. The fluorescence of bacteria in DMEM ceased within 48 h while McCoy and RPMI caused an increase in fluorescence over 72 h. The overall fluorescence strength in McCoy and RPMI cultures was considerably higher as compared to relatively low signals in glucose-minimal-medium and EMEM. Transwell cultures were conducted to investigate, if the induction is dependent on the bacterial density. We could show that an increasing bacterial density dose-dependently induces a higher fluorescence of the putative promotor construct. This effect was stronger when the bacteria were incubated in McCoy medium. We then tested different eukaryotic cell types as possible inductors, since UPECs should recognize them to impair their innate immune response. RAWs did not have an influence on the putative promotor. However, more cells of the urogenital tract have to be tested.

P.D4.02.10

Altered IL-12/IFN-γ pathway in extrapulmonary tuberculosis and visceral leishmaniosis in pediatric patients and related controls

*A. Esteve-Sole[1,2], À. Deyà-Martínez[1,2], A. Noguera-Julian[3], A. Martin-Nalda[4], E. Cobos[4], C. Fortuny[3], P. Soler-Palacin[4], L. Gonzalez-Granado[5,6], C. Gianelli[7], W. Córdova[8], M. Anton[9], V. Bolaño-Doctor[9], A. Sainz-Loyola[10,11], A. Vlagea[9,2], A. Perera-LLuna[10,11], J. Yagüe[9], A. M. Plaza[1], **M. Juan**[9,2], L. Alsina[1,2];*

Hospital Universitario Ramón y Cajal, Madrid, Spain, [8]Centro de referencia nacional de alergia Asma Inmunologia. Instituto Nacional de Salud del Niño, Lima, Peru, [9]Immunology Department. Biomedical Diagnostics Center, Hospital Clinic-IDIBAPS, Universitat de Barcelona, Barcelona, Spain, [10]B2SLab, Departament d'Enginyeria de Sistemes, Automàtica i Informàtica Industrial, Universitat Politècnica de Catalunya, CIBER-BBN, Barcelona, Spain, [11]Department of Biomedical Engineering, Institut de Recerca Pediàtrica Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain.

Genetic defects in IL-12/IFN-γ pathway (known as MSMD, OMIM: 209950) confer increased susceptibility to intracellular pathogens, most commonly mycobacteria. We aimed to define the status of the IL-12/IFN-γ pathway in pediatric patients diagnosed with severe intracellular infections, such as extrapulmonary tuberculosis (TB) or visceral leishmaniasis (VL).
We performed an ambispective cohort study in patients with VL (n=23; mean age 7.42 years old), extrapulmonary TB (n=24, mean age 7.28 years old), and controls (n=41, non-related, n=18 and family-related, n=23). Whole-blood culture in the presence of BCG with or without IL-12p70 or IFN-γ co-stimulation was performed to analyze cytokine secretion. No complete defect of the IL-12/IFN-γ pathway was detected. Yet, patients with VL and extrapulmonary TB showed a statistically significant alteration in IL-12/IFN-γ function, with reduced IFN-γ production and response, respectively. Genetic evaluation is ongoing. Interestingly, related-controls presented a cytokine production pattern closer to that of patients than to that of unrelated-controls.
Pediatric extrapulmonary TB and VL in our media do not seem to be a warning sign for MSMD complete defects. Altered anti-mycobacterial response both in patients and related-controls suggests that the genetic background puts some children at higher risk of these infections. Thorough genetic studies searching for partial or somatic defects in genes related with the IL-12/IFN-γ pathway are needed in these patients.

P.D4.02.11

Viral co-option of IFN driven glycolytic programming in infected macrophages

***K. Kotzamanis**[1], J. Edwards-Hicks[1], A. Alghamdi[2], P. Lacaze[1], M. Blanc[1], D. G. Watson[2], A. Finch[1], P. Ghazal[1];*
[1]University of Edinburgh, Edinburgh, United Kingdom, [2]University of Strathclyde, Glasgow, United Kingdom.

Immunity and metabolism have been viewed as separate fields, however, recent evidence show that these two systems are intimately integrated, share resources and cross-regulate each other. Activated immune cells alter their metabolism in order to support effector functions. On the other hand, viruses are obligatory parasites that counter and exploit host pathways, including metabolism in infected cells, to effectively propagate.
The regulation of metabolism in immune cells or virally infected cells has been well studied. However, the precise metabolic regulation that ensues when both immune system and viral infection, in immune cells, interact and compete for the limited resources and available metabolic pathways is not clear. Here, we have sought to investigate this integrative process by studying the metabolic programming of macrophages infected with murine cytomegalovirus (MCMV). Our hypothesis is that productive infection of macrophages by MCMV takes advantage of the early inflammatory metabolomic reprogramming of activated macrophages to establish infection in the cells.
To study this interaction, we have analysed temporally the transcriptome and metabolome of wild type and IFNB-/- or IFNAR-/- macrophages infected with productive and non-productive (attenuated) MCMV strains. This allows unravelling host versus virus directed metabolic alterations observed upon infection of macrophages. We find that cytomegalovirus co-opts early pro-inflammatory changes in glycolysis for establishing infection of macrophages.
This represents a novel previously unappreciated host pathogens interactions pathway.

P.D4.02.12

Murine neutrophils modulate adaptive immunity during brucellosis

***R. Mora-Cartín**[1], C. Gutiérrez-Jiménez[1], A. Alfaro-Alarcón[2], E. Chaves-Olarte[3,1], E. Barquero-Calvo[1], E. Moreno[1];*
[1]Programa de Investigación en Enfermedades Tropicales, Universidad Nacional, Heredia, Costa Rica, [2]Departamento de Patología, Escuela de Medicina Veterinaria, Universidad Nacional, Heredia, Costa Rica, [3]Centro de Investigación en Enfermedades Tropicales, Universidad de Costa Rica, San José, Costa Rica.

Polymorphonuclear neutrophils (PMNs) are part of the first line of defense against microbial pathogens. We have previously demonstrated that PMNs negatively influence the Th1 immune response at early times of *Brucella* infection (PLoS Pathog 9: e1003167). To investigate the influence of PMNs in the adaptive immune response during chronic brucellosis, we removed these leukocytes by means of antibodies against PMNs. during the course of the infection. We have demonstrated that at later times of *Brucella abortus* infection, the bacterium is killed more efficiently in the absence of PMNs than in their presence. Removal of neutrophils during infection decreased spleen inflammation, induced elevated production of INF-γ, IL-6, IL-12 and IL-10, and caused transient cachexia. The absence of PMNs during *Brucella* infection caused a decrease in most antibody isotypes against *B. abortus* LPS. The only exception was the increase of IgG3 isotype, an event linked to the high amounts of IFN-γ produced in neutropenic mice. These results reveal that late removal of PMNs have an unexpected influence in modulating the immune response against brucellosis.

P.D4.02.13

Role of TRPV4 calcium ion channel in immune response against *Mycobacterium tuberculosis* infection

S. K. Naik[1,2], *J. Eich*[2], *M. Hauptmann*[2], *U. Schaible*[2], *A. Sonawane*[1,2,3];
[1]*School of Biotechnology, KIIT University, Bhubaneswar, India,* [2]*Research Centre Borstel, Borstel, Germany,* [3]*Indian Institute of Technology, Indore, India.*

Tuberculosis is caused by the bacteria *Mycobacterium tuberculosis* (Mtb). As a successful human pathogens, Mtb can subvert host defence system and is very difficult to eliminate. Phagosome maturation is essential in innate immune cell effector functions to eliminate bacterial pathogens. Mtb is known to interfere with phagosome maturation through various virulence mechanisms. We found that Mtb infection of macrophages down-regulates expression of TRPV4, a calcium permeable ion channel and member of the Transient Receptor Potential Vanilloid protein family. Initially characterized as an osmolality sensor, TRPV4 can be activated by various physical and chemical stimuli and is involved in phagosome maturation. We found that growth of Mtb in macrophages is increased in the absence of TRPV4, even upon IFN-gamma stimulation when compared to wild type ones. The failure to control mycobacterial growth is likely due to the incapability of IFN-gamma stimulated TRPV4-KO macrophages to drive mycobacteria into phago-lysosomes. Using a pharmaceutical inhibitor in macrophages infected with attenuated mycobacteria resulted in TRPV4 down-regulation of the phagosomal proteins, EEA1 and Rab7 and concomitant failure to promote phagosome maturation thereby leading to increased survival of intracellular mycobacteria. Mycobacterial ESX-1 encoded virulence factors may be involved in TRPV4 modulation as ESX-1 KO strains of Mtb, in contrast to WT ones, failed to down-regulate TRPV4 expression and to promote cell death 48hr post infection. Taken together, our study indicates that TRPV4 calcium ion channel is crucial for the control of Mtb by immune activated macrophages but can be modulated by virulent Mtb in an ESX-1 mediated manner.

P.D4.02.14

Association between NMDA-receptor antibody positivity and infection by herpes virus

I. Nieto-Gañán[1], *P. Walo Delgado*[1], *P. Lapuente Suanzes*[1], *J. Galán Montemayor*[2], *A. Jiménez-Scrig*[3], *Á. Carrasco Sayalero*[1];
[1]*Immunology Department. Hospital Universitario Ramón y Cajal, Madrid, Spain,* [2]*Microbiology Department. Hospital Universitario Ramón y Cajal, Madrid, Spain,* [3]*Neurology Department. Hospital Universitario Ramón y Cajal, Madrid, Spain.*

Introduction: Anti-neuronal antibodies are classified as intracellular and extracellular according to the localization of the antigenic target. Anti-NMDAR antibodies are extracellular antibodies linked to neoplastic disease usually benign ovarian teratoma, with or without encephalitis. They appear occasionally in encephalitis by herpes simplex virus type 1 (HHV1) and enterovirus. The mechanism of this association is not clear. Whether their presence changes the clinical symptoms and prognosis of these encephalitis or if these cases require additional therapy with inmunosupressors is not well known. There are reports of anti-NMDAR antibodies and other herpes virus group encephalitis but they are limited to single case reports.
Material and methods: Retrospective study of anti-NMDAR determined by IFI in neuronal tissues and transfected cells in 39 patients with suspected encephalitis from the Pediatric, adult Neurology and Emergency Departments, which had a positive PCR test for herpes virus not HHV1 (HHV2, VZV, EBV, CMV, HHV6 and HHV7) in CSF.
Results: Two patient tested were positive for anti-NMDAR antibodies in CSF, diagnosed of Handl Syndrome and glioblastoma multiforme and both of them infected by HHV7. Additional 6 patients showed fluorescence in synaptic button.
Conclusions: In addition to HHV1 encephalitis our series reinforce that anti-NMDAR can be present less frequently in other herpes virus infections, with a more complex antigenic pattern than non infectious encephalitis. The presence of fluorescence with nonspecific patterns in neuronal tissues may be due to antigens not described so far. Additional studies are needed in this regard to completely unravel their pathogenic and clinical importance.

P.D4.02.15

Bone marrow contains an expandable reservoir of poly-functional resident-memory CD8$^+$ T cells, which is dependent on IL-15 and Hobit, but not on local antigen recognition

M. Pascutti[1], *S. Geerman*[1], *N. Collins*[2], *G. Brasser*[1], *B. Nota*[3], *R. Stark*[1], *F. M. Behr*[1], *A. E. Oja*[1], *E. Slot*[1], *P. Hombrink*[1], *R. Arens*[4], *L. K. Mackay*[2], *K. P. van Gisbergen*[1], *M. A. Nolte*[1,3];
[1]*Department of Hematopoiesis, Sanquin Research, Amsterdam, Netherlands,* [2]*Department of Microbiology and Immunology, Peter Doherty Institute for Infection and Immunity, The University of Melbourne, Melbourne, Australia,* [3]*Department of Research Facilities, Sanquin Research, Amsterdam, Netherlands,* [4]*Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands.*

The bone marrow (BM) is a large reservoir of memory CD8$^+$ T cells, but it is not clear to what extent these cells belong to the circulatory pool. Using different models of viral and bacterial infections, immunization, cell transfer and parabiosis, we here demonstrate that the BM hosts a population of *bona fide* CD8$^+$ tissue-resident memory T cells (T_{RM}) cells that can develop independently of BM infection or local antigen presentation. BM CD8$^+$ T_{RM} share the transcriptional program of resident lymphoid cells in other tissues, are polyfunctional cytokine producers and depend on IL-15, Blimp-1 and Hobit for their maintenance. They also express a particular set of genes related to tissue remodeling and adhesion that might be induced by the BM environment. Unlike T_{RM} from other tissues, BM T_{RM} reside in the parenchyma, but are also in close connection to the blood stream, due to the high permeability of the BM vasculature. Remarkably, the pool of BM T_{RM} can expand after multiple immunizations with a particular antigen. When mice were sequentially challenged with two different pathogens, T_{RM} against the first pathogen were not deleted to make room for newly formed T_{RM} against the second challenge. These results indicate that BM contains, next to recirculating memory CD8$^+$ T cells, also a unique, functional and expandable pool of cells that take up residency in the tissue. As BM T_{RM} cells develop against numerous pathogens, independently on whether the BM is infected, these findings are highly relevant for successful development of protective vaccination strategies.

Several viral proteins have been shown to localize in subcellular specific compartments and interact with host molecules, producing changes in the spatial distribution of cellular proteins and inducing alterations in different signaling pathways. HCV Core protein have been described as modulator of biological functions as proliferation, apoptosis, cell cycle, oxidative stress and in CD4+ T lymphocytes, the presence of HCV Core protein induce a regulatory phenotype. Intending to elucidate the mechanisms underlying the cellular alterations caused by this viral protein, we have analyzed HCV Core subcellular localization and its associations with host proteins in Jurkat T cells. We performed immunogold electron microscopy techniques to analyze the subcellular localization of Core protein. Moreover, in order to identify proteins associated with HCV Core, in Jurkat T cells, we carried out pull-down assays combined with Mass Spectrometry Analysis. Thus, in this work, we show the ultrastructural localization of HCV Core in Jurkat T cells and the host molecular interaction networks associated to HCV Core protein.

P.D4.02.17

Early life cytomegalovirus infection

F. Stahl;
University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Congenital infection with cytomegalovirus (CMV) in newborns is the most frequent infectious cause of permanent disabilities. Currently, there is no established therapy available to prevent neonatal CMV disease. Although recognized as a global clinical problem, prenatal factors determining vertical virus transmission from mother to foetus are still unknown. Moreover, it remains poorly understood why most infected neonates remain asymptomatic whereas some show moderate or severe disease symptoms. Here, I aim to investigate factors that could increase the risk of prenatal CMV-infection and severity of neonatal CMV disease. Utilizing human samples in combination with a mouse model for congenital CMV infection I will determine the role of prenatal challenges and the anti-CMV T cell response of mother and child.
Using an established CMV mouse model, I will clarify if maternal stress and medication intake during pregnancy - challenges which are potentially avoidable - render the offspring more prone to develop a severe course of early life CMV infection. In depth characterisation of maternal and neonatal antigen-specific T cells will define their role in control of CMV infection during the early life phase. In summary, I intend to answer pending questions of CMV infection biology at the interface of reproduction, paediatrics, immunology, and virology that could lay the basis for new diagnostic or therapeutic approaches.

P.D4.02.18

Diagnostic potential of rKLO8 and rK28 in discriminating canine visceral leishmaniasis from *Leishmania* vaccinated dogs

*I. E. Pereira[1], L. M. Menegati[1], K. P. Silva[1], M. P. Araujo[2], U. Steinhoff[3], M. S. Duthie[4], **H. C. Teixeira**[1];*
[1]Federal University of Juiz de Fora, Juiz de Fora, Brazil, [2]Santo Agostinho Veterinary Hospital, Belo Horizonte, Brazil, [3]Philipps University of Marburg, Marburg, Germany, [4]Infectious Disease Research Institute, Seattle, United States.

Canine visceral leishmaniasis (CVL) is a major health issue in many tropical and sub-tropical countries and an accurate diagnosis still remains a challenge. The present study aimed to compare the diagnostic accuracy of rKLO8, a new antigenic kinesin-related protein of *Leishmania donovani*, and rK28, a recombinant fusion polyprotein comprising rK26, rK39 and rK9 in detecting CVL. IgG reactivity against *Leishmania braziliensis* whole antigen was also investigated. Sera samples from diseased dogs (CVL, n=44) and healthy endemic controls (EC, n=44) were evaluated for the presence of antigen-specific IgG, IgG1 and IgG2 antibodies by ELISA. The sensitivity and specificity of each ELISA was investigated by ROC curve analysis. Antigen-specific reactivity was also tested against sera from Leish-Tec®-vaccinated dogs. Enhanced levels of IgG and mainly IgG2 to both rKLO8 and rK28 were found in diseased dogs. The ELISAs using rKLO8 and rK28 showed a sensitivity of 77% and 84% for IgG and 78% and 88% for IgG2, respectively. A specificity of 94% for rKLO8 and 95% for rK28 was observed using IgG2 ELISA, and specificity of 100% for both antigens was observed using IgG ELISA. rK28 was the only antigen able to demonstrate differences between vaccinated and infected groups ($p < 0.001$), but showing no difference between vaccinated and control (EC) groups. These results indicate the usefulness of rKLO8 and rK28 in the serodiagnosis of CVL, and suggest that rK28 generates a more accurate diagnosis which can be applied to vaccinated dogs. Financial support: CNPq and FAPEMIG, Brazil.

Complement factor H family proteins associate with severity of bacterial infections in children

***A. E. van Beek**[1,2], N. A. Schweintzger[3], R. B. Pouw[1,2], D. S. Klobassa[3], M. C. Brouwer[1], J. Geissler[4], A. Biebl[5], M. Sagmeister[3], D. Wouters[1], W. Zenz[3], T. W. Kuijpers[2,4], the EUCLIDS consortium;*
[1]Department of Immunopathology, Sanquin Research and Landsteiner Laboratory of the Academic Medical Center, Amsterdam, Netherlands, [2]Departent of Pediatric Hematology, Immunology and Infectious Diseases, Emma Children's Hospital, Academic Medical Center, Amsterdam, Netherlands, [3]Department of General Pediatrics and Adolescent Medicine, Medical University of Graz, Graz, Austria, [4]Department of Blood Cell Research, Sanquin Research and Landsteiner Laboratory of the Academic Medical Center, Amsterdam, Netherlands, [5]Department of Pediatrics, Kepler University Clinic, Medical Faculty of the Johannes Kepler University, Linz, Austria.

Introduction: Complement is part of the innate immune defense against invading pathogens. Concurrent protection from complement is acquired by Factor H (FH), although this protection is thought to be inhibited by FH-related proteins (FHRs). As pathogens recruit FH from human plasma as escape mechanism to increase survival in blood, binding of FHRs instead of FH might prove beneficial for clearing an infection. However, little is known about the plasma levels of these FH family proteins during invasive bacterial infections.
Methods: We included pediatric patients with acute invasive bacterial infections as part of the EUCLIDS study, together with age-matched healthy controls. In-house ELISAs were used to determine FH and FHR plasma levels.
Results: FH levels were low during the acute phase and associated strongly with severity. Similarly, FHR-2 and FHR-4A levels were low in the most severe patients. In contrast, FHR-5 levels were elevated during the acute phase, irrespective of severity or causative microbe, although levels were generally low in patients who suffered from meningococcal disease.
Conclusions: Our study shows that plasma levels of FH family proteins associate with severity of invasive bacterial infections in children. Moreover, we found indications for a novel role for FHR-5 as acute phase protein. Functional in vitro experiments will be needed to further clarify the role of FHR-5. These results highlight a yet unknown role for the FHR proteins in infectious diseases. A better insight into their level and function during invasive infections will help to improve critical care for pediatric patients.

P.D4.02.20

Respiratory Syncytial Virus directly infects natural killer cells and affects anti-viral effector functions

***E. A. van Erp**[1,2], D. Feyaerts[2], M. Duijst[1], L. H. Mulder[1], O. Wicht[1], W. Luytjes[1], G. Ferwerda[2], P. B. van Kasteren[1];*
[1]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [2]Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands.

Respiratory syncytial virus (RSV) infection can lead to severe respiratory illness and is the main cause of hospitalization in infants under 1 year of age. No vaccines or antivirals are currently available and the determinants of severe disease remain elusive. Natural killer (NK) cells are important effector cells in the anti-viral immune response and likely form a critical component of the early response against RSV infection. NK cells that are recruited to the lung during RSV infection encounter the virus in the presence of (maternal) antibodies. We investigated whether RSV and RSV-antibody complexes affect NK cell functionality, since these cells potentially contribute to immunopathology. We demonstrate for the first time that RSV can directly infect adult and neonatal NK cells. Incubation of RSV with sub-neutralizing antibody concentrations significantly increased the percentage of infected NK cells, and this increase was FcγRIII/CD16 dependent. Upon infection, large numbers of NK cells produced IFN-γ, but this was not accompanied by enhanced killing capacity, as evidenced by the percentage of perforin-secreting cells. RSV-infected NK cells therefore appear geared towards a pro-inflammatory rather than a cytotoxic response. Our findings show that RSV can affect NK cell functionality, an effect that is enhanced in the presence of sub-neutralizing antibody concentrations. Considering that most vaccines that are currently being developed aim at inducing (maternal) antibodies against RSV, it is extremely important to have a good understanding of the possible interactions between innate immune effector cells and virus-specific antibodies and their role in the development of (severe) RSV disease.

P.D4.03 Exploiting host pathogen interaction - Part 3

P.D4.03.01

Characterisation of the effects of interleukin-17A (IL-17A) on toll-like receptor 3 (TLR3)-function and its role in accelerating disease progression in human idiopathic pulmonary fibrosis (IPF)

***M. E. Armstrong**[1], L. Bergin[1], A. N. McElroy[1], G. Cooke[2], P. G. Fallon[1], C. M. Hogaboam[3], N. Hirani[4], S. C. Donnelly[5];*
[1]Trinity Biomedical Sciences Institute, Dublin 2, Ireland, [2]Institute of Technology Tallaght, Dublin 24, Ireland, [3]Cedar-Sinai Medical Centre, Los Angeles, United States, [4]University of Edinburgh, Edinburgh, United Kingdom, [5]Trinity Centre for Health Sciences, Tallaght Hospital, Dublin 24, Ireland.

Introduction: In this study, we investigated the ability of IL-17A to modulate TLR3 function in primary lung fibroblasts from patients with idiopathic pulmonary fibrosis (IPF). Using a case-control study, we also investigated the role of the IL-17A promoter-polymorphism, *IL-17A* G197A (rs2275914) in the development of IPF. Previously, our laboratory demonstrated that defective TLR3 function was associated with a significantly greater risk of mortality and an accelerated rate of decline in lung function, in IPF patients (*AJRCCM*; 188(12):1442-50). We additionally detected increased levels of IL-17A in bronchoalveolar lavage fluid and lung tissue from IPF patients (*PNAS; 111(1):367-72*). Materials and Methods: Primary human lung fibroblasts from IPF patients were treated with Poly(I:C) in the presence or absence of IL-17A. Cytokine, chemokine and type I interferon levels in IPF fibroblasts were determined by ELISA and qPCR, respectively. Patients with IPF were additionally genotyped for the *IL-17A G197A* polymorphism. Results: We established that IL-17A can modulate TLR3-function in IPF lung fibroblasts in order to reduce production of the anti-viral mediators, IFN-β and RANTES. Concomitantly, IL-17A can also synergistically increase TLR3-induced IL-8 from IPF lung fibroblasts. Using a case-control study for IPF, we also demonstrated that individuals who are homozygous for the variant A allele of the *IL-17A* G197A-promoter polymorphism, are significantly more at risk of developing IPF. Conclusions: These results support a novel role for IL-17A in promoting disease progression in IPF via its modulation of TLR3 function in IPF fibroblasts. In addition, this study reveals *IL-17A* G197A as a candidate biomarker in IPF.

P.D4.03.02

In silico identification of *Taenia solium* excretory secretory protein and it's suppressive activity for PI3K/AKT pathway

***N. Arora**, A. Prasad;*
Indian Institute of Technology Mandi, Mandi, Himachal Pradesh, India.

Objective: *Taenia solium* is a parasitic infection of central nervous system, causing neurocysticercosis (NCC). Parasite secretome products modulate host immune response. To understand the cross talk between parasite and human host, excretory secretory (ES)-proteins make up for a suitable target. The objective was to predict *T. solium* ES Protein related with AKT pathway and validate it with LC- MS and wet lab tools. Material & Methods: Cysts were isolated from infected swine and cultured for 24Hrs. The ES-proteins (30ug) was prepared for LC-MS analysis by in-gel tryptic digestion and the protein spectra obtained was annotated. Simultaneously, in silico *T. solium* ES-proteins were predicted using tools TargetP, SignalP, SecretomeP and THMM. Blast2GO was used to perform BlastP, protein annotation and KEGG mapping. After comparing the LC-MS and predicted annotations, PI3K regulatory subunit was identified in both the data sets and investigated the activation of AKT-pathway in response to ES- proteins treatment on human primary macrophages. Results: The *T. solium* proteome consist of ~12000 proteins, ~1000 were predicted as ES-proteins and 355 mapped to global metabolic pathways of which 8 were related with PI3K pathway. LC-MS analysis of in-vitro cultured ES-protein annotated 307 proteins and two were related with PI3K regulation. The cells treated with ES proteins had significantly less activation of pAKT compared to untreated cells. Conclusion: ES proteins are important for immune modulation of host by *T. solium*, and ES-proteins target PI3K/AKT pathway by down regulating it and thus suppressing the immune response.

P.D4.03.03

IMPACT OF ART ON DYNAMICS OF GROWTH FACTORS AND CYTOKINES IN PRIMARY HIV INFECTION

***V. Bordoni**, A. Sacchi, R. Casetti, E. Cimini, C. Pinnetti, A. Mondi, A. Ammassari, A. Antinori, C. Agrati;*
INMI L.Spallanzani, Rome, Italy.

Antiretroviral treatment (ART) of Primary HIV Infection (PHI) has demonstrated virological and immunological benefits. The effect of early ART during PHI on the level of growth factors and chemokines modulating immune cell functions remain to be established. The aim of our work was to analyze the dynamics of 27 cytokines (pro-inflammatory, Th1, Th2), chemokines (IL-8, CCL27, CXCL9, MCP-1, MIP-1b, RANTES) and growth/regulation factors (TRAIL, SCF, SCGF-b, HGF, M-CSF, G-CSF, GM-CSF, LIF) in plasma of HIV infected patients treated during PHI.Patients with PHI (n=43) were enrolled before, 24 and 48 weeks after therapy initiation. Quantification of soluble immune mediators described above was evaluated in HIV infected patients and healthy donors (HD, n=9) by Luminex technology . The cytokines profile was strongly perturbed in primary HIV infected patients when compared to HD. After 48 weeks of ART, some of these factors were restored to HD level (IL-7, IL-9, LIF) while others persisted higher than HD (IL-6, IL-10, G-CSF). Interestingly, a subset of chemokines, such as MCP-1, IL-8, MIP-1b, RANTES and CCL27, as well growth factors such as HGF, SCF and GM-CSF, increased during ART reaching values significantly higher than HD after 48 weeks. The increase of chemokines with antiviral activity and of growth factors with hematopoietic and immunomodulatory properties may have a beneficial effect. Other studies are mandatory to evaluate the long lasting levels of these factors to clarify their possible role in the context of protection/pathogenesis.

P.D4.03.04

Stimulation of MAC-inhibitory protein (CD59) but no complement decay-accelerating factor (CD55) induces release of neutrophil extracellular trap (NETs)

***O. Ciepiela**, W. Bystrzycka, J. Holka, P. Tarnowska, A. Manda-Handzlik, M. Wachowska;*
Medical University of Warsaw, Warsaw, Poland.

Introduction: MAC-inhibitory protein, also known as CD59 is a membrane inhibitor of reactive lysis found on cell surface of leukocytes and erythrocytes. When complement activation leads to deposition of C5b678 on host cells, CD59 can prevent C9 from polymerizing and forming the complement membrane attack complex. CD55 recognizes C4b and C3b fragments that are created during activation of C4 (classical or lectin pathway) or C3 (alternative pathway) thus indirectly blocks the formation of the membrane attack complex. CD59 and CD55 attach to host cells via a glycophosphatidylinositol (GPI) anchor. A mutation of PIG-A gene, which leads to deficiency of GPI, is found in patient with paroxysmal nocturnal hemoglobinuria. The aim of the study was to establish, if release of neutrophil extracellular traps might be dependent on CD59 or CD55 activation. Materials and methods: Neutrophils were isolated from the blood of healthy donors. Cells were obtained by density gradient centrifugation and subsequent polyvinyl alcohol sedimentation of erythrocytes. Subsequently, neutrophils were incubated with human antiCD59 or antiCD55 monoclonal antibody and 100 nM PMA was added to stimulate NETs release. The process of NETs release was assessed 3h post stimulation by fluorescent microscopy and fluorometry. Results: Anti-CD59 antibody induced NETs release in a concentration-dependent manner, with the highest release at 0.25 - 1.25 µg/ml. Fluorescent microscopy confirmed results of quantification method. None of studied anti-CD55 monoclonal antibody concentration lead to release of NETs. Conclusion: Neutrophil extracellular traps release is dependent on activity of GPI-anchored proteins which regulates complement activation pathway.

P.D4.03.05

The role of Fas/FasL receptors in pathogenesis of the inflammation of the nervous system induced by HSV-1 and 2 infection

***M. Krzyzowska**[1], A. Kowalczyk[1], K. Eriksson[2];*
[1]Wroclaw Research Centre EIT+, Wroclaw, Poland, [2]University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden.

Introduction. The aim of this project was to determine the role of Fas/FasL receptor signalling in pathogenesis of the inflammatory lesions occurring during herpes simplex virus type 1 and 2 (HSV-1/2) infection of the central and peripheral nervous system. Materials and methods. In vitro models consisted of mixed glial culture, primary micgroglia culture obtained from C57BL6 mice. In vivo studies used intranasal model of C57BL6 mice infected with HSV-1 McKrae strain, and genital model of C57BL6 mice infected with HSV-2 333 strain. Apoptosis, Fas and FasL expression and phenotype of immune competent cells were accessed using confocal microscopy and flow cytometry. Results. Upon HSV-1 or HSV-2infection, microglia underwent early apoptosis and up-regulated FasL expression, while HSV-1/2 infected astrocytes also up-regulated FasL and were resistant apoptosis. Both microglia and astocytes were resistant to Fas-induced apoptosis. However, Fas- stimulated microglia became M1-type cells and switched the profile of produced cytokines. In vivo, FasL expression was detected on astrocytes surrounding infected sites in spinal cord (HSV-2) and brain (HSV-1) as well as on microglia within glia limitans and infected neuronal tissue. Fas positive cells were mostly infiltrating lymphoidal cells. Conclusion. We found that there is a correlation between HSV infection and reaction of cells to Fas/FasL induced apoptosis. Fas/FasL signalling can participate both in direct elimination of HSV infection, but also in a complex regulation of the local inflammatory response and mounting of the specific anti-viral response through non-apoptotic signalling. This work was supported by 2015/18/M/NZ6/00414 grant.

P.D4.03.06

Lack of Polyfunctional Cytomegalovirus-specific T cells in Hemodialysis Patients

***F. Lay**[1], K. Shu[1], I. Chen[1], J. Chia[2], Y. Chiu[1,2];*
[1]Far Eastern Memorial Hospital, New Taipei City, Taiwan, [2]National Taiwan University, Taipei, Taiwan.

Background: Polyfunctional T cells are critical for maintaining protection against pathogens. Patients with end-stage renal disease (ESRD) are at increased risks for infectious complications and their T cell immunity against viruses may be impaired. The current study intends to investigate T cell immunity in ESRD patients by analyzing T cell differentiation and polyfunctionality against cytomegalovirus (CMV), an ubiquitous pathogen. Method: 21 healthy individuals, 13 patients with chronic kidney disease (CKD) and 47 ESRD patients were enrolled in this study. All donors were seropositive for CMV.
Two CMV peptide pools (IE1 and pp65) were used to stimulate PBMCs and four effector functions were measured by multicolor flow cytometry (IL-2, TNFα, IFNγ and CD107a) to identify polyfunctional cells. Result: Age of the three groups was similar (mean, 60 years old). Patients with renal disease, especially ESRD patients, showed increase levels of T cell differentiation, including the increase in $CD4^+$ and $CD8^+$ TEM and TEMRA cells. While the cellular frequencies of CMV-reactive $CD4^+$and $CD8^+$T cell were comparable, polyfunctionality were dramatically reduced in ESRD. Among healthy individuals, CKD and ESRD patients, CD4+ CMV-IE1-reactive polyfunctional cell frequencies were 2.0%, 2.2% and 0%, respectively (p=0.002). CD8+ CMV-pp65-reactive polyfunctional cell frequencies were 12.4%, 8.8% and 0.8% in the three groups (p<0.001). The impairment of polyfunctionality correlated with increased PD-1 expression. Conclusion: ESRD patients are characterized by the loss of polyfunctional, CMV-specific T cells and increased PD-1 expression. Whether impaired CMV-specific polyfunctionality could be reversed by PD-1 blockade requires further study.

P.D4.03.07

Crosstalk of autophagy and reactive oxygen species synthesis in reactive nitrogen species-induced neutrophil extracellular traps formation

***A. Manda-Handzlik**[1,2], M. Wachowska[1], W. Bystrzycka[1,2], O. Ciepiela[1], U. Demkow[1];*
[1]Medical University of Warsaw, Warsaw, Poland, [2]Postgraduate School of Molecular Medicine, Medical University of Warsaw, Warsaw, Poland.

Autophagy is a natural, self-degradative process which regulates neutrophil antimicrobial functions. One of the neutrophils' antimicrobial strategies is the formation of neutrophil extracellular traps (NETs). Although mechanisms of NETs formation are extensively studied, some aspects of this process, e.g. the role of reactive nitrogen species (RNS), remain poorly understood. Our aim was to investigate RNS as NETs stimuli and to identify the role of autophagy in this process.
Human blood neutrophils were stimulated with nitric oxide (NO) donor - SNAP (S-Nitroso-N-acetylpenicillamine), peroxynitrite or phorbol 12- myristate 13-acetate (PMA). NETs release and the synthesis of reactive oxygen species (ROS) were assessed by fluorometry and fluorescent or light microscopy. Autophagy was analyzed by western blotting as accumulation of LC3-II protein.
We found that contrary to PMA, RNS stimulate NETs release without accumulation of LC3-II. Inhibitors of class III PI3 kinases (3-methyladenine, 3-MA, and wortmannin, used as inhibitors of autophagy), but not inhibitors of the autolysosome formation, drastically reduced NETs formation upon RNS treatment. RNS only slightly increased ROS production by neutrophils, but 3-MA and wortmannin significantly decreased ROS production by RNS-stimulated neutrophils. Finally, we found that activity of NADPH oxidase was necessary for SNAP-induced NETs release and contributed to peroxynitrite-induced NETs formation.
We conclude that RNS efficiently stimulate NETs formation and PI3K activity, but not autophagic flux, is necessary for this process. PI3K influences NETs formation via regulation of NADPH oxidase activity.

Functional roles of atypical IkB family members in macrophages

A. Matthies[1,2]*, K. Katsoulis-Dimitriou*[1,2]*, C. Plaza-Sirvent*[1,2]*, I. Schmitz*[1,2]*;*
[1]*Helmholtz Centre for Infection Research, Braunschweig, Germany,* [2]*Otto von Guericke-University, Magdeburg, Germany.*

The activation of the transcription factor NF-κB is regulated by inhibitor of NF-κB proteins (IκB proteins), which include not only classical cytoplasmic proteins such as IκBα, but also atypical nuclear proteins such as Bcl-3, IκBζ and $I\kappa B_{NS}$. Notably, the functions of the atypical IκB proteins in macrophages as well as their interactions remain poorly understood. To address this, we tested whether the atypical IκB proteins Bcl-3, IκBζ and $I\kappa B_{NS}$ in macrophages exhibit interdependent regulation of their expression and function. Our results showed that the atypical IκB proteins are expressed in primary bone-marrow-derived macrophages by Toll-like agonist with different kinetics. Interestingly, following LPS stimulation of RAW 264.7 macrophages, IκBζ and $I\kappa B_{NS}$ are upregulated early on, whereas Bcl-3 is upregulated at later time points. To analyze the functional relevance of IκB expression in macrophages, we infected wildtype and IκB-deficient macrophages with GFP-expressing *Staphylococcus aureus in vitro*. In preliminary experiments, we detected no alterations of intracellular bacteria in IκB-deficient macrophages compared to wildtype controls suggesting that IκB deficiency does not affect the phagocytosis capacity of macrophages. Furthermore, we found no difference in proliferation of intracellular *S. aureus* of IκB-deficient macrophages revealing that IκB deficiency does not alter the killing activity of macrophages. To extend this analysis also in *in vivo* experiments, we generated LysM-Cre,$I\kappa B_{NS}^{flox/flox}$ mice that lack $I\kappa B_{NS}$ specifically in macrophages and neutrophils. An initial immune phenotyping revealed no alterations in frequencies or absolute numbers of macrophages, neutrophils and dendritic cells suggesting that $I\kappa B_{NS}$ is dispensable for the development of these cells.

P.D4.03.09

Modulation of T-cell cytokine profiles by (killer) B-cells during Tuberculosis disease

D. K. Moore*, I. C. Van Rensburg, A. G. Loxton;*
Stellenbosch University, Cape Town, South Africa.

Rationale: Emerging evidence has implicated B-cells as important players in the defense against *Mycobacterium tuberculosis*. This study aimed to identify potential mechanisms by which B-cells may modulate T-cell functioning, as they have been regarded as the main immune cells involved in eradicating TB disease. **Method:** T-cells were cultured with BCG-exposed or naive B cells that had been pulsed with or without CD40L and IL5, to induce a regulatory B-cell subtype. These killer B_{regs} cell function in TB disease is still unclear. **Results:** Killer B_{reg} frequencies are elevated in Mtb unexposed healthy individuals when compared to healthy exposed individuals, however this difference was not significant but similar to studies that have found an increase in killer B_{reg} frequencies following successful TB treatment. This suggests a role of B-cells in protective immune responses to TB disease. An increase in the frequency of effector T-cells, although non-significant, was observed in healthy Mtb exposed individuals following cultured with unstimulated B-cells and a decrease following culture with BCG-stimulated B-cells. This may imply a role of B-cells in T-cell functioning through regulation of phenotypic frequencies. Finally, B-cells that were CD40L/IL-5 pulsed or not induced cytokine production by both CD4 and CD8 T-cells in healthy exposed and unexposed individuals. However, these alterations in cytokine profiles were not significant. **Conclusion:** B-cells and killer B_{regs} influence T-cell behavior by modulating phenotype development and cytokine secretion. These results suggest a key role of B_{regs} in initiating and guiding the immune response against Mtb.

P.D4.03.10

Multiparameter analysis of association between host immune reactivity and pulmonary tuberculosis activity

I. Y. Nikitina*, A. V. Panteleev, T. A. Nenasheva, T. R. Bagdasarian, V. A. Shorokhova, R. B. Amansahedov, I. V. Lyadova;*
Central Tuberculosis Research Institute, Moscow, Russian Federation.

Tuberculosis (TB) is a highly heterogeneous infectious disease characterized by different outcomes. Both impaired and exacerbated immune responses contribute to TB pathogenesis. However, the exact role of immunological hypo- and hyper-reactivity in TB pathology and their biomarkers are unknown. Here we analyzed how various indicators of innate and adaptive immunity are associated with TB severity.
Sixty four TB patients (TBP) and 28 healthy contacts (HC) were included in the study. In each participant, we performed QuantiFERON-TB Gold Plus assay and analyzed 46 immune factors in serum and antigen-induced plasma using xMAP multiplex assay. In TBP, the degree of pulmonary destruction, TB extent, systemic intoxication and bacteria excretion were accurately evaluated.
TBP and HC could be well discriminated based on the levels of IL-2, IFN-γ, IP-10 and IL-8 in antigen-induced plasma ($p<0.005$) and GM-CSF in serum ($p<0.0001$). Analysis of immunological analytes in antigen-induced plasma of TBP identified 14 factors that discriminated TBP into immunologically “hypo-” and “hyper-reactive” groups. The factors included type I and III interferons, members of IL-10 and IL-12 cytokine superfamilies. Based on the level of IP-10 in serum, TBP clustered into other two groups. High IP-10 levels (>730 pg/ml) were indicative of severe pulmonary destruction ($p<0.05$) and predicted its slow/unfavorable dynamics.
In conclusion, we identified factors that discriminated TBP into groups with high and low immune reactivity, which may be helpful for personalized implementation of pathogenetic therapy. IP-10 can serve as a candidate biomarker of TB infection activity and patients’ responsiveness to anti-TB treatment.

Evaluation of interferon-gamma role during zika virus murine experimental infection

C. M. Polonio*, N. Zanluqui, L. Oliveira, C. Longo, J. Peron;*
Neuroimmune Interactions Laboratory - Department of Immunology - University of São Paulo, São Paulo, Brazil.

The flavivirus Zika (ZIKV) was recently introduced in Brazil causing an alarming increase of babies born with microcephaly. Genetic differences, mainly related to Interferons (IFN), may greatly influence the susceptibility to infection. IFNs are classified in Type I – III, a major cytokine family involved in antiviral and anti-tumoral immune response. IFN-γ is a Type II IFN mainly produced by T lymphocytes and NK cells. Interestingly it is known that during DENV infection, also a flavivirus, IFN-γ-dependent mechanisms were associated with DENV resistance. Thus, we evaluated the IFN-γ role during ZIKV infection. We infected WT and IFN-$\gamma^{-/-}$ C57BL/6 mice with $1x10^2$ PFU intravenously and analyses were performed 1 and 3 days post infection. Our results demonstrated an important role of the IFN-γ in suppressing ZIKV infection, since IFN-$\gamma^{-/-}$ mice had higher viral load at spleen 1 and 3 days post infection when compared to controls.
In addition, we observed an increase in type I IFN cytokines production on the first day of infection in the WT mice, followed by a decrease, unlike the deficient animals, which production peaked on day 3. Interestingly, the same was observed for the expression of the IRF7 and IRF9 transcription factors, as well as for interferon-induced gene expression. Taken together, our data demonstrate the importance of the IFN-γ cytokine during the initial antiviral response against ZIKV, as the expression of factors responsible for this response were somehow delayed.

Taenia solium **cyst’s excretory/secretory (ES) proteins suppress Th1 immune response in human macrophages**

A. Prasad*, N. Arora;*
School of Basic Sciences, Indian Institute of Technology Mandi, Mandi, HP, India.

Objective: Larvae of *Taenia solium*cause Neurocysticercosis (NCC), which is most widespread cause of acquired epilepsy in developing countries. Excretory/secretory (ES) proteins released by larvae of *T. solium* are crucial for parasite survival and represent potential targets for novel intervention strategies. The current study was carried out to immune characterise ES proteins of *T. solium*. **Method**: Cysts were isolated from naturally infected pork muscles and cultured in RPMI-1640 complete media for 24 hours. ES proteins were characterized by silver staining, 1D-NMR, LC-MS spectroscopy and enzyme electro immune transfer blot (EITB) with NCC patients serum. Human macrophages isolated from buffy coat were stimulated with the ES proteins for 24hrs to look for their immune cell stimulating capabilities. **Results**: NMR spectra showed a number of metabolites being excreted by the cyst. We identified several bands of <50kDa on EITB. LC-MS analysis of in vitro cultured ES protein annotated 307 proteins and two were related with PI3K regulation.QPCR and ELISA had shown significantly low IL6, IL1βand enhanced IL4 cytokines expression. **Conclusion**: The ES proteins of *T. solium*suppress the Th1 immune response and help in parasite survival in host.

Complement factor H-related protein 1 impairs factor H acquisition during complement evasion by the malaria parasite *Plasmodium falciparum*

T. Reiß[1], *T. F. Rosa*[1], *R. P. Bobbert*[1], *P. F. Zipfel*[2], *C. Skerka*[2], *G. Pradel*[1];
[1]*RWTH Aachen University, Aachen, Germany,* [2]*Hans-Knöll-Institute, Jena, Germany.*

Human complement is the first defense line against invading pathogens, including the unicellular malaria parasite *Plasmodium falciparum*. We previously demonstrated that human complement represents a particular threat for the clinically relevant blood stages of the parasite. To evade complement-mediated destruction, these acquire factor H (FH) via specific receptors, resulting in inactivation of complement factor C3b. We now report that the FH-related protein FHR-1 competes with FH for binding to the malaria parasite. FHR-1, which is composed of five short consensus repeat domains with variable homology to FH but which lacks the C3b regulatory activity, accumulates on the surfaces of the intraerythrocytic schizonts as well as of free merozoites. While binding of FH to schizont-infected red blood cells is increased in FHR-1-deficient human serum, the addition of recombinant FHR-1 decreases FH-binding and in consequence parasite viability. We conclude that FHR-1 acts as a modulator of human immunity by counteracting FH-mediated microbial complement evasion.
This work was funded by grants PR905/8-2 and PR905/12-1 of the Deutsche Forschungsgemeinschaft (to GP and CS). TFAR received a fellowship from the Science without Borders Foundation Programme CAPES.

P.D4.03.14

Immune regulation by myeloid cells leads to protection of *Plasmodium berghei* ANKA-infected Ifnar ko mice from experimental cerebral malaria

P. J. Korir[1], *L. M. Jenster*[1], *J. M. Kuepper*[1], *J. F. Scheunemann*[1], *J. J. Reichwald*[1], *A. Mueller*[2], *A. Hoerauf*[1,3], *D. R. Engel*[4], ***B. Schumak***[1];

Inflammatory responses aim at pathogen elimination but need tight control as excessive immune activation can cause severe host-induced pathology. Cerebral malaria is a fatal complication of Plasmodium ssp. infection and an important example for overwhelming Th1-driven inflammation. This disease can be studied with the help of experimental models. Whereas wildtype (WT) mice develop experimental cerebral malaria (ECM) upon infection with *Plasmodium berghei* ANKA (PbA), transgenic mice that lack type I interferon receptor (*Ifnar*) dependent signalling are protected from ECM. Using transgenic *Plasmodium berghei* ANKA parasites expressing ovalbumin (PbA-OVA), we show that ECM-protected IFNAR ko mice did not differ in their antigen-specific cytotoxic T cell responses compared to infected WT mice suffering from ECM. Importantly, spleens of ECM-negative *Ifnar1*$^{-/-}$ mice but not of ECM-positive WT mice contained increased numbers of both CD8^{+}T cells and distinct myeloid cells, including M2 macrophages, confirmed by expression of typical markers such as RELMα and YM1 as well as their function shown by elevated arginase activity. Furthermore, *in vitro* coculture experiments demonstrated that individual myeloid cells derived from bone marrow were capable to exhibit suppressive capacities. We conclude that type I IFN signalling is not required for the generation of antigen-specific T cells in *PbA*-infected *Ifnar1*$^{-/-}$ mice but its lack rather results in the successful induction of immune regulatory pathways driven by myeloid cells that control CD8 T cells resulting in protection from ECM.

P.D4.03.15

Combined IL17 and IL22 secretion profile characterizes the efficacy of MTB response

Y. Todorova[1], *R. Emilova*[1], *V. Milanov*[2], *M. Zamfirova*[3], *T. Varleva*[3], *M. Nikolova*[1];
[1]*National Reference Laboratory of Immunology, National Centre of Infectious and Parasitic Diseases, Sofia, Bulgaria,* [2]*Clinic of Phthisiatry, Multiprofile Hospital for Active Treatment of Lung Diseases "St. Sofia", Sofia, Bulgaria,* [3]*Programme "Improving the sustainability of the National Tuberculosis Programme", Ministry of Health, Sofia, Bulgaria.*

Tuberculosis remains a major cause of death and morbidity worldwide. Current interferon-γ release assays for diagnosis of MTB infection do not predict its clinical course and the need of specific therapy. The mechanisms of protective MTB-specific immune response have not been clarified. IL-17 and IL-22 were pointed out as key players, but data from human studies remain contradictory. Aim: To characterize IL-17 and IL-22 secretion profiles in subjects with different efficacy of MTB-specific immune response. Materials and methods:Peripheral blood samples from: A.QFT(-) healthcare workers in intensive contact with MTB (n=11); B.QFT(+)healthy persons (LTBI, n=21), C.QFT(+) active TB patients (ATB, n=12) were analyzed. IL-17 and IL-22 production was determined after 18h stimulation with phytohemagglutinin (A-C) or CD4- and CD8-specific MTB peptides (Quiagen) (B,C) by ELISA (Affymetrix, eBioscience). Results: Non-specific stimulation revealed significantly decreased IL-17 and IL-22 secretion potential in ATB as compared to individuals with efficient response to MTB (A,B): (mean pg/ml): 71vs.204 and 190 ($p<0.05$), and 272vs.719 and 1027 ($p<0.05$). Efficient containment of MTB in LTBI was associated with domination of IL-17+ and IL-22+CD8 T while increase of IL-17+CD4 and decrease of IL-22+CD8 was observed in ATB. Finally, high level of MTB- stimulated IFN-γ (>5 IU/ml) in LTBI was combined with significantly increased level of CD8 IL-22+ MTB-specific CD8 (162vs.77, $p<0.05$). Our data suggest that while both IL-17 and IL-22-CD8 T are engaged in the protective response to MTB, the level of IL-22+CD8 may be determinant for containment of latent infection. Supported by research grant No13-1/14.12.2017, Bulgarian National Science Fund.

P.D4.03.16

Effect of probiotics on cytokines gene expression in gingival epithelial cells challenged with *Porphyromonas gingivalis*

G. C. Vale[1,2], *E. S. Ando-Suguimoto*[1], *E. Albuquerque-Souza*[1], *M. P. Mayer*[1];
[1]*University of São Paulo, São Paulo, Brazil,* [2]*Federal University of Piauí, Teresina, Brazil.*

Although there is a vast amount of data supporting the pivotal role for cytokines in mediating the host response to periodontal pathogens and the associated tissue damage, literature is scarce regarding the mechanisms underlying the beneficial effect of probiotics. Thus, this study aimed to evaluate the effect of probiotics on gene expression of cytokines by gingival epithelial cells (GECs) challenged with *P. gingivalis.* OBA-9 GECs (~2,5x 10^5cells/well) were challenged with *P. gingivalis* strain (W83 or ATCC 33277) and co-infected with two tested probiotic strains (*L. rhamnosus* and *L. acidophilus*) at a multiplicity of infection (MOI) of 1:1,000 for 2h. OBA-9 viability was measured by trypan blue exclusion assay. Levels of gene expression encoding cytokines (IL-1β, IL-8, IL-6, IL-18, TNFα) were evaluated by RT-qPCR. *P. gingivalis* challenge with both strains resulted in a significant loss of OBA-09 cells viability, which was partially reversed by the use of both probiotics. *P. gingivalis* W83 or ATCC 33277 promoted an increase in the transcription of pro-IL1-β, IL-8, and TNFα when compared to control no infected cells (OBA). The addition of both probiotics to *P. gingivalis* challenged cells resulted in decreased production of IL-1β and TNFα. Furthermore, challenged OBA-9 cells showed decreased expression of IL-18, which was further decreased by co-infection with the probiotics. Overall, the two probiotics have induced an altered cytokines expression profile, regarding the transcription of other inflammatory mediators such as IL-6 and IL-8. In conclusion, the probiotics tested seems to have a direct immunomodulatory effect on gingival epithelial cells.

P.D4.03.17

CD300a expression on T lymphocytes from naïve HIV-1 infected patients for cART is associated to good prognosis and a higher polyfunctional HIV-specific CD8+ T cell response

J. Vitallé[1], *I. Terrén*[1], *L. Gamboa*[1], *A. Orrantia*[1], *L. Tarancón-Díez*[2], *M. Genebat*[2], *E. Ruiz-Mateos*[2], *M. Leal*[2], *S. García-Obregón*[1], *O. Zenarruzabeitia*[1], *F. Borrego*[1,3,4];

CD300a inhibitory receptor, in healthy donors, is differentially expressed on CD8+ and CD4+ T cell subsets. CD300a expression identifies a population that is highly polyfunctional on Th1 cells and it has been related to a higher cytotoxic capacity on CD8+ T lymphocytes. Importantly, this receptor is known to be involved in viral mechanisms to enter host cells and to escape from immune system attack. In this study, we observed a differential expression of CD300a on CD8+ and CD4+ T cell subsets from naïve chronically HIV-1 infected patients for combined antiretroviral treatment (cART) and patients on suppressive cART, in comparison with healthy donors. Moreover, we found a negative correlation of CD300a expression on T cells with markers of HIV-1 infection progression, only in untreated patients. Finally, we stimulated CD8+ T lymphocytes from naïve patients for cART with a pool of HIV-1 peptides during 6 hours and we measured the degranulation (CD107a) and the IFNγ, TNFα and MIP-1β production. We observed a higher polyfunctional HIV-specific response in cells expressing CD300a than in cells negative for the receptor. Our results suggest that CD300a could have an important role on T cell regulation during chronic HIV-1 infection and reveal the potential applicability of this molecule as a biomarker for the prognosis of these patients. IL-18, IL-18BP, IL-37 and IP-10 levels in severe and non-severe cases of pulmonary tuberculosis (TB)

S. Wawrocki[1], *G. Kielnierowski*[2], *M. Druszczynska*[1];
[1]*Division of Cellular Immunology, Department of Immunology and Infectious Biology, Faculty of Biology and Environmental Protection, University of Lodz, Lodz, Poland,* [2]*Regional Center Hospital for Tuberculosis Lung Diseases and Rehabilitation in Tuszyn, Tuszyn, Poland.*

Introduction: The identification of improved markers of pulmonary TB severity has been recognized as a key research area. The development of active TB depends on the strength of immune-driven mechanisms involving the chain of multiple cytokines and chemokines including interleukin 18 (IL-18), IL-18 binding protein (IL-18BP), IL-37 and Interferon γ-induced protein 10 (IP-10). Aim: The aim of the study was to compare the serum and *M.tb* -stimulated whole blood levels of IL-18, IL-18BP, IL-37 and IP-10 in pulmonary TB patients with different disease severity.

Materials and Methods: Serum and *M.tb*-stimulated whole blood cultures were obtained from 95 adult individuals with active pulmonary TB classified into two groups according to the extent and type of chest radiograph findings. The studied proteins in sera and plasma were determined immunoenzymatically (DuoSet®ELISA, R&D). Results: The results showed the similar levels of IL-18, IL-37 and IP-10 in patients with severe and non-severe forms of TB. Significantly higher levels of IL-18BP in *M.tb*-stimulated cultures of blood from severe TB cases compared with non-severe patients were noticed (p=0,04). The levels of IL-18BP were correlated with the concentration of IL-18 in such cultures . Severe TB cases were characterized by increased ratio of IL-18BP/IL-37 and IL-18/IL-37 in serum as well as IL-18BP/IL-37 and IL18BP/free IL-18 in *M.tb*-stimulated cultures. Conclusion: The ratio of IL18BP/IL-37 measured in both serum and M.tb-stimulated cultures may serve for distinguishing severe TB forms from non-severe. This work was supported by the National Science Centre Grant no. 2015/19/N/NZ6/01385 and 2016/21/B/NZ7/01771.

P.D4.04 Exploiting host pathogen interaction - Part 4

P.D4.04.01

The translation elongation factor-1 alpha (Tef1) of *Candida albicans* modulates mouse CD4+ T cell responses *in vitro*

K. Alberter[1], *P. Dasari*[2], *P. Zipfel*[3], *N. Beyersdorf*[1];
[1]*University of Würzburg, Institute for Virology and Immunobiology, Würzburg, Germany,* [2]*Institute for Natural Product Research and Infection Biology, Hans-Knöll-Institute, Jena, Germany,* [3]*Leibniz Institute for Natural Product Research and Infection Biology, Hans-Knöll-Institute, Friedrich Schiller University, Jena, Germany.*

Invasive infections with the saprophytic yeast *Candida albicans* are a major cause of morbidity in immunocompromised patients. While the interaction of cells and molecules of innate immunity with *C. albicans* has been studied to great depth, comparatively little is known about the modulation of adaptive immunity by *C. albicans*. In particular, direct interaction of proteins secreted by *C. albicans* with $CD4^+$ T cells has not been studied extensively. We here report that the translation elongation factor-1 alpha (Tef1), which is secreted by *C. albicans,* binds to mouse $CD4^+$ T cells and to a lower degree also to mouse B and $CD8^+$ T cells. Functionally, purified Tef1 recombinantly expressed in *Pichia pastoris* enhanced IFNγ and IL-17 secretion by anti-CD3 monoclonal antibody-stimulated splenocytes identifying it as a factor inducing pro-inflammatory cytokine secretion. Our preliminary data further indicate that $CD4^+$ $Foxp3^+$ $CD25^+$ regulatory T cells (Treg) bind Tef1 much better than $CD4^+$ $Foxp3^-$ $CD25^-$ conventional $CD4^+$ T cells. We assume that binding of Tef1 to Treg might 'neutralize' its activity as IFNγ secretion upon anti-CD3 monoclonal antibody and Tef1 stimulation was enhanced in the absence of Treg. The interaction of Tef1 and Treg might, thus, contribute to the commensalism of *C. albicans* and might be an important pathway protecting the organism form overshooting pro-inflammatory immune responses in invasive or even septic candidiasis. This study was funded by a grant from the DFG (CRC124 FungiNet - project C6).

P.D4.04.02

An impact of holo-transferrin on release of Neutrophils Extracellular Traps (NETs)

W. Bystrzycka[1,2], *A. Manda-Handzlik*[1,2], *M. Wachowska*[1], *U. Demkow*[1], *O. Ciepiela*[1];
[1]*Department of Laboratory Diagnostics and Clinical Immunology of Developmental Age, Medical University of Warsaw, Warszawa, Poland,* [2]*Postgraduate School of Molecular Medicine, Medical University of Warsaw, Warsaw, Poland.*

Metal ions, were reported to be found in the structure of Neutrophil Extracellular Traps (NETs). However, to this end, little is known about the exact functions of these ions in NETs formation. Taking into account the invaluable role of microelements in innate immunity, an in-depth understanding of the impact of metal ions on NETs release is desirable.
The aim of this study was to investigate the impact of human holo-transferrin (hT) on the release of NETs.
Neutrophils were isolated from the blood of healthy donors using density gradient centrifugation method and incubated with hT. PMA or calcium ionophore CI were added to stimulate NETs release. The process of NETs release was assessed 3h post stimulation by fluorescent microscopy and fluorometry. Intracellular production of reactive oxygen species (ROS) was assessed by fluorometrical analysis using dihydrorhodamine 123 (DHR123). Nitro blue tetrazolium (NBT) reduction assay was performed to determine how much superoxide is produced.
The delivery of hT to neutrophils contributed to an inhibition of netosis after stimulation with PMA. Transferrin at concentration of 5 µg/ml significantly decreased the amount of released extracellular DNA. Analysis of oxidative burst by DHR oxidation and NBT reduction assay exposed that hT does not affect ROS release. Moreover, hT did not affect NADPH-oxidase-independent NETs release.
Iron is a microelement involved in the formation of NETs. Further studies focusing on the mechanism in which hT affects netosis are of great importance.
This study was supported by funding from the National Science Centre, Poland; Preludium grant no. 2017/25/N/NZ6/00142 (WB).

Antimicrobial peptide derived from chemotactic factor and adipokine -chemerin provides protection against skin invading bacteria by targeting bacteria inner membrane

J. Cichy[1], *U. Godlewska*[1], *A. Zegar*[1], *B. Bilska*[2], *P. Kuleta*[1], *E. Pyza*[2], *A. Osyczka*[1], *B. A. Zabel*[3];
[1]*Faculty of Biochem. Biophys. & Biotech. Jagiellonian Univ., Krakow, Poland,* [2]*Institute of Zoology and Biomedical Reserach, Jagiellonian Univ., Krakow, Poland,* [3]*Palo Alto Veterans Institute for Research, Palo Alto, United States.*

Antimicrobial peptides originating from endogenous human proteins have received significant attention as potential drug targets. Chemerin is chemoattractant and adipokine. Given abundance of chemerin in epidermis and subcutaneous fat tissue, chemerin and chemerin-derived peptides may confer protection against skin invading microbes. Therefore, understanding the modes of action of peptide 4 (p4), the most potent antimicrobial chemerin derivative is of high significance. Here we demonstrate that p4 displayed killing activity against pathogenic MRSA strains *in vitro* and suppressed microbial growth *in vivo* in mouse topical skin and subcutaneous infection models. We also show that p4 binding to bacteria and its bactericidal activity were critically dependent on formation of disulfide-stabilized dimers, suggesting that p4 acts as antimicrobial agent under oxidized conditions. High doses of p4 rapidly damaged internal membrane of bacteria but did not cause lysis of human erythrocytes. P4 in either lethal or sublethal concentration was found to interfere with bacteria respiratory chain function by inhibiting cytochrome bc1-dependent pathway. These data provide new insights into how chemerin shapes host defense by showing previously uncharacterized mechanisms of antimicrobial activity of chemerin derived peptide.
This work was supported by Polish National Science Center grant UMO 2014/12/W/NZ6/00454. The Faculty of Biochemistry, Biophysics and Biotechnology of the Jagiellonian University is a partner of the Leading National Research Center (KNOW) supported by the Polish Ministry of Science and Higher Education.

P.D4.04.04

***In vitro* and *in vivo* posology optimization for an original bacterial immunomodulator**

S. I. Ciulean;
'Cantacuzino' National Institute for Medical-Military Research and Development, Bucharest, Romania.

This study aims to evaluate different oral formulations for an original 13 strain, heat inactivated, bile-lysed, gram positive and negative bacterial immunomodulator formerly used as an injectable product.
THP1 differentiated monocytes were exposed to stimuli derived from the immunomodulator's composition. TLR4 blockage effects were determined on similar cultures.
Female BALB/c mice were administered the immunomodulator in food (1ml/day) or water (10%) for 5 days. Cytokines, NFkB and intracellular reactive oxygen species (ROS) were determined in the spleen, bone marrow and Peyer patches and in THP1 culture supernatants. Animal experiments where approved by the Internal Ethics Committee (CE/101/24.06.2016).
Gram negative bacteria determined higher levels of NFkB and proinflammatory cytokines compared to gram positive. An immunomodulator stimuli equivalent induced greater TNFα and IL8 production, as did sodium deoxycholate compared to bile formulation. TLR4 blockage determined lower TNFα secretion compared to the control and stimuli equivalent. Oral administration did not alter animal health. Compared to the control, both immunomodulator variants down regulated serum MMP9 levels, tended to increase IL10 secretion in Peyer patches and to have a proinflammatory effect in water compared to food administration. Bile-lysed immunomodulator water formulation determined high NFkB levels in Peyer patches. Food administration induced a lower medullar ROS production and inconsequential changes in the cytokine profile of culture supernatants from investigated organs.
Our data suggests that both immunomodulatory formulations have pro-inflammatory effects *in vitro* and anti-inflammatory properties *in vivo*, probably due to oral administration.
This study was supported by PN16390207 project granted by The Ministry of Research.

Th17 cytokine profile in active and latent childhood tuberculosis

M. Druszczyńska[1], *S. Wawrocki*[1], *M. Baranowska*[1], *A. Pankowska*[2], *M. Kowalewska-Pietrzak*[2];
[1]*Division of Cellular Immunology, Department of Immunology and Infectious Biology, Faculty of Biology and Environmental Protection, University of Lodz, Łódź, Poland,* [2]*Regional Center Hospital for Tuberculosis Lung Diseases and Rehabilitation in Lodz, Łódź, Poland.*

Introduction: Tuberculosis (TB) as a consequence of *Mycobacterium tuberculosis* (*M.tb*) infection results from breaking the balance between protective immunity and destructive pathology. Aim: Since the correlates of protective immunity against TB are not known, our study of cytokine profiles of sera and soluble effectors of blood cells responding to *M.tb* antigens was aimed at the identification of immunological signatures of protective immunity and *M.tb* induced pathology in childhood TB. Materials and Methods: In total, 161 BCG-vaccinated HIV-negative pediatric patients were investigated. All children underwent standard clinical and radiological examination including the interferon-gamma release assay (IGRA) testing. On the basis of the results of the current diagnostics children were classified into three groups: TB children, IGRA(+) and IGRA(-) children. A 15-plex Human Th17 Panel (Bio-Rad) was used to measure the concentration of IL-17 pathway-related cytokines in serum and plasma samples recovered from whole blood cultures stimulated with *M.tb* specific antigens performed during IGRA testing. Results: The quantification of 16 proinflammatory and regulatory cytokines and chemokines showed that serum levels of IL-4, IL-10, IL-21 and IL-22 were significantly higher in TB patient group than IGRA(+) children. Moreover, the concentration of IP-10 in *M.tb*-stimulated cultures of blood from TB children was significantly increased as compared to IGRA(+) and IGRA(-) pediatric patients. Conclusion: The analysis of serum/whole blood cultures cytokine profiles may be a useful correlate of active TB in children. This work was supported by the National Science Centre Grant no. 2016/21/B/NZ7/01771.

Leishmaniasis is a vector-borne disease caused by protozoan parasites from the genus *Leishmania*. The most severe form of disease is visceral leishmaniasis (VL), which is fatal if left untreated. It has been demonstrated that interleukin (IL)-10, a potent anti-inflammatory cytokine, is associated with disease progression and susceptibility.
We took advantage of a transgenic mouse model that expresses high levels of IL-10 upon zinc sulfate administration (pMT-10). We addressed the role of IL-10 during the initial stages of *L. donovani* infection by analyzing the parasite burden in the spleen and liver of the infected pMT-10 and WT mice as well as the histopathological alterations upon IL-10 induction. Furthermore, the profile of cytokines expressed by T cells was assessed.
Our results demonstrate that high levels of IL-10 during the initial 12 days of infection leads to a higher susceptibility to VL, demonstrated by increased parasite burden in the spleen and the liver. This increased susceptibility of pMT-10 animals was also associated with increased serum levels of alanine transaminase and aspartate transaminase, usually related with hepatic toxicity. Interestingly, the observed phenotype is also correlated with a decreased frequency of multifunctional CD4 T cells and decreased IFN-γ/IL-10 ratio, usually associated with susceptibility against *Leishmania* infection. Such immunologic landscape contributes for the establishment of a successful infection
Our data suggests that overexpression of IL-10 during the initial steps of the infection impacts host ability to control *L. donovani* infection by limiting the development of a protective adaptive immune response.

P.D4.04.07

Human dendritic cell sequestration onto the *Necator americanus* larval sheath during ex-sheathing: a possible mechanism for immune privilege

A. Hassan[1], *A. M. Ghaemmaghami*[1], *D. I. Pritchard*[2];
[1]*Division of Immunology,School of Life Sciences,Faculty of Medicine & Health Sciences, University of Nottingham, Nottingham, United Kingdom,* [2]*School of Pharmacy, University of Nottingham, Nottingham, United Kingdom.*

Despite the profound health implications of Necator americanus infection in humans, many aspects of its interaction with the host immune system are poorly understood. Here we investigated the early events at the interface of N. americanus larvae (L3) and human dendritic cells (DCs). Our data show that co-culturing DCs and the larvae trigger ex-sheathing of hookworms rapidly where a majority of DCs are sequestered onto the larval sheath allowing the ex-sheathed larvae to migrate away unchallenged. Intriguingly, DCs show negligible interaction with the ex-sheathed larvae, alluding to differences between the surface chemistry of the larva and its sheath. Furthermore, blocking of two key C-type lectin receptors on DC surface (i.e. DC-SIGN and mannose receptor) resulted in inhibition of ex-sheathing process and DC sequestration, highlighting the importance of C-type lectins on DCs in the induction of the ex-sheathing. Analyses of DC phenotype and cytokine profile after co-culture with the N. americanus larvae showed an immature phenotype as evidenced by the low expression of the maturation markers and cytokines. These data provide new insights into early events at the interface of human DCs and N. americanus larvae and could explain how L3 evade immune recognition upon initial interaction with DCs.

P.D4.04.08

NEK7 deglutathionylation by GSTO1-1 is required for NLRP3 inflammasome activation

M. M. Hughes*;*
Trinity Biomedical Sciences Institute, Dublin, Ireland.

The NLRP3 inflammasome is a cytosolic complex sensing phagocytosed material and various damage associated molecular patterns, triggering production of the inflammatory cytokines IL-1β and IL-18, promoting pyroptosis. Here, we characterise Glutathione transferase omega 1-1 (GSTO1-1) as a critical NLRP3 inflammasome regulator. Using a small molecule inhibitor of GSTO1-1 termed C1-27, endogenous GSTO1-1 knockdown and GSTO1-1-/- mice, we report that GSTO1-1 is required for NLRP3 inflammasome activation. Mechanistically, GSTO1-1 deglutathionylates cysteine 253 in NIMA related kinase 7 (NEK7) to drive NLRP3 activation. This is the first report of GSTO1-1 as an NLRP3 inflammasome component, and also identify GSTO1-1 as a drug target to limit NLRP3 inflammasome-mediated inflammation.

P.D4.04.09

Identification of the first naturally processed CD4+ T cell epitope of mumps virus

P. Kaaijk*, M. E. Emmelot, M. C. Poelen, W. Han, C. A. van Els, J. de Wit;*
RIVM, Bilthoven, Netherlands.

Several mumps outbreaks have been reported amongst young adults despite vaccination. Poor induction of the T cell response after vaccination may play a role, but has not yet been studied extensively. T cell epitopes can be useful in exploring T cell responses against mumps virus in more detail, but so far no epitope has been identified. Mumps virus nucleoprotein may be a good target for T cell responses as it has been indicated as immunodominant protein, and other viral nucleoproteins have already shown to be a major T cell target. A $CD4^+$ T cell clone was generated from a mumps case using recombinant mumps nucleoprotein as antigen. The T cell clone proved to be directed against a naturally processed epitope, as it recognized mumps virus-infected cells. Using a 2D-matrix peptide pool of 15-mers peptides covering the complete protein, the peptide-specificity could be identified as GTYRLIPNARANLTA. Upon peptide-specific stimulation, the T cell clone responded in a HLA-DR restricted manner by expression of the activation marker CD137, production of IFN-γ, TNF and IL-10, and by exerting different cytotoxic properties. The epitope seems to be widely applicable as it contains binding motifs for at least 12 HLA-DR molecules and is conserved amongst various mumps virus strains. Good (cytotoxic) $CD4^+$ T cell responses against the epitope found in all 8 tested mumps cases indicated its clinical relevance. Therefore, the mumps-specific $CD4^+$ T cell epitope could provide a useful tool to detect and characterize mumps-specific T cell responses following mumps virus infection or vaccination.

P.D4.04.10

Glycan-mediated binding of extracellular vesicles from *Schistosoma mansoni* juvenile worms to DC-SIGN on dendritic cells triggers cytokine release

M. E. Kuipers[1,2], *E. N. Nolte-'t Hoen*[2], *A. J. van der Ham*[1], *A. Ozir-Fazalalikhan*[1], *D. L. Nguyen*[1], *K. F. Hoffmann*[3], *H. H. Smits*[1], *C. H. Hokke*[1];
[1]*LUMC, Leiden, Netherlands,* [2]*Utrecht University, Utrecht, Netherlands,* [3]*Aberystwyth University, Aberystwyth, United Kingdom.*

Extracellular vesicles (EV) are known intercellular communicators and can transport various molecular cargo. Although it is known that the parasitic worm *Schistosoma mansoni* releases EV, their exact composition and interaction with the host immune system are largely uncharacterised. One of the main classes of molecules from schistosomes involved in parasite-host interaction are glycans. Therefore, we investigated the glycosylation of EV released by *S. mansoni* juvenile worm (schistosomula) and their effect on human monocyte-derived dendritic cells (moDC), known to be key cells affected by schistosome-derived products.

Mass spectrometric glycosylation analysis, performed on EV obtained from cultured schistosomula, revealed the composition of N-glycans on the in- and outside of the EV: i.e. expressing oligomannose and Galβ1-4(Fucα1-3)GlcNAc (Lewis^x) motifs, respectively. To investigate binding of EVs by host immune cells, moDCs were incubated with fluorescently labelled vesicles for 1h. Subsequent flow cytometric analysis showed a dose-dependent binding of the EV to moDCs. This binding was significantly reduced after preincubation with anti-DC-SIGN antibodies but not in the presence of anti-mannose receptor or isotype control when measuring the cells after 48h stimulation. In addition, EV induced IL-12 release by moDC was also reduced by blocking DC-SIGN. This suggests that schistosomula EV affect host immune cells via the C-type lectin receptor DC-SIGN. Because DC-SIGN is capable of binding mannose and fucose containing ligands on EV, these results are in agreement with the glycan analysis.

P.D4.04.11

Adenosine-mediated immunomodulatory action on alveolar macrophages during *Klebsiella pneumoniae* B5055 induced acute lung infection

***V. Kumar**, S. Chhibber;*
Panjab University, Chandigarh, India.

Adenosine is considered as a potent metabokine with potential immunoregulatory function. It is produced during condition causing metabolic stress including hypoxia and inflammation. In the current study, we have investigated the effect of 2-cholroadenosine (2-CADO) an analog of adenosine on the lung innate immune response during acute lung infection induced by *Klebsiella pneumoniae* B5055. Acute lung inflammation was induced by intranasal instillation of *K. pneumoniae* B5055 into mice. Subsequently, mice were treated with 2-CADO (10 µg/kg/day/iv) using a treatment schedule. 2-CADO treatment modulated the pro-inflammatory function of alveolar macrophages by significantly ($p \leq 0.05$) decreasing their phagocytic activity, nitric oxide (NO) and hydrogen peroxide (H_2O_2) release. 2-CADO also significantly ($p \leq 0.05$) decreased neutrophil infiltration into the lungs. Levels of pro-inflammatory cytokines (IL-1α and TNF-α) were decreased significantly ($p \leq 0.05$) decreased. However, levels of IL-10 were found to be significantly ($p \leq 0.05$) elevated. Thus, adenosine, a metabokine has promising immunomodulatory action during gram-negative bacterial pneumonia.

P.D4.04.12

Toll-like receptor 7 sustains early VSV replication in draining lymph nodes and prevents VSV-induced neurovirulence

*G. Solmaz[1], F. Puttur[1], M. Francozo[1], **M. Lindenberg**[1], M. Gohmert[1], M. Swallow[1], C. Detje[2], V. Duhan[3], V. Khairnar[3], U. Kalinke[2], B. Ludewig[4], B. E. Clausen[5], H. Wagner[6], K. S. Lang[3], T. Sparwasser[1];*
[1]Institute of Infection Immunology, Twincore, Hanover, Germany, [2]Institute of Experimental Infection Research, Twincore, Hanover, Germany, [3]Institute of Immunology, University of Essen, Essen, Germany, [4]Institute of Immunobiology, Kantonsspital St. Gallen, St. Gallen, Switzerland, [5]Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany, [6]Institute for Medical Microbiology, Immunology and Hygiene, Technical University Munich, Munich, Germany.

Vesicular stomatitis virus (VSV) is an insect-transmitted rhabdovirus that is neurovirulent in mice. Upon peripheral VSV infection, CD169$^+$ subcapsular sinus (SCS) macrophages capture VSV in the lymph, support viral replication and prevent CNS neuroinvasion. Till date, the precise mechanisms controlling VSV infection in SCS macrophages remain incompletely understood. Here we show that toll-like receptor 7 (TLR7), the main sensing receptor for VSV, is central in mechanistically controlling lymph-borne VSV infection. The absence of TLR7 function impedes VSV infection in the draining lymph nodes (dLN), attenuates viral replication and fuels CNS neuroinvasion. By generating novel TLR7 floxed mice, we interrogate the cell-specific importance of TLR7 and demonstrate for the first time that mice lacking TLR7 function in SCS macrophages showed a trend towards reduced VSV titers in the dLN, whereas CD11c- and LysM-Cre conditional TLR7 knock-out mice showed no reduction. Overall, we identify TLR7 as an essential host factor that facilitates VSV replication, promotes anti-VSV immunity and controls the onset of neurovirulence.

P.D4.04.13

Treatment with recombinant interleukin-12 protects against secondary cystic echinococcosis

***D. MEZIOUG**, C. Touil;*
Laboratory of Cellular and Molecular Biology- Faculty of Biological Sciences- University of Sciences, Algiers, Algeria.

Human cystic echinococcosis is a parasitic disease caused by the development in humans and other mammals by the larval form of Taenia *Echinococcus granulosus*. The present studies aimed to identify anti hydatic molecules, which reduce the risk of relapse during hydatidosis. We investigate *in vitro,* IFN-γ, IL-12, IL-4, IL-13, IL-10 and TGF-β effect on the protoscoleces of *Echinococcus granulosus* in co-cultures with peripheral blood mononuclear cell (PBMC) and monocytes/macrophages (Mo/Mac) from hydatid patients (n=65). We observed 20 relapse cases. The supernatant was collected for nitrite (NO_2- +NO_3) and urea determination. PSC viability was assayed using eosin staining. Our results showed that NO levels were significantly higher in supernatants of co-cultures treated with IFN-γ, IL-12 when compared to untreated cultures supernatants ($p<0.01$). This production was concomitant with a decrease in the percentage of viable protoscoleces. However, the treatment of co-cultures with exogenous IL-4, TGF-β down regulated the NO production and enhanced protoscolices viability and urea production. We observed with interest relapsing patients did not respond to protoscoleces stimulation and their PBMC and Mo/Mac did not secrete significant amounts of NO when stimulated with parasitic antigen. The reduction of nitrite production in relapsing patients correlates with the lack of IFN-γ and decrease in production of IL-12. Interestingly, addition of IL-12 to co-cultures of relapsing patients reduced protoscoleces viability. Collectively, our results show that IL-12 cytokines plays a relevant role in the scolocidal activity of mononuclear cells. Our finding may provide an alternative approach to the treatment of patients with hydatic disease.

P.D4.04.14

Neutrophil surface phenotype and oxidative output alterations in sepsis

***I. Obraztsov**[1], A. Ryabov[2], M. Sukhina[1], N. Tsuranova[1], E. Balykova[1], A. Paramonov[1];*
[1]A.N. Ryzhikh State Scientific Centre for Coloproctology, Moscow, Russian Federation, [2]Ludwig-Maximilians-Universität, München, Germany.

Sepsis is defined as life-threatening organ dysfunction caused by a dysregulated host response to infection. Neutrophils play a key role in initializing and regulating host response, neutrophil functional deficiency might lead to sepsis development and progression.
Our aim was to evaluate the kinetics of the neutrophil's oxidative output and surface phenotype features associated with surgical sepsis development.
Oxidative metabolism was evaluated in the blood by means of luminol-enhaced chemiluminescence (CL) induced by incubation with 50 ng/ml 4-phorbol-12-myristate-13-acetate (PMA) prior to 10 µM N-formyl-methionyl-leucyl-phenylalanine (fMLP) stimulation. This approach enabled to obtain a signal of high intensity and reproducible pattern. Phenotypic shift kinetics of the neutrophils under our assay conditions was also investigated by means of flow cytometry; we revealed the time-dependent change of CD62L, CD11b and CD15 after PMA stimulation. Assay was held in a control group of 95 healthy individuals to build a reference for CL parameters. Investigation of 17 patients with severe burns in dynamics revealed that insufficiency of intracellular CL was associated with development of severe septic complications. A linear combination of 3 fitting power exponent functions (1) was suggested to model experimental CL curves and clinically relevant kinetic parameters were substantiated.
y(t)=A*(t-t0)^n*e(- (t-t0)/τ) (1)
Investigation of 86 colorectal cancer patients after surgery revealed that increase of sequential organ failure assessment score is associated with the increase of CD64 and CD44 expression ($p < 0.05$) as well as the increase and subsequent loss of intracellular CL intensity. The proposed parameters are promising for early sepsis diagnosis.

P.D4.04.15

Therapeutic effect of DNA vaccine containing the 60-kDa-heat shock protein gene from *Paracoccidioides brasiliensis* in experimental paracoccidioidomycosis in mice

*I. L. Souza[1], F. F. Fernandes[1], M. L. Schiavoni[1], **A. Panunto-Castelo**[2];*
[1]Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil, [2]Departamento de Biologia - Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil.

Paracoccidioides brasiliensis and *P. lutzii* are the etiological agents of paracoccidioidomycosis (PCM). PCM is the most prevalent deep mycosis in Latin America and Brazil, which holds most of the cases (~80%). We have previously shown that *P. brasiliensis*-infected mice treated with 50 µg of recombinant 60-kDa-heat shock protein from *P. brasiliensis* (rPbHsp60) had a worsening of infection. Here we analyzed whether the treatment of infected mice with PbHsp60 gene cloned into a plasmid (pVAX1-*PB_HSP60*) would render an efficient immune response and improvement of the disease. To this end, mice were infected intratracheally with 10^5 *P. brasiliensis* yeasts and, on day 20 postinfection, treated intramuscularly with either only one dose or three doses at 15-days interval of 100 µg pVAX1-*PB_HSP60* or empty plasmid, 50 µg rPbHsp60 or vehicle. Thirty days after treatments, lungs from mice that received only one dose of rPbHsp60 had 3-fold higher fungal burden, a more severe inflammatory reaction and a higher concentration of cytokines IL-6, IL-10, and IL-17 when compared with the other groups. Treatment with one dose of pVAX1-*PB_HSP60* did not show a considerable difference compared with controls. In contrast, infected mice treated with three doses of pVAX1-*PB_HSP60* or rPbHsp60 had a significant decrease in the fungal burden, milder inflammation, a higher concentration of cytokines IFN-γ, TNF-α, IL-6, and IL-17 and a lower amount of IL-10 when compared with controls. The detrimental impact of a single-dose treatment with rPbHsp60 on experimental PCM in mice is under investigation. Financial support: FAPESP (2017/01390-8).

P.D4.04.16

Using oligonucleotides to control a dysregulated type I interferon response in severe influenza

***J. C. F. Rappe**, A. Wack;*
Francis Crick Institute, London, United Kingdom.

Influenza virus infection causes respiratory disease leading to 500.000 deaths each year worldwide. During infection, one important component of the innate immune response is the expression of type I interferons (IFN-I). Signalling through its receptor IFNAR1/IFNAR2, this cytokine family will interfere with viral replication and induce an antiviral state in infected and bystander cells. Many publications demonstrated the beneficial effects of a moderate IFN-I response during infection. However, in humans, severe influenza is associated with high IFN-I levels. Similarly, mouse strain 129 responds to influenza infection by producing excessive IFN-I amounts that drive pathogenic innate immune responses. Genetic removal of IFN-I signalling ameliorates disease. Depletion experiments determined that IFNα was mainly produced by plasmacytoid dendritic cells (pDCs). The signal inducing pDCs to produce IFNα in influenza infection is commonly thought to be Toll-like receptor 7 (TLR7)-mediated recognition of viral RNAs. While Ab-mediated pDC depletion ameliorated disease in severe influenza in 129 mice, a pharmacological approach using small molecules would be preferable and of clinical interest. Thus, the oligonucleotide antagonist of TLR7 661 was tested in vitro and showed a high efficacy at reducing influenza-triggered IFNα production by bone marrow-derived pDC already at 0.75uM. In vivo, 661 anti-IFNα effects during influenza infection were observed only when administered locally (intranasally) at a dose of 4.8mg/kg. Studies are currently ongoing to determine if reducing excessive IFNα production during influenza infection in the pro-inflammatory 129 model will reduce overall influenza severity.

P.D4.04.17

***Candida albicans* CRASP11 modulates the host-mediated dendritic cell response by binding the pattern-recognition-receptors dectin-1 and dectin-2**

***N. Reiher**[1,2], M. Reza[2], C. Skerka[2], P. Zipfel[2,1,3];*
[1]Center for Sepsis Control and Care, Jena, Germany, [2]HKI-Leipniz Institute for Natural Product Research and Infection Biology, Jena, Germany, [3]Freidrich-Schiller University, Jena, Germany.

Introduction: The human organism is continuously challenged by an arsenal of microorganisms. To detect and clear these microbes and to maintain homeostasis it is fundamental to recognize these intruders. Therefore, the host utilizes dendritic cells (DC) that express pattern-recognition-receptors (PRR) which bind highly conserved microbial-associated-molecular-patterns (MAMPS). Dectin-1 and dectin-2 are mainly responsible for detection of fungal pathogens. *Candida albicans* an obligate pathogenic fungus colonizes mucosal surfaces in most humans without causing symptoms. However, in immunosuppressed patients candida can cause superficial and severe systemic infections that have lethal outcome. Aim of this project is to characterize how candida by secreting immune modulatory proteins interferes with immune recognition.
Methods: Candida protein CRASP11 is expressed in *E. coli*. For binding analyzes Biolayer Interferometry, Confocal Microscopy, ELISA and Western Blot were used. For functional studies dendritic cells were generated and function was assayed with cytokine measurements and Flow Cytometry.
Results: We identified *Candida albicans* CRASP11 as a new ligand for both dectin-1 and dectin-2. CRASP11 is surface exposed and secreted and binds dectin-1 and dectin-2 on the surface of monocyte-derived DC. The CRASP11::dectin-complexes have affinities of 10 and 200 nM. By binding dectin-1 and dectin-2 CRASP11 activates DC and induces expression of maturation marker CD83 and CD86 and the production of pro- and anti-inflammatory cytokines.
Conclusion: *Candida albicans* CRASP11 can bind both dectin-1 and dectin-2 with high affinities and by binding to the surface of dendritic cells it induces cell activation and cytokine response.

P.D4.04.18

Influenza virus infection induces *Heatr9* upregulation in lung alveolar epithelial cells

***C. J. Stairiker**[1,2], M. v. Meurs[1], Y. Mueller[1], I. Brouwers-Haspels[1], S. Erkeland[1], P. Katsikis[1];*
[1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Drexel University College of Medicine, Philadelphia, United States.

Influenza virus infection poses a serious threat to public health. It infects lung alveolar epithelial cells in the respiratory tract, utilizing them to reproduce, spreading the infection. Understanding genes that are dynamically regulated during influenza virus infection may help elucidate essential genes and pathways that affect influenza virus infection. We examined the *in vivo* RNASeq gene expression profiles of alveolar epithelial cells sorted from A/Puerto Rico/8/1934-GFP (PR8-GFP) expressing influenza virus infected mice. We identified a novel influenza virus-induced gene, *Heatr9* (also known as *Gm11435*), that was upregulated by >200-fold in vivo in mouse alveolar epithelial cells. The upregulation of *Heatr9* by influenza virus was further confirmed *in vitro* in PR8-GFP influenza virus infected human lung A549 cells. *In vivo Heatr9* upregulation was found to be indirect as bystander alveolar epithelial cells in lungs exhibited similar levels of *Heatr9* induction as infected cells. Furthermore, supernatants of influenza virus infected A549 cells were capable of potently inducing *Heatr9* mRNA even in the absence of infection. To identify factors that upregulate *Heatr9* we examined the effect of cytokines on *Heatr9* expression in vitro. Although not induced by IFNβ, TNFα, and IL-1β alone in A549 cell, when used in combination, IFNβ and TNFα or IFNβ and IL-1β potently induced *Heatr9* mRNA. Currently, we are generating Heatr9 deficient cell lines to examine the function of this gene in infection. In summary, we have identified *Heatr9* as a cytokine- and influenza virus infection inducible gene, the function of which has a yet to be determined.

P.D4.05.01

Manipulation of the Th2/1 to Th2 ratio affects the fitness of parasitic nematodes

***N. Affinass**[1], M. Löhning[2], S. Hartmann[1], S. Rausch[1];*
[1]Freie Universität Berlin, Berlin, Germany, [2]DRFZ, Berlin, Germany.

Helminths are highly prevalent in livestock and infect a quarter of the human population. The dominant immune response to helminths is characterized by type 2 T helper (Th2) cells mediating partial immunity to these parasites in the majority of cases. There are no vaccines available for the use in humans. Hence, a better understanding of the immune response to helminth infections is needed.
Heligmosomoides polygyrus is a natural mouse parasite serving as a model for gastrointestinal nematodes chronically infecting humans. We have previously shown that a substantial proportion of helminth-reactive CD4+ T cells display a Th2/1 phenotype by co-expressing the transcription factors GATA-3 and T-bet as well as Th2 cytokines and IFN-γ. To survey if the oral route of infection and the microbiota promote the instruction of Th2/1 cells, the responses to subcutaneous immunization with parasite products and immune responses of germfree mice were compared to those of conventional mice infected with *H. polygyrus.* Th2 and Th2/1 differentiation was similar in all conditions, arguing against a dependency of Th2/1 instruction on microbial signals. However, Th2/1 differentiation was more prominent in more susceptible C57BL/6 compared to more resistant BALB/c mice. In addition, mice lacking the IFN-γ receptor displayed a more pronounced conventional Th2 response which was associated with decreased worm fitness. In conclusion, Th2/1 hybrid cells are a prominent population within the helminth-reactive CD4+ T effector pool. Whether different proportions of conventional Th2 and Th2/1 cells determine the effectiveness of immune responses to nematode infections is the focus of ongoing work.

P.D4.05.02

Systemic bacterial infections affect DCs by favouring monocyte development

*K. Bieber[1], M. Günter[2], **S. E. Autenrieth**[1];*
[1]Department of Internal Medicine II, University of Tübingen, Tübingen, Germany, [2]Departement of Internal Medicine II, University of Tübingen, Tübingen, Germany.

Dendritic cells (DCs) are critical in host defense against infection bridging the innate and adaptive immune system. Animal and human data suggest that systemic DC depletion is an early event in the course of sepsis that may impair the host defense mechanisms. Previously, we showed that systemic bacterial infection irrespectively of the particular pathogen (Gram-negatives such as *E. coli* and *Y. enterocolitica*, Gram-positives such as *S. aureus* and *L. monocytogenes*) reducedthe numbers of bone marrow hematopoietic progenitors of the DC lineages. Moreover, *Y. enterocolitica* infection led to TLR4/IFN-γ-dependent monopoiesis at the expense of DC differentiation. Herein, we extend these studies to gain insights into the mechanisms of DC progenitor reduction as well as impaired *de novo*DC-development upon infections with different Gram-positive and Gram-negative pathogens. The reduction of the DC progenitors was TLR4 dependent for Gram-negative and TLR2-dependent for Gram-positive bacteria. However, induction of monopoiesis by the various infectious agents was TLR-independent. Although the de novo DC generation was dramatically impaired, IFN-γ was dispensable for the induction of DC-progenitor reduction and concomitant monopoiesis upon infections caused by Gram-positive bacteria, indicating the involvement several mechanisms. Our study supports the notion, that systemic bacterial infection leads to general attrition of myeloid progenitors in the bone marrow and DCs in the periphery, which can be compensated by emergency monopoiesis not only to sustain but even to increase the numbers of innate immune monocytes to promote pathogen control.

P.D4.05.03

Characterisation of interferon-induced protein 44 mediated inhibition of respiratory syncytial virus (RSV) infection

D. C. Busse[1], *S. Smith*[2], *C. Brandt*[2], *S. Clare*[2], *P. Kellam*[2], *J. S. Tregoning*[1];
[1]*Imperial College London, London, United Kingdom,* [2]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom.*

RSV infection represents a major global cause of morbidity and mortality, yet the factors that influence disease severity are not fully understood. One possibility is that disease severity is linked to the ability of the infected host cells to recognise and control viral infection. Respiratory viral infection triggers the production of interferons which in turn induce an array of intracellular antiviral proteins encoded by Interferon-stimulated genes (ISGs). Whilst some ISGs have been linked to the development of severe RSV disease, little is known about the mechanism of many of these important antiviral genes. The ISGs IFN-induced protein 44 (IFI44) and IFN-induced protein 44-like (IFI44L) are upregulated after RSV infection, but they do not as yet have a defined mechanism of action. We hypothesised that their upregulation after infection was linked to a protective role. The effects of IFI44 and IFI44L on viral infection were analysed via siRNA-mediated knockdown or through overexpression in relevant human cell lines. The impact of IFI44 on RSV infection was further investigated in *Ifi44*$^{-/-}$ mice. Both IFI44 and IFI44L were confirmed as ISGs upregulated during RSV infection both *in vitro* and *in vivo*. Knockdown of IFI44 in epithelial cell lines resulted in elevated viral infection. RSV infection in *Ifi44*$^{-/-}$ mice was associated with more severe disease relative to wild type controls with increased viral load during infection. This therefore suggests that IFI44 plays an important antiviral role in the prevention of RSV infection.

P.D4.05.04

Beta-glucan modulates human macrophage differentiation and polarization toward macrophages with unique properties

G. Camilli*, J. Quintin;*
Pasteur Institute, Paris, France.

β-glucan, a naturally derived polysaccharide present in the cell wall of fungi, positively impact the outcome of cancer and a number of infectious diseases, although the exact mechanisms remain to be elucidated. Macrophages derived from monocyte precursors undergo specific differentiation that depends on microenvironmental signals. In tissue, they mature and acquire distinct functional phenotype in response to environmental cues. Evidences suggest that β-glucan treatment converts the immunosuppressive M2 (alternatively activated macrophages) and TAM (tumor associated macrophages) toward the M1 (classically activated macrophages) pro-inflammatory and antitumor phenotype. Recently, several seminal studies showed that stimulation of human monocytes by β-glucan bring monocytes into a long-term enhanced functional state, through metabolic and epigenetic changes (trained immunity). Trained monocytes show a stronger proinflammatory response to a second stimulus and provide non-specific protection against several types of infections. Although a stronger proinflammatory response is generally acknowledged as beneficial in controlling infection and cancer progression, it can in some circumstances cause damage to healthy tissue and contribute to pathology. As such, exacerbated secretion of inflammasome-derived cytokines (i.e. IL-1β) have a critical pathogenic role in several inflammatory diseases.
Providing the new concept of trained immunity and its non-specific protective properties, we sought to investigate how the fungal β-glucan modulates the differentiation of human monocytes into macrophages. Here, we show that treatment of human monocytes with fungal β-glucan skews their differentiation, triggered by either M1 or M2 stimuli, into macrophages with a specialized functional phenotype. As such, these macrophages exhibit a non-deleterious secretion of inflammasome-related molecule IL-1β.

P.D4.05.05

Role of Immunoglobulin A in *Mycoplasma pneumoniae* upper respiratory tract carriage

R. C. A. de Groot[1], *P. M. Meyer Sauteur*[2], *L. M. Verhagen*[3], *A. Perkasa*[1], *E. B. Spuesens*[4], *S. E. Estevão*[1], *T. Hoogenboezem*[1], *A. M. van Rossum*[1], *W. W. Unger*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*University Children's Hospital of Zurich, Zurich, Switzerland,* [3]*Utrecht University Medical Center – Wilhelmina Children's Hospital, Utrecht, Netherlands,* [4]*Van Weel-Bethesda Hospital, Dirksland, Netherlands.*

Introduction: *Mycoplasma pneumoniae (Mp)* is the most common bacterial cause of community-acquired pneumonia in children. Infection in the lower respiratory tract (LRT) is preceded by asymptomatic carriage in the upper respiratory tract (URT). We studied the role of the humoral response to *Mp* in the URT and compared it to the LRT.
Methods: *Mp* or medium was installed intranasally in C57BL/6 or B cell-deficient μMT mice. Healthy children and children with selective IgA deficiency (sIgAD) were recruited. On respiratory tract samples we determined *Mp* copy number by qPCR and *Mp*-specific IgM, IgA and IgG titers using an in-house ELISA.
Results: In *Mp* infected mice, *Mp*-specific IgG was markedly elevated in the bronchoalveolar lavage fluid. In contrast, the nasal lavage fluid contained high levels of *Mp*-specific IgA. Serum transfer of infected wild-type mice to μMT mice rescued LRT clearance of *Mp.* Interestingly, the serum transfer had no effect on *Mp* load and *Mp*-specific IgA levels in URT. Immunofluorescence showed the presence of IgA-positive B cells in the URT starting from day 7. To translate our findings to children we measured *Mp*-specific antibodies in children. We included 33 children with sIgAD and 477 healthy control subjects.
Conclusions: *Mp*-specific IgG responses dominated in the LRT, whereas *Mp*-specific IgA was increased in the URT, where it seemed to lower *Mp* load. Insights into the humoral response to *Mp* can benefit vaccine development and immunoglobulin treatment of patients with primary antibody deficiency.

The effect of immunonutrien intake on severity of pulmonary tuberculosis clinical symptoms

T. Faadhila*, D. Sulastri, A. Ana, I. M. Sari;*
Andalas University, Padang, Indonesia.

Introdution: Tuberculosis (TB) is one of the top 10 causes of death worldwide. The severity of pulmonary TB symptoms is affected by the immune status which is strongly influenced by nutrition. Immunonutrient can be defined as the effect of the provision of specific nutrients on immune function. Vitamin D is known to enhance immune response to mycobacteria. In addition, protein products cytokine which help body defense to mycobacteria. The aim of this study was to determine the effect vitamin D and protein intake as the immunonutrient on severity of pulmonary tuberculosis clinical symptoms.
Materials and methods : The method of this study is cross sectional study of 52 pulmonary tuberculosis patients. They were interviewed with questionnaire of FFQ. The amount of vitamin D and protein intake is calculated by using the nutrisurvey. Clinical symptoms of TB patients are measured by using Bandim TBScore. Statistical analysis of the two variables is allegedly linked using SPSS.
Results : The average intake of vitamin D is 5.86 mcg/day, SD 5.45 . The average intake of protein is 78,477 gram/day, SD 29,30. The respondents who have degree TBScore I is 92.3% (48 persons), TBScore II is 7.69% (4 persons), TBScore III is 0% (0 persons). The average of TBScore is 2,04 ± 1,89.
Conclusions : Based on the statistical analysis, vitamin D and protein intake are not significantly affect the severity of pulmonary TB clinical symptoms. However, the average intake of TBScore II group is much lower than the intake of TBScore I group.

Immunomodulatory role of radiations in the control of Epstein-Barr virus fate

D. Faicchia[1], *C. Procaccini*[1], *S. Bruzzaniti*[1], *C. Fusco*[2], *T. Micillo*[3], *M. Cirone*[4], *A. Faggioni*[4], *G. Matarese*[2];
[1]*Isitituto di Endocrinologia e Oncologia Sperimentale, Consiglio Nazionale delle Ricerche, Napoli, Italy,* [2]*Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università di Napoli "Federico II", Napoli, Italy,* [3]*Dipartimento di Biologia, Università di Napoli "Federico II", Napoli, Italy,* [4]*Department of Experimental Medicine, "Sapienza" University of Rome, Roma, Italy.*

Autophagy is a catabolic pathway involved in cell survival under stress conditions. Cells engage autophagy as a detoxification mechanism and/or to solve infections, but some micro-organisms are learning to evade it or to appropriate of this machinery for their own benefit. Recent studies have highlighted a central role of autophagy in supporting the lytic phase of Epstein-Barr virus (EBV). Furthermore, data from literature have suggested a potential immunomodulatory role exerted by ionizing radiation in controlling viral fate. In this study, we investigated the effect of radiations on immortalized B lymphocytes, which have integrated EBV in episomal form. Upon radiation exposure, EBV-infected B cells showed a reduced activation of the mammalian-target of rapamycin (mTOR) pathway, which resulted in an increased autophagic flux. Concomitantly, in EBV-infected B cells, irradiation induced the expression of proteins of the early phases of EBV lytic cycle (Zebra, EA); these phenomena were accompanied by an enhanced release of pro-inflammatory cytokines (IFN-γ, IL-17, TNF-α), a reduced secretion of anti-inflammatory cytokines (such as IL-10), together with an increased expression of the activation marker CD40 on infected B cells. Taken together, these data suggest a key role of radiation in the loss of EBV latency in B lymphocytes and in the reactivation of viral lytic cycle, through autophagy induction. A better understanding of the mechanisms that regulate the interplay between radiation and viral activation could help to improve the treatment of EBV-associated diseases.

P.D4.05.08

***Listeria monocytogenes* adapt to the host cells by inducing the AP-1/Fra-1 level thus inhibiting the *guanylate-binding proteins* expression**

N. Hannemann[1], *S. Cao*[1], *G. Schett*[1], *D. Soulat*[2], *A. Bozec*[1];
[1]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany,* [2]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Institute of Microbiology Clinical Microbiology, Immunology and Hygiene, Universitätsklinikum Erlangen, Erlangen, Germany.*

Macrophages have a broad arsenal of microbicidal features. During *Listeria monocytoges* (*L.m.*) infection, they are the first line of defence against liver and spleen damage. The activator protein (AP)-1 transcription factor family, specifically its subfamily of FOS proteins (cFos, FosB, Fra-1 and Fra-2), can regulate macrophage cytokines production. To delineate whether Fra-1 is involved in the antimicrobial defence of macrophages, chromatin-immunoprecipitation (ChIP) sequencing analysis using thioglycollate-elicited macrophages pooled down for Fra-1 were performed. This analysis revealed that Fra-1 binds to the promoter regions of guanylate-binding protein (Gpb) -11, -2b, 3 and 5. To investigate whether Fra-1 is involved in the defence against *L.m*. infection, bone marrow-derived macrophages (BMDM) from Fra-1 deficient and wildtype mice were infected with *L.m.* (MOI10). Interestingly, we found a decreased CFU in Fra-1 deficient BMDM. In accordance decreased LDH levels reflecting a decreased toxicity was quantified in the supernatant of the Fra-1 deficient cells when compared to controls. RNA analysis of infected BMDM revealed no difference in type-1 interferons, but increased expression of *Gpb-5*, *-6* and *-10*. To address the role of Fra-1 *in vivo*, Fra-1 deficient mice (Fra-1$^{fl/fl}$ MxCre$^{-/+}$) and their wildtype littermates were infected intraperitoneally with *L.m.*. In line with the previous finding, CFU of *L.m.* was reduced in the spleen and liver of Fra-1 deficient mice. Moreover, the expression of *Gbps-5, -6, -7* and *-10* was increased in the liver and spleen of Fra-1 deficient mice. Our data suggest that Fra-1 in macrophages inhibits microbicidal factors, especially GBPs, promoting bacterial growth.

P.D4.05.09

Sirtuin 5 deficiency does not compromise innate immune responses to bacterial infections

T. Heinonen[1], *E. Ciarlo*[1], *C. Théroude*[1], *A. Pelekanou*[1], *J. Herderschee*[1], *D. Le Roy*[1], *J. Auwerx*[2], *T. Roger*[1];
[1]*Lausanne University Hospital, Epalinges, Switzerland,* [2]*Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland.*

Background and aim: Sirtuins (SIRT1-7) belong to the highly conserved family of NAD$^+$-dependent lysine deacetylases. SIRT5, one of the least characterized sirtuins, resides mainly in the mitochondria and catalyses lysine deacetylation, demalonylation, desuccinylation and deglutarylation to regulate metabolic and oxidative stress response pathways. Pharmacologic inhibitors of SIRT5 are under development for oncologic conditions. Nothing is known about the role of SIRT5 in innate immune responses. The aim of the study was to investigate whether SIRT5 deficiency impacts on host defenses against infection.
Methods: Mice were housed in SPF conditions. Thymic and splenic subpopulations were analyzed by flow cytometry. Bone marrow-derived macrophages and splenocytes were stimulated with TLR ligands, bacteria, exotoxins and polyclonal activators and analyzed for metabolic status, cytokine production and proliferation. Mice were challenged i.p. with LPS or *E.coli*, i.n. with *K.pneumoniae* or *S.pneumoniae* and i.v. with *L.monocytogenes* or *S.aureus*. Blood was collected to quantify cytokines and bacteria. Weight, severity score and survival were registered.
Results: SIRT5 deficiency did not affect immune cell development. SIRT5 deficiency increased oxidative phosphorylation over glycolysis in macrophages, but did not modulate cytokine production and proliferation by macrophages and splenocytes. SIRT5 deficiency had no impact on cytokine blood levels, bacteremia and survival rates in models of endotoxemia, pneumonia, peritonitis, listeriosis and staphylococcal sepsis.
Conclusions: These data suggest that SIRT5 has no major impact on innate immune responses to bacterial infections and support the safety profile, in terms of susceptibility to infections, of SIRT5-directed therapies under development for oncologic diseases.

P.D4.05.10

Platelets and the regulation of tissue destruction in tuberculosis.

D. E. Kirwan[1], *A. M. Whittington*[1], *K. A. Fox*[1], *R. H. Gilman*[2], *K. A. Taylor*[1], *M. Emerson*[1], *J. S. Friedland*[1];
[1]*Imperial College London, London, United Kingdom,* [2]*Johns Hopkins University, Baltimore, United States.*

Introduction Tuberculosis (TB) is characterised by inflammation and immune-mediated tissue damage by enzymes, particularly matrix metalloproteinases (MMPs). Platelets are increasingly recognised as immune regulators but their role in TB is poorly understood.
Methods Platelet-derived markers were measured in 50 TB patients before and during treatment, and in 50 healthy controls.
Fresh platelets were incubated with live, virulent TB, TB-derived secreted antigens, or control medium for 30min. Monocytes were cultured with autologous platelets ±TB for 24h. Supernatants were analysed by ELISA and gene expression by qPCR. Platelet function was assessed using light transmission aggregometry.
Results Platelet factor 4 (PF4) concentrations were significantly higher in TB patients than healthy controls (median 1,129 [IQR 1,769] vs 462.5 [IQR 693] ng/ml, p<0.0001). PF4 concentrations transiently increased at treatment day 14 and normalised by day 60 (612.7 [IQR 1,806] ng/ml, p=0.073 vs controls). CD40L, PDGF-BB, and PTX-3 concentrations followed similar trends.
Incubation with TB did not affect platelet PF4 secretion but soluble TB antigens increased PF4 secretion from 141.8 ±6.6 to 255.8 ±13.8 ng/ml (p=0.0017) and also impacted functional platelet responses. Platelets significantly increased MMP-1 and -10 secretion from TB-infected monocytes from 231.9 ±29.1 to 1,820 ±59.2 pg/ml (p=0.0017) and from 530.8 ±45.3 to 1,341 ± 84.2 pg/ml (p=0.014) respectively. MMP-1 and -10 gene expression were similarly upregulated.
Conclusion Platelet activity is increased in TB patients, which is driven by TB-secreted antigens. Platelets drive tissue-degrading enzyme secretion by TB-infected monocytes which may contribute to TB immunopathology. Platelets may constitute a potential therapeutic target for TB.

P.D4.05.11

Effector mechanisms of neutrophilic granulocytes in realization of systemic and local immune response in children suffering from purulent-inflammatory diseases of soft tissues

I. V. Nesterova[1], *G. A. Chudilva*[2], *V. A. Tarakanov*[2], *N. K. Barova*[2], *T. B. Rusinova*[2], *S. V. Kovaleva*[2], *A. A. Evglevsky*[2];
[1]*Peoples' Friendship University of Russia, Moscow, Russian Federation,* [2]*Kuban State Medical University, Krasnodar, Russian Federation.*

Neutrophilic granulocytes (NG) play a crucial role in antibacterial defense realizing its functions by phagocytose, transmembrane degranulation, formation of neutrophilic extracellular traps (NET) and ectosomes. Staphylococcus(Stph.), causing the purulent-inflammatory diseases of soft tissues, emit virulence factors that violate the mechanisms of NG' phagocytosis. We had studied 16 children (group 1), 3-8 years, suffering from purulent-inflammatory diseases of soft tissues (abscesses, phlegmons). Control group consist 7 healthy children. In both groups we evaluated phagocytosis NG of peripheral blood (PB), using Stph.aureus 209: phagocytic activity - % PAN, capture (PN, IP), digestion (% D, DI) functions. NG ability to form NET was tested in smear-prints from site of purulent inflammation (PI) in group 1. NG PB of patients of group 1 had shown inadequate response on the purulent process, causing by Stph.aureus or Stph.epidermidis: NG number and their phagocytic activity didn't differ significantly from control. In smear-prints % PAN was in 1,4 times lower than in PB - 37,5[20;39]%, PN, IP was reduced. Formation of NET was visualized in smear-prints. The number of NET was 21.3% [14,7:31,95] relatively to NG total number. The realization of NG bactericidal potential in site of PI is carried out by 2 mechanisms - phagocytosis and NET formation. We had concluded, that ineffective phagocytic activity of PB NG in systemic immune response, defects of phagocytosis of NG in the local site of PI were associated with the damaging influences of Stph. We assume that the formation NET compensated impaired phagocytic function of NG in site of PI.

P.D4.05.12

Mitocondrial dynamic, beta tubulin and extracellular traps in cultures of human autologous leukocytes stimulated with LPS

R. Rinero, M. V. Reyna, F. M. Rodriguez, ***I. Novak****;*
Institute of Cell Biology, Faculty of Medicine, Cordoba, Argentina.

Introduction: the endotoxemia produced by the effects of endotoxins such as LPS in the blood circulation lead to inflammation in multiple organs. Extracellular traps (ETs) are structures of chromatin and intracellular proteins which are extruded in leukocytes in inflammatory conditions. Some protein components of the cytoskeleton have been described in the traps, but the presence of beta-tubulin has not been reported. Not all Ets are created equal, this depend on source of stimulation. Mitochondria are currently considered to have regulatory functions of innate and adaptive immunity and are determinants in the phenotypes adopted by immune cells in their responses. Objectives: generation of ETs in leukocyte cultures, challenged with LPS and perform marking beta-tubulin and on the other hand, to observe the morphology characteristics of mitochondria of lymphocytes in LPS assay. Methods: autologous leukocyte cultures from healthy human blood samples with ethical consent, anticoagulated with heparin were stimulated with 25 ng/ml LPS, 30 min. Immunofluorescence technique with anti-beta-tubulin Abs, DNA stain with DAPI. Paired blood samples provided controls. Cell pellets from cultures were performed to studied with electron microscope transmission. Results: beta-tubulin molecules were observed in ETs. We observed altered mitochondrial morphology in samples of LPS assay with an increase in size and cristae complexity with electrolucid images in lymphocytes. Conclusions: the expression of beta-tubulin allow to better understand the composition of ETs generated by LPS. Is this similar in the ETs triggered by different stimulous? Mitochondrial morphological changes conduce to improve or deteriorate lymphocyte functions? Further experiments are necesary.

P.D4.05.13

CD72/CD100 and PD-1/PD-L1 markers are increased on T and B cells in HIV-1 viremic patients, and CD72/CD100 axis is correlated with T-cell exhaustion

R. Correa-Rocha, J. Lopez-Abente, V. Perez-Fernandez, A. Prieto-Sanchez, M. Muñoz-Fernandez, ***M. Pion****;*
Instituto de Investigacion Sanitaria Gregorio Marañon, Madrid, Spain.

During HIV-1 infection, PD-1/PD-L1 axis' role in dysfunction of the immune response was described, and high expression of PD-1 and PD-L1 was associated with an immunosuppression state by limiting HIV-1-specific T-cell response. On the other hand, CD100 was demonstrated to play a relevant role in immune response and its expression at the surface of T cells is unknown, although it may play a role in immune deregulation during HIV-1 infection. We researched the PD-1/PDL-1, and CD72/CD100 axes-related markers expression on T and B cells in HIV-1$^+$ naïve-treated patients and in healthy individuals. We analyzed the frequencies and fluorescence intensities of these four markers on CD4$^+$ and CD8$^+$ T cells and on B cells. Expression of these markers was increased during active HIV-1 infection. The frequency of CD100 on T cells was positively associated with the expression of PD-1 and PD-L1 on T cells from naïve-treated HIV-1$^+$ patients. In addition, the frequency of CD72-expressing T cells was associated to the IFN-γ production in naïve-treated HIV$^+$ patients. Our data suggest that CD72/CD100 and PD-1/PD-L1 axes all together may participate in deregulation of immunity during HIV-1 infection and could explain in part the hyper-activation of the immune system.

P.D4.05.14

p.p1 {margin: 0.0px 0.0px 0.0px 0.0px; font: 11.0px Arial} The long pentraxin PTX3 has a non-redundant role in the control of *Streptococcus pneumoniae* invasive infections

R. PORTE*[1], R. Parente[1], M. Sironi[1], F. Pasqualini[1], T. van der Poll[2], C. Garlanda[1], B. Bottazzi[1], A. Mantovani[1];*
[1]Humanitas Cinical and Research Center, Pieve Emanuele (Milan), Italy, [2]Academic Medical Centre, Amsterdam, Netherlands.

Pentraxin 3 (PTX3) is a fluid phase pattern recognition molecule which has served as a paradigm for linking the cellular and humoral arms of innate immunity. PTX3 is an important component of host resistance to pulmonary infections for selected pathogens. Our aim was to investigate the role of PTX3 in the control of pneumococcal infections caused by *Streptococcus pneumoniae*, the most common causative bacteria in community-acquired pneumonia and an important cause of mortality world-wide. By using a model of invasive pneumococcal infection in young-adult mice, we observed a strong expression of PTX3 by non-hematopoietic cells. Comparing the pneumococcal load and survival of infected mice, we observed a higher sensitivity *of Ptx3*$^{-/-}$ animals during the invasive phase of the infection which could be restored by a systemic administration of recombinant PTX3. Infected *Ptx3*$^{-/-}$ mice also showed an increased inflammatory profile. Furthermore, the local exogenous instillation of PTX3 during the ongoing infection was able to reduce the expression of numerous inflammatory cytokines and the pulmonary pneumococcal load. We also observed that PTX3 specifically bind on *S. pneumoniae* but not in physiological conditions found during *in vivo* infection. The mechanism of the protective function of PTX3 remains to be fully elucidated. Our results suggest a non-redundant role of PTX3 in the control of *S. pneumoniae* infections. As inflammation and coagulation are important during pneumococcal invasive diseases, we are now studying the involvement of PTX3 in these systems for control of the infection.

P.D4.05.15

High incidence of primary immunodeficiencies in patients hospitalized for invasive pneumococcal diseases

E. Hernández-Brito[1], E. Colino[2], M. García-Luzardo[2], M. T. Martínez-Saavedra[1], F. Artiles-Campelo[3], M. Santana-Hernández[2], N. Gonzalez-Quevedo[1], ***C. Rodríguez-Gallego****[1];*
[1]Department of immunology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas, Spain, [2]Department of pediatrics, Hospital Universitario Materno-Infantil, Las Palmas de Gran Canaria, Las Palmas, Spain, [3]Department of Microbiology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Las Palmas, Spain.

Introduction.*Streptococcus pneumoniae* is a leading cause of bacterial pneumonia, meningitis, and sepsis in children. Some primary immunodeficiencies (PIDs) confer predisposition to invasive pneumococcal disease (IPD). **Methods.** Identification of pediatric (younger than 14 years) patients with IPD between January 2000-February 2017 from the province of Las Palmas (one million inhabitants). Clinical and epidemiologic data and immunological explorations. **Results.**We identified 186 children who suffered from IPD, of whom 68 patients (mean age 32 months; range, 0 days-13 years) required hospitalization. Fourteen of the 68 children (20,6%) had classical risk factors. Immunological evaluation could be performed to 36 patients. Seven patients suffered from a genetically confirmed PID: IRAK-4 deficiency (1 patient), X- linked agammaglobulinemia (1), congenital asplenia (2), Ataxia-telangiectasia (1), DiGeorge Syndrome (1), and Charge Syndrome (1). Oneonly patient with PID (IRAK-4 deficiency) had suffered from recurrent IPD or previous hospitalizations, and only one patient with PID (DiGeorge syndrome) developed severe respiratory infections after diagnosis. In addition, a patient with partial Chromosome 16 trisomy and recurrent pneumonias had low numbers of switched-memory B cells and high numbers of CD21^{low} B cells, and one patient, whose brother had been diagnosed with STAT3 negative AD Hyper IgE syndrome, had high IgE levels (996.00 UI/mL) and eosinophilia. **Conclusions.** PID may be the cause of 20% of pediatric patients with IPD. Prompt diagnosis and treatment after one episode of hospitalization for IPD, even in the absence of previous severe and/or recurrent infections, protect against posterior severe infections in patients with PID.

P.D4.05.16

Sex and pathogen influence on monocyte activation - A special feature arising from *Entamoeba histolytica* infection

J. Sellau*[1], M. Groneberg[1], S. Hoenow[1], B. Krause[1], C. Marggraff[1], J. Diekhoff[2], H. Ittrich[2], T. Jacobs[1], H. Lotter[1];*
[1]Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [2]Department and Clinic for Diagnostic and Interventional Radiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Men and male mice are more proned to develop amebic liver abscess (ALA) following infection with the parasite *Entamoeba (E.) histolytica*. In the murine model for the disease, a CCL2-dependent recruitment of Ly6C^{hi} monocytes and TNFα is responsible for tissue damage. Interestingly, in *E. histolytica* infected human, men show higher CCL2 levels compared to women suggesting a similar mechanism underlying the disease. Here, we analyzed sex-specific characteristics of human monocytes in response to *E. histolytica*. *E. histolytica*-dependent liver destruction in mice was analyzed by magnet resonance imaging (MRI), monocytes were characterized by FACS and serum cytokines by using a multiplex assay. Human macrophages or monocytes were stimulated with various antigens (LPS, LTA, *E. histolytica*) or conditioned medium, supernatants were analyzed using multiplex assays and cells were characterized by FACS. Male mice showed larger abscess lesions, higher blood and liver CD11b$^+$Ly6C^{hi} monocyte frequencies as well as an altered cytokine profile including TNFα, CCL2 and CXCL1 compared to female mice. In human, we found TNFα and CXCL1 as being regulated in a sex dependent manner in macrophages and monocytes, respectively. Furthermore, only the stimulation with *E. histolytica* led to an increased population of CCR2-expressing CD14$^+$ monocytes in men, but not in women. Inflammatory monocytes play an important role in inducing a sex difference in the outcome of ALA in mice. We were able to generate a comparable inflammatory phenotype monocyte population in a human *in vitro* model with the same sex difference, which might be able to induce a strong immune pathology.

P.D4.05.17

Dynamics and trafficking of mGBP protein complexes within membranous compartments during infection with *Toxoplasma gondii*

N. Steffens*, L. Legewie, E. Kravets, D. Degrandi, K. Pfeffer;*
Medical Microbiology and Hospital Hygiene, Düsseldorf, Germany.

Introduction: During invasion of target cells, *Toxoplasma gondii* (*T. gondii*) creates a parasitophorous vacuole (PV). Members of the murine guanylate binding protein family (mGBPs) assemble at the cytoplasmic side of the PV and interact with this membranous compartment via yet uncharacterized mechanisms.
Objectives: This analysis aims at unravelling the molecular mechanisms by which mGBPs impair the vital functions of *T. gondii*.
Methods: Stable cell lines expressing fluorescent mGBPs were generated and infected with GFP-/mCherry-expressing *T. gondii* to analyze the dynamics of mGBPs via Confocal Live Cell Imaging. Super-resolution technologies were used to analyze the doubly transduced cell lines during infections in detail. Giant unilamellar vesicles technology (GUV) is in progress to investigate the binding capacity of mGBP2 and mGBP7 to membranes and their modulation of membrane integrity. Also, cytosolic compartments of mGBPs (vesicle-like structures, VLS) and the *T. gondii*-PV will be characterized by electron microscopy.
Results: First results suggest that mGBP7 localizes in VLS after Interferon-γ stimulation. Furthermore, mGBP7 colocalizes with mGBP3 and partially with mGBP6 and mGBP9 but virtually not with mGBP2. mGBP2 appears to recruit faster to the PV compared to mGBP7. Additionally, mGBP7, mGBP3, mGBP6 and mGBP2 are able to accumulate directly at the plasma membrane of *T. gondii*, subsequently leading to parasite death.
Conclusion: mGBPs belong to a family of GTPases that can interact with the *T. gondii*-PV and selected members directly attack the parasite membrane. The analysis of the mechanisms will help to understand Toxoplasmosis and to find new treatment opportunities in the long term.

P.D4.05.18

Immunovirological response of people living with Human Immunodeficiency Virus on highly active antiretroviral therapy in Senegal

M. D. SYLLA NIANG[1], *B. Mbengue*[1], *M. Mbow*[1], *A. Sylva*[2], *S. Atsou*[1], *R. Derwiche*[1], *T. N. Dieye*[1], *A. Dieye*[1];
[1]*University Cheikh Anta Diop of Dakar - SENEGAL, Dakar, Senegal,* [2]*General Hospital of Grand-Yoff, Dakar, Senegal.*

Introduction: The objective of this study was to evaluate the immuno-virological response of HIV-infected patients by analyzing the peripheral CD4 lymphocytes rates and viral load following highly active antiretroviral therapy (HAART).
Material and methods: A cross-sectional prospective study was conducted from January to September 2017. The study population included patients living with HIV (PLHIV) regularly followed up at General Hospital of Grand-Yoff (HOGGY). The analysis focused on socio-demographic, clinical, and biological parameters. Data were analyzed by descriptive and analytical statistical methods using Statview 5.0 software.
Results: The cohort of PLHIV was composed of 127 patients. The median age at diagnosis was 41 years. The circumstances of discovery were dominated by opportunistic infections (47,3%). HIV-1 infection was predominant (88%). The most represented therapeutic combinations were Tenolam / Efavirenz (46% of patients) and Combivir / Efavirenz (27.8%) with 44 months as average length of HAART. Following HAART, the median TCD4 counts has increased from 293 cells/µL at diagnosis to 401 cells/µL. The progression of TCD4 median was significant ($p < 0.0001$) only for PLHIV-1 under HAART. Among treated patients, 22.8% underwent an immune restoration during the follow-up whilst 30% had immunological failure.
The immunovirological discordance was 23.6%. For PLHIV with detectable viral load, there was no significant difference between the initial viral load and the viral load after treatment.
Conclusion: These data allow to optimize existing treatments and contribute, through a multidisciplinary care, to improve the patient survival.

P.D4.05.19

Ageing outweighs the impact of cART regimen on the immune restoration of virally suppressed long-term treated HIV patients

R. Emilova[1], ***Y. Todorova***[1], *N. Yancheva*[2], *D. Strashimirov*[2], *I. Elenkov*[2], *I. Alexiev*[3], *M. Nikolova*[1];
[1]*NRL of Immunology, National Center of Infectious and Parasitic Diseases, Sofia, Sofia, Bulgaria,* [2]*Specialized Hospital for Active Treatment of Infectious and Parasitic Diseases, Sofia, Bulgaria,* [3]*NRL of HIV, National Center of Infectious and Parasitic Diseases, Sofia, Sofia, Bulgaria.*

Life-long combined antiretroviral therapy (cART) is the only current strategy in HIV+patients. The factors impacting residual immune activation and long-term prognosis have not been completely elucidated. Aim: To evaluate the relative impact of cART regimen and ageing on the immune restoration in virally suppressed long-term treated HIV+ patients. Material & Methods: Data for 182 HIV+ patients (52 F, 130M), mean age 43 (24-76), on continuous cART for at least 5y, with SVR (HIVVL<2.0 $\log_{10}$copies/ml) after the second year were analyzed. Subgroups according to regimen were: INSTI-based (n=14), NNRTI-based (n=28), LPV-based (n=89), DRV-based (n=54). Percentage and absolute counts (AC) of CD4, CD8, CD4-CD8-DNT and CD4+CD8+DPT were determined at 2 and 5y of cART by flow cytometry (Multitest,FACSCantoII,BD).The impact of cART regimen, age, gender, HCV/HBV coinfection and transmission category on immune restoration was evaluated by multiple regression analysis (SPSS21). Results: CD4AC and CD4/CD8 ratio did not differ between subgroups at 2y ($p>0.05$), and increased significantly at 5y of treatment (mean 629vs.519, and 0.74vs.0.58, $p<0.0001$). CD4AC and CD4/CD8 restoration were not affected by regimen ($R^2=0.01$ and, $R^2=0.003$, $p>0.05$). Age was the most important predictor for CD4/CD8 restoration(0.12vs.0.20, $F=8.30$, $p<0.029$).However, LPV-based cART was associated with lower level of DPT reflecting low thymic activity ($F=8.76$, $R^2=0.154$, $p<0.01$). In addition, advancing age predicted a lower level of DNT regulating immune activation.(109vs.171, $F=15.02$, $p<0.01$). Age is a major factor for immune restoration in long-term treated HIV patients. Old-generation PI may directly impact the regeneration and activation of T cells and should be avoided in the elderly patients.

P.D4.05.20

Extracellular matrix destruction in Tuberculosis is regulated by an acidic inflammatory microenvironment

A. M. Whittington[1], *D. E. Kirwan*[1], *F. S. Turner*[2], *R. H. Gilman*[3], *J. S. Friedland*[1];
[1]*Imperial College, London, United Kingdom,* [2]*Edinburgh Genomics, University of Edinburgh, Edinburgh, United Kingdom,* [3]*Johns Hopkins University, Baltimore, United States.*

Background: The inflammatory microenvironment is acidic. Extracellular pH at sites of *Mycobacterium tuberculosis* (M.tb) infection nears 7.0 compared to physiological pH 7.4. Acidosis is detected by pH-sensing G-Protein coupled rectors (TDAG8, OGR1 and GPR4). Tuberculosis is characterised by marked inflammation and tissue destruction driven by host derived Matrix Metalloproteinases (MMPs). This study investigates how extracellular acidosis modulates immune responses in TB.
Methods: Transcriptome profiling of primary human monocyte-derived macrophages (MDMs) infected with virulent M.tb H37Rv at pH 7.4 or with acidosis (pH 7.0) was performed by RNA-seq. MDM expression of acidosis receptors was determined by qPCR and immunohistochemistry of biopsies from TB patients. Protein secretion by infected MDMs was measured by Luminex.
Results: Acidosis produces system level transcriptional change in M.tb infected MDMs with 2616 genes upregulated and 2919 downregulated at pH 7.0 compared with 1556 up- and 1441 downregulated at pH 7.4. Genes uniquely upregulated by acidosis have multiple immune and metabolic functions including inflamasome activation and glycolysis. The most significantly upregulated pathways by acidosis are extracellular matrix degradation pathways due to upregulation of MMPs (MMP-1, MMP-3 and MMP-10 are increased 5.2, 4.2 and 6.2 fold respectively. $p<0.01$). TDAG-8 and OGR-1 are expressed by MDMs and highly expressed in M.tb infected tissue. Acidosis increased MMP-1, MMP-3 and IL-1β secretion and suppressed TNF-α from infected MDMs. These effects are dependent upon acidosis receptor signalling.
Conclusions: The acidic microenvironment enhances tissue degradation pathways and MMP secretion in TB. TDAG-8 and OGR-1 are potential novel targets for host directed therapy in TB.

Investigation the role of syntenin in Salmonella Typhimurium uptake

F. F. Ali[1], *M. Jones*[2], *F. Berditchevski*[3], *P. Monk*[4], *L. J. Partridge*[5];
[1]*Mosul Technical institute, Northern Technical University, Mosul, Iraq,* [2]*Dept. Molecular Biology & Biotechnology, University of Sheffiel;d, Sheffield, United Kingdom,* [3]*Institute of Cancer and Genomic Sciences, University of Birmingham, Birmingham, United Kingdom,* [4]*Department of Infection, Immunity and Cardiovascular Disease, University of Sheffield, Sheffield, United Kingdom,* [5]*Dept. Molecular Biology & Biotechnology, University of Sheffield, Sheffield, United Kingdom.*

*Salmonella*is an infectious pathogen linked with human and animal diseases world-wide. These bacteria are characterized by the ability to infect a variety of human cells. Syntenin is a scaffolding protein that is involved in various cell functions and is reported to associate with the tetraspanin protein CD63, which has previously been implicated in the adhesion of *Salmonella*Typhimurium to human monocyte derived macrophages (MDMs). The aim of this research was to investigate association ofthe bacteria with cells that had been stably knocked down for syntenin expression.The HeLa syntenin knock down (KD) cell line was generated and used using a pLKO-sh Syntenin clone, while the control cell line was transfected with pLKO-puro vector. HeLa syntenin KD and WT control were infected with different strains of *Salmonella*Typhimurium. The bacteria were stained and the bacterial-cells association were analysed using flow cytometer. Surprisingly, the HeLa syntenin KDwere more susceptible to *Salmonella* infection than control cells; however, no significant changes were observed in early stages of *Salmonella* binding. Tetraspanin expression levels were similar for the KD and the WT cells, but stochastical optical reconstruction microscopy (STORM) analysis did indicate some differences in the distribution of CD63 molecules. Overall, our results suggest that the effects of syntenin KD on *Salmonella* infection could relate to alternative syntenin partner proteins such as syndecan.

P.D4.06.02

Toward a prognostic marker for chronic Chikungunya disease

V. R. de Oliveira[1], *L. Moraes*[1], *P. M. Casais*[2,1], *T. Silva*[1], *C. Orge*[2], *L. Pamplona*[3], *B. B. Andrade*[2], *L. A. Santos*[2], *R. Venancio*[4], *A. Barral*[2,5], *M. Barral-Netto*[2,5], *R. Khouri*[2,1], ***V. Boaventura***[2,1,6];
[1]*Federal University of Bahia, Salvador, Brazil,* [2]*Oswaldo Cruz Foundation, Salvador, Brazil,* [3]*Federal University of Ceará, Fortaleza, Brazil,* [4]*Oswaldo Cruz Foundation, Rio de Janeiro, Brazil,* [5]*Institute for Investigation in Immunology, Salvador, Brazil,* [6]*Santa Casa de Misericordia da Bahia, Salvador, Brazil.*

Introduction - Chikungunya disease (CHIKD) is an arboviroses that evolves to recurrent chronic skeletal muscle symptoms in 14,4 to 87,2% of affected patients. In order to identify prognostic markers of persistent disease, we started a cohort study in four cities during an outbreak of CHIKD in Brazil . Methods - Blood, urine and saliva samples were obtained from 233 patients with acute (<10 days) symptoms of arbovirosis. Positive PCR / IgM cases (n=132) not including co-infection with DENV or ZIKAV were clinically reevaluated after two months in order to detect chronic CHIKD. Expression of chemokines and cytokines during acute phase were determined by citofluorimetry and PCR of plasma and saliva samples, respectively. Results - Chronic CHIKD occurred in 67,7% of individuals with increased risk if edema, pruritus, rash, retroocular pain and dizziness were reported during acute phase. CHIKV or IgM level were not related to disease progression. High expression of CCL2 and CXCL10 and low levels of cytokines was observed in both plasma and saliva samples, with no difference between recovered and progressors. In saliva samples, a positive correlation was observed between expression of IL-1beta and the presence of CHIKV. Conclusion - Despite a local and systemic expression of CCL-2 and CXCL10 during acute CHIKV infection, only clinical markers were found to be related to CHIKD progression to chronic stage. Positive CHIKV saliva samples exhibited an increased expression of IL-1beta, possible suggesting a CHIKV- induced activation of inflammasome. <!--EndFragment-->

P.D4.06.03

Cryptic high mannose self-recognition by macrophage Mannose Receptor leads to severe anaemia in sickle cell disease

H. Cao[1], *J. Shepherd*[1], *B. Patel*[1], *J. Brewin*[2], *A. Masson*[1], *H. Wassall*[1], *M. Forrester*[1], *E. Black*[1], *S. Leishman*[1], *A. Antonopoulos*[3], *Y. Cao*[4], *S. Henderson*[5], *G. Konieczny*[1], *H. Wilson*[1], *A. Dell*[3], *S. Haslam*[3], *D. Rees*[2], *R. N. Barker*[1], *M. A. Vickers*[1];
[1]*Institute of Medical Sciences, Aberdeen, United Kingdom,* [2]*Paediatric Haematology, Kings college Hospital, Denmark Hill, London, United Kingdom,* [3]*Department of Life Sciences, Imperial College London, London, United Kingdom,* [4]*Cranfield University, Cranfield, United Kingdom,* [5]*Scottish National Blood Transfusion Services, Aberdeen, United Kingdom.*

Sickle cell anaemia (SCA), the most haemolytic form of sickle cell disease (SCD), is characterised by genetic homozygosity of the haemoglobin S allele, severe anaemia and vascular pathology. Hypersensitive mass-spectrometry glycomic analysis of SCA red blood cell membrane (RBCs) reveals previously unrecognised high mannose N-glycans. Terminal-mannose specific lectins, snowdrop and daffodil, identify intense high mannose expression on SCA but not healthy RBCs, while annexin V binding indicated lack of phosphatidylserine exposure. Such high mannoses are found cryptically expressed in all RBCs, hidden with cytoskeletal protein spectrin and is exposed in discrete patches upon oxidation, as shown by super resolution microscopy. Strong clinical correlations between mannose exposure and markers of haemolysis, such as haemoglobin, RBC and reticulocyte counts are observed. Lack of correlation between mannose and LDH, an intravascular haemolysis indicator, suggests mannose is specifically associated with extravascular haemolysis, which accounts for 70% of total haemolysis. Macrophage phagocytosis of SCD RBCs is almost exclusively associated with Mannose Receptor positivity. Glycans (mannan/chitin) and antibody blockade of Mannose Receptor inhibit macrophage uptake of SCD RBCs. It was suggested in 1954 that sickle cell trait conferred resistance to malaria, explaining selection for the allele. Sickle heterozygous RBCs expose extra high mannose in response to oxidation, which occurs during plasmodium infection. We propose that exposure of high mannoses acts to recruit clearance by the innate immune system in the form of splenic macrophages through the Mannose Receptor. Manipulation of this high mannose recognition may assist future treatment of both SCD and malaria infection.

Helminth-specific CD4$^+$ T cell responses during *Ascaris* infection in the pig

F. Ebner, *J. Schlosser, L. Tedin, S. Hartmann;*
Institute of Immunology, Center for Infection Medicine, Department of Veterinary Medicine, Berlin, Germany.

The pig represents the ideal human-relevant research model to study the immune response to *Ascaris* spp., the most common of the soil-transmitted helminths. The large roundworms infecting humans and pigs, *A. lumbricoides* and *A. suum,* are genetically almost identical and cross-transmission occurs, highlighting the role of pig studies to understand the host-parasite interplay. The quality of an immune reaction largely depends on a relatively small fraction of antigen-specific CD4$^+$ T cells that orchestrate the adaptive immune response. Our study therefore aimed to investigate frequency, phenotype and specificity of *Ascaris*-reactive CD4$^+$ T cells in the pig as a natural host. We used CD40L (CD154) expression as an early TCR activation marker of swine CD4$^+$ T cells to study the development of an *Ascaris*-specific CD4$^+$ T cell pool. Our data demonstrates the onset of a robust, antigen-specific Th2 response already during larval tissue migration. *Ascaris*-specific CD4$^+$ T cells are directed against excretory-secretory proteins and parasite lysates. To improve functional analysis of antigen-specific lymphocytes we adapted the method of antigen-reactive T cell enrichment (ARTE) to porcine, parasite-specific CD4$^+$ T cells. Enrichment analysis revealed phenotypic differences in CD4$^+$ T cells from peripheral *vs.* migration affected compartments, such as lung parenchyma. Our approach thereby offers a novel strategy to identify and characterize *Ascaris*-specific CD4$^+$ T cells directly in the pig, and will be used to unravel mechanisms of protection and protective antigens.

P.D4.06.05

A comparison of selected immunological parameters in cyclophosphamide treated C57BL/6 and C3H mice immunized with BCG or rBCGmIL-18

M. Wlodarczyk, A. Bednarek, J. Kowalska, M. Bromirski, M. Druszczynska, M. Kowalewicz-Kulbat, A. Krupa, W. Rudnicka, ***M. Fol****;*
Department of Immunology and Infectious Biology, Faculty of Biology and Environmental Protection, University of Lodz, Lodz, Poland.

The work addressed the question of potentially superior immunogenicity of recombinant *M. bovis* BCG producing mouse IL-18 compared to the parent strain BCG under immunosuppressive conditions in the context of different sensitivity of mice strains to mycobacterial infection (susceptible C57BL/6 and resistant C3H mice). Mice were intradermally immunized with BCG or rBCGmIL-18 and after 6 weeks intraperitoneally treated with cyclophosphamide (CP, 50μg/g b.w.) for 7 days. The following specimens were isolated: serum - to measure the concentration of selected cytokines (Bio-Plex Pro™ Assay), alveolar macrophages - to investigate the effectiveness of phagocytosis (acridine orange staining), bone marrow cells (immunofluorescently stained cytospins) - to estimate the expression of CD34 and CD117. The mean percentage of alveolar macrophages involved in phagocytosis, isolated form control C57BL/6 mice, both immunocompetent and immunosuppressed was similar, and it was significantly higher than in control C3H mice. Both BCG and rBCGmIL-18 immunization caused a decrease in the phagocytic activity of macrophages, however the increase in the killing effectiveness was observed. C3H mice were more efficient producers of IL-2, IL-10, IL-12 and GM-CSF, but not TNF-α, than C56BL/6 mice. The impact of immunosuppression or type of BCG strain was moderate at most and ambiguous. There were not significant differences regarding the level expression of CD34 as well as CD117 on bone marrow cells between the mouse strains. The use of CP and recombinant BCG strain did not significantly affect the expression of the receptors. This work was supported by the National Science Centre (Poland) under Grant number 2013/11/B/NZ6/01304.

Complex interplay between Ly49 receptors and cytomegalovirus

V. Juranic Lisnic[1], *J. Zeleznjak*[1], *B. Popovic*[1], *B. Lisnic*[1], *M. Babic*[1], *M. Cesarec*[1], *A. Halenius*[2], *L. Doelken*[3], *A. Krmpotic*[1], *S. Jonjic*[1];
[1]*Faculty of Medicine, Rijeka, Croatia,* [2]*Institute of Virology, Universitatsklinikum, Freiburg, Germany,* [3]*Institute of Virology, Wurzburg, Germany.*

Cytomegaloviruses downregulate MHC I from the cell surface in order to avoid recognition by T cells. Since this strategy could trigger the NK cell-mediated "missing-self" recognition, murine cytomegalovirus (MCMV) encodes m04/gp34, a protein which brings a portion of MHC I molecules back to the cell surface enabling them to engage inhibitory Ly49 receptors (iLy49s). However, m04 brings only a small portion of MHC I to the surface. We have identified and characterized 11kDa viral protein MATp1 encoded by the MCMV's most abundant transcript (MAT) that helps in the m04-mediated MHC I surface rescue and strengthens the interaction between inhibitory Ly49 receptors and their MHC I ligands. Viruses lacking this protein are attenuated in vivo in mice of various MHC I haplotypes in an NK cell-dependent manner. Interestingly, ORF encoding this protein is highly variable among different virus strains which has prompted us to investigate whether it has been under strong selection pressure by the immune system. Differential sensitivity of various mouse strains to MCMV has been linked to the capacity of NK cells to recognize infected cells via activating Ly49 receptors and we and others have previously shown that activating Ly49P receptors require MHC I, m04 and additional virally encoded factor. Using multiple MCMV mutants we show that the unknown virus factor is the same MAT encoded protein involved in the recognition by inhibitory Ly49 receptors. Thus, MATp1 evasion of inhibitory Ly49 receptor has prompted the evolution of activating Ly49 receptors.

Chitinase 3-like 1 protein plays a critical role in RSV-induced airway inflammation

M. Kim[1], *D. Shim*[1], *H. Cha*[1], *K. Moon*[1], *C. Yang*[1], *K. Kim*[1], *J. Park*[1], *C. Lee*[2], *J. A. Elias*[2], *M. Sohn*[1], *J. Lee*[1];
[1]*Yonsei University College of Medicine, Seoul, Korea, Republic of,* [2]*Brown University, Providence, United States.*

Background: Chitinase 3-like 1 protein (CHI3L1) (YKL-40 in humans and breast regression protein [BRP]-39 in mice) is required for optimal allergen sensitization and Th2 inflammation in various chronic inflammatory diseases including asthma. However, the role of CHI3L1 in airway inflammation induced by respiratory viruses has not been investigated. The aim of this study is to investigate the relationship between CHI3L1 and airway inflammation caused by respiratory syncytial virus (RSV) infection. Methods: We measured YKL-40 levels in human nasopharyngeal aspirate (NPA) from hospitalized children presenting with acute respiratory symptoms. Wild-type (WT) and BRP-39 knockout (KO) C57BL/6 mice were inoculated with live RSV (A2 strain). Bronchoalveolar lavage fluid and lung tissue samples were obtained on day 7 after inoculation to assess lung inflammation, airway reactivity, and expression of cytokines and BRP-39. Results: In human subjects, YKL-40 and IL-13 levels in NPA were higher in children with RSV infection than in control subjects. Expression of BRP-39 and Th2 cytokines, IL-13 in particular, were increased following RSV infection in mice. Airway inflammation caused by RSV infection was reduced in BRP-39 KO mice as compared to WT mice. Th2 cytokine levels were not increased in the lungs of RSV-infected BRP-39 KO mice. BRP-39 regulated M2 macrophage activation in RSV-infected mice. Additionally, treatment with anti-CHI3L1 antibody attenuated airway inflammation and Th2 cytokine production in RSV-infected WT mice. Conclusions: These findings suggest that CHI3L1 could contribute to airway inflammation induced by RSV infection. CHI3L1 could be a potential therapeutic candidate for attenuating Th2-associated immunopathology during RSV infection.

P.D4.06.08

Targeting Inhibitory Receptors LAG-3 and TIM-3 to Enhance Anti-parasitic CD4⁺ T cell Responses in Visceral Lesihmaniasis

R. Kumar[1], *N. Singh*[2], *B. Singh*[2], *C. Engwerda*[3], *S. Sundar*[2];
[1]*Institute of Science, Banaras Hindu University, Varanasi, India,* [2]*Institute of Medical Science, Banaras Hindu University, Varanasi, India,* [3]*QIMR Berghofer Medical Research Institute, Brisbane, Australia.*

Introduction: CD4⁺ T cells exhaustion is a common phenomenon during chronic visceral leishmaniasis (VL) which causes reduced IFN-γ secretions, critical for controlling the parasite replication. This can be mediated by abnormal expression of immunosuppressive receptors LAG-3 and TIM-3 on the surface of CD4⁺ T cells. The present study aims to investigate the role of LAG-3 and TIM-3 in patients with VL. **Methods:** Peripheral blood mononuclear cells (PBMCs) were collected from VL patients before and after drug treatment. CD4⁺ T cells were enriched using magnetic beads. Ex-vivo mRNA expression of TIM-3 and LAG-3 was measured in both PBMCs as well as enriched CD4⁺ T cells by Real-Time PCR and surface expression were examined by flow cytometry. To know the functional relevance of LAG-3 and TIM-3, whole blood cells of VL patients were stimulated for 24 hours with soluble leishmania antigen in presence of anti LAG-3 or anti TIM-3 antagonistic antibodies or isotype controls and IFN- γ secretion was measured. **Conclusion:** We observed enhanced mRNA expression of TIM-3 and LAG-3 in whole PBMCs as well as CD4+ T cells of VL patients in pre treatment stage compared to post treatment as well as enhanced surface expression as revealed by flow cytometry analysis. We observed an enhanced IFN- γ secretion in whole blood culture after LAG-3 blockade compared but there was no any effect of TIM-3 blockade on IFN- γ secretion. These results identify LAG-3 as an important immunotherapeutic target to enhance anti-parasitic CD4⁺ T cell response and treat VL patients.

P.D4.06.09

Protocadherin-1 in Respiratory Syncytial Viral bronchiolitis

K. KUMAWAT[1,2], *U. Brouwer*[3,4], *S. Fens*[1], *A. Petersen*[3], *B. Lambrecht*[5,6], *M. Nawijn*[3,4], *G. Koppelman*[3,4], *L. Meyaard*[1,2], *L. Bont*[1];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Oncode Institute, University Medical Center Utrecht, Utrecht, Netherlands,* [3]*University Medical Center Groningen, Groningen, Netherlands,* [4]*Groningen Research Institute for Asthma and COPD, University Medical Center Groningen, Groningen, Netherlands,* [5]*VIB Center for Inflammation Research, Ghent, Belgium,* [6]*Ghent University, Ghent, Belgium.*

Early life Respiratory syncytial viral (RSV) bronchiolitis is linked to declined lung function and development of asthma in later life. SNPs in Protocadherin-1 (PCDH1), an airway epithelial surface protein, have been associated with increased susceptibility to airway hyperresponsiveness (AHR). Since aberrant AHR indicates diminished lung function and is a key feature of RSV bronchiolitis, we investigated whether PCDH1 could play a role in RSV disease.
Human bronchial epithelial cell line, 16HBE, was infected with RSV-A2 and PCDH1 expression was measured by qPCR and western blotting. C57BL/6 wild-type (WT) and PCDH1 knock-out (KO) mice were infected with RSV-A2. Body weight loss was monitored as clinical parameter for RSV disease. On 5-day post-infection (dpi), lung inflammation was determined by broncho-alveolar (BAL) fluid analyses and lung function was measured by FlexiVent.
In vitro, RSV-A2 infection decreased PCDH1 protein expression in 16HBE cells with variable effects on mRNA. *In vivo*, RSV-A2 infection led to body weight loss and showed increased viral titres in the BAL fluid, indicating an ongoing RSV disease. Moreover, BAL fluid showed significantly increased cellular influx to the lungs. Furthermore, RSV infection augmented AHR in response to methacholine. There were no differences between WT and KO mice in weight loss, lung inflammation, AHR or viral replication post-RSV infection.
In conclusion, we confirm RSV causes airway inflammation and hyperresponsivenees in adult mice, but these effects are independent of PCDH1. Ongoing studies aim to define the role of PCDH1 in the pathogenesis of RSV-enhanced allergic airway inflammation.

Adaptation to complex host niches drives resistance to neutrophils by fungal pathogen *C. albicans*

J. Lopes[1,2], *E. Backman*[1,2], *S. Holmberg*[1], *M. Stylianou*[3], *J. Jass*[3], *R. Claesson*[4], *C. F. Urban*[1,2];
[1]*Department of Clinical Microbiology, Umeå University, Umeå, Sweden,* [2]*The Laboratory for Molecular Infection Medicine Sweden (MIMS)., Umeå, Sweden,* [3]*School of Science and Technology Örebro University, Örebro, Sweden,* [4]*Section Molecular Periodontology, Department of Odontology, Umeå University, Umeå, Sweden.*

Immune systems have developed to prevent harm inflicted by other organisms. As a consequence, successful colonizers have evolved traits to escape from immune attack. *Candida albicans* is a successful colonizer of humans and its virulence is connected to the ability to adapt to stress or nutrient scarcity within the host. This environment shapes the niche for *C. albicans*. The yeast has evolved to anticipate environmental clues by predicting and adapting to secondary stimuli, thereby improving the organism's fitness. In this case the niche shapes the environment. Here, we describe one such event. Upon infection, neutrophils are rapidly infiltrating into the mucosal niche. Circulating neutrophils are effective phagocytes which serve as first line defense against fungal pathogens. High numbers of infiltrating cells coupled with the formation of microbial structures, such as biofilms, lead to induction of hypoxic and anoxic microniches. We have characterized the effect of anoxia on neutrophil responses encountering *C. albicans* both under the form of different planktonic morphotypes and under biofilm growth. We found that a persistent anoxic milieu did not affect neutrophil function, however, hampered neutrophil responses towards *C. albicans*. PAMP sensing and subsequent responses against *C. albicans* were reduced under anoxic conditions allowing the yeast to escape from neutrophil attack. In addition, anoxia contributed to increased fungal growth, a trait we found to be conserved in many *Candida* species. We therefore conclude that adaption to low oxygen is not only an evolutionary advantage but rather a pre-requisite for successful colonization and infection of the host.

P.D4.06.11

The Syk-Coupled C-type lectin receptors Dectin-2 and Dectin-3 are involved in *Paracoccidioides brasiliensis* recognition by human plasmacytoid dendritic cells

N. Preite[1], *C. Feriotii*[1], *B. Silva*[1], *D. Souza de Lima*[1], *A. Condino-Neto*[1], *A. Pontillo*[1], *V. Calich*[1], ***F. V. Loures***[2,1];
[1]*Departamento de Imunologia, Instituto de Ciências Biomédicas, Universidade de São Paulo, São Paulo, Brazil,* [2]*Instituto de Ciência e Tecnologia, Universidade Federal de São Paulo, São José dos Campos, Brazil.*

Plasmacytoid dendritic cells (pDCs), which have been extensively studied in the context of the immune response to viruses, have recently been implicated in host defense mechanisms against fungal infections. Nevertheless, the involvement of human pDCs during paracoccidiodomycosis (PCM), a fungal infection endemic to Latin America, has been scarcely studied. However, pDCs were found in the cutaneous lesions of PCM patients, and in pulmonary model of murine PCM these cells were shown to control disease severity. These findings led us to investigate the role of human pDCs in the innate phase of PCM. Moreover, considering our previous data on the engagement of diverse TLRs and CLRs receptors in *P. brasiliensis* recognition, we decided to characterize the innate immune receptors involved in the interaction between pDCs and yeast cells. Purified pDCs were obtained from peripheral blood mononuclear cells from healthy donors and they were stimulated with *P. brasiliensis* with or without blocking antibodies to innate receptors. We demonstrated that *P. brasiliensis* stimulation activates pDCs that inhibit fungal growth and secrete pro-inflammatory cytokines and type I IFNs. Importantly, we also demonstrate that dectin-2 and dectin-3 are expressed on pDCs and appear to be involved (via Syk signaling) in the pDC-*P. brasiliensis* interaction. Moreover, *P. brasiliensis*-stimulated pDCs exhibited an efficient antigen presentation and were able to effectively activate CD4⁺ and CD8⁺ T cells. In conclusion, our study demonstrated that pDCs are involved in *P. brasiliensis* recognition and may play an important role in the innate and adaptive immunity against this fungal pathogen.

Leishmania parasites are the causative agents of leishmaniases, a group of diseases that range in manifestations from skin lesions to fatal visceral disease. Dendritic cells (DCs) hold a key role in orchestrating immune responses against leishmaniasis by regulating the activation of adaptive immunity. The aim of the present study was to investigate changes in the whole transcriptome of murine bone marrow-derived DCs infected with *Leishmania infantum* using next generation sequencing (RNA-seq). DCs exposure to parasite resulted in infection of almost 50% of DCs. The infected DCs were sorted using flow cytometry and whole RNA was isolated for transcriptome analysis. According to RNA-seq results, we identified 718 differentially expressed genes (DEGs) in DCs infected with *L. infantum* (352 up-regulated and 366 down-regulated). Comparative analysis of DEGs in infected DCs compared to DCs exposed to chemically inactivated parasites, revealed that twice as many DEGs were more abundant during infection demonstrating the influence of parasite infection on host gene transcription. KEGG pathway analysis revealed that metabolic pathways including glycolysis/gluconeogenesis and HIF-1 signaling were among the most significantly enriched pathways in infected DCs. On the other hand, DCs exposure to fixed parasite enhanced the expression of genes related to cytokine-cytokine receptor interaction and antigen processing. These data provided insights into the molecular mechanisms underlying *L. infantum* infection of DCs and might extend the knowledge regarding the interplay between metabolic processes and innate immune response against leishmaniasis.

This work was funded by the NSRF 2014-2020 and co-financed by Greece and the European Union (MIS 5002486)

P.D4.06.13

Target specific design and synthesis of a novel water soluble ferrocenylquinoline derivative as potential anti-leishmanial agent

D. Mukherjee[1], *S. Dey*[1,2], *M. Yousuf*[3], *S. Chakraborty*[1], *A. Chaudhuri*[4], *A. Dutta*[1], *A. Hussain*[1], *S. Chakraborty*[4], *S. Adhikari*[5], *C. Pal*[1];
[1]*Department of Zoology, West Bengal State University, Barasat, Kolkata, India,* [2]*PG Department of Zoology, Barasat Government College (Present Address), Barasat, Kolkata, India,* [3]*Biomaterials Group, Chemical Biology Division, CSIR-Indian Institute of Chemical Technology [IICT], Hyderabad, India,* [4]*Department of Microbiology, West Bengal State University, Barasat, Kolkata, India,* [5]*Department of Chemistry, University of Calcutta, Kolkata, India.*

Background: Visceral Leishmaniasis (VL), a neglected parasitic disease caused by Leishmania donovani, is responsible for severe health problems in India. Despite of significant progress in anti-leishmanial research, ultimate introduction of novel, safe and cost-effective drugs is far away from agreeable destination. This failure is majorly attributed to poor water solubility of drugs, in consequence, oral administration becomes challenging. Thus, the development of water-soluble oral drugs with low manufacturing prices remains highly desirable to treat VL.
Methods: We adopted quaternization strategy, where 7-Chloro-N-[2-(1H-5-ferrocenyl-1, 2, 3-triazol-1-yl) ethyl] quinolin-4-amine was modified to yield 7-Chloro-quinolin-4-yl-methyl-[2-(4-ferrocenyl-[1,2,3]triazol-1-yl)-ethyl]-ammonium chloride (CQFCWS) and tested the anti-leishmanial efficacy, both in vitro and in vivo (oral and intramuscular administration in BALB/c mice).
Results: CQFCWS was highly efficient at very low IC50 concentrations and was nontoxic towards host splenocytes, in vitro and in vivo. CQFCWS maintained hematopoietic bone marrow cell proliferation, in situ and did not alter Phase I and Phase II detoxification enzyme components in host liver. Immunomodulating potential of CQFCWS was confirmed by its ability to skew Th2 response towards Th1. CQFCWS did not induce drug resistance genes (MDR1 and MRPA) in L. donovani, in vitro. CQFCWS acted through a putative target and limited the expressions of L. donovani survival enzymes, trypanothione reductase and ornithine decarboxylase. To explore the binding efficiency of CQFCWS to trypanothione reductase, molecular docking followed by dynamic simulation was performed. CQFCWS could also induce apoptosis by upregulating PARP1 and downregulating SIR2 in parasites. Pharmacokinetic study regarding the bioavailability of CQFCWS revealed a short elimination half-life of the drug.

P.D4.06.14

The role of TAM receptors, and their ligand, Gas6, in resistance and susceptibility during ZIKV infection

L. G. Oliveira*, N. G. Zanluqui, C. M. Polonio, C. L. Freitas, J. S. Peron;*
University of São Paulo, São Paulo, Brazil.

Introduction. Zika virus (ZIKV) has gained worldwide attention as it has been correlated with severe fetal malformations, causing the Zika Congenital Syndrome (ZCS). However only 6-12% of mothers infected with ZIKV give birth to babies with malformations. These observations suggest that ZIKV infection during pregnancy is not deterministic for ZCS, but other susceptibility factors might be involved. The viral entry receptors are important candidates. Tyro3, Axl, Mertk (TAM receptors), and their ligands, Gas6 and Protein S are important candidates for ZIKV internalization and can facilitate viral entry by bridging viral envelope phosphatidylserine in a mechanism called *viral apoptotic mimicry*. Although, their correlation with resistance or susceptibility to infection, is largely unknown. **Objective.** Evaluate the immunobiology of TAM receptors, and their ligand, Gas6, in resistance and susceptibility to ZIKV infection. **Results.** We observed that SJL, susceptible mouse lineage, showed higher levels in mRNA expression of *Tyro3*, *Axl* and *Gas6* compared with C57BL/6, resistant lineage. In this context, we demonstrated that the combination of rmGas6+ZIKV in SJL and C57BL/6 infection increase the viral load in spleen while the use of Axl kinase blocker, R428, decrease the amount of viral particles. Interestingly, the use of rmGAS6+ZIKV led to the development of C57BL/6 affected offsprings, turning this lineage susceptible to ZCS. **Conclusion.** Our results suggest the crucial role of TAM receptors**,** and the intracellular kinase portion of Axl, during ZIKV infection. These data contribute for a better knowledge about the invasion mechanisms of ZIKV, *in vivo*, that could be involved in the ZCS.

P.D4.06.15

Virulent *Salmonella enterica*serovar Typhimurium modulates the production of neutrophils extracellular traps

B. M. Schultz[1,2]*, S. P. Muraro*[3]*, G. Fabiano de Souza*[3]*, S. Dias de Oliveira*[3]*, B. N. Porto*[3]*, S. M. Bueno*[1,2]*;*
[1]*Pontificia Universidad Católica de Chile, Santiago, Chile,* [2]*Millennium Institute on Immunology and Immunotherapy, Santiago, Chile,* [3]*Pontifical Catholic University of Rio Grande do Sul, Porto Alegre, Brazil.*

Salmonella enterica serovar Typhimurium is an important cause of gastrointestinal diseases worldwide. To infect the host, *S.* Typhimurium has several virulence factors encoded in chromosomal cluster known as *Salmonella* Pathogenicity Islands (SPI). It has been described that *S.* Typhimurium infected cells secrete anti-inflammatory cytokines, promoting a tolerogenic environment. During this infection, the initial innate immune response triggered by the bacteria is the migration of neutrophils to the site of infection. These cells clear the infecting microorganisms through different mechanisms, such as neutrophils extracellular traps (NETs). However, this innate immune response is not enough to avoid *S.* Typhimurium dissemination. For this reason, it is important to evaluate the immune response mediated by neutrophils against *S.* Typhimurium. We isolate human blood or mice bone marrow derived neutrophils and induce the production of the NETs at different multiplicity of infection. $1x10^5$ cells were infected for 10 or 180 minutes, in order to, evaluate if the *S.* Typhimurium induce NETs in the early or classical way, respectively. We also performed inhibitions assays , to evaluate the NETs pathways production. We found that human blood and mice bone marrow derived neutrophils infected with a *S.* Typhimurium induce NETs production in a MOI dependent manner and by the classical way. Interestingly, a mutant strain of the SPI- 2 induces NETs in greater proportion. Our results suggest that *S.* Typhimurium infection induce NETs production, however, the bacteria has virulence factors that could be related with the suppression of the immune response, which favor the bacterial dissemination.

P.D4.06.16

The effect of hookworm co-infection on pneumococcal carriage and invasive disease

R. K. Shears*, L. C. Jacques, A. Law, N. French, D. R. Neill, A. Kadioglu;*
Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom.

Background and aims: Hookworm infections are highly prevalent in sub-Saharan Africa and South-East Asia, where the incidence of invasive pneumococcal disease is also high. Hookworms are gastrointestinal nematodes that naturally reside within the small intestine of their host for months or years, causing long-lived chronic infection. In addition, hookworm larvae migrate through the lung, which is associated with significant tissue damage. Chronic helminth infections promote an immunoregulatory environment, which is associated with increased numbers of T regulatory (Treg) cells and higher levels of the immunosuppressive cytokines, TGF-β and IL-10, which can alter the immune response to bystander pathogens. Resistance to pneumococcal disease is based upon a delicate balance between Treg-driven immune tolerance and pro-inflammatory responses which may clear infection but can also lead to tissue damage, providing a route for bacterial dissemination. Thus, the tissue damage caused by larval migration through the lung and the immunoregulation associated with adult hookworms in the small intestine may influence pneumococcal disease progression.
Methods: We are currently investigating the effect of hookworm (*Nippostrongylus brasiliensis* and *Heligmosomoides polygyrus*) co-infection on pneumococcal disease progression using mouse models of pneumococcal carriage and pneumonia.
Results: Our data suggest that both lung migration and chronic gastrointestinal infection caused by these helminths lead to increased mortality in mouse pneumococcal pneumonia models and may also promote bacterial seeding from the nasopharynx to the lungs in pneumococcal carriage models.
Conclusions: These studies suggest that hookworm co-infections can worsen disease outcome in pneumococcal pneumonia and promote progression from asymptomatic carriage to invasive disease.

P.D4.06.17

Leishmania donovani: CD2 biased immune response skews the SAG mediated therapy for a predominant Th1 response in experimental infection

S. Sinha*, S. Sundaram;*
Centre for Biotechnology, University of Allahabad, Allahabad, India.

We have evaluated the effect of combining CD2 with conventional antimonial (sb) therapy in protection in BALB/c mice infected with either drug sensitive or resistant strain of Leishmania donovani with 3 $x10^7$ parasites via-intra-cardiac route. Mice were treated with anti CD2 adjunct SAG sub-cutaneously twice a week for 4 weeks. Assessment for measurement of weight, spleen size, anti-Leishmania antibody titer, T cell and anti-leishmanial macrophage function was carried out day 0, 10, 22 and 34 post treatments. The combination therapy was shown boosting significant proportion of T cells to express CD25 compared to SAG monotherapy. Although, the level of IFN-gamma was not statistically different between combination vs monotherapy ($p = 0.298$) but CD2 treatment even alone significantly influenced IFN-gamma production than either SAG treatment ($p = 0.045$) or with CD2 adjunct SAG treatment ($p = 0.005$) in Ld-S strain as well as in Ld-R strain. The influence of CD2 adjunct treatment was also documented in anti-leishmanial functions in macrophages.Unlike SAG treatment, treatment of SAG with CD2 also led to production of nitric oxide and TNF-a, resulting in resulting in most effective clearance of L. donovani from infected macrophages. Our results indicate that CD2, which can boost up a protective Th1 response, might also be beneficial to enable SAG to induce Macrophages to produce Leishmanicidal molecules and hence control the infection in clinical situation like Visceral Leishmaniasis.

P.D4.06.19

Protective effects of soluble human CD5 in experimental fungal sepsis

M. Velasco-de Andrés[1], *M. Martínez-Florensa*[1], *C. Català*[1], *I. Simões*[1], *E. Carreras*[1], *O. Zaragoza*[2], *F. Lozano*[1,3,4];
[1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain,* [2]*Mycology Reference Laboratory, National Centre for Microbiology, Instituto de Salud Carlos III (ISCIII), Majadahonda, Spain,* [3]*Servei d'Immunologia, Centre de Diagnòstic Biomédico, Hospital Clínic de Barcelona, Barcelona, Spain,* [4]*Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain.*

Sepsis due to invasive fungal infections (IFIs) are an emerging problem worldwide related to the widespread adoption of aggressive immunosuppressive therapy among certain patient populations and the increasing use of invasive surgical interventions. Fungal recognition relies on a series of soluble or membrane-bound receptors (e.g. C-type lectins, scavengers or TLRs) expressed by host innate and/or adaptive immune cells, which could have therapeutic usefulness. Previous work by our group showed that the ectodomain of CD5, a scavenger-like lymphocyte-specific surface receptor, binds to and aggregates pathogenic and saprophytic fungal cells through recognition of β-glucans, a conserved constituent of fungal cell walls. Moreover, *i.p.* infusion of recombinant soluble human CD5 (rshCD5) protein showed protective effects in a mouse model of septic shock-like syndrome induced by zymosan, a glucan-rich particle from yeast. The present work confirms the *in vivo* efficacy of rshCD5 infusion in two experimental models of fungal infection caused by pathogenic fungal species, namely *C. albicans* and *C. neoformans.* Following therapeutic *i.v.* administration of rshCD5 to fungal-infected CD1 mice, significant time- and dose-dependent effects on mouse survival, body weight loss and fungal load were observed. Increased leukocyte infiltration (at expenses of relevant immune cell subsets such as NKs, cDCs, granulocytes and B cells) were also evidenced in targeted organs (namely kidney). Altogether, these results support the potential therapeutic value of rshCD5 administration in invasive fungal infections.

P.D4.07 Exploiting host pathogen interaction - Part 7

P.D4.07.01

The impact of T cell-derived Neuropilin-1 on immune cell infiltration and pathogen clearance during *Plasmodium* infection

H. Abberger, *J. Buer, W. Hansen;*
Institute of Medical Microbiology, University Hospital Essen, Germany.

Malaria is induced by the parasite *Plasmodium spp.* which, in 2016, affected 216 million people and led to 445,000 deaths worldwide. Characteristic symptoms include fever, headaches, seizures and in severe cases, malaria can lead to neurological complications. Cerebral malaria is caused by obstruction of brain vessels and disruption of the blood brain barrier resulting in peripheral immune cell infiltration into the brain. As we reported earlier, Neuropilin-1, a receptor of class III semaphorins and VEGF, mediates regulatory T cell migration into tumor tissue resulting in suppression of effector T cells accompanied by reduced anti-tumor response. Here, we aim to analyse whether T cell-expressed Neuropilin-1 also has an impact on immune cell infiltration into the brain with possible effects on destructive $CD8^+$ T cells during cerebral malaria. For this purpose, we infected T cell-specific Nrp-1-deficient mice with murine *Plasmodium berghei* parasites and studied pathogen clearance and development of cerebral malaria. In addition, we investigated immunological mechanisms within peripheral lymphoid organs, blood and brain by flow cytometry. Results from our study give further insights into immunological processes during cerebral malaria being of particular interest for the identification of new potential therapeutic targets.

P.D4.07.02

Characterization of newly established anti-human Dectin-1 monoclonal antibody

Y. Adachi, *M. Soda, K. Ishibashi, J. Tetsui, D. Yamanaka, N. Ohno;*
Tokyo University of Pharmacy and Life Sciences, Hachioji, Tokyo, Japan.

Dectin-1 is a small C-type lectin receptor that recognizes fungal cell wall beta-glucan, and is responsible for host defense against fungal infection by producing proinflammatory cytokines. Recent reports suggest that the Dectin-1 contributes the development of diseases such as DSS-induced colitis and house dust mite-induced allergy. Controlling dectin-1 function may regulate the inflammatory diseases. To obtain antagonistic monoclonal antibody against human Dectin-1, we tried to prepare hybridoma clones by immunizing Dectin-1 KO mice with human Dectin-1 soluble protein as an antigen.
The newly established clone 2D9 produced mouse IgG1 kappa chain. The affinity of 2D9 to solid-phase human Dectin-1 molecule was monitored by BLItz. The association and dissociation constant were, $2.7x10^5$(1/Ms), and 9.2×10^{-4}(1/s), respectively. The KD of 2D9 was 3.4 nM. The 2D9 significantly inhibited the binding of soluble Dectin-1 to 1,3-β-D-glucan from *Candida albicans*. To compare the specificity of 2D9, various commercially available Dectin-1 monoclonal antibodies are applied. The binding of PE-labeled 2D9 to human Dectin-1-expressing lymphoma-transfectant was not blocked with 15E2 (BioLegend), 259931 (R&D), GE2 (GeneTex), but only by pretreatment with 2D9. While other commercial antibodies showed partially competed between 15E2 and 259931.
These results suggest that 2D9 is a unique antagonistic monoclonal antibody specific to human Dectin-1.

P.D4.07.03

In HIV primary infection, early cART reduced gd T cell activation but failed to restore their polyfunctionality

R. Casetti[1], *A. Sacchi*[1], *V. Bordoni*[1], *E. Cimini*[1], *C. Pinnetti*[1], *R. Libertone*[1], *A. Ammassari*[1], *A. Antinori*[1], ***C. Agrati***[2];
[1]*National Institute for Infectious Diseases "Lazzaro Spallanzani", Roma, Italy,* [2]*National Institute for Infectious Diseases, Roma, Italy.*

HIV infection alters phenotype, distribution and function of γδ T cells during HIV infection. There are no body of evidence about the impact of early cART on γδ T cells dynamics. HIV+ patients were divided into Early Primary Infection (EPI, Fiebig: II/IV) and Late Primary Infection (LPI, Fiebig: V/VI). Phenotype/functional analysis of γδ T cells were performed by flow cytometry before (T0) and 6 months (T6) post-therapy. γδ polyfunctional profile was assessed after specific antigens stimulation. Before therapy, higher frequency of Vδ1 and Vδ2 T cells was observed in LPI respect to HD. cART restored a normal Vδ2 T cell frequency but failed to normalize Vδ1 T cells in LPI. At T0, activation of Vδ1 and Vδ2 T cells was observed in both groups. Activated Vδ1 T cells positively correlated with viral load and negatively correlated with CD4 T cell count. cART significantly reduce the γδ T cell activation to level of HD. In both groups, CD107A expressing Vδ1 T cells was significantly lower than HD but was restored after cART. Polyfunctional profile of Vδ1 T cells of both groups was comparable to HD, except for CD107A+MIP1β+ Vδ1 T cell subset and therapy failed to restore that subset. At T6 a lower CD107A, IFNγ or TNFα producing Vδ2 T cells in EPI and a lower TNFα producing Vδ2 T cells in LPI was observed compared to HD. Our data show that HIV strongly impact γδ T cell immunity soon after infection and these alterations were only partially restored by therapy.

P.D4.07.04

Mass cytometry analysis reveals the landscape and dynamics of $CD32a^+$ $CD4^+$ T cells from early HIV infection to effective cART

S. Coindre[1], *N. Tchitchek*[1], *L. Alaoui*[1], *B. Vaslin*[1], *C. Bourgeois*[1], *C. Goujard*[2], *V. Avettand-Fenoel*[3], *C. Lecuroux*[1], *P. Bruhns*[4,5], *R. Le Grand*[1], *A. Beignon*[1], *O. Lambotte*[1,2], *B. Favier*[1];
[1]*CEA-Université Paris Sud 11-INSERM U1184, Immunology of Viral Infections and Autoimmune Diseases (IMVA), IDMIT Department, IBJF, DRF, Fontenay-aux-Roses, France,* [2]*Assistance Publique-Hôpitaux de Paris, Service de Médecine Interne et Immunologie Clinique, Groupe Hospitalier Universitaire Paris Sud, Hôpital Bicêtre, Le Kremlin-Bicêtre, France,* [3]*Paris Descartes University, EA 7327, Sorbonne Paris Cité, APHP, Necker Hospital, Virology Department, Paris, France,* [4]*Institut Pasteur, Department of Immunology, Unit of Antibodies in Therapy and Pathology, Paris, France,* [5]*INSERM, U1222, Paris, France.*

CD32a has been proposed as a specific marker of latently HIV-infected $CD4^+$ T cells. However, CD32a was recently found to be expressed on $CD4^+$ T cells of healthy donors, leading to controversy on the relevance of this marker in HIV persistence. Here, we used mass cytometry to characterize the landscape and variation in the abundance of $CD32a^+$ $CD4^+$ T cells during HIV infection. To this end, we analyzed $CD32a^+$ $CD4^+$ T cells in primary HIV infection before and after effective combination antiretroviral therapy (cART) and in healthy donors. We found that $CD32a^+$ $CD4^+$ T cells include heterogeneous subsets that are differentially affected by HIV infection. Our analysis revealed that Naive ($_N$), central memory ($_{CM}$), and effector/memory ($_{Eff/Mem}$) $CD32a^+$ $CD4^+$ T-cell clusters that co-express LILRA2 and CD64 activating receptors were more abundant in primary HIV infection and cART stages. Conversely, $LILRA2^-$ $CD32a^+$ $CD4^+$ T-cell clusters of either the T_N, $T_{CM,}$ or $T_{Eff/Mem}$ phenotype were more abundant in healthy individuals. Finally, an activated $CD32a^+$ $CD4^+$ $T_{Eff/Mem}$ cell cluster co-expressing LILRA2, CD57, and NKG2C was more abundant in all HIV stages, particularly during primary HIV infection. Overall, our data show that multiple abundance modifications of $CD32a^+$ $CD4^+$ T-cell subsets occur in the early phase of HIV infection, and some of which are conserved after effective cART. Our study brings a better comprehension of the relationship between CD32a expression and $CD4^+$ T cells during HIV infection.

P.D4.07.05

Matrix metalloproteinase 10 plays a role in dampening the host inflammatory response to *Salmonella* infection

K. Ehrhardt[1], *R. Kappelhoff*[2], *N. Steck*[3], *C. M. Overall*[2], *B. B. Finlay*[4], *G. A. Grassl*[1];
[1]*Institute of Medical Microbiology and Hospital Epidemiology and German Center for Infection Research (DZIF), Partner Site Hannover, Hannover Medical School, Hannover, Germany,* [2]*Department of Oral Biological and Medical Sciences, Centre for Blood Research, University of British Columbia, Vancouver, Canada,* [3]*Institute for Experimental Medicine, Christian-Albrechts University of Kiel and Research Center Borstel, Borstel and Kiel, Germany,* [4]*Michael Smith Laboratories, University of British Columbia, Vancouver, Canada.*

Salmonella cause a variety of diseases ranging from self-limiting enterocolitis to severe systemic infections. Dependent on the serovar, 2-5% of immunocompetent individuals become chronic carries thus representing a reservoir for transmission. The factors contributing to persistent *Salmonella* infection are incompletely understood. We identified matrix metalloproteinase 10 (MMP-10) among the highest upregulated proteases in the intestine during chronic *Salmonella* Typhimurium infection of 129Sv/J mice using a protease gene chip array. Upon in vitro infection a high upregulation of *Mmp10* mRNA was detected in primary bone marrow-derived macrophages. Infection of primary bone marrow-derived macrophages from MMP-10 deficient mice induced an increased proinflammatory response as observed by higher levels of MCP-1, IFN-beta, IFN-gamma, and nitrosative stress in comparison to infected wild type macrophages. While there was no difference in bacterial survival inside the cells at early points post-infection (6 hours and 1 day), we detected that *Salmonella* can survive better when MMP-10 is absent in long-term infected cells (3 days). Furthermore, filamentous growth of *Salmonella* was strongly increased in *Mmp10* deficient macrophages 3 days post infection. Filamentous growth can be caused by intracellular stress like nitrosative stress and might represent a survival strategy. Similarly to macrophages, *Salmonella* infection of primary intestinal fibroblasts from *Mmp10* deficient mice showed higher levels of MCP-1, nitrosative stress, filamentous growth, and increased intracellular survival (3 days) in comparison to infected wild type fibroblasts. In conclusion, our results show that MMP-10 plays a role in restricting *Salmonella* survival and dampening the host inflammatory response to infection.

P.D4.07.06

Regulation of gene and protein expression of critical factors in the etiology of colon cancer by the Microsporidia infection

C. Hurtado Marcos*, Y. Sáez, F. Izquierdo, S. Fenoy, C. Del Águila;*
Universidad San Pablo-CEU, Madrid, Spain.

Colon cancer is one of the most prevalent cancers in most countries and presents a health problem worldwide, with an incidence over one million new cases annually.In addition, the **International Agency for Research on Cancer** has identified that certain infectious agents are capable of inducing cancer in humans (18% of the global cancer burden). Based on this background our research is trying to demonstrate the correlation between colorectal cancer and infection by Microsporidia, that are obligate intracellular parasites that cause opportunistic infections in immunocompromised patients. In previous research, it was determined that Microsporidia modulates certain immune responses by regulating the apoptosis pathway and the cell cycle, inhibiting the activation of apoptotic proteins such as caspase-3 and p53 that is a key protein in the process of malignancy of epithelial cells in the intestine, hence the interest to analyze the possible association of colon cancer and Microsporidia. So, we have studied the possible regulation of proteins involved in the regulation of apoptosis and cell cycle, critical factors related to the development of colon cancer (APC, PTEN, TGF-Beta) by Flow Citometry and the expression of certain oncogenes (RAS, KRAS PI3k) by retrotranscription-PCR, in the microsporidia infection "in vitro" cellular models. The results obtained showed a clear correlation between the increase of the expression of the oncogenes with microsporia infection, as well as an induction of the proteins responsible for cell cycle. It will enrich the knowledge of the colon cancer etiology and the involvement of microsporidia infection in this pathology.

P.D4.07.07

Role of nutritional status and energetic/lipid metabolism on outcome of tuberculosis in mice

C. La Rocca[1], *V. Gigantino*[2], *T. Micillo*[3], *D. Faicchia*[1], *S. Bruzzaniti*[1], *C. Fusco*[3], *C. Palma*[4], *G. Matarese*[3];
[1]*CNR-IEOS, Naples, Italy,* [2]*Istituto Nazionale Tumori "Fondazione Pascale", Naples, Italy,* [3]*University of Naples "Federico II", Naples, Italy,* [4]*Istituto Superiore di Sanità, Rome, Italy.*

Tuberculosis (TB), a chronic infectious disease caused by *Mycobacterium tuberculosis* (Mtb), still causes high mortality in the world. Mtb is an intracellular pathogen mainly harbored by macrophages, which can attack innate and adaptive host immune response for its survival. Considering that, nutritional status and energetic metabolism highly influence the host immune function, here, we investigated the role played by a reduced caloric intake and the adipocyte hormone leptin, a factor linking energy expenditure, nutritional status and immune functions, in the outcome of Mtb infection. We found that caloric restriction reduced lung and spleen bacterial load and immune-mediated lung damage in infected DBA/2 mice.
Granuloma lesions, the number of foam cells, -a sign of Mtb-driven dysregulation of host lipid metabolism- the levels of leptin and pro-inflammatory cytokines/chemokines such as IFN-gamma, interleukin (IL)-1, IL-6 and CCL-4, were reduced in the lungs and granuloma of infected mice at CR. All this was also associated with a significant reduction in the lungs of mTOR (mammalian target of rapamycin) pathway expression, suggesting profound alterations in cell metabolism and functions. Moreover, spleen cells of CR mice better restricted bacterial growth when infected *in vitro* with Mtb. This capability correlated with a reduced development of foam cells and the switch to anaerobic glycolysis (Warburg effects). Our study suggests that the outcome of TB is influenced by nutritional status and host energetic/lipid metabolism; all these factors can be novel targets for host-directed therapy to control TB.

P.D4.07.08

The C-type lectin receptor CLEC12A recognizes plasmodial hemozoin and contributes to cerebral malaria development

M. K. Raulf[1,2], *T. Johannssen*[1,3,4], *S. Matthiesen*[1], *K. Neumann*[5,6], *F. Steinbeis*[3], *P. H. Seeberger*[3,4], *C. Strube*[2], *J. Ruland*[6,7,8], ***B. Lepenies***[1];
[1]*Immunology Unit, University of Veterinary Medicine Hannover, Hannover, Germany,* [2]*Institute for Parasitology, University of Veterinary Medicine Hannover, Hannover, Germany,* [3]*Max Planck Institute of Colloids and Interfaces, Potsdam, Germany,* [4]*Institute of Chemistry and Biochemistry, Freie Universität Berlin, Berlin, Germany,* [5]*Institute of Clinical Chemistry, Hannover Medical School, Hannover, Germany,* [6]*Klinikum rechts der Isar, Technische Universität München, München, Germany,* [7]*German Cancer Consortium (DKTK), Heidelberg, Germany,* [8]*German Center for Infection Research (DZIF), München, Germany.*

Malaria represents a major cause of death from infectious disease. Hemozoin constitutes a *Plasmodium*-derived product that contributes to disease progression of cerebral malaria. However, there is a gap of knowledge of how hemozoin is recognized by innate immunity. Myeloid C type lectin receptors (CLRs) encompass a large family of carbohydrate-binding receptors that act as pattern recognition receptors in innate immunity.
In the present study, we investigated whether and how CLRs contribute to *Plasmodium* recognition and antimalarial host defense. Using a CLR-Fc fusion protein library and CLR reporter cell lines, we identified the CLR CLEC12A (MICL) as a novel receptor for plasmodial hemozoin. Dendritic cell/T cell co-culture assays indicated that the CLEC12A/hemozoin interaction enhanced $CD8^+$ T cell cross-priming. Using the *Plasmodium berghei* ANKA mouse model of experimental cerebral malaria (ECM), we found that CLEC12A deficiency protected mice from ECM, illustrated by an increased survival, ameliorated clinical symptoms, and modulated T cell effector functions.
In conclusion, we have identified CLEC12A as an innate sensor for plasmodial hemozoin. This is the first study that shows a direct recognition of a *Plasmodium*-derived ligand by a myeloid CLR.

P.D4.07.09

"Classical" and "non-classical" Th1 lymphocytes in tuberculosis protection

I. V. Lyadova*, I. Y. Nikitina, A. V. Panteleev, T. V. Radaeva, Y. V. Serdyuck, T. A. Nenasheva, A. A. Nikolaev;*
Central Tuberculosis Research Institute, Moscow, Russian Federation.

Infection with *Mycobacterium tuberculosis* (*Mtb*) results in different outcomes ranging from pathogen clearance to severe tuberculosis (TB). Knowing immunological correlates associated with the protection of TB-exposed individuals against TB and TB patients against severe disease is important, but these correlates remain largely unknown. We have examined the features of $CD4^+$ T cells associated with TB protection.
We evaluated Th1, Th17, Th1Th17, non-classical Th1 (Th1*) and polyfunctional $CD4^+$ populations in TB patients (TBP) and *Mtb*-exposed healthy individuals. The populations were identified based on intracellular cytokines (IFN-γ, IL-17, TNF-α, IL-2) and surface expression of chemokine receptors; the frequencies, numbers, differentiation and "exhaustion" status of each population were determined.
The frequencies of Th17 and Th1Th17 lymphocytes were rare in both, TBP and *Mtb*-exposed healthy individuals. Compared to TBP, *Mtb*-exposed healthy individuals had: more "non-classical" $CXCR3^+CCR6^+$ Th1* lymphocytes; less "classical" $CXCR3^+CCR6^-$ Th1 lymphocytes; more polyfunctional $TNF\text{-}\alpha^+IFN\text{-}\gamma^+IL2^+$ cells; less bi-/monofunctional $TNF\text{-}\alpha^+IFN\text{-}\gamma^+IL2^-$ and $TNF\text{-}\alpha^+IFN\text{-}\gamma^-IL2^-$ cells. In both TBP and *Mtb*-exposed healthy individuals, Th1* and Th1 populations were functionally similar, but differed by their differentiation degree: Th1* population contained more low-differentiated $CD27^+$ effectors and lacked terminally differentiated $CD27^-CD28^-$ effectors. $TNF\text{-}\alpha^+IFN\text{-}\gamma^+IL2^+$ lymphocytes were less differentiated than $TNF\text{-}\alpha^+IFN\text{-}\gamma^+IL2^-$ and $TNF\text{-}\alpha^+IFN\text{-}\gamma^-IL2^-$ populations, however the latter were largely un-exhausted ($PD\text{-}1^-$).
In conclusion, the degree of T helper cell differentiation rather that their quantities or functional properties represents a potential correlate of TB protection. The results suggest that effective vaccine should avoid T cell over-differentiation and are relevant to the development of new vaccination strategies for TB control.
Supported by Grant RSF-15-15-00136.

P.D4.07.10

Mitochondrial fission is associated with mROS dependent microbicidal responses to *Streptococcus pneumoniae* in macrophages

M. MOHASIN[1,2], *H. M. Marriott*[1], *D. H. Dockrell*[1,3];
[1]*University of Sheffield, Sheffield, United Kingdom,* [2]*University of Dhaka, Dhaka, Bangladesh,* [3]*University of Edinburgh, Edinburgh, United Kingdom.*

Introduction: Pneumonia is a leading cause of infection-related death and *Streptococcus pneumoniae*, the commonest cause, accounts for approximately one million deaths in children each year. Macrophages are key effectors of innate immune responses but the precise microbicidal mechanisms used to control pneumococci are incompletely characterised. Recently, we demonstrated that macrophages use mitochondrial reactive oxygen species (mROS) as a component of the microbicidal response and mROS are important in an apoptotic programme that contributes to intracellular bacteria killing. West AP et al. reported that TLR agonists augment intracellular bacterial killing through inducing mROS. We hypothesized that mitochondrial homeostasis would be altered in response to intracellular bacteria as an important element of the microbicidal response to pneumococci.Methodology: Macrophages metabolic profiles, mROS generation, bacterial killing and fission/mitophagy were evaluated by XF24 analyser, flow-cytometry, gentamicin protection assay and confocal or electron microscopy/immunoblotting, respectively.Findings: *S. pneumoniae* significantly increased mitochondrial fission resulting in reduced mitochondrial network complexity 12 hours after bacterial-challenge, before apoptosis induction. Fragmented mitochondria were co-localised or adjacent to an E3 ligase Parkin, phagolysosomes and intracellular bacteria but LC3B was not recruited. mROS co-localized with mitochondria that had undergone fission. Fission was reversed by PI-3K inhibitor 3-methyladenine but was not altered by the Drp1 inhibitor Mdivi-1. Pneumococci also reprogrammed macrophages metabolism from oxidative phosphorylation to glycolysis. Mitochondrial fission was associated with increased mROS production and intracellular bacterial killing. Conclusions: Modulation of mitochondrial fission is a potential cellular target with which to recalibrate host innate immune responses against internalized pathogens.

P.D4.07.11

An *in vivo* biosensor identifies CD11c^{hi} monocytes as a cellular reservoir for *Leishmania major* proliferation and cell-to-cell spread at the site of infection

S. Heyde[1], *L. Philipsen*[1], *P. Formaglio*[1], *E. A. Seiß*[1], *P. Bousso*[2], *B. Schraven*[1,3], ***A. J. Müller***[1,3];
[1]*Institute of Molecular and Clinical Immunology, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany,* [2]*Dynamics of Immune Responses, Institut Pasteur, Paris, France,* [3]*Helmholtz Centre for Infection Research, Braunschweig, Germany.*

The virulence of intracellular pathogens such as *Leishmania major* (*L. major*) relies on their ability to undergo cycles of replication within phagocytes, release, and uptake into new host cells. While all these steps are critical for successful establishment of infection, neither the cellular niche of efficient proliferation, nor the spread to new host cells have been characterized *in vivo*.
Here, we used a biosensor for measuring pathogen proliferation by intravital 2-photon microscopy and multiparameter histocytometry in the ongoing infection. We found that monocyte-derived CD11c^{hi} cells constituted the main cell type harboring rapidly proliferating *L. major*. Synchronization of monocyte recruitment by adoptive cell transfer showed that these high proliferating parasites preferentially underwent cell-to-cell spread, however newly recruited host cells were infected irrespectively of their cell type or maturation state. We propose that among these newly infected cells, only CD11c^{hi} cells, most probably monocyte-derived dendritic cells, are permissive for efficient proliferation. In contrast, macrophages, monocytes and neutrophils may represent an obstacle in the cycle of *L. major* proliferation, release and infection of new cells.
Therefore, besides their well-described function for priming and activating T cell effector functions against *L. major*, monocyte-derived dendritic cells provide a reservoir for rapidly proliferating parasites that disseminate at the site of infection.
Supported by funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (ImmProDynamics, grant agreement n° 714233) and the German Research Foundation DFG (MU 3744/2-1 and SFB854-Z01/02) to A.J.M.

RAS-blocking drugs: effect on Candida proteins and on metabolism of immune cells

K. H. Pinke[1], *R. A. da SIlva*[1], *B. L. Colombini-Ishikiriama*[1], *T. F. Garbieri*[1], *T. J. Dionísio*[1], *M. Fernandes*[1], *M. A. Buzalaf*[1], *S. H. de Oliveira*[2], *V. S. Lara*[1], *C. F. dos Santos*[1];
[1]*Bauru School of Dentistry; University of São Paulo., Bauru, Brazil,* [2]*Department of Basic Sciences, School of Dentistry, São Paulo State University-UNESP, São Paulo, Brazil.*

Growing evidences have linked activation of local renin-angiotensin system (RAS) with inflammatory conditions. Therefore, pharmacological interference on RAS components may exert an anti-inflammatory activity. Development of denture stomatitis, a *Candida*-associated inflammatory condition of denture-bearing mucosa, could also be affected by RAS-blocking drugs targeting renin due to molecular similarities with secreted aspartic proteases released by *Candida*. Considering that, we have evaluated the effects of blocking-RAS drugs on metabolism of human epithelial palate cells (HEPC), human gingival fibroblasts (HGF) and macrophages, and on production of pathogenic proteins by *C. albicans*. Human cells and *C. albicans* (SC5314 strain) were separately in vitro cultivated and incubated with losartan (50 µM) or aliskiren (250 µg/mL) by 24 hours, at 37ºC. Metabolism of human cells was evaluated by alamarblue assay by fluorescence reading at 488/600nm (excitation/emission).
C. albicans proteins were extracted from total fungal cells and subjected to proteomic analysis by shotgun strategy. Identified proteins from losartan- or aliskiren-treated fungi were compared with those obtained from untreated fungi using bioinformatics tools and *Candida*genome database. Among results, we highlighted upregulation exerted by losartan on WH11p, and downregulation induced by aliskiren on Adh1p, proteins related to morphological switching and to fluconazole resistance in *C. albicans*, respectively. On human cells, greater reductions in metabolism were observed after aliskiren treatment, especially on HEPC. Unlikely, losartan increased metabolism, mainly on macrophages. Altogether, our results suggest a possible modulation of pathological features related to DS by losartan and aliskiren.This work was supported by São Paulo Research Foundation (grant numbers: 2015/03965-2; and 2017/13202-1).

P.D4.07.13

Heat-killed *Mycobacterium tuberculosis* enhanced cytotoxicity to A549 lung cancer cells in classically activated-macrophage and tumor educated-macrophage through distinct responses

D. U. Putri[1,2], *S. M. Haryana*[3], *K. Y. Lee*[4,5];
[1]*Graduate Program, Faculty of Medicine, Yogyakarta, Indonesia,* [2]*International PhD Program in Medicine, Taipei Medical University, Taipei, Taiwan,* [3]*Department of Histology and Cell Biology, Faculty of Medicine, Yogyakarta, Indonesia,* [4]*Division of Pulmonary Medicine, Shuang Ho Hospital, New Taipei City, Taiwan,* [5]*Division of Pulmonary Medicine, Taipei Medical University, Taipei, Taiwan.*

Introduction: *Mycobacterium tuberculosis* (MTB), the causative agent of Tuberculosis (TB) disease is firstly recognized by alveolar macrophages. Low virulence-mycobacteria and/or its antigen have shown anti-tumor properties and are used as immunotherapy. However, the response of different macrophage phenotypes, especially in the presence of lung tumor, is poorly understood. Thus we utilized heat-killed MTB (HKTB) to elucidate the responses in different macrophage phenotypes. **Materials and Methods**: The classically activated-macrophage (MΦ) and tumor-educated macrophage (TEM) were derived from THP-1 cells, stimulated with heat-killed TB (HKTB), and analyzed for their phenotypes, protein quantification, and inflammatory cytokines expression. Furthermore, we co-cultured these HKTB-stimulated macrophages with A549 lung cancer cells to observe the cytotoxic activity. **Results:** HKTB enhanced killing potential to A549 cell in both MΦ and TEM models in a concentration-dependent manner. Cytokine analysis revealed an obvious increase of TNFα secretion from MΦ group, while TEM showed more IFNγ upregulation. Accordingly, addition of anti-TNFα to MΦ and anti-IFNγ to TEM reversed the observation. HKTB stimulation also induced proliferation towards the pro-inflammatory M1 phenotype in both macrophages. Furthermore, MΦ model showed subsequent increase of PI3K and AKT signaling which modulates inflammation and survival, as well as SUV39H1 which limits inflammation and may acts as a balance or fine-tune of macrophage polarization. **Conclusions:** Our results showed that HKTB stimulation increased cytotoxicity to A549 cancer cells by inducing pro-inflammatory responses in both MΦ and TEM models, suggesting an immunotherapeutic potential for lung cancer. However, further study should warrant the detailed mechanism and address any potential side effect.

P.D4.07.14

Enhanced interferon response genes in bronchial epithelial cells after *in vivo* rhinovirus challenge of asthma patients

A. Ravi, *J. Koster, A. Dijkhuis, S. Bal, P. J. Sterk, R. Lutter;*
Academic Medical Center, Amsterdam, Netherlands.

Rhinovirus (RV) induces acute worsening of asthma symptoms, which is linked to inadequate anti-viral responses. Bronchial epithelial cells (PBECs) are primary targets of RV and direct inflammatory and immune responses. We aim to determine anti-viral responses by PBECs from asthma patients *in vivo*.
Mild asthma patients (*n*=17) and healthy controls (*n*=4) were challenged with RV16. PBECs were obtained by bronchial brushes before and 6 days after RV16. The transcriptome was determined by RNAseq and correlated with clinical outcomes.
Anti-viral interferon response of 21 genes were upregulated (>3-fold) in asthmatics after RV16, but not in healthy controls. Interferon response genes correlated positively with the viral load (p=0.03) in bronchoalveolar lavage fluid (BALF) from asthmatics. The increased interferon response genes correlated with drop in forced expiratory volume$_1$ (R^2=0.25) and not with PC_{20} metacholine challenge tests, indicating its relation with lung function and not with airway hyperresponsiveness. BALF eosinophil cationic protein (ECP) levels increased (p=0.006) after RV16 in asthmatics and enhanced interferon response genes correlated positively with ECP (R^2=0.47) and percentage eosinophils (R^2=0.66) in BALF, but not with percentage neutrophils and myeloperoxidase. Ingenuity pathway analysis showed both type I and II interferons underlie interferon responses by PBECs in asthma.
Contrary to current thinking, asthmatics display marked interferon response genes *in vivo* to RV16, that relates to increased viral load, eosinophilic inflammation and loss of asthma control.

P.D4.07.15
RANKL improves macrophage-mediated immunity to *Leishmania major* infection

***T. S. Rigoni**, M. P. Cabral-Piccin, A. A. Filardy, M. F. Lopes, G. A. DosReis;*
Institute of Biophysics Carlos Chagas Filho, Rio de Janeiro, Brazil.

Macrophages are central effector cells in the immune response to *Leishmania* infection and their functional characteristics can be modulated by environmental stimuli. Whereas M1 macrophages (promoted by IFNγ and LPS) are associated with parasite control through the production of nitric oxide, M2 macrophages (promoted mainly by IL-4) are permissive to infection. Signals from the anatomical site in which macrophages are found can also control their tissue-specific functions. For example, receptor activator of nuclear factor kappa-B ligand (RANKL) is an important factor for macrophage differentiation to osteoclasts in the bones and also exerts regulation of the immune response in infections. However, the role of RANKL in macrophage functions in parasitic infections is still unknown.
Here, we demonstrated that treatment of inflammatory macrophages of B6 mice with RANKL and IFNγ increased nitric oxide (NO) production, as well as production of inflammatory cytokines (IL-12 and TNFα). In addition, we observed reduced expression of the M2 marker MGL-1 and increased IL-12 and iNOS expression in macrophages treated with RANKL only. Treatment with RANKL and IFNγ also reduced parasite load in macrophages infected with *L. major*, in an iNOS and reactive oxygen species (ROS)-dependent manner.
Together, these data suggest that RANKL *per se* and/or in cooperation with IFNγ enhances the effector activity of macrophages, by inducing M1 macrophage phenotype and promoting parasite control via NO and ROS production.

P.D4.07.16
Cathelicidins have their own unique fingerprint for antimicrobial and immunomodulatory activity

***M. R. Scheenstra**, M. Coorens, A. van Dijk, E. J. Veldhuizen, H. P. Haagsman;*
University Utrecht, Utrecht, Netherlands.

Cathelicidins are short cationic peptides, which play a crucial role during the innate immune response upon infection. Due to the combination of a strong antimicrobial effect combined with immunomodulatory capacities, they are promising alternatives to traditional antibiotics. The human cathelicidin LL-37, chicken cathelicidin-2 (CATH-2) and porcine PMAP-36 show similar antibacterial activities against *E. coli*. However, transmission electron microscopy (TEM) indicated that the mechanism used by these cathelicidins to kill *E. coli* are highly divergent, ranging from disrupting the membrane to complete lysis of the bacterial membrane. The immunomodulatory capacities of the cathelicidins were tested by stimulation of murine RAW264.7 macrophage cells with LPS in the presence of the cathelicidins. All three peptides efficiently inhibited LPS-induced macrophage activation. Using isothermal calorimetry (ITC), we were able to show that the mechanism of LPS inhibition differs greatly between the peptides. PMAP-36 is able to bind up to three LPS molecules, whereas CATH-2 and LL-37 bind only one LPS molecule. In addition, the binding of PMAP-36 and CATH-2 to LPS is very strong, whereas LL-37 only weakly binds LPS. In conclusion, although LL-37, CATH-2 and PMAP-36 are equally efficient in *E. coli* killing and inhibiting LPS-induced macrophage activation, their mode of action differ greatly. Understanding the inhibitory mechanisms of cathelicidins during LPS-induced immune activation could help avoid unwanted immune activation and sepsis.

P.D4.07.17
A single subcutaneous injection of chicken cathelicidin-2 in mice enhances the immune response against specific TLR ligands

***M. R. Scheenstra**, A. van Dijk, T. Cuperus, J. L. Tjeerdsma-van Bokhoven, E. J. Veldhuizen, H. P. Haagsman;*
University Utrecht, Utrecht, Netherlands.

Cathelicidins are short cationic peptides, containing both antimicrobial and immune modulatory activities. Previously it was shown that *in ovo* administration of a D-analog of chicken cathelicidin-2 (D-CATH-2) has a protective effect against a respiratory *E. coli* infection after hatch. D-CATH-2 treated chickens had reduced mortality, morbidity and bacterial load 7 days post infection. Similarly, a subcutaneous injection in mice of a truncated analogue of D-CATH-2, (DC-2_T), resulted in a protective effect against infection. To determine the mode of action of DC-2_T, different concentrations were administered subcutaneously in a single dose in mice. Increased numbers of monocytes in the blood of mice receiving the highest dose (10 mg/kg) were observed for up to 7 days. In addition, *ex vivo* stimulation of total splenocytes showed an increased immune response for specific TLR-agonists 24 hours post-injection, especially for the lower doses of DC-2_T (0.1 and 1 mg/kg). Bone marrow derived macrophages (BMDM), cultured 7 days after DC-2_T treatment, showed an increased activation upon stimulation with lipoproteins, indicating a prolonged effect of DC-2_T treatment. To show this was really due to DC-2_T injection, BMDM of naïve mice were treated *in vitro* with DC-2_T early in culture. Upon stimulation, the DC-2_T-treated BMDM showed a similar phenotype as the *in vivo* trained mice. In conclusion, this study showed that a single subcutaneous injection of DC-2_T has a prolonged protective effect in both chickens and mice. This suggests a promising role for derivatives of CATH-2 as alternatives to traditional antibiotics.

P.D4.07.18
ADCC antibodies correlate with reduced infection in a household model of influenza transmission

***S. A. Valkenburg**[1], N. Kavian[1], A. P. Li[1], N. H. Leung[2], L. L. Poon[2], B. J. Cowling[2];*
[1]HKU Pasteur Research Pole, Pokfulam, Hong Kong, [2]School of Public Health, Pokfulam, Hong Kong.

Immune correlates of protection need to be defined for the development of next generation influenza vaccines. Cross reactive antibodies which engage NK cells, to mediate Antibody Dependent Cellular cytotoxicity (ADCC), have been shown to be increased in older adults accounting for reduced H1N1 pandemic infection and risk of infection in a human challenge study, whilst also showing evidence for cross reactivity to avian viruses. Furthermore, human experimental challenge studies have shown a correlation with higher baseline titers and reduced risk of infection. Data on the protective role these cross reactive responses play in acquisition of infection and the severity of infection from baseline levels prior to infection is scarce. Our study reports on the context of household acquired infection in the Hong Kong community, and baseline PBMC and serum samples were collected from households reporting an index case of infection. Contacts of infected subjects were recruited and monitored for acquisition of infection. The baseline ADCC influenza-specific responses of uninfected contacts was found to be higher in magnitude and avidity to multiple influenza proteins than infected contacts, indicating a protective role of ADCC antibodies in the acquisition of influenza infection. Experiments are ongoing for the role of glycan effector expression for these responses. This study provides rare data on the context of community acquired influenza infection and the protective threshold of baseline immune responses for ADCC antibodies.

P.D4.07.19
Imaging Intracellular Pathogens Using Correlative Superresolution Electron Microscopy

***S. I. van Kasteren**;*
Leiden Institute of Chemistry, Leiden, Netherlands.

Intracellular pathogens can survive inside phagocytes, despite a powerful arsenal of anti-bacterial agents present in these cell. Understanding the interaction and survival mechanisms of these pathogens is therefore of utmost important to ensure the development of better antibiotics against these agents. To achieve this, we have developed a new imaging approach to study this interaction in detail: we can image pathogens selectively inside host cells using a technique called correlative light-electron microscopy, which overlays a fluorescent image (e.g. originating from a fluorescent protein) onto an electron micrograph to place it in the ultrastructural context of the cell. We have combined this technique with bioorthogonal pathogen labelling, which allows the labelling of the proteome of a pathogen with very small click-chemistry handles. This approach negates the use of genetic modification of the pathogen, broadening the application of the technique to unmodified pathogens (in our case Salmonella). To maximise the information obtained, we have recently combined super-resolution microscopy with electron microscopy. This way we can get information of the pathogen with 20 nm resolution and place this on the electron micrograph (with 1 nm resolution).

P.D4.08 Exploiting host pathogen interaction - Part 8

P.D4.08.01
Silent recruitment of TLR4 and MD-2 to the *Chlamydia trachomatis* serovar D inclusion in epithelial cells of the human urogenital tract

***S. Albrecht**, T. Miethke;*
Institute for Medical Biology and Hygiene, Mannheim, Germany.

Cells recognize invading microorganisms through pattern recognition receptors presented on their surface, resulting in the release of inflammatory cytokines. For example, the Toll-like receptor (TLR) family member TLR4 in combination with MD-2 and CD14 has been identified as the principle signal transducer in lipopolysaccharide (LPS) recognition. In the past, the role of TLR4 in *Chlamydia* recognition in epithelial cells of the urogenital tract has been controversially discussed. Whereas in rat prostate epithelial cells endogenous TLR4 is recruited to the *C. muridarum* inclusion, the co-localization of YFP-labeled TLR4 to the *C. trachomatis* serovar L2 inclusion in human cervix cancer cells could not be monitored. With our studies of endogenous TLR4 in human cervix cancer and bladder cancer cells infected with *C. trachomatis* serovar D we want to give this discussion a new turn.

Immunofluorescence studies of endogenous TLR4 and MD-2 in these cells revealed that TLR4 and MD-2 are recruited to the bacterium as early as 6 h p.I. At later time points (24-30 h p.I.), TLR4 and MD-2 are still associated with the bacterial inclusion. Additionally, we analyzed the localization of the intracellular TLR4 adapters MyD88, TIRAP and TRAM. We observed that MyD88 and TIRAP, but not TRAM, are recruited to the *C. trachomatis* inclusion. However, our data show that IL-6 and IL-8 production could not be induced by *C. trachomatis* infection. We assume that *C. trachomatis* recognition by TLR4/MD-2 does not lead to a pro-inflammatory signal and therefore remains silent.

P.D4.08.02
NLRP3 suppresses neutrophil-mediated innate immunity to helminth infection.

***R. Alhallaf**, Z. Agha, R. Eichenberger, L. Jones, J. Sotillo-Gallego, A. Kupz, A. Loukas, P. Giacomin;*
AITHM, Cairns, Australia.

Neutrophils are an important first line of defense against invading microorganisms but their role in immunity to large pathogens such as parasitic helminths is becoming increasingly appreciated. However, the mechanism of how these cells are activated and regulated following helminth infections is unclear. We demonstrate that rapid neutrophil recruitment to the lung is important for innate immunity to the nematode *Nippostrongylus brasiliensis* and these responses are suppressed by the NLRP3 inflammasome. NLRP3 deficient mice displayed elevated recruitment of neutrophils to the lung and enhanced protective type 2 immunity including elevated IL-4 and IL-13 expression in the lung and ,goblet cell hyperplasia in the intestine. Co-culture of sort-purified neutrophils with *Nippostrongylus* larvae resulted in killing of the parasite, potentially representing a mechanism of how these cells may provide protection against infection. Our findings suggest that neutrophils are important for regulating the early innate immune response to gastrointestinal helminth infections, suggesting that targeting NLRP3 may be a novel approach for limiting parasitic helminth health burdens.

P.D4.08.03
An in vitro study on the recruitment and differentiation of blood monocytes by splenic macrophages leading to macrophage hyperplasia during malaria

***J. J. Dalimot**[1], T. R. Klei[1], R. Arisz[1], J. Geissler[1], G. Bouyer[2], S. Egée[2], R. van Bruggen[1];*
[1]Sanquin Research, Amsterdam, Netherlands, [2]CNRS Station Biologique de Roscoff, Roscoff, France.

Malaria is still a global health and economic burden, responsible for 2 million deaths annually. *Plasmodium falciparum* is the most pathogenic Plasmodium species causing severe clinical symptoms like cerebral malaria, renal failure and lactic acidosis. The less understood pathology and main cause of infant mortality in endemic countries is severe malarial anemia (SMA). SMA is accompanied by splenomegaly and macrophage hyperplasia. Therefore, the elucidation of the mechanism facilitating the massive accumulation of phagocytes in the spleen could give an insight into the severe pathology of malarial anemia. By applying confocal microscopy and live cell imaging, we visualized the recruitment of circulating monocytes to splenic macrophages, which had been challenged with *P. falciparum* infected red blood cells (iRBCs). Moreover, the recruited monocytes show a red pulp macrophage-like phenotype characterized by the upregulation of the RPM specific transcription factor, SpiC. This process is dependent on the direct cell interaction with splenic macrophages and the erythrophagocytosis of iRBCs. Together these findings indicate the recruitment and accumulation of monocytes to the spleen upon malaria infection, thus, contributing to macrophage hyperplasia and the subsequent massive destruction of uninfected and infected red blood cells, ultimately leading to severe malarial anemia.

P.D4.08.04
Respiratory epithelial cells enhance IFN-γ production by natural killer and mucosal associated invariant T cells in response to *Bordetella pertussis*

***G. den Hartog**, M. Schijf, G. A. Berbers, F. R. van der Klis, A. Buisman;*
National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands.

IFN-γ is important for protective immunity to *Bordetella pertussis,* the causative bacterium for whooping cough. Here we identify an innate mucosal mechanism for the production of IFN-γ in the early stages of infection.
PBMCs from healthy donors were stimulated with proteins or inactivated intact *B. pertussis* (B1917) for 20h in the presence or absence of respiratory epithelial cells. Cell culture supernatants were analysed for cytokine production and cells for intracellular IFN-γ and CXCL10 production.
Stimulation of PBMCs with multiple isolates of *B. pertussis*, but not soluble ligands of *B. pertussis*, and IL-15 resulted in synergistically increased secretion of IFN-γ. Intracellular staining revealed that NK cells and mucosal associated invariant T (MAIT) cells were the main source of IFN-γ, but not CD4 or CD8 T cells. Depletion of monocytes or pDCs did not impair but rather increased the levels of IFN-γ. Purification of untouched NK cells showed that NK cells can produce IFN-γ following exposure to *B. pertussis* and IL-15 independent of other immune cells. Both levels of IFN-γ in the supernatant and intracellular IFN-γ increased when PBMCs were cultured in the presence of respiratory epithelial cells. Also, IFN-γ inducible chemokines CXCL9 and CXCL10 increased and staining showed that CXCL10 was mainly derived from epithelial cells.
We conclude that respiratory epithelial cells enhance rapid IFN-γ production by NK and MAIT cells following stimulation with *B. pertussis*. These data provide insight into immune responses to *B. pertussis* that could aid the development of therapeutic strategies.

P.D4.08.05
Rhinovirus induces an anabolic reprogramming in host cell metabolism essential for viral replication

***G. A. Gualdoni**, K. A. Mayer, A. Kapsch, K. Kreuzberg, A. Puck, F. Oberndorfer, K. Frühwirth, S. Winkler, D. Blaas, G. J. Zlabinger, J. Stöckl;*
Medical University Vienna, Vienna, Austria.

Rhinoviruses (RVs) are responsible for the majority of upper airway infections; despite their high prevalence and the resulting economic burden, effective treatment is lacking. We report herein that RV induces metabolic alterations in host cells, which offer an efficient target for antiviral intervention. Metabolomic analysis of RV infected cells revealed a critical role of glucose-mobilization from extracellular and intracellular pools -via glycogenolysis- for viral replication. The virus-induced enhancement of glucose uptake was dependent on PI3-Kinase and was accompanied by the upregulation of GLUT1 surface expression. Glucose was primarily required to attain a highly anabolic state in the infected cells including enhanced nucleotide synthesis and lipogenesis. Consistently, we observed that glucose-deprivation both from medium and via glycolysis inhibition by 2-deoxyglucose (2-DG) potently impairs viral replication. Metabolomic analysis showed that 2-DG specifically reverts the RV-induced anabolic reprogramming. In addition, treatment with 2-DG inhibited RV infection and inflammation in a murine model. Thus, we demonstrate that the specific metabolic fingerprint of RV infection can be used to identify new targets for therapeutic intervention.

P.D4.08.06
The mitochondrial sirtuins SIRT3 and SIRT5 control NLRP3 inflammasome activation and interleukin-1β (IL-1β) secretion

***T. Heinonen**[1], E. Ciarlo[1], D. Le Roy[1], J. Auwerx[2], T. Roger[1];*
[1]Lausanne University Hospital, Epalinges, Switzerland, [2]Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland.

Background: IL-1β is involved in host defences against infections, but dysregulated expression of IL-1β is involved in inflammatory and metabolic disorders. The NLRP3 inflammasome, which is activated by reactive oxygen species (ROS), cleaves pro-IL-1β into mature, secreted, IL-1β. SIRT3 and SIRT5 are mitochondrial lysine deacetylases regulating the activity of ROS detoxifying enzymes. We previously showed that single knockout in SIRT3 or SIRT5 has no impact on innate immune responses. Hypothesizing that SIRT3 and SIRT5 may have compensatory activities, we assessed whether double deficiency in SIRT3 and SIRT5 impacts on inflammasome activity, IL-1β production and host defences against *Listeria* infection.
Methods: Mice were housed in SPF conditions. Bone marrow derived macrophages (BMDMs) were primed with TLR ligands and stimulated with monosodium urate (MSU) crystals to assess the production of ROS and cytokines. Mice were injected i.p. with MSU crystals and i.v. with *Listeria monocytogenes*. Peritoneal lavage and blood were collected to quantify ROS, cytokines and bacteria. Weight, severity scores and survival were registered.
Results: SIRT3/5 deficiency increased ROS production and IL-1β release by BMDMs, and ROS production by peritoneal cells. In a model of listeriosis, SIRT3/5 deficiency was associated with reduced bacterial burden, but had no significant effect on mouse survival.
Conclusion: These results suggest that SIRT3 and SIRT5 cooperate to control inflammasome activity and IL-1β production, and to protect from listeria burden. Thus, dual targeting of SIRT3 and SIRT5 may represent an attractive strategy for treating IL-1β-mediated inflammatory and metabolic diseases without increasing the risk of infection.

P.D4.08.07
Metabolic re-programming of the innate antiviral response during dengue virus infection of myeloid dendritic cells

*M. Ferrari[1], A. Zevini[1], L. Castiello[1], E. Palermo[1], M. Muscolini[1], C. Holm[2], D. Olagnier[2], **J. Hiscott**[1];*
[1]Istituto Pasteur Italia, Rome, Italy, [2]Aarhus University, Aarhus, Denmark.

Dengue virus (DENV), the leading arthropod-borne viral infection in the world, infects more than 300 million people worldwide, leading to 50,000 deaths annually. Markers associated with oxidative stress have been identified in patients with severe DENV infection, suggesting a relationship between oxidative stress and viral pathogenesis. Using genetic, biochemical and pharmacologic approaches, we demonstrated that the antioxidant gene network induced by Nrf2 transcription factor limited antiviral and cell death responses to DENV infection in primary human monocyte-derived dendritic cells (Mo-DC). Recent studies have further demonstrated that Nrf2, activated by the chemical sulforaphane (SFN) or by the Krebs cycle metabolite itaconate, dampened the release of pro-inflammatory cytokines, type I IFNs and IFN-stimulated genes, including the cGAS-STING, in response to DENV infection. Silencing of Nrf2 by RNA interference or CRISPR/Cas knockout increased both DENV infection and the associated antiviral and inflammatory responses.

As a viral evasion strategy, *de novo* DENV infection in turn targeted Nrf2 for proteasome-mediated degradation, and also down-regulated metabolic pathways involved in NADPH and glutathione synthesis, resulting in further accumulation of ROS and oxidative stress. Metabolic re-programming of the antioxidant response during DENV infection potentially establishes metabolic conditions for ROS accumulation and oxidative stress that aggravates DENV pathogenesis. Collectively, these data identify that Nrf2 and the anti-oxidant gene network as important regulators of the innate antiviral and inflammatory response, and as a target for DENV-mediated metabolic re-programming of the host response to infection.

P.D4.08.08

Immune evasion strategies of HCMV: Functional characterization of the highly polymorphic HCMV Fcγ receptor *RL12*/gp95

K. Hoffmann[1], *E. Mercé-Maldonado*[2], *H. Reinhard*[2], *E. Corrales-Aguilar*[3], *V. Khanh Le-Trilling*[4], *P. Lacher*[2], *H. Hengel*[1];
[1]*Institute of Virology, Freiburg, Germany,* [2]*Institute for Virology, Heinrich-Heine-University, Düsseldorf, Germany,* [3]*Virology-CIET, Faculty of Microbiology, San José, Costa Rica,* [4]*Institute for Virology, University Duisburg-Essen, Essen, Germany.*

Interactions of IgG with Fc-γ-Receptors (FcγRs), expressed on many immune cells, are essential for opsonization, phagocytosis and antibody-dependent cellular cytotoxicity. To avoid harmful IgG effector responses HCMV has evolved evasion strategies by expressing viral FcγRs (vFcγRs) interfering with host FcγR activation. HCMV encodes several, vFcγRs, i.e. gp34 (*RL11*), gp68 (*UL119-UL118*) and gp95 (*RL12*).
For gp34 and gp68 we have demonstrated a powerful inhibition of all activating FcγRs, i.e. FcγRI/CD64, FcγRII/CD32A and FcγRIII/CD16 . Here we focused on *RL12*/gp95 as a further potential antagonist of host FcγRs. Compared to gp34 and gp68, gp95 exhibited a remarkably different pattern of IgG-subclass-binding: while gp34 and gp68 bind readily to all human IgG-subclasses, gp95 binding is restricted to human IgG1 and IgG3. Further differences were observed with respect to gp95 efficiency to antagonize human FcγRs. Using Rituximab (anti-CD20) isotypes as a subclass-dependent reference IgG strong effects against FcγRIII/CD16 > FcγRII/CD32A/FcγRII/CD32B were noted while only minor effects on FcγRI/CD64 were seen, contrasting gp68 which invariably blocked all human FcγRs with a comparable efficiency.
Unlike *RL11* and *UL119-UL118*, *RL12* is one of the most polymorphic genes found in the HCMV genome. Phylogenetic-analysis based on 62 *RL12* sequences revealed 4 distinct genetic-clades. Most strikingly, extended low-complexity-regions (LCRs) reside in the N-terminus of all *RL12*-alleles. LCRs are known for their ability to rapidly adapt to dynamic changes. In line with our hypothesis that LCRs may thus modify the strength of gp95 inhibitory potential, substantial HCMV strain specific differences in gp95 attenuation of human FcγRIII responses were noted.

P.D4.08.09

Dynamic signatures of human lung resident memory CD8+ T cells during experimental influenza infection

S. Kar[1], *S. Paterson*[1], *S. Ung*[1], *A. Jozwik*[1], *Z. Gardener*[1], *S. Ascough*[1], *J. Maertzdorf*[2], *J. Weiner*[2], *H. Jarvis*[3], *O. Kon*[3], *S. Kaufmann*[2], *P. Openshaw*[3], *C. Chiu*[4], *PREPARE Consortium;*
[1]*1Section of Infectious Diseases & Immunity, Imperial College London, London, United Kingdom,* [2]*Max Planck Institute for Infection Biology, Department of Immunology, Berlin, Germany,* [3]*2National Heart and Lung Division, Imperial College London, St. Mary's Campus, London, United Kingdom,* [4]*Imperial College London, London, United Kingdom.*

Resident memory T (Trm) cells confer protection in murine models of influenza but have been little studied in humans. Here, for the first time, we show CD8+ Trm cell-mediated responses *in vivo* following human influenza challenge. Healthy adults (n=24) were challenged intra-nasally with influenza A(H1N1)2009. Blood and nasal samples were obtained throughout infection; 12 participants also underwent bronchoscopy for lower airway sampling at days 0, 7 and 28 post-inoculation. Thirteen volunteers (54%) were symptomatically infected while 11 remained uninfected. Symptoms peaked at day 4 and resolved by day 8 post-inoculation. CD8+ T cells in blood and bronchoalveolar lavage (BAL) were analysed by flow cytometry with tetramer-labelling of influenza-specific T cells. Antigen-specific CD8+ T cells in BAL were significantly enriched compared with blood and predominantly expressed the canonical Trm markers CD69 and CD103. Activation and proliferation peaked at day 7 before contracting to leave an enlarged memory pool. Matched blood and BAL CD8+ T cells were sorted by FACS and analysed by RNA sequencing to compare transcriptional profiles between anatomical compartments and differentially expressed genes (DEGs) over the course of infection. At baseline, >4000 DEGs were identified, reflecting the marked divergence between circulating and tissue populations. The most highly significant DEGs were subsequently investigated as potential novel markers of human lung Trm. The dynamic molecular profiles of pulmonary CD8+ Trm cells identified in this study thus enable further mechanistic understanding of Trm differentiation and lay the groundwork to enable the induction of local cell-mediated protection by future universal influenza vaccines.

IL-26 inhibits Hepatitis C virus replication in hepatocytes

V. Larochette[1,2], *É. Beaumont*[3], *L. Preisser*[1,2], *P. Pignon*[1,2], *S. Blanchard*[1,4,2], *J. Dauvé*[5], *M. M. Poranen*[6], *A. Morel*[1,5,2], *H. Fickenscher*[7], *Y. Delneste*[1,4,2], *P. Roingeard*[3], *P. Jeannin*[1,4,2];
[1]*CRCINA INSERM U1232 Team 7, Angers, France,* [2]*Labex IGO, Angers, France,* [3]*INSERM U966, Tours, France,* [4]*Hospital of Angers, Angers, France,* [5]*ICO Paul Papin, Angers, France,* [6]*University of Helsinki, Helsinki, Finland,* [7]*University Christian Albrecht of Kiel, Kiel, Germany.*

Initially identified as a molecule overexpressed in virus-transformed human T cells, IL-26 has been classified as a proinflammatory cytokine due to its capacity to induce inflammatory cytokines production by myeloid and epithelial cells. Nevertheless, its biological functions remain largely unknown, in part because of its absence of orthologs in rat and mouse.
Our team has previously reported that IL-26, overexpressed in HCV-infected patients, activates NK cells, rendering them able to kill HCV-infected hepatocytes (Miot et al. 2015). Results also showed that IL-26 accumulates in hepatocytes of HCV-infected patients, a localization inconsistent with a classical role for a cytokine. Another study reported that IL-26 modulates in vitro the infectivity of three enveloped viruses, independently of the immune system.
In this study, we demonstrate that IL-26 protects hepatocytes from HCV infection. Confocal microscopy revealed that IL-26 colocalizes with dsRNA. This direct antiviral activity appears to rely on the capacity of IL-26 to bind to viral RNA and inhibit its replication. This study identifies a direct protective role of IL-26 against HCV infection and increases our understanding of the antiviral defense mechanisms contributing to control HCV infection.
Collectively, our studies show that IL-26 may have a dual protective role during HCV infection: (i) an indirect role via its capacity to induce NK cell-mediated death of HCV-infected cells and (ii) a direct role through its ability to inhibit viral replication.

mGBP7 and interacting proteins in the combat against *Toxoplasma gondii* infection and emerging insights into the biochemical properties of mGBP7

L. Legewie[1], *S. Smits*[2], *N. Steffens*[1], *E. Kravets*[1], *M. Prescher*[2], *D. Degrandi*[1], *L. Schmitt*[2], *K. Pfeffer*[1];
[1]*Institute of Medical Microbiology and Hospital Hygiene, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany,* [2]*Institute of Biochemistry, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany.*

Introduction: *Toxoplasma gondii* (*T. gondii*) is an obligate intracellular parasite and the causative agent of toxoplasmosis. During host cell invasion, *T. gondii* forms an unique membranous compartment called the parasitophorous vacuole (PV). Members of the murine guanylate binding protein (mGBP) family translocate to the PVM leading to its disruption, but the underlying molecular mechanisms are poorly understood. The aim of this project is to provide a better understanding of the biochemistry of mGBPs as well as to elucidate the molecular mechanisms by which this IFNγ-inducible protein family is able to attack the parasite directly.
Methods: The GTPase activity of mGBP7 and its oligomerization status were analysed using the malachite green phosphate assay and SEC-MALS. For the identification of potential mGBP7 interaction partners originating from the host cell or the invading *T. gondii* co-immunoprecipitation (co-IP) and mass spectrometry (MS) experiments were performed.
Results: The Hill coefficient *h* of mGBP7 indicates a positive cooperativity of GTP hydrolysis and a half maximal concentration constant $K_{0.5}$ in the µM range. In accordance to the Hill coefficient the SEC-MALS results support the assumption that mGBP7 stimulates the GTPase acitivity in a cooperative manner and constitutes a very transient oligomer. The MS results on the other hand offer hints about potential mGBP7 interaction partners and reveal that mGBP7 is ubiquitinated independent of *T. gondii* infection.
Conclusions: The biochemical characterization of mGBP7 as well as the identification of potential mGBP7 interacting proteins provide new insights into the dynamic interactions at the interface of parasite and host.

P.D4.08.12

Mechanisms of immune evasion to alpha beta T cells in Cytomegalovirus infection, positively impinge on gamma delta T cells response

L. L. MASSARA[1], *C. Fieldings*[2], *H. Kaminski*[1], *J. Visentin*[1,3], *V. Pitard*[1,4], *A. Stum*[1,4], *M. Pierre*[1,3], *W. Gavin*[2], *D. Julie*[1];

Human cytomegalovirus(CMV),a βHerpes virus, is considered as a paradigm for viral evasion. It is an important opportunistic pathogen in immunocompromised patients and a major cause of congenital birth defects when acquired in utero. HCMV encodes at least four US genes to prevent antigen presentation to αβ T cells through inhibition of HLA-I expression. CMV also decreases NK cell functions by mimicking or down-regulating ligands for NK receptors. However,the impact of these evasion mechanisms on γδ T cells is unknown. We studied the influence of the modulation of HLA-I expression on the reactivity of αβ versus γδ T cells. We infected cells with either HCMV wild type(CMV-WT) or HCMV lacking US encoding genes involved in HLA-I downregulation(CMV-ΔUS). CMV-ΔUS-infected fibroblasts expressed much more HLA-I than CMV-WT-infected cells. Interestingly,γδ T cell clones were activated to produce INF-γ when cultured with CMV-WT infected fibroblasts, but not when fibroblasts were infected with CMV-ΔUS.Furthermore, when isolated from the same CMV-infected patient, purified γδ and αβ T cells respond in an opposite way to CMV-WT vs CMV-ΔUS infected cells, according to the magnitude of HLA-I molecules.

We have previously reported that γδ T cells responding to CMV express high levels of killer Ig-like receptors (KIR). We are therefore currently studying the implication of KIR receptors and of the different US genes in the HLA-I dependent modulation of γδ T cell response to HCM.In conclusion,the immune escape processes evolved by CMV could promote γδ over αβ T cell response and increase our knowledge on how γδ T cells respond to the virus which is important in immunosuppressed individuals.

P.D4.08.13

C-type lectin receptor (CLR)-Fc fusion proteins as a tool to screen for novel CLR/bacteria interactions

S. Mayer[1], *R. Moeller*[1], *J. Monteiro*[1], *K. Ellrott*[2,3], *C. Josenhans*[2,4,5], *B. Lepenies*[1];
[1]*Immunology Unit & Research Center for Emerging Infections and Zoonoses, University of Veterinary Medicine Hannover, Hannover, Germany,* [2]*Institute for Medical Microbiology, Medical School Hannover, Hannover, Germany,* [3]*German Center for Infection Research (DZIF), Partner site Hannover-Braunschweig, Germany,* [4]*Max von Pettenkofer Institute, Ludwig Maximilian University Munich, Munich, Austria,* [5]*German Center for Infection Research (DZIF), Partner site Hannover-Braunschweig and Munich, Germany.*

The host is challenged every day by a huge number of various pathogens. Highly conserved microbial structures (pathogen-associated molecular patterns (PAMPS)) are recognised by pattern-recognition receptors (PRRs) localised on immune cells. Upon PAMP detection, several effector functions like phagocytosis and antigen presentation are induced. C-type lectin receptors (CLRs) represent one group of PRRs. While the interaction of CLRs with several pathogens-derived ligands has been described, still little is known about the role of CLRs in bacterial recognition.
This work describes innovative methods based on a comprehensive library of recombinantly expressed CLR-hFc fusion proteins to unravel novel CLR-bacteria interactions. For demonstration, the important human pathogens *Group A Streptococcus* and *Campylobacter jejuni* were used for exemplary studies to demonstrate that these methods can be easily applied to Gram-positive as well to Gram-negative bacteria. First, a plate-bound ELISA-based assay was established to allow for a high-throughput pre-screening of potential bacteria-CLR interactions. Furthermore, a flow cytometry-based assay was used to screen for CLR-bacteria interactions in solution and finally, confocal microscopy allowed for visualization and direct characterisation of the interaction. Using this combination of different techniques, we have identified candidate CLRs that may play a role in bacterial recognition. Our study enables new insights into the host innate immune response against the respective bacteria.

Type I interferon induction by *Orientia tsutsugamushi* depends on nucleic acid recognition but does not require bacterial viability

Z. Orfanos[1], *V. Hefter*[1,2], *S. Bauer*[3], *C. Keller*[1,2];
[1]*Institute of Virology, Philipps University Marburg, Marburg, Germany,* [2]*German Centre for Infection Research at the Institute of Virology, Philipps University Marburg, Marburg, Germany,* [3]*Institute of Immunology, Philipps University Marburg, Marburg, Germany.*

Scrub typhus, a potentially lethal infection caused by the obligate intracellular Gram-negative bacterium *Orientia tsutsugamushi*, is a mite-borne zoonosis associated with strong cytokine induction. Upon infection, *Orientia* enters phagocytic cells by receptor-mediated endocytosis and shortly after escapes the endosome to replicate in the cytoplasm. Infection results in a strong induction of TNF-α and type I interferon within a few hours. Previous work proposed that interferon (IFN)-β is exclusively induced by live bacteria in macrophages. However, ligands and receptors responsible for this induction remain unknown.
We are investigating type I interferon induction by *Orientia* in mouse bone marrow-derived dendritic cells (BMDC). Our experiments show that live organisms induce IFN-β mRNA in C57BL/6 BMDC within hours after infection. Stimulation of BMDC with bacteria inactivated at 95°C showed a dramatically reduced IFN-β induction. Surprisingly, bacteria inactivated at a lower temperature induced as much IFN-β as live bacteria. These results point to a heat-stable ligand that is differentially accessible to innate receptors depending on the viability or degree of damage of the bacteria. The IFN-β induction was dependent on the endosomal Toll-like receptors 3, 7 and 9, suggesting that the ligand is a nucleic acid. Thus, IFN-β induction in BMDC in response to *Orientia* does not require viable bacteria but can also be recapitulated by dead organisms under certain conditions. We propose that the accessibility of nucleic acid ligands to innate receptors is different in live, dead or damaged bacteria, and that their exposure in the endosome leads to distinct type I interferon responses.

P.D4.08.15

Preparation, identification, and preliminary application of mAbs against Sao-M protein of S.suis 2

X. Pan[1], *J. Wang*[2], *X. Li*[1], *D. Hu*[1], *C. Wang*[1];
[1]*Hua Dong Research Institute for Medicine and Biotechnics, Nanjing, China,* [2]*Wuxi Maternity and Child Health Care Hospital, Wuxi, China.*

Introduction: Streptococcus suis serotype 2 (S.suis 2) has becoming a highly invasive zoonotic pathogen. In particular, two large-scale outbreaks of lethal S.suis 2 infections had emerged in China. Previous experiments showed that Sao-M was an excellent candidate for detection of S.suis 2. In this research, We prepared monoclonal antibodies (mAbs) against Sao-M and analyzed their biological characteristics. Materials and Methods: BALB/c mice were immunized three times with purified Sao-M protein plus adjuvant. Two weeks after the final immunization, mice were immunized with Sao-M alone. Then, spleen cells were isolated three days after the last immunization, and fused with SP2/0 myeloma cells using PEG. Hybridoma cells secreting mAbs were screened by continuously subculture, which were then injected into mice to produce mAbs ascites. Titers of mAbs from ascites were determined with ELISA.
Isotyping was performed with an Ig subtype ELISA kit. The ability of mAbs binding to native Sao-M was detected by incubating with S.suis 2. Results: Four hybridoma cell lines were obtained and all of them were able to secrete mAbs stably. The mAbs from the four cell lines all belonged to IgG1 subtype and the titers were all higher than 1:102,400. Analysis revealed that the mAbs could bind to Sao protein on the surface of S.suis 2 and had a significant effect on bacterial morphology.Conclusion: We prepared four mAbs against Sao-M protein successfully, which laid the foundation for rapid detection of S.suis 2 infection and the function research of Sao proteins.

P.D4.08.16

The secrets of the adaptation of *Brucella* to the hostile environment of the host

G. Potemberg[1,2], *J. Sternon*[1], *A. Demars*[1], *X. De Bolle*[1], *E. Muraille*[2];
[1]*University of Namur, Namur, Belgium,* [2]*Université Libre de Bruxelles, Bruxelles, Belgium.*

Understanding how pathogenic bacteria adapt to the specific microenvironment of the host to successfully colonize is matter of importance especially with bacteria that can evade immune system and are able to induce chronic infection. Infection by the bacteria *Brucella* results in common chronic disease in humans and animals called brucellosis. Actually with still no efficient vaccine available brucellosis represents huge economical losses. Moreover chronicity and recurrence of this infection cause significant morbidity despite heavy antibiotic treatments.
To better understand *Brucella* infectious cycle in mice lungs after intranasal infection, we used in situ visualization approach of the bacterial multiplication with fluorescent reporter system. Our observations by microscopy suggest that replicative bacteria are more sensitive to the immune response. A fraction of the non growing bacteria that survive the first 24h later give rise to an intensive proliferation in some alveolar macrophages. This non replication strategy may reflect adaptation to host hostile environment.
Here we have identified a set of genes that are essential for colonization of mice lungs by high density transposon insertion site sequencing Tn-Seq on the whole genome of *Brucella melitensis*. Using this method at selected time point during the first 48 hours of *Brucella* pulmonary infection, our analysis show that efficient host colonization by *Brucella* not only rely on virulence gene expression but also on important adaptation of the metabolism to the divers environment encountered during infectious cycle. Identification of essential genes for bacterial survival in context of pulmonary infection may lead to more effective prophylactic strategies.

P.D4.08.17

Human and bacterial antimicrobial peptides activate signal inhibitory receptor on leukocytes-1

M. Rumpret[1], *M. van der Linden*[1], *J. van Strijp*[2], *N. M. van Sorge*[2], *L. Meyaard*[1];
[1]*Laboratory for Translational Immunology, University Medical Centre Utrecht, Utrecht, Netherlands,* [2]*Department of Medical Microbiology, University Medical Centre Utrecht, Utrecht, Netherlands.*

Bacteria of the genus *Staphylococcus* commonly colonize humans and although closely related, comprise species with vastly different pathogenic potential. This makes *Staphylococci* a good model to study differential immune responses to commensals and pathogens. Signal inhibitory receptor on leukocytes-1 (SIRL-1) is a negative regulator of anti-microbial and inflammatory functions of myeloid cells. Phenol-soluble modulins (PSMs) are short amphipathic peptides secreted by different staphylococci. Structurally, they are very similar to the human antimicrobial peptide cathelicidin LL-37. We found that *S. aureus* is able to activate a SIRL-1-reporter cell line and using a transposon library screen, identified PSMs as potential ligands. Knock-outs of PSMs in *S. aureus* failed to activate SIRL-1 reporter cells, which was rescued by re-introducing PSM by plasmid complementation in two different *S. aureus* strains. Moreover, synthetic PSMs, as well as synthetic human LL-37, activated SIRL-1 reporter cells, further demonstrating that staphylococcal PSMs and human LL-37 ligate SIRL-1. We propose that the SIRL-1 / LL-37 interaction is in place to limit immune cell activation or restore immune homeostasis after clearance of the microbial threat. Further, pathogenic *Staphylococci* may exploit SIRL-1 as an immune evasion strategy in the context of skin and soft tissue infections, which are frequently caused by *S. aureus* and related PSM-producing *Staphylococci*.

P.D4.08.18

Human Epidermal Langerhans cells might constitute an underestimated HIV reservoir

***S. Saluzzo**, J. Strobl, N. Bayer, A. Rieger, V. Touzeau-Roemer, G. Stingl, G. Stary;*
Medical University of Vienna, Vienna, Austria.

Introduction: Viral reservoirs are major obstacle to HIV eradication. The skin is a highly immunologically active organ and containing CD4+ T cells and Langerhans cells (LCs), the major targets of HIV infection. LCs can restrict HIV viral replication and are thought to be determinant in reducing the risk of HV transmission at mucosal level. However, recent evidence suggests that also antigen presenting cells (APCs) could remain latently infected with HIV upon establishment of a chronic infection. Our project aims at understanding if the skin resident cells could harbor latently infected cells and eventually provide new insides in the mechanisms of HIV latency. **Methods:** We collected skin biopsy from individuals during the viremic phase of HIV infection as well as under antiretroviral therapy (ART) with undetectable viral load (ndVL). We investigated HIV latency analyzing p24 expression by Tissue-FACS software and electron microscopy (EM). **Results:** IF staining showed the presence of a $CD4^+$ $CD3^-$ epidermal immune cell population still harboring p24 expression both in viremic patients and those with ndVL. We identified this population as being exclusively composed by LCs. **Conclusions and future prospects:** Although preliminary, our results suggest that LCs might still harbor HIV virions in individuals with suppressed viral replication. Further analysis will prove if $p24^+$ cells contain HIV RNA and DNA by RT-PCR as well as RNA and DNA Scope analysis and electron microscopy. If this is the case, our experiments will focus in understanding infected LCs could present replication competent virus and constitute an underestimated HIV reservoir.

P.D4.08.19

The Use of CRISPR-Cas9 Based Genome-Scale Screening for Mapping the Intracellular Immune Response of NK Cells Against Lentiviral Gene Delivery

***A. Sarac**[1,2,3], E. Sayitoglu[4], A. E. Eyupoglu[1,2], D. Ozkazanc[1,2], B. Erman[2,1], A. D. Duru[4], T. Sutlu[1];*
[1]Nanotechnology Research and Application Center, Sabancı University, İstanbul, Turkey, [2]Faculty of Engineering and Natural Sciences, Sabancı University, İstanbul, Turkey, [3]Genetic Engineering and Biotechnology Institute, TUBITAK, MAM, Kocaeli, Turkey, [4]NSU Cell Therapy Institute, Nova Southeastern University, Fort Lauderdale, United States.

Immunotherapies based on Natural Killer (NK) cells show promise in the treatment of cancer. However, the biological and practical challenges of viral vector based gene delivery to NK cells significantly reduces clinical possibilities. There is scarce information about the intracellular immune response pathways triggered by viral vector entry. Anti-viral responses have been studied thoroughly in wild-type virus infections but the field has been mostly overlooked from the perspective of gene therapy vectors. In this study, we used the genome-wide screening ability of CRISPR/Cas9 system to discover mechanisms taking part in resistance to lentiviral gene delivery.
We utilized Genome-scale CRISPR Knock-out Libraries (GeCKO) in addition to next-generation sequencing technologies to screen genes taking part in these responses. By means of the controlled experiment set-up, we were able to determine that RIG-I/MDA5 and certain members of Toll-like receptor families (TLRs) are candidate pathways which play a crucial role in the response to lentiviral vector entry, triggering the secretion of antiviral factors in NK cells. Our data suggest that TLR or RLR mediated detection of viral vector components activates an anti-viral response, negatively affecting the efficiency of lentiviral gene delivery. Development of novel gene transfer protocols based on the inhibition of intracellular antiviral responses will open up the possibility to enlarge the base of cell types which can efficiently be used in gene therapy protocols.

P.D4.08.20

Estrogen Receptor Alpha agonist and antagonist differentially modulate host immunity during ascending Urinary Tract Infection

***A. Sen**[1], S. Boddu[1], J. Iyer[2], A. Kaul[1], R. Kaul[1];*
[1]Oklahoma State University Center for Health Sciences, Tulsa, United States, [2]Northeastern State University, Tahlequah, United States.

The protective role of estrogen against Urinary Tract Infection (UTI) has been well-established, but the underlying mechanisms are still unknown. Our *in vivo* studies showed that estrogen via estrogen receptor alpha (ERα) protects against Dr *E. coli* induced UTI by altering CD55 (Dr *E. coli* receptor) and TNFα expression in kidney. *We hypothesized that ERα agonist and antagonist treatment in mice modulates CD55 and TNFα expression in bladder and kidney altering UTI pathogenesis.* This study determined the effects of ERα agonist, propyl-pyrazole-triol (PPT), and ERα antagonist, methyl-piperidino-pyrazole (MPP), on inflammation and UTI outcome.
PPT or MPP pre-treated mice received Dr *E. coli* induced UTI. Bacterial load, CD55 and TNFα levels in bladder and kidney were determined. PPT and MPP showed opposite effects on these markers in bladder vs kidney. PPT treatment significantly reduced bacterial load($P<0.05$) and CD55 expression($P<0.01$) with minimal changes in TNFα levels in kidney, while in bladder, higher bacterial load correlated with increased TNFα levels($P<0.01$). In contrast, MPP reduced bacterial load and CD55 expression in bladder, but not in kidney. MPP pre-treatment in uninfected state significantly increased TNFα levels ($P<0.05$) only in bladder, resulted in better bacterial clearance and lowered the TNFα levels ($P<0.01$) upon UTI induction.
These results confirmed the protective role of ERα in kidney, however in the bladder other ERs may be involved. Our results have important clinical implications for women undergoing hormonal therapy. Also, boosting TNFα production in the bladder by drugs like MPP will serve as novel therapeutic strategy to prevent UTI recurrence.

P.D4.08.21

***In vivo* identification of cell type-specific and redundant functions of interferons in protection against influenza**

***S. A. Stifter**[1,2], N. Bhattacharyya[1,2], A. Sawyer[1], A. Sher[3], W. J. Britton[1,2,4], C. G. Feng[1,2];*
[1]The University of Sydney, Sydney, Australia, [2]The Centenary Institute, Sydney, Australia, [3]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [4]Royal Prince Alfred Hospital, Sydney, Australia.

Interferons (IFNs) regulate immunity by controlling the recruitment and activation of cells, and by inducing direct anti-viral effector mechanisms via expression of hundreds of IFN regulated genes. While these effector mechanisms have been studied extensively in the context of genetically deficient mice, gene expression analysis and direct anti-viral activity *in vitro*, little is known about individual cellular responses to IFNs *in vivo*. Using a novel line of transgenic mice expressing DsRed fluorescent protein under the control of the IFN inducible gene *Irgm1* (M1Red mice), we herein characterise the response to IFN signalling at the single cell level *in vivo* following infection with influenza A virus. Although all lung-leukocytes showed a propensity to respond to IFNs, cells of the monocyte/macrophage lineage were by far the most IFN-sensitive. Unexpectedly, among pulmonary epithelial cells, alveolar type-I pneumocytes (AT-I), but not surfactant producing type-II pneumocytes (AT-II) exhibited a robust IFN-response. Conversely, AT-II demonstrated 10-100 fold higher viral gene expression than AT-I following *in vivo* IAV infection. Interestingly, although genetic deletion of IFN receptors led to a decreased IFN-response in pneumocytes, viral load was unchanged in *Ifnar1*$^{-/-}$, *Ifngr1*$^{-/-}$ *Il28ra*$^{-/-}$ or *Ifnar1*$^{-/-}$*Il28ra*$^{-/-}$ lung epithelial cells, indicating a significant redundant role in the IFN system in directing anti-viral functions. Indeed, only complete deletion of the IFN-response using *Stat1*$^{-/-}$ mice led to exacerbated early viral loads, revealing the cooperation of all three IFN systems, rather than any single one, is essential for controlling early influenza infection.

P.D4.08.22

Pre-existing AAV8 $CD8^+$ T cells are present in all donors and arbor a cytotoxic function.

***R. XICLUNA**[1], C. VANDAMME[2], M. DEVAUX[1], N. JAULIN[1], M. GUILBAUD[1], C. COUZINIE[1], J. LE DUFF[1], L. HESNARD[3], X. SAULQUIN[3], O. ADJALI[1];*
[1]Inserm UMR1089, NANTES, France, [2]Institute of clinical medicine, Kuopio, Finland, [3]UMR 1232, NANTES, France.

Recombinant adeno-associated virus (rAAV) is the most largely used viral vector for *in vivo* gene therapy. Despite promising results in preclinical and clinical studies, pre-existing immunity against the viral capsid remains a major hurdle to the efficiency and safety of AAV-based gene transfer. Particularly, pre-existing anti-AAV $CD8^+$ T lymphocytes can hamper gene transfer but their impact remains poorly defined.In our study, we previously reported the use of Tetramer-Associated Magnetic Enrichment (TAME) to analyze frequency and phenotype of AAV-specific CD8+ T cells by flow cytometry in order to set up a more sensitive and comprehensive method to detect and characterize these cells. Tetramers loaded with several AAV8 peptides allowed detection of AAV8 capsid-specific CD8+ T cells among PBMCs, without amplification, in all healthy $HLA\text{-}A2^+/B7^+$ donors tested even in absence of anti-AAV8 IFN-γ ELISpot positive response. Moreover, phenotypic assessment of the detected cells revealed a T_{EMRA} profile.To be more restrictive, we tested TAME with the immunodominant peptides described since. We also detected AAV8 capsid-specific CD8+ T cells in all tested donors but at lower frequencies.To characterize the impact of this T_{EMRA} cells, we sorted AAV8-specific $CD8^+$ T cells after TAME and we succeeded in generating AAV-specific $CD8^+$ T cell lines that were cytotoxic when faced with AAV8-loaded target cells. The dissimilarities observed between presence of AAV-specific CD8+ T cells and IFN-γ responses, highlight the need to understand the onset of pre-existing anti-AAV immunity on rAAV-based gene transfer and its impact on clinical outcome in order to develop optimal strategies.

P.D4.09 Exploiting host pathogen interaction - Part 9

Comparison of Techniques Measuring Cellular Reactive Oxygen Species in Circulating and Tissue Rat Neutrophils

*N. Fazal, **M. Baig**;*
Chicago State University, Chicago, United States.

Objectives: Production of ROS is considered as an important neutrophil function. Neutrophils utilize oxygen radicals to kill phagocytized bacteria as well as remodeling endothelial and epithelium tissues. Neutrophils have an important role to play both in innate immune response as well as tissue-remodeling and tissue repair. There are many known techniques to ascertain production and release of ROS in cultured cells, especially neutrophils. In this study we compared the efficacy and use of different methods and determined the kinetics of intracellular and extracellular oxidants production and/or release.
Methods: We used fluorometry to determine hydrogen peroxide, Photometry to measure superoxide dismutase inhibitable reduction of Cytochrome C and Luminometry to gauge peroxidase-dependent chemiluminiscence namely (Isoluminol, Luminol and Lucigenein). We used rat neutrophils to obtain blood (circulatory) and peritoneal (tissue) to study both activated, PMA- or fMLP- or LPS-stimulated and /or un-activated cells.
Results: Our results show that all the techniques used in this study were able to measure both oxidant production as well as oxidant release in neutrophil cell culture assays. Kinetics of ROS production in studied Neutrophils show nice curves over 60-minutes assay times. Intracellular vs. Extracellular production/release of ROS were followed over every 5-10 minutes and depict different patterns of peak values, which were considered statistically significant.
Conclusions: Our studies established a kinetic cell culture assay that established base-line values of reactive oxygen species production and release, over first hour of neutrophil / cell stimulation with PMA and/or fMLP and/or LPS. These assays could determine the efficacy of therapeutic agents.

P.D4.09.02
***Cutibacterium acnes* plays a role in the maintenance of skin barrier and homeostasis**

***B. S. Bolla**[1], L. Erdei[1], G. Tax[1], E. Urbán[2], L. Kemény[1,3], K. Szabó[3];*
[1]Department of Dermatology and Allergology, University of Szeged, Szeged, Hungary, [2]Institute of Clinical Microbiology, University of Szeged, Hungary, Szeged, Hungary, [3]MTA-SZTE Dermatological Research Group, Szeged, Hungary, Szeged, Hungary.

Our skin provides a physical barrier to separate our body from the external environment. Little is known how the cutaneous microbiota may affect these functions, so our aim is to investigate the role of *Cutinebacterium acnes* (*C. acnes*), member of the cutaneous microbiome using an *in vitro* cultured human keratinocyte cell line (HPV-KER) and 3D organotypic skin models (OS). Calcium-differentiated confluent HPV-KER cultures were treated with *C. acnes*. Barrier changes were monitored measuring transepithelial electrical resistance (TEER), performing an xCELLIgence analysis and lucifer yellow (LY) penetration assays. We also analysed the expression changes of tight junction (TJ) proteins (CLDN1, 4, OCLN and ZO-1) by western blotting and immunohistochemical staining. In the presence of high dose *C. acnes* bacterium the barrier properties deteriorated: TEER and cell index (CI) values gradually decreased, while parallel to that LY penetration increased at 24 and 72 hours after bacterial treatment in the HPV-KER cultures. Dye penetration was also enhanced in the OS models upon *C. acnes* treatment. The level and distribution of TJ proteins also changed, OCLN and ZO-1 increased and CLDN1 decreased after treatment in the monolayer cultures, which was similar to changes we observed in the differentiated, granular layer of the OS models. We hypothesize that *C. acnes* may actively modify the properties of our epidermal barrier by changing the expression and localization of certain TJ proteins and through this it can play a role in the maintenance of cutaneous homeostasis.

P.D4.09.03
A role for miRNA-mRNA interactions in host immunomodulation during controlled human hookworm infection

***M. M. Cooper**, S. Staal, C. Loiseau, T. S. Watkins, M. Field, J. Croese, J. J. Miles, A. Loukas, D. L. Doolan, P. Giacomin;*
Australian Institute of Tropical Health and Medicine, Smithfield, Cairns, Australia.

Helminths have evolved to modulate the human immune response. Recent reports have demonstrated that live helminth therapy has a beneficial effect in treating inflammatory disease, suggesting that helminths alter host immune profiles by promoting an anti-inflammatory environment. MicroRNAs (miRNAs), small negative regulators of mRNA translation, have recently been implicated in immune control in other diseases. We hypothesised that miRNAs play an important role in immumomodulation during helminth infection. Previous investigations of the human immune response to helminths have largely focused on field studies, where significant confounders have influenced study outcomes.
To define the role of miRNA in immunomodulation during helminth infection, we utilised a unique, well-controlled model of experimental *Necator americanis* infection in naive individuals and conducted a comprehensive study of host blood miRNA and mRNA expression. We demonstrate for the first time that hookworm infection induces significant changes to host miRNA and mRNA profiles (Principal Components Analysis, $p<5x10^{-5}$ and $p<5x10^{-4}$, respectively) that are readily detectable in peripheral blood. Specifically, we identified a panel of 18 immune and T cell related mRNAs and 29 miRNAs that are significantly associated with helminth infection and with the degree of infection-induced eosinophilia (all $p<5x10^{-2}$). We further identified a network of miRNA-mRNA interactions resulting from helminth infection that is involved in promoting a Th2-biased immune response.
This study expands our understanding of the immune response to parasitic worm infections and has significant implications for the development of helminth-based, immunomodulatory therapies for inflammatory disease.

P.D4.09.04
ADAM10 and ADAM17 control of skin dendritic cell function

***N. Diener**[1], R. Backer[1], S. Papaioannou[1], K. Dietze-Schwonberg[2], E. von Stebut[2,3], B. E. Clausen[1];*
[1]Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, 55131 Mainz, Germany, [2]Department of Dermatology, University Medical Center of the Johannes Gutenberg-University Mainz, 55131 Mainz, Germany, [3]Department of Dermatology, University of Cologne, 50937 Cologne, Germany.

Dendritic cells (DC) are strategically positioned at epithelial borders to the environment like the skin and are crucial modulators of immune responses. The 'a disintegrin and metalloproteinase' (ADAM) family of surface-expressed ectodomain-shedding proteases regulate multiple cell functions such as cell adhesion, migration or cytokine release/ signaling. Dysregulated shedding by ADAM10 and ADAM17 is critical for the development of different immune-mediated diseases. Both sheddases are expressed on DC in the skin and skin-draining lymph nodes (sdLN). To investigate their role in DC, we generated conditional knockout mice of either one of these proteases in all CD11c$^+$ cells ($ADAM10^{\Delta CD11c}$ and $ADAM17^{\Delta CD11c}$ mice).
Analysis by flow cytometry revealed reduced DC numbers in the skin of $ADAM10^{\Delta CD11c}$ mice, whereas DC homeostasis in $ADAM17^{\Delta CD11c}$ mice was unchanged compared to control mice. Although DC migration to the sdLN was not altered under steady-state conditions and following FITC-painting in $ADAM10^{\Delta CD11c}$ and $ADAM17^{\Delta CD11c}$ mice *in vivo*, it was significantly decreased in skin explant cultures *in vitro*. Moreover, while the phenotypic maturation of bone marrow-derived DC (BMDC) was only impaired in the absence of ADAM17, both ADAM10- and ADAM17-deficient BMDC secreted reduced levels of TNF-α upon TLR stimulation. Intriguingly, after physiologic low-dose infection with *Leishmania major*, $ADAM17^{\Delta CD11c}$ mice developed significantly larger, persisting skin lesions with increased parasite burdens as compared to controls with self-healing lesions. In conclusion, these data demonstrate that ADAM10 and ADAM17 regulate DC homeostasis and maturation/activation. In ongoing experiments we are dissecting the mechanism of ADAM17 governing skin DC function during cutaneous leishmaniasis.

P.D4.09.05
Characterisation of *Schistosoma mansoni* Larval Extracellular Vesicle protein 1 (SmLEV1) an immunogenic, schistosome-specific protein, exhibiting developmentally regulated alternate splicing

***T. A. Gasan**[1], S. Wilson[2], J. Wawrzyniak[2], E. M. Tukahebwa[3], K. F. Hoffmann[1], I. W. Chalmers[1];*
[1]IBERS, Aberystwyth, United Kingdom, [2]Cambridge University, Cambridge, United Kingdom, [3]Ugandan Ministry of Health, Kampala, Uganda.

An integral component of cellular communication, Extracellular Vesicles (EV) have been described in protozoa and metazoan parasites. Both larval and adult *Schistosoma mansoni* worms release pre-packaged EVs, but to what end? Characterising proteins within schistosome EVs will aid in discerning their function(s) and may help develop schistosomiasis control strategies. Threfore, this project aims to characterise the most abundant EV protein in the tissue-migrating schistosomula stage - *Schistosoma mansoni* Larval Extracellular Vesicle protein (SmLEV1). Comparative sequence analysis demonstrates that SmLEV1 has orthologs in all published *Schistosoma* genomes, but not outside of the genus, nor has any characterised protein domains. By employing qRTPCR, we discovered differential expression of SmLEV1 across the schistosome lifecycle, with peak expression in cercariae as well as male-biased expression in sexually-reproductive adults. Importantly, SmLEV1 exhibits developmentally regulated alternative splicing during infection of the mammalian host. Cercariae displayed a significantly different population of isoforms, with over twice the level of exon-5 expression, compared with adult worms, but only two-thirds the expression of exon-8. Recombinant expression of SmLEV1, has enabled investigation of the host's response to SmLEV1, in the mouse model and endemic human populations.

Interestingly, preliminary serological analysis from *S. mansoni* infected individuals shows a strong IgG_1 response against SmLEV1 with minimal antigen-specific IgG_4 and IgE; this finding is congruent to antibody responses generated against other surface/secreted schistosome proteins. Collectively, these results highlight SmLEV1 as an abundant, novel schistosome-specific, EV protein. Finally a mouse vaccination trial has been conducted to investigate the potential protective capabilities of an SmLEV1 vaccine.

P.D4.09.06
Co-inhibitory receptors expression on $CD8^+$ T cells during *T. cruzi* infection

***R. Grote-Gálvez**, Y. Arana, T. Jacobs;*
Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany.

Trypanosoma cruzi is an obligate intracellular protozoan parasite that in 30 % of cases causes Chagas disease. Chagas disease remains the most important neglected vector-borne disease in Latin America affecting more than 10 Million people. Although an initial $CD8^+$ T cell mediated immune response controls parasite replication successfully, a complete clearance fails, which leads to chronic infection. To address this question, we established mouse-*models* based on infection of C57BL/6 mice with different *T. cruzi* strains. We found that during acute infection with *T. cruzi* the T cell compartment is modulated by transient induction of different co-inhibitory molecules. Tim-3 was most significantly induced and this upregulation correlated with a reduced TNFα production. Using different blocking strategies, we explored Tim-3 function during infection *in vivo*. The blockade of Tim-3 restored $CD8^+$ T cell function and reduced parasitic reservoirs in the tissue. We also found that Tim-3 ligands were strongly expressed on cells from the myeloid compartment. According to our data, we think that the upregulation of co-inhibitory receptors, in context of acute infection, might be a physiological mechanism to avoid immunopathology but *T. cruzi* exploits these pathways to alter parasite specific $CD8^+$ T cell responses and circumvent elimination. We hypothesize that, this provides parasites with valuable time to disseminate throughout the host and to hide in multiple tissues. Our results are an important contribution towards the better understanding of the immune evasion strategies of *T. cruzi* and identification of potential targets for novel immunotherapies.

P.D4.09.07
Helminth-induced interference with bystander immune responses and the role of type 1 regulatory T cells

***W. Hartmann**, M. Brunn, M. Breloer;*
Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany.

Helminths are large multicellular parasites that infect approximately one third of the human population. To prolong their survival, helminths manipulate the immune response of their hosts. Thereby, not only helminth-specific but also non-helminth-specific bystander immune responses such as the immune response to a vaccine are suppressed. We have previously shown that infection of mice with the filarial nematode *Litomosoides sigmodontis* leads to systemic suppression of IgG responses to thymus-dependent model antigens. This suppressive status was still visible after clearance of *L. sigmodontis* infection indicating that immunosuppression, once established, is preserved independent of the presence of living helminth parasites. We now demonstrate the relevance of this helminth-induced interference with bystander immune responses and performed vaccinations with the commercially available anti-influenza vaccine*:* Reduced hemagglutinin-specific Ig responses were linked with an impaired protection against influenza H1N1 A/Hamburg/NY1580/09 challenge infection. Mechanistically, B cell function was suppressed indirectly, via accessory follicular T helper cells (TFH). Likewise proliferation of adoptively transferred ovalbumin-specific CD4+ T cells was suppressed in *L. sigmodontis*-infected mice, reiterating suppressed TFH expansion. To analyse the mechanism we performed flow cytometry cluster analysis. $Foxp3^+$ regulatory T cells increased locally, but not systemically and were dispensable for helminth-induced suppression of bystander immune responses. By contrast, we observed a sustained local and systemic expansion of type 1 regulatory T cells expressing LAG-3 and CD49b in helminth-infected mice and those with a history of helminth infection. We are currently characterizing the role of Tr1 cells as potential mediators of suppression.

P.D4.09.08
Mycobacterial Growth Inhibition is associated with trained innate immunity

***S. A. Joosten**[1], K. E. van Meijgaarden[1], S. M. Arend[1], C. Prins[1], F. Oftung[2], G. Korsvold[2], S. V. Kik[3], R. J. Arts[4], R. van Crevel[4], M. G. Netea[4], T. H. Ottenhoff[1];*
[1]Leiden University Medical Center, Leiden, Netherlands, [2]Norwegian Institute of Public Health, Oslo, Norway, [3]KNCV Tuberculosis Foundation, The Hague, Netherlands, [4]Radboud University Medical Center, Nijmegen, Netherlands.

The lack of defined correlates of protection hampers development of vaccines against tuberculosis (TB). *In vitro* mycobacterial outgrowth assays are thought to better capture the complexity of the human host/ *Mycobacterium tuberculosis* (Mtb) interaction. Here, we used a PBMC-based "mycobacterial-growth-inhibition-assay" (MGIA) to investigate the capacity to control outgrowth of Bacille Calmette-Guérin (BCG). Interestingly, strong control of BCG outgrowth was observed almost exclusively in individuals with recent exposure to Mtb, but not in (long-term) latent TB infection, and only modestly in BCG vaccinees. Mechanistically, control of mycobacterial outgrowth strongly correlated with the presence of a $CD14^{dim}$ monocyte population, but also required the presence of T-cells. The non-classical monocytes produced CXCL10, and CXCR3-receptor blockade inhibited the capacity to control BCG outgrowth. Expression of CXCR3 splice variants was altered in recently Mtb exposed individuals. Since we observed strong MGIA control recently after Mtb exposure and we found a strong association with monocytic cells we hypothesized that trained innate immunity was responsible for the observed MGIA control. Indeed, cytokines previously associated with trained immunity were detected in MGIA supernatants, and CXCL9, CXCL10 and CXCL11 represent new markers of trained immunity. These data indicate that CXCR3-ligands are associated with trained immunity and critical factors in controlling mycobacterial outgrowth. In conclusion, control of mycobacterial outgrowth early after exposure to Mtb is the result of trained immunity mediated by a CXCL10-producing non-classical $CD14^{dim}$ monocyte subset.

P.D4.09.09
Enhanced cancer immunosurveillance by viral infection and Toll-like receptor ligation

***M. F. Mandour**[1,2], J. P. Coutelier[1];*
[1]Deduve institute - UCL, Brussels, Belgium, [2]Department of Clinical Pathology, Faculty of Medicine, Suez Canal University, Ismailia, Egypt.

Introduction: At early stages of cancer development, appropriate immunosurveillance eliminates most of the transformed cells. In addition to cytotoxic T cells, innate immune cells such as natural killer cells and NK/T cells play a major role in this protection against cancer development, especially through production of interferon-gamma (IFN- γ). Since infections deeply modulate the immune microenvironment and particularly its innate components, we investigated their role in cancer immunosurveillance. Materials and Methods: The effect of infections on plasmacytoma (TEPC.1033.C2) and mesothelioma (AB1) cell growth was analysed in BALB/c mice after infection with lactate dehydrogenase-elevating virus (LDV), a usually non-pathogenic mouse nidovirus. Infections were also mimicked by ligation of various Toll-like receptors (TLRs). The mechanisms of immunosurveillance were analysed by using anti-NK cell depleting polyclonal antibody and cytokine neutralizing monoclonal antibodies. Results: Acutely infected animals were significantly protected against both plasmocytoma and mesothelioma development. The protection was mediated by NK cell activation, through IFN- γ production. In addition, TLR-3, 7 and 9 ligation significantly protected mice against mesothelioma, but not plasmacytoma development. Conclusions: Our results indicate that modulation of the mouse immune microenvironment, and especially of innate immune responses, following either a non-pathogenic viral infection or a TLR ligation protects against mesothelioma and plasmacytoma early development.

P.D4.09.10
Hypoxia-inducible factor-1 alpha deficiency results in dysregulated lipid metabolism associated with increased susceptibility to*Leishmania donovani*infection

***I. Mesquita**[1,2], C. Ferreira[1,2], D. Moreira[1,2], G. Kluck[1,3,2], A. Barbosa[1,2], E. Torrado[1,2], R. Dinis-Oliveira[4,5,6], F. Rodrigues[1,2], C. Cunha[1,2], A. Carvalho[1,2], A. Castro[1,2], J. Estaquier[7,8], R. Silvestre[1,2];*
[1]Life and Health Sciences Research Institute (ICVS), School of Medicine, Braga, Portugal, [2]ICVS/3B's–PT Government Associate Laboratory, Braga, Portugal, [3]Medical Biochemistry Institute, Rio de Janeiro, Brazil, [4]Faculty of Medicine, Porto, Portugal, [5]University Institute of Health Sciences, Porto, Portugal, [6]Faculty of Pharmacy, Porto, Portugal, [7]Université Paris Descartes, Paris, France, [8]Centre de Recherche du CHU de Québec, Université Laval, Québec, Canada.

Metabolic manipulation of host cells by intracellular pathogens is recognized to play an important role in the pathology of infection. Hypoxia inducible factor-1 alpha (HIF-1α) is a critical regulator of myeloid cell function, namely in infectious contexts. We demonstrate that specific deletion of HIF-1α in the myeloid compartment increases susceptibility to *Leishmania donovani* infection, which associates with an increased de novo lipogenesis. Infected myeloid-restricted HIF-1α-deficient mice developed hypertriglyceridemia and enhanced accumulation of lipids in splenic myeloid cells. Upon pharmacological inhibition of fatty acid synthase, the observed susceptibility is abrogated, and the parasite load is restored to the levels of WT counterparts. Importantly, *Leishmania* infection of macrophages from individuals with homozygous loss-of-function polymorphisms in HIF1A gene displayed increased parasite burdens associated with lipid accumulation. Our results provide direct evidence that genetic deficiency of HIF-1α impacts the anti-*Leishmania* effect of the myeloid compartment via lipid accumulation.

P.D4.09.11

NLRP10 affects the stability of Abin-1 to control inflammatory responses

N. Mirza[1], *A. Sowa*[1], *K. Lautz*[2], *T. Kufer*[1,2];
[1]*Institute of Nutritional Medicine, University of Hohenheim, 70599 Stuttgart, Germany,* [2]*Institute for Medical Microbiology, University of Cologne, 50935 Cologne, Germany.*

Introduction: NOD-like receptors (NLR) are critical regulators of innate immune signaling with a conserved structure containing a central oligomerization NACHT domain, an N-terminal interaction domain and a variable number of C-terminal leucine rich repeats (LRRs). NLRP10 is the only NLR-protein lacking the LRR and has been implicated in multiple immune pathways, including the regulation of inflammatory response towards *L. major* and *S. flexneri* infection. However, our current understanding of NLRP10 is limited and its function in immune signaling pathways require further clarification.
Materials and Methods: Interaction of NLRP10 and Aibn-1 was identified by a yeast to hybrid screening and verified in co-immunoprecipitation experiments. *Shigella flexneri* was used as an infection model in human epithelial cell lines and primary murine cells derived from *Nlrp10* knock-out animals.
Results: Here we identify Abin-1, a negative regulator of NFκB, as an interaction partner of NLRP10, which binds to the NACHT domain of NLRP10. While the interaction of the proteins increased with time of *S. flexneri* infection, NLRP10 decreased Abin-1 protein stability in response to bacterial infection in HEK cells as well as in murine embryonic fibroblasts, primary murine skin fibroblasts and keratinocytes derived from *Nlrp10* knockout mice.
Conclusions: We revealed a novel interaction between NLRP10 and Abin-1 and a subsequent regulation of Abin-1 protein levels by NLRP10. Our data give insight into the molecular mechanism underlying the function of NLRP10 in innate immune responses and provide an explanation for the role of NLRP10 in bacterial induced inflammatory responses.

P.D4.09.12

Quantitative proteomic analysis of CD4+T cells-expressing HCV core protein

C. Fernández Ponce[1], *M. C. Durán-Ruiz*[1], *J. Olid Franco*[1], ***L. Olvera-Collantes***[1], *A. Rodríguez-Moreno*[1], *J. Niño-Ramirez*[1], *J. P. Muñoz- Miranda*[1], *M. M. Arbulo-Echevarria*[1], *I. Narbona-Sánchez*[1], *A. Serna-Sanz*[2], *C. Baumann*[2], *R. Litrán*[3], *E. Aguado*[1], *F. García-Cózar*[1];
[1]*Department of Biomedicine, Biotechnology and Public Health, University of Cadiz - Institute of Biomedical Research Cadiz (INIBICA), Cadiz, Spain,* [2]*Sciex, Darmstadt, Germany,* [3]*Department of Condensed Matter Physics, University of Cádiz, Puerto Real, Spain., Cadiz, Spain.*

Hepatitis C virus (HCV) infection is a significant public health problem affecting more than 80 million people worldwide. Up to 80% of HCV infected patients develop chronic viral hepatitis with clinical progression to hepatic fibrosis, cirrhosis, liver failure and hepatocellular carcinoma. Currently, the molecular mechanisms used by HCV to cause a chronic infection and their implications in the innate and adaptive immune system have not been fully explained. Several HCV viral proteins have been described as immune modulators, being HCV core protein closely related with pathogenicity, virulence, immune evasion and immune regulation. Interestingly, the presence of HCV Core protein in $CD4^+$ T cells has been associated with the induction of a regulatory T cell phenotype. In order to elucidate the molecular networks changes induced by the presence of HCV Core protein in $CD4^+$ T cells, we performed a quantitative analysis of the proteome of T lymphocytes transduced with Core protein. The study was accomplished using mass spectrometry. The identified and quantified proteins, and the biological networks associated were analyzed using IPA (Ingenuity pathway analysis) software. We found changes in the expression of proteins implicated in molecular networks related with lymphocyte activation, regulation and reorganization of the cytoskeleton, induction of regulatory activity in T lymphocytes, cell adhesion, tissue invasion and oxidative stress signaling pathways.

P.D4.09.13

Intracellular immunodynamics of lentiviral gene delivery in human Natural Killer cells

C. Pamukcu[1,2], *E. C. Sayitoğlu*[3], *D. Ozkazanc*[1,2], *A. Parlar*[1,2], *A. E. Eyupoglu*[1,2], *B. Erman*[1,2], *A. D. Duru*[3], *T. Sutlu*[1];
[1]*Nanotechnology Research and Application Center, Sabancı University, Istanbul, Turkey,* [2]*Faculty of Engineering and Natural Sciences, Sabancı University, Istanbul, Turkey,* [3]*NSU Cell Therapy Institute, Nova Southeastern University, Fort Lauderdale, United States.*

Cancer immunotherapy approaches using genetically modified NK cells continue to inspire clinical trials with promising results but the protocols for genetic modification of NK cells are suboptimal. NK cells they show strikingly high resistance to lentiviral gene delivery when compared to other cells of the immune system. Previously, we have shown that the use of BX795, a small molecule inhibitor of TBK1/IKKε complex downstream of Toll-like Receptors and RIG-I-like receptors, significantly enhances lentiviral gene delivery to NK cells.
In the current study, we demonstrate that while viral vector entry to NK cells can take place without major problems, the activation of antiviral signaling pathways leads to the intracellular elimination of the vector. To study roles of 20 candidate genes in this process, CRISPR/Cas9 system was used and single-gene disruptions were applied in 293FT and NK-92 cell lines.
Our results demonstrate that capsid recognition by TRIM5α in 293FT cells and dsRNA-induced signaling through RIG-I and TRIM25 in NK-92 cells represent major players affecting lentiviral gene delivery. Additionally, viral vector exposure was shown to increase MAPK activity in host cells, specifically p38 and JNK phosphorylation in NK-92 cells, as observed in wildtype HIV infections.
Overall, this study confirms that lentiviral gene delivery evokes an innate immune response in NK cells through multiple PRRs and cellular restriction factors. Small molecule inhibitors help to overcome this obstacle for promising applications in immunotherapy using genetically modified NK cells.

P.D4.09.14

LPCAT2 Knockdown Influences both Rough and Smooth Lipopolysaccharide-Induced Toll-Like Receptor 4 Signalling in RAW264.7 Macrophages.

V. I. Poloamina*, W. A. Woldie, G. Fejer, S. K. Jackson;*
School of Biomedical Sciences, Faculty of Medicine and Dentistry, University of Plymouth, Plymouth, UK. PL6 8BU, Plymouth, United Kingdom.

Recognition of bacterial lipopolysaccharide (LPS) by TLR4 and its co-receptors leads to inflammation through the interaction of TLR4 signaling adaptor proteins and other proteins downstream. We have previously shown that TLR4 signaling is reduced when LPCAT2 (a phospholipid modifying enzyme) is knocked down. Smooth and Rough LPS may possess differential mechanisms of regulating TLR4 signaling, however, it is not known if the knockdown of LPCAT2 would have the same effect on TLR4 signaling induced by both smooth LPS and rough LPS.
RAW264.7 macrophages were transfected with LPCAT2 siRNA. After 48hours, RAW264.7 were stimulated with 100ng/ml of E. Coli O111: B4, J5, and K12 LPS for 6hours to determine mRNA and TNF-alpha protein, and 24hours to determine IL6 and IP10 protein by ELISA. Total RNA was isolated, quantified, and used for analysis of mRNA expression by real-time RT-PCR. Statistical analysis was carried out using GraphPad Prism Software.
Rough LPS (J5 and K12) induced MyD88-dependent cytokines (IL6 and TNF-alpha) about 2-fold more than smooth LPS (O111:B4), but there was no difference in the induction of MyD88-independent cytokines (IP10 and IFN-beta). Moreover, both rough and smooth LPS-induced cytokines were significantly reduced when LPCAT2 was knocked down (>70 percent).
LPCAT2 does not show a differential influence on inflammation induced by rough and smooth LPS. Moreover, LPCAT2 knockdown might be affecting the MyD88-dependent TLR4 signaling pathway more than the MyD88-independent pathway. LPCAT2 plays a role in TLR4 signaling which is important in innate immunity. Therefore, LPCAT2 can be an effective target for anti-inflammatory treatments.

P.D4.09.15

Evaluation of miRNAs role in the immunopathogenesis of microcephaly caused by ZIKV in experimental models

C. M. Polonio[1], *W. Brandão*[1], *F. Cugola*[2], *N. Zanluqui*[1], *L. Oliveira*[1], *C. Longo*[1], *P. Beltrão-Braga*[2], *J. Peron*[1];
[1]*Neuroimmune Interactions Laboratory - Department of Immunology - University of São Paulo, São Paulo, Brazil,* [2]*Disease Modeling Laboratory- Department of Microbiology - University of São Paulo, São Paulo, Brazil.*

Viral infections have always been the cause of serious human diseases, usually increasing rates of morbidity and mortality worldwide. Recently, the flavivirus Zika virus (ZIKV) was introduced especially in Brazil, causing alarming increase in the number of babies born with microcephaly. The expression of Interferons stimulated genes (ISGs) is very important in blocking viral replication during disease, and they may be modulated by several different factors through post-transcriptional mechanisms, in which, *miRNAs* play a key role. Still very little is known about the involvement of *miRNAs* during ZIKV infection. In this context, we evaluated the role of *miRNAs* during ZIKV experimental infection. We performed miRNAs analysis *in vitro* using cells of the central nervous system and, *in vivo*, with SJL animals susceptible to infection. Analyzing human neuronal precursor cells we observed that miR-29, miR-425, miR-15A and miR-126 were up-regulated. miR-29 is known to be present in HPV patients blood and to induce the PRRSV viral replication. ZIKV was also able to down-regulate 19 different miRNAs, among them, miR-9, known to increase mesenchymal stem cells differentiation towards neuronal cells, being an important factor for neurogenesis. In SJL fetal brain, we observed nine miRNA up-regulated and only miR-32 was down-regulated. Taken together, these data are indicative that ZIKV is able to modulate miRNA profile, evidencing the importance of these regulatory molecules, which may help us to better understand immunopathogenic mechanisms of microcephaly caused by ZIKV.

P.D4.09.16
Site-specific effects of IL-33 treatment during helminth infection

***M. Reitz**, N. Rüdiger, M. Brunn, M. Breloer;*
Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany.

Strongyloides ratti is a rodent specific parasitic nematode that displays tissue migrating and intestinal life stages. Infective larvae actively penetrate the skin of their host, migrate within 2 days via the skin and lung to the mouth. They are swallowed, reach the intestine and moult to adults that reproduce by day 5. Infected mice terminate the infection in the context of a type II immune response. Thereby infection-induced expression of the alarmin IL-33 by alveolar epithelial cells was shown to promote the type II response in the lung and was associated with efficient expulsion of *S. venezuelensis* from the intestine. Here, we intend to dissect IL-33 mediated effects on the immune response to *Strongyloides* infection in the tissue and the small intestine. *S. ratti* infected mice showed a drastic reduction of parasitic adults in the intestine on day 6 after previous intranasal and intraperitoneal treatment with recombinant IL-33 (rIL-33). The reduced parasite burden correlated with increased activation of mast cells that are central for expulsion of *S. ratti* from the intestine. Of note, also rIL-33 administration after the tissue migration phase reduced intestinal parasite burden. In contrast, numbers of migrating larvae in skin, lung and head were significantly increased in rIL-33 treated mice indicating that the reduced intestinal parasite burden is not due to an improved immunity in the tissue. In summary, our data show that IL-33 displays contradictory and site specific effects on tissue migrating and intestinal *S. ratti* parasites. We are currently investigating the underlying mechanism.

P.D4.09.17
Malaria-induced FOXP3$^-$ regulatory T cells in disease progression and memory establishment

***M. Riehn**, M. S. Mackroth, A. Abel, C. Steeg, T. Jacobs;*
Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany.

Malaria is still a major burden on global health with approximately 1200 deaths per day. After infection, immunity has to be strictly regulated to control the parasite but also to avoid immune pathology. Interestingly, in malaria experienced patients protection against severe malaria develops faster than protection against parasitemia.
Recently, we could show that acute malaria induces CD4$^+$PD1$^+$Foxp3$^-$ T cells in humans. These cells can suppress effector T cells, which may contribute to reduced immune pathology but also may suppress protective immunity.
We could confirm induction of these suppressive cells by blood stage infection employing the *P. berghei* ANKA mouse model. High numbers of these T_{r1}-like cells correlated with reduced immune pathology during reinfection, whereas parasitemia is not altered in comparison to the initial infection.
By combining flow cytometry and t-Distributed Stochastic Neighbor Embedding (t-SNE), we could delineate a unique phenotype of these malaria-induced T cells characterized by a high expression of multiple co-inhibitory molecules. The highest amount of these T_{r1}-like cells was found in the liver compared to spleen. Furthermore these cells exhibit different phenotypes in liver and spleen with regard to the expression of co-inhibitory molecules. This indicates an organ-specific component implicated in the induction of malaria-specific T_{r1}-like cells.
Taken together, we could show that malaria-induced T_{r1} cells have an important immune regulatory function in mice and humans and should be considered in malaria therapy and vaccination. Moreover, the accumulation of T_{r1} in the liver highlights the unique tolerogenic environment of this organ and the influence on disease progression.

P.D4.09.18
Batf3 deficient mice are protected against experimental cerebral malaria due to successful immune regulation

*M. P. Borsche[1], J. M. Kuepper[1], P. J. Korir[1], A. Mueller[2], A. Hoerauf[3], K. Hildner[3], I. R. Dunay[4], **B. Schumak**[1];*
[1]Institute of Medical Microbiology, Immunology and Parasitology, University of Bonn, Bonn, Germany, [2]Centre for Infectious Diseases, Parasitology Unit, Heidelberg, Germany, [3]Medical Department 1, University Hospital Erlangen, Erlangen, Germany, [4]Institute of Inflammation and Neurodegeneration, University of Magdeburg, Magdeburg, Germany.

Excessive inflammatory immune responses are made responsible for severe complications during infections with *Plasmodium* parasites such as cerebral malaria (CM). The parasite-specific immune response is initiated by dendritic cells, especially by cross-presenting DCs that efficiently activate cytolytic CD8 T cells. Batf3 ko lack CD8a positive dendritic cells (DCs), which are well known for the induction of strong Th1 responses. Here we show that BATF3 mice were protected from ECM upon infection with *Plasmodium berghei ANKA* (PbA), characterized by a stable blood brain barrier and lacking infiltration of peripheral immune cells into the brain. Importantly, the absence of ECM correlated with attenuated responses of cytotoxic T cells, since their parasite-specific lytic activity as well as production of interferon gamma was strongly decreased and granzyme B was absent. Remarkably, we detected in the ECM-negative mice elevated levels of IL-10 that was produced predominantly by myeloid cells. We conclude that in the absence of excessive Th1 signaling due to the lack of crosspresenting DCs, immune regulatory mechanisms were successfully induced that were associated with protection from excessive brain inflammation.

P.D4.09.19
Identification of new natural products with anti-microbial activity against Apicomplexa and multiresistant gram-negative rods (4MRGN)

***S. Shaneh Sazzadeh**[1], S. Schmidt[1], K. Buchholz[1], P. Proksch[2], K. Pfeffer[1];*
[1]Institute of Medical Microbiology and Hospitalhygiene, Duesseldorf, Germany, [2]Institute of Pharmaceutical Biology and Biotechnology, Duesseldorf, Germany.

Introduction: Anti-microbial therapies have successfully treated infectious diseases. However, the recent occurrence of (multi-) resistant pathogens increases lethality and morbidity of infected patients. Apicomplexa also develop resistance against established treatments. Therefore the need for new anti-microbial drugs is urgent. The primary aim of this project will be the identification of novel natural products with anti-microbial activities against *Toxoplasma gondii* and multidrug resistant gram-negative rod-shaped bacteria (4MRGN), and the elucidation of their targets in pathogens in order to develop new leads for anti-microbial therapies.
Materials and Methods: Screening of natural products, which are able to inhibit *T. gondii* proliferation without being cytotoxic against HFF (human foreskin fibroblasts). This is accomplished via Toxoplasma proliferation and MTT assays. To identify anti-4MRGN products microdilution assays are performed.
Results: Within a first round of screening, promising candidates could be detected. This project will hopefully identify new anti-microbial products for novel therapies of multiresistant pathogens. Furthermore, after performing the MTT assay none of the natural products demonstrate cytotoxicity against both cell lines, which were used in toxoplasma proliferation assay except Bionectriamide A.
Conclusions: A total of 300 new natural products and 30 derivatives thereof were analysed against *T.gondii* (type I, BK strain and also type II, ME49 strain). Eleven products demonstrated anti-Toxoplasma activity and have been selected for further analyses.
Funding: GRK 2158, DFG

P.D4.09.20
Lymphotoxin β receptor: A crucial role in *Toxoplasma gondii* infection

***A. Wichert**, U. R. Sorg, D. Degrandi, K. Pfeffer;*
Institute of Medical Microbiology and Hospital Hygiene, Düsseldorf, Germany.

Introduction: After infection with the obligate intracellular protozoan parasite *Toxoplasma gondii* (*T. gondii*) the production of cytokines induces potent cell autonomous effector mechanisms which can inactivate the pathogen. Lymphotoxin β receptor (LTβR) signalling plays an important role in efficient initiation of innate and adaptive host responses to a variety of pathogens. The up-regulation of the murine 65kDa guanylate-binding proteins (mGBPs) via interferon γ receptor (IFNGR) signalling plays an essential role in survival of mice after infection with *T. gondii.* mGBPs recruit towards the parasitophorous vacuole (PV) encapsulating the parasite, leading to the disruption of the PV and subsequent killing of the parasite. Compared to wildtype mice, LTβR deficient (LTβR$^-$) mice show a markedly increased mortality and delayed up-regulation of mGBP expression in the acute phase of *T. gondii* infection. Methods: Immune responses (particularly B and T cell responses) as well as mGBP localization and function in LTβR$^{-/-}$ compared to WT mice after *T. gondii* infection were investigated in *in vivo* and *in vitro* experiments. Results: Analysis of IgM and IgG antibody responses suggests defects in Ig-class switching in LTβR$^{-/-}$ mice while FACS analysis of immune cell populations demonstrates that these mice are generally able to generate *T. gondii* specific CD8$^+$ T cells. Initial *in vitro* experiments demonstrate that after IFNγ stimulation mGBPs in LTβR$^{-/-}$ fibroblasts are able to localize to the PV. Conclusion: These data suggest that defects in IFNγ mediated mGBP upregulation as well as dysfunctional Ig-class switching may contribute to the decreased survival rates of LTβR$^{-/-}$ mice.

P.D4.09.21
Host-Targeted Therapeutic Immune Protection against Anthrax

***M. Zeng**[1], Y. Yan[1,2], H. Wang[1,2], Y. Chen[1], Z. Zheng[1,2], H. Yang[1,2], S. Franco[1];*
[1]Center of Emphasis in Infectious Diseases, Texas Tech University Health Sciences Center El Paso, El Paso, United States, [2]Key Laboratory of Oral Medicine, Guangzhou Institute of Oral Disease, Stomatological Hospital of Guangzhou Medical University, Guangzhou, China.

Introduction: To combat emerging and re-emerging infectious disease, it is more cost effective to use therapeutic vaccines for postexposure treatment than mass vaccination with preventive vaccines. Anthrax is an infectious disease caused by *Bacillus anthracis* that can secrete anthrax toxins including protective antigen (PA), lethal factor (LF), and edema factor (EF). Previously, we have shown that RNA inhibition of anthrax toxin receptors (TEM8 and CMG2) was protective against the cytotoxicity of anthrax toxins. However, inefficient cytosolic delivery and toxicity of siRNA delivery vehicles limit the use of siRNA as therapeutics.

Materials and Methods: In this study, we have developed a detoxified anthrax edema toxin, which consists of PA and nontoxic N-terminal fragment of EF (EFn) conjugated with a peptide nona-D-arginine residues (EFn-9dR) to enable siRNA binding. The detoxified toxin-siRNA was used to treat cells and C57BL/6 mice and evaluate if they can be protected against anthrax.
Results: The detoxified toxin complex was able to deliver specific siRNA to induce *cmg2* gene silencing in different cell lines and C57BL/6 mice, and provide significant protection against anthrax lethal toxin challenge. Survived mice from toxin challenge were fully protected against lethal challenge with *B. anthracis* Sterne spores. The immune protective mechanism is mainly due to the significantly high serum neutralizing antibody response against anthrax toxins in these mice.
Conclusions: The detoxified anthrax toxin complex provides a tool for delivery of host-targeted siRNA into anthrax pathogenesis-associated host cells, and it can be used as a lifesaving postexposure therapeutic vaccine against anthrax.

P.D4.10.01
Influence of regulatory T cells in immune answer of dogs with visceral leishmaniasis

***P. H. L. Bertolo**, P. R. Moreira, M. B. Conceição, R. O. Vasconcelos;*
Sao Paulo State University (UNESP), Jaboticabal, Sao Paulo, Brazil.

Introduction - The visceral leishmaniasis (VL) is a chronic zoonotic disease, marked by macrophages infection with *Leishmania infantum,* which is distributed to many organs. Parasitic load is very different in each organ, showing that some tissues are more susceptible to this parasite, as spleen. The regulatory T cells (Treg) can avoid pro inflammatory answer, thus, evaluate your role in canine VL would be important. This way, the aim of this study was detect Treg cells in the popliteal and pre-scapular lymph node, liver, spleen and skin (nose and ear) of dogs naturally infected with *L. infantum*, in endemic area for VL. Methods - The dogs were distributed in two groups: infected (n=29) and control (n=5), this had dogs of free VL areas. Immunohistochemistry was used to detect Treg cells in the tissue (FoxP3 antibody, diluted in 1:2500). Results - The immunostaining of Treg cells was observed predominantly at cell nucleon. In lymph nodes it was seen more at cortical area, in liver at intralobular granuloma, in spleen, at white pulp and in skin, at granulomas present around the cutaneous appendages. Comparing these two groups by each organ, significant difference was observed for Treg cells load in nose (P=0,0118), spleen (P=0,0541) and pre-scapular lymph node (P=0,0214), much of these cells was seen in infected group. Conclusion - Lymphoid organs and skin maybe has some influence in Treg cells regarding parasite surviving.

P.D4.10.02
Vitamin D deficiency:a potential predisposition factor for sepsis development

***M. Buc**[1], M. Olejarova[1], A. Dobisova[2], J. Koutun[2], S. Blazickova[3], M. Bucova[1];*
[1]Institute of Immunology, Bratislava, Slovakia, [2]1st Department of Anaesthesiology and Intensive Care Medicine, Comenius University Faculty of Medicine and University Hospital, Bratislava, Slovakia, [3]Piestany Laboratories, Ltd, Piestany, Slovakia.

Introduction: Vitamin D hormonal actions influence mineral metabolism and skeletal health. However, vitamin D has an impact on function of the immune system, e.g. it acts as important stimulant for innate immunity and enhances the antimicrobial effects of macrophages and monocytes. In the frame of our project to find biomarkers distinguishing sepsis from non-infectious SIRS, we paid attention to this hormone. Material and methods: We investigated 32 patients suffering from SIRS/sepsis. 5 ml of blood was taken into EDTA tubes on day of admission to the clinic and subsequently on days 2, 3, 5, 7 or exceptionally day 10. Different cytokines and inflammatory markers were investigated. Except them, plasma levels of 25hydroxyvitamin D /25(OH)D/ were evaluated by electrochemiluminiscent binding test and were correlated with levels of CRP and presepsin (sCD14) - all from the 1st sample. Results: We found significantly decreased levels of 25(OH)D in septic patients (N=25; 11,084±4,965 µg/l) compared to SIRS patients (N=7; 19.071±8.44 µg/l; p=0.0097). The significant lower levels of 25(OH)D were found also in the group of patients who did not survive (N=5; 6.540 ±3.966) compared to those, who survived the 7th day of hospital care (N=27; 13.996±6.416; p=0.0076). We also disclosed a correlation between the levels of 25(OH)D, CRP (p=0.0003), presepsin (p=0.0032), and SOFA (sequential organ failure assessment) score (p=0.0385). Conclusions: Our results indicate that low levels of vitamin D predispose patients to the development of sepsis and influence their survival.

P.D4.10.03
Depletion of regulatory T cells in ongoing Paracoccidioidomycosis reverses disease severity

*N. Galdino, F. V. Loures, E. F. Araujo, T. A. Costa, **V. L. G. Calich**;*
Institute of Biomedical Sciences, University of Sao Paulo, Sao Paulo, Brazil.

In many infectious diseases, the suppressive activity of Treg cells has been associated with deleterious effects, however in certain experimental settings this activity can be protective due to the control of excessive inflammation. In paracoccidioidomycosis, the most important deep mycosis in Latin America, most studies on Treg cells function were performed by depleting Treg cells before or early in the infection. However, human PCM is diagnosed late, when the disease is already established. This fact led us study the effect of Treg cells depletion in a model of ongoing pulmonary PCM. Then, Treg cells depletion was performed by treatment of C57BL/6DTR/eGFP (DEREG) mice with diphtheria toxin (DT) after 3 weeks of infection with 1 x 10^6 *Paracoccidioides brasiliensis* yeasts by the intratracheal route. At weeks 6 and 10 after infection, DT treated DEREG mice showed reduced number of Treg cells that was associated with decreased fungal burdens in the lungs, liver and spleen as well as diminished tissue pathology when compared with control mice (infected and treated with saline). Additionally, DT treated mice showed an increased influx of CD4+ and CD8+ effector cells into the lungs paralleling the increased production Th1 and Th17 cytokines and reduced mortality. Altogether, our data demonstrate for the first time the beneficial effects of Treg cells depletion in established PCM. This procedure ameliorated all parameters of disease severity and immunity. More importantly, these findings indicate that the control of Treg cells in the course of PCM can be explored as a novel immunotherapeutic procedure.

P.D4.10.04
Identification of *Borrelia burgdorferi* phagocytic receptors and their role in the inflammatory response

***A. Carreras Gonzalez**, D. Barriales, I. Martin-Ruiz, J. Lavín, M. Azkargorta, N. Navasa, F. Elorza, A. M. Aransay, H. Rodriguez, J. Anguita;*
CIC bioGUNE, Derio, Spain.

Borrelia burgdorferi, the causative agent of Lyme disease, causes a range of inflammatory complications including arthritis, carditis and immune system disorders that can become long lasting if not properly treated.
In the context of carditis, as the heart presents little exposure to antibodies, the control of the infection relies majoritarily on the phagocytic activity of macrophages. In turn, phagocytosis is required for the full response of macrophages including the production of proinflammatory factors. In spite of its importance, little is known about the complement of receptors and signals that mediate the internalization of *B. burgdorferi*.
Through the use of transcriptomic and proteomic approaches we identified potential phagocytic receptors implicated in the clearance of *B. burgdorferi* in human and mice, with the differential capacity to induce pro-or anti-inflammatory signals. As a result, we have found that Fc Receptor CD64 seem to play an important role in the clearance of the bacteria and in the inflammatory outcome. Moreover, we have described the regulatory role of the TLR family member, CD180, which influences *Borrelia burgdorferi* phagocytic receptor CR3, and is implicated in the complex pathogen-host defense equilibrium.
The identification of the full complement of phagocytic receptors and their pro/anti-inflammatory activity will allow to define internalization alternatives and, in the future, devise novel strategies to increase phagocytosis without a consequent intensification of local inflammatory responses.

Low CCR5 expression protects specific CD4+ T cells of HIV controllers from viral entry

M. Claireaux[1,2], R. Robinot[1,2], I. Staropoli[1,2], A. Brelot[1,2], M. Héry[1,2], M. Patgaonkar[1,2], A. Nouël[1,2], S. Volant[3], E. Perthame[3], F. Boufassa[4], D. Zucman[5], P. de Truchis[6], O. Lambotte[7,8,9], ***L. A. Chakrabarti***[1,2]*;*

[1]Virus and Immunity Unit, Pasteur Institute, PARIS CEDEX 15, France, [2]INSERM U1108, Paris, France, [3]Bioinformatics and Biostatistics Hub, Pasteur Institute, PARIS CEDEX 15, France, [4]INSERM U1018, Center for Research in Epidemiology and Population Health, Le Kremlin-Bicêtre, France, [5]HIV Unit, Foch Hospital, Suresnes, France, [6]AP-HP, Infectious and Tropical Diseases Department, Raymond Poincaré Hospital, Garches, France, [7]INSERM U1184, Center for Immunology of Viral Infections and Autoimmune Diseases, Le Kremlin-Bicêtre, France, [8]AP-HP, Department of Internal Medicine and Clinical Immunology, University Hospital Paris Sud, Le Kremlin-Bicêtre, France, [9]Université Paris Sud, UMR1184, Le Kremlin-Bicêtre, France.

HIV controllers, who spontaneously contain HIV replication to very low levels, develop particularly efficient antiviral T responses. To gain insights into the contribution of the CD4 helper subset to HIV control, we characterized the differentiation status of HIV-specific CD4+ T cells at the single cell level. CD4+ T cells reactive with MHC-II tetramers specific for the most immunodominant HIV epitope (Gag293) were analyzed by multiplexed real-time qPCR combined with multiparametric flow cytometry. HIV controllers from the ANRS CODEX-CO21 cohort with a viral load <50 copies/mL were compared to efficiently treated patients with an equivalently low viral load. Gag293-specific cells from HIV controllers proved to express lower levels of PD-1 and of the HIV coreceptor CCR5 than those of treated patients, while CCL5 and TRBV2 expression were increased. Interestingly, HIV controller specific cells proved less susceptible to fusion with an HIV-JRFL reporter virus (P=0.017). Moreover, CCR5 expression correlated with HIV fusion (R=0.83, P<0.005). CCR5 expression in total CD4+ T cells did not reveal significant differences between groups. However, a negative correlation was observed between CCR5 expression in total CD4+ T cells and the frequency of Gag293-specific cells, indicating that the subset of controllers with low CCR5 expression maintained strong CD4 responses. Genetic analysis of one controller with particularly low fusion susceptibility uncovered biallelic mutations that impaired CCR5 expression. Taken together, these findings reveal a lower susceptibility of HIV controller specific CD4+ T cells to HIV entry, and point to a role for low CCR5 expression in promoting spontaneous HIV control.

P.D4.10.06

Toll-like receptor 9 is required for the maintenance of $CD25^+FoxP3^+CD4^+T_{reg}$cells during *Listeria monocytogenes*infection

J. S. Dolina*, J. Lee, S. P. Schoenberger;*
La Jolla Institute for Allergy and Immunology, La Jolla, United States.

It has long been appreciated, but not understood, that the $CD8^+$ cytotoxic T lymphocyte (CTL) dependence on $CD4^+$ T cell help (T_h) is conditional; needed for some immunogens but not others. One explanation for this phenomenon envisions T_h requirement as an intrinsic property of the pathogen itself rather than its introduction to the immune system. Here we show that dependence of the optimal $CD8^+$ T cell response to *Listeria monocytogenes* (*Lm*) on $CD4^+$ T cells is a function of the immunogen dose used for priming, with low dose *Lm* (LD; 50 or 10^3 CFU WT or Δ*actA*, respectively) inducing a primary antigen-specific CTL response profoundly dependent on $CD4^+$ T_h cells while that induced by high dose *Lm* (HD; 4×10^3 or 10^6 CFU WT or Δ*actA*, respectively) is significantly inhibited by $CD4^+CD25^+FoxP3^+$ regulatory T cells (T_{reg}). The T_h-independence of HD immunization is not overcome by additional antigen but instead involves the inflammatory response to more bacteria. Evaluation of various toll-like receptor (TLR) pathways as the relevant sensing mechanism showed that HD immunization in the absence of TLR9 results in a simultaneous loss of $CD25^+FoxP3^+CD4^+$ T_{reg} cells and increase in conventional $CD4^+$ T_h cells and CTLs. Our data thus reveal that the CTL response to the same pathogen is determined by distinct roles for $CD4^+$ T cells as helpers versus regulators based on immunogen dose and demonstrate a previously undescribed role for TLR9 in the regulation of $CD4^+$ T_h and T_{reg} cells.

P.D4.10.07

Focussing in on inflammasomes: Exploring new regulators of innate immune signalling pathways in the host defence against *K.pneumoniae*

K. Edwards*[1], A. Dumigan[1], Y. Dombrowski[1], J. Bengoechea[1], A. Kissenpfennig[1], P. Moynagh[1,2];*
[1]Centre for Experimental Medicine, Queen's University Belfast, Belfast, United Kingdom, [2]Institute of Immunology, Department of Biology, National University of Ireland Maynooth, Maynooth, Ireland.

Introduction: The innate immune system induces inflammation in response to injury or infection. Inflammasomes are innate immune signalling complexes vital in the activation of caspase-1, inflammation and wound healing. This study explored the contributions of inflammasomes to host defence against *Klebsiella pneumoniae* (*Kp*), a multi-drug resistant pathogen, and whether *Kp* virulence mechanisms target inflammasome pathways. Materials and Methods: Two *Kp* strains with different virulence, *Kp43816 (Kp43)* and *KP52145 (Kp52)*, were used to infect C57BL/6J mice intranasally for 24h to assess inflammation (ELISA) and virulence within the lung, spleen and NALT (CFU). Bone marrow-derived macrophages (BMDMs) from C57BL/6J and NLRP3 knockout (KO) mice were infected with *Kp43* or hypermucoid *Kp52* at 70:1 multiplicity of infection and assessed for bacterial burden, inflammasome activation (Western blot) and inflammation. Results: *Kp43*-infected C57BL/6J mice had significantly greater weight loss (p=0.0208) and bacterial burden within the nasal-associated lymphoid tissue (NALT) (p<0.0001) and spleen (p=0.0133) compared to *Kp52*-infected mice. *In vitro*, after 24h, *Kp43*-infected BMDMs produced more mature IL-1β (p≤0.01) and caspase-1 than *Kp52*-infected BMDMs. Phagocytosis of *Kp43* by BMDMs was increased compared to *Kp52* (p<0.001). Intracellular survival of either strain of *Kp,* however, did not differ. NLRP3KO BMDMs mounted effective inflammasome and anti-bacterial responses to *Kp*. Conclusions: Our results demonstrate that hypermucoid *Kp52* elicits a weaker inflammatory response and is therefore less virulent compared to *Kp43 in vivo*. NLRP3 was not vital for clearing *Kp* infection suggesting other inflammasomes are responsible. Informatively targeting inflammasomes during infection may be useful in aiding clearance of *Kp* infection.

P.D4.10.08

Transcriptional regulation of CD38 by Liver X receptors and inflammation: roles for CCAAT/enhancer-binding protein β (C/EBPβ)

E. Glaria*[1], J. Matalonga[1], J. Saura[2,3], A. F. Valledor[1];*
[1]University of Barcelona, Barcelona, Spain, [2]University of Barcelona/IDIBAPS, Barcelona, Spain, [3]Institute of Neurosciences, University of Barcelona, Barcelona, Spain.

Macrophages are essential players of the innate immune response against pathogens. Following recognition of pathogen-associated molecular patterns (PAMPs), they produce inflammatory mediators and trigger phagocytosis to fight infection. Liver X Receptors (LXRs) are ligand-activated transcription factors with relevant activities in the regulation of metabolism and the immune response. Recently, our group identified a new role for LXRs reducing macrophage infection by invasive *Salmonella* Typhimurium through transcriptional activation of CD38 and a subsequent increase in its NADase activity. Interestingly, we found that inflammatory mediators and bacterial components act synergistically with LXR agonists to induce CD38 expression. Remarkably, CD38 expression in bone marrow-derived cells was necessary for the ameliorating effects of pharmacological administration of an LXR agonist in an *in vivo* model of infection by *Salmonella*. To explore mechanisms of cooperation between inflammatory stimuli and LXRs, we investigated the role of the transcription factor C/EBPβ in the transcriptional control of CD38. Macrophages were differentiated *in vitro* from bone marrow precursors of wild-type mice or mice with myeloid C/EBPβ deficiency. Compared to wild-type cells, C/EBPβ-deficient macrophages underwent de-repression of CD38 expression in basal conditions. In contrast, CD38 induction by inflammatory cytokines, bacterial lipopolysaccharide or LXR agonists was drastically impaired in mice lacking C/EBPβ. Altogether, these results suggest crosstalk between LXRs and C/EBPβ to tightly regulate CD38 expression in the inflammatory context.

P.D4.10.09

CD4+ T cell mediated HLA class II cross-restriction in HIV controllers

M. Galperin[1], C. Farenc[2], M. Mukhopadhyay[1], J. Rossjohn[2], L. Chakrabarti[1], ***S. Gras***[2]*;*
[1]Pasteur Institute, Paris, France, [2]Monash University, Clayton, Australia.

Rare individuals, termed HIV controllers, spontaneously control HIV infection by mounting efficient T cell responses against the virus. Protective $CD4^+$ T cell responses from HIV controllers involve high affinity public T cell receptors (TCRs) recognizing an immunodominant capsid epitope (Gag293) presented by a remarkably broad array of HLA class II molecules. Here we determine the structures of a prototypical public TCR bound to HLA-DR1, -DR11, and -DR15 molecules presenting the Gag293 epitope. TCR recognition was driven by contacts with the Gag293 epitope, a feature that underpinned the extensive HLA cross-restriction. These high affinity TCRs promoted mature immunological synapse formation and cytotoxic capacity in both $CD4^+$ and $CD8^+$ T cells. The public TCRs suppressed HIV replication in multiple genetic backgrounds *ex vivo*, emphasizing the functional advantage conferred by broad HLA class II cross-restriction.

P.D4.10.10

Induction of neutrophil extracellular traps by *Mycoplasma bovis* and degradation of them by MnuA the major membrane exonuclease

F. Haile[1], *C. Hartley*[1], *F. Sansom*[1], *J. Coombe*[2], *P. Mansell*[2], *D. Beggs*[2], *G. Browning*[1];
[1]*Asia Pacific Centre for Animal Health, The University of Melbourne, Melbourne, Australia,* [2]*Department of Veterinary Clinical Sciences, Melbourne Veterinary School, Faculty of Veterinary and Agricultural Sciences, University of Melbourne, Melbourne, Australia.*

Mycoplasma bovis is recognised as an important pathogen of cattle and uses a range of cell surface proteins to evade the host immune system. We investigated the capacity of *M. bovis* to induce Neutrophil Extracellular Trap (NET) formation and the effect of the major membrane nuclease MnuA, which *in vitro* is responsible for the majority of the nuclease activity of *M. bovis,* on the process of NET formation. The wildtype *M. bovis* PG45, the nuclease deficient mutant MBOVPG45_0215 (*MnuA*), the putative nuclease Δ310 deficient mutant, and the *mnuA* complemented strain (*mnuA*-pIRR45) were grown in modified Frey's broth and their nuclease activities were compared using nuclease zymograms. Fluorescence microscopy was employed to visualise the presence of NETs in neutrophils isolated from healthy cows while a Sytox-Green based assay was used to quantify the formation of NETs. A luminol-based ROS assay was used to determine the role of reactive oxygen species (ROS) in the process of NET formation. NETs were detected following exposure of neutrophils to the *mnuA* mutant but not after exposure to either the wild-type or the *mnuA*-pIRR45 complemented mutant, and NETs were degraded in the presence of even low concentrations of wild type *M. bovis*. Our study demonstrates that *M. bovis* can induce NET formation in bovine neutrophils, albeit in the absence of induction of ROS, but that the major membrane nuclease MnuA is able to rapidly degrade them, and thus is likely to play a significant role in virulence.

P.D4.10.11

Unraveling the regulation of T cell - pathogen equilibration during chronic infection

J. Handschuh[1], *M. Alabdullah*[1], *P. Formaglio*[2], *L. Philipsen*[1], *J. Mohr*[1], *A. J. Müller*[1,3];
[1]*Institute for Molecular and Clinical Immunology, Magdeburg, Germany,* [2]*Institut Pasteur, Paris, France,* [3]*Helmholtz Centre for Infection Research, Braunschweig, Germany.*

Chronic infections require the escape of the pathogen from sterilizing immune responses, while the immune system may downregulate its effector functions to prevent damage at the cost of pathogen persistence. However, little is known about the mechanisms by which the immune response equilibrates with the pathogen in order to stabilize the infectious burden at a low level, which is key to permit chronic and often even asymptomatic infection. Particularly, it is unknown how the interactions of effector and regulatory T cells (Teff and Treg) among each other, as well with the pathogen, impact the establishment of a persisting pathogen reservoir.
We are using the intracellular parasite *Leishmania major* as a model for infections efficiently contained by T cells, yet persisting at the site of infection after resolution of pathology. The persisting parasite reservoir is important for maintenance of immunity against reinfection and is dependent on the presence of Treg.
We have set up in vivo biosensors in order to unravel the interplay of the T cell compartment and pathogen physiology at the site of infection by intravital 2-photon microscopy. This approach allows for probing not only pathogen viability, but also the activation of effector T cells during their dynamic interaction with *Leishmania*-infected phagocytes. By mapping immune cell activation and pathogen clearance in the context of the cellular microenvironment at the site of infection, we now aim at elucidating how the equilibrium between pathogen containment and immune activation is realized during the persistence of *Leishmania major*.

P.D4.10.12

Investigating the capacity of Kupffer cells to acquire an innate memory function through sensing of apoptotic cells

I. Liebold[1,2], *L. Bosurgi*[1,2];
[1]*University Hospital Eppendorf, Hamburg, Germany,* [2]*Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany.*

Schistosoma are trematodes that are responsible for Schistosomiasis. Around 240 million people are infected with the parasite worldwide. Upon host infection, the release of parasite eggs leads to granuloma formation in the liver and induces a type 2 immune response. Macrophages, which react to type 2 cytokines, such as IL-4 and IL-13, are responsible and necessary for the switch from a type 1 to a type 2 immune response. Although this switch is essential for the initial survival of the host, at later stages of the disease, macrophages are also associated to the induction of liver fibrosis. Interestingly, Kupffer cells (KCs), resident macrophages in the liver, are not only highly phagocytic cells but they also have a long-lived capacity. Here we hypothesize that, similar to long lived cells of the adaptive immune system, KCs can acquire an innate memory capacity, driven by the phagocytosis of apoptotic cells. We have recently described that sensing of apoptotic cells is essential for the response to type 2 cytokines and acquisition of a tissue remodeling function in macrophages. Here we show that in the liver, Kupffer cells express phagocytic receptors such as AXL and MERTK, and can increase their tissue remodeling function upon sensing of apoptotic cells both in *in vitro* and *in vivo* experimental settings. Understanding new mechanisms for regulating, KCs activation and induction of tissue remodeling may reveal novel therapeutic targets and provide crucial insights for long lasting protection against hepatic infections, while avoiding liver fibrosis.

Ovine C-type lectin receptor (CLR)-Fc fusion protein library - a novel tool in veterinary immunology to screen for virus/CLR interactions

D. Lindenwald[1], *K. Jung*[2], *S. Becker*[3], *S. Rautenschlein*[4], *M. Buettner*[5], *G. Alber*[5], *B. Lepenies*[1];
[1]*Immunology Unit & Research Center for Emerging Infections and Zoonoses (RIZ), University for Veterinary Medicine Hannover, Foundation, Hannover, Germany,* [2]*Institute for Animal Breeding and Genetics & Research Center for Emerging Infections and Zoonoses (RIZ), University of Veterinary Medicine Hannover, Foundation, Hannover, Germany,* [3]*Institute for Parasitology & Research Center for Emerging Infections and Zoonoses (RIZ), University for Veterinary Medicine Hannover, Foundation, Hannover, Germany,* [4]*Clinic for Poultry, University for Veterinary Medicine Hannover, Foundation, Hannover, Germany,* [5]*Institute of Immunology/Molecular Pathogenesis, Center for Biotechnology and Biomedicine, College of Veterinary Medicine, University of Leipzig, Leipzig, Germany.*

Innate immunity is the first line of defense against parasitic, bacterial, fungal and viral pathogens and depends on the recognition of evolutionarily conserved pathogen patterns by innate immune receptors. Among other pattern recognition receptors, C-type lectin receptors (CLRs) recognize pathogen-derived patterns and thus are important cross-linkers of innate and adaptive immunity. Knowledge on how CLRs contribute to defense against infections is, however, incomplete. While to date most studies have focused on the role of CLRs in innate immunity in mice and men, little is known on the function of CLRs in larger animals. To this end, a library of chimeric CLR-Fc fusion proteins composed of the extracellular domain of ovine CLRs and human IgG Fc-fragment has been generated, thus extending the currently available murine and human CLR-Fc libraries by a veterinary relevant species.
The utility of the library was verified by ELISA-based binding studies. First, its functionality was confirmed using known ligands of the murine CLR paralogs, such as the Saccharomyces cerevisiae derived polysaccharide mannan as a ligand of ovine Dectin-1. Subsequent pathogen screenings revealed a selective affinity of some ovine CLR-Fc fusion proteins such as ovine Dendritic cell immunoreceptor (DCIR) to the contagious pustular dermatitis (ORF) virus.
In conclusion, the here generated ovine CLR-Fc fusion protein library represents a useful tool to screen for novel CLR/pathogen interactions in the field of veterinary immunology.

P.D4.10.15

The clinical efficacy of the combine interferon- and immunomodulatory therapy in patients with the atypical chronic active Epstein-Barr herpes-viral infection

I. V. Nesterova[1], *E. O. Khalturina*[2], *V. V. Malinovskaya*[3];
[1]*The Peoples' Friendship University of Russia, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation,* [3]*Federal Research Center of Epidemiology and Microbiology. N.F. Gamalei, Moscow, Russian Federation.*

Postviral chronic fatigue syndrome (pCFS) is often associated with atypical chronic active herpesviral Epstein-Barr infection (ACA-EBI). The methods of treatment of ACA-EBI are imperfect. We observed 148 adult patients suffering from ACA-EBI. The diagnostic complex included: the complaints, anamnestic, clinical features, the laboratory and immunological (the main cell'antiviral mechanisms, the interferon(IFN) system) investigations that was based on the our algorithm. Herpes viruses were tested by PCR and sero-diagnostic methods. All studied patients with ACA-EBI had mono- EBI (5%) and mixed EBI with another herpesviruses (95%). Symptoms of pCFS- in 97,97%, throat transient pain - in 100%, subfebrile temperature - in 67%, lymphadenopathy - in 90% of cases were identified. Secondary combine immunodeficiencies were detected: defect of induced production of INFα and INFγ - in 100% of cases; combine defects of immune system (number, functional deficiency of NK cells, T killers, EKT, neutrophils) - in 92.4% of patients. The program of combine IFN- and immunomodulatory therapy was created: suppositories of the recombinant INFα2 in combination with antioxidants, using gradually decreased doses - prolonged course (4.5 months); immunomodulatory therapy: glucosaminylmuramyl- dipeptide (GMDP), inosine pranobex and the synthetic antiherpesvirus drugs.
The course of combine IFN- and immunomodulatory therapy was lasted 4.5 month. The received clinical and immunological data clarified the immunopathogenetical mechanisms of ACA-EBI, that begun the basis for the development and application of targeted IFN-, immunomodulatory and antiviral therapy. Positive clinical and immunological dynamics was observed in 100% of cases, including the regression of CFS in 99% of patients.

P.D4.10.16

Analysis of the imbalance between regulatory B and T cells and circulating T follicular helper cells in HIV-infected patients

*J. Lopez-Abente[1], C. Gutierrez[2], V. Perez-Fernandez[1], A. Prieto-Sanchez[1], R. Correa-Rocha[1], S. Moreno-Guillen[3], M. Muñoz-Fernandez[1], **M. Pion**[1];*
[1]Instituto de Investigacion Sanitaria Gregorio Marañon, Madrid, Spain, [2]Hospital Ramón y Cajal, Madrid, Spain, [3]Hospital General Universitario Gregorio Marañón, Madrid, Spain.

Background: HIV infection *in vitro* produces alterations in regulatory T (Treg) and B (Breg) subsets. These subsets play a crucial role in the maintenance of immune homeostasis, and it has been recently described that T follicular helper cells (Tfh) are pivotal for the development of Breg, and could also modulate the Treg maintenance.
Methods: We have analyzed the phenotypes of four different Breg subsets, Treg and circulating Tfh (cTfh) compartments along with the frequencies of IL-10, IL-17, IL-4 and INFγ-secreting cells in naïve-treated HIV$^+$ patients, in treated-HIV$^+$ patients and in healthy individuals. Finally, we analyzed the suppressive capacity of Breg from HIV-infected patients or healthy individuals.
Results: Absolute counts of Treg and Breg were decreased and frequency of cTfh was increased in naïve-treated HIV$^+$ patients in comparison to treated-HIV$^+$ patients or healthy individuals. Positive correlation between cTfh and Treg observed in healthy individuals were lost in naïve-treatment HIV$^+$ patients, but surprisingly correlations between Breg subsets and Treg were established in naïve-treatment HIV$^+$ patients in comparison to healthy individuals. **Conclusions:** We demonstrated that the balance between cTfh, Treg and some Breg subsets are deregulated in HIV-infected patients and that these cellular compartments might participate in the immune system hyperactivation and exhaustion.

An unusual presentation of hip pain in a patient with known hyper IgE syndrome and multiple calcified pelvic apophyses

***A. Saad**, S. Shahban, T. ElGamal;*
Heart of England NHS trust, Birmingham, United Kingdom.

Introduction Hyper-IgE syndrome (HIES) is a relatively rare condition which, from childhood, renders patients susceptible to infection. Typically patients with HIES can develop various orthopaedic manifestations of this disease, namely, scoliosis, pathological fractures, osteoporosis and potentially septic arthritidies. Case report We present the case of WJ, a 44-year old patient with known HIES and a 7 week history of left hip pain. We discuss the clinical presentation, and the curveballs which came our way when investigating this patient and how we overcame them. We also demonstrate a very interesting pelvic radiograph from this patient which shows multiple sites of calcified apophyses. Something which is firstly unexpected in such patients and secondly something not previously reported in the literature. Conclusion Several issues and conundrums can present themselves when dealing with patients known to have HIES. We demonstrate how we managed such a patient and maintained a high level of suspicion in such patient.

RNA derived from *Plasmodium falciparum* and *Litomosoides sigmodontis* is potent to induce a pro-inflammatory immune response in human cells

***J. F. Scheunemann**[1], A. L. Neumann[1], S. J. Frohberger[1], A. Ehrens[1], C. Coch[2], M. P. Huebner[1], A. Hoerauf[1,3], B. Schumak[1];*
[1]Institute of Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany, [2]Institute of Clinical Chemistry and Clinical Pharmacology, University Hospital Bonn, Bonn, Germany, [3]German Center for Infection Research (DZIF), partner site Bonn-Cologne, Germany.

Introduction: The elimination of infectious diseases like malaria and filariasis is an important aim of the United Nations. Despite tremendous research progress regarding the underlying mechanisms of these parasitic diseases, it still remains elusive how initial parasite recognition works. In contrast to surface structures and parasite products, the role of their nucleic acids is weakly characterized. Here we investigate the potential of parasitic nucleic acids and corresponding host receptors as targets for successful disease modification.
Materials and Methods: We investigated the potential of *P. falciparum* and *L. sigmodontis*-derived RNA to evoke an immune response, compared to human and *E. coli*-RNA, by *in vitro* cultures of human peripheral blood mononuclear cell (PBMC) and reporter cell lines. We quantified the secreted cytokines and analyzed cell activation by flow cytometry.
Results: ELISA revealed that cytosolic delivery of *L. sigmodontis*-RNA induced a strong induction of IFN-a in PBMCs, whereas *P. falciparum*-RNA was more stimulatory if delivered to the endosome, resulting in a cytokine pattern associated with NFκB activation. We further showed that monocytic cell populations were strongly activated after the challenge with parasitic RNA that was RIG-I-dependent.
Conclusion: Parasitic RNA derived from *P. falciparum* and *L. sigmodontis* harbors a pro-inflammatory potential, manifesting in the activation of monocytes, type I IFN secretion and presumably NFκB activation. The evoked immune response differs between endosomal and cytosolic recognition. The cytosolic RNA receptor RIG-I was crucial for recognition of parasitic RNA and subsequent cell activation.

P.D4.10.19

Reverse immunology as a tool to identify broadly recognized pneumococcal proteins targeted by human T-cells

***M. D. B. van de Garde**, E. van Westen, M. C. Poelen, N. Y. Rots, C. A. van Els;*
Centre for Infectious Disease Control, National Institute for Public Health and the Environment (RIV, Bilthoven, Netherlands.

Introduction: T-cell mechanisms, which are implied in protection against pneumococcal colonization, should be unraveled to understand the mode of action of future universal protein-based pneumococcal vaccines. Here we apply reverse immunology to predict and verify broadly recognized human T-cell epitopes for a semi-large array of pneumococcal proteins. Methods: Hundred pneumococcal proteins of diverging subcellular localization were selected for *in silico* prediction of T-cell immunogenicity based on HLA-DR binding and absence of cross-reactivity against human proteins (Epivax). For 20 potentially T-cell immunogenic proteins, peptides predicted to bind >4 of 8 common HLA-DRB1 alleles were synthesized, pooled per protein and tested in T-cell proliferation and cytokine assays using PBMCs from a panel of healthy adults and (ex-) pneumococcal pneumonia cases. Results: Peptide pools of 19/20 proteins evoked T-cell responses in healthy adults. Most frequent responses (in ≥ 25% of 20 donors tested) were found for SP_0117 (PspA), SP_0468 (putative sortase), SP_0546 (BlpZ), SP_1650 (PsaA), SP_1923 (pneumolysin), SP_2216 (PcsB), and SPR_0907 (PhtD). Healthy adults and cases had diverging patterns of protein immunodominance and cytokine profiles (IFNg, TNFa, IL-13 and IL17A) against single peptides. Conclusions: We demonstrated proof of principle for a reverse immunology approach to screen human pneumococcus specific T-cell responses at a semi-large proteome scale. Single peptides can evoke measurable proliferative and cytokine responses, including IL17, thought to play a role in the protection against *S. pneumoniae*. Currently, in depth T-cell analyses are ongoing in pneumococcal carriers and (ex-) cases of various age groups.

HIV-1 modulates TRAF proteins to promote pro-inflammatory condition and avert Interferon induction

***S. Trivedi**, A. C. Banerjea;*
National Institute of Immunology, New Delhi, India.

The most obvious route for infection available to HIV-1 in humans is via epidermis, dermis and lymph nodes and doing so it encounters a lot of resistance as every nucleated cell it comes across can potentially mount an innate immune response against it. Especially, the tissue dendritic cells and macrophages where the virus faces various pattern recognition receptors (PRRs) before it can establish a productive infection. An important family of signaling adaptor proteins involved in different PRR pathways is TRAF (TNF-α Receptor Associated Factor) Family of proteins. Almost all PRRs involved in detection of HIV-1 converge down to TRAF family of proteins which in turn leads to differential effecter functions. On one hand, TRAF6 activates Nf-κB and AP-1, which binds to the LTR region of HIV-1 and promotes its transcription, while on the other hand, TRAF3 activates IRF-3 and IRF-7 which promote synthesis of interferons and in turn provide anti-viral activity. Thus modulation of these two effecter arms at the right time can be very beneficial for the virus and delineating this phenomenon can provide better insights into the pathogenicity of the virus. In our work we are able to show that HIV-1 modulates these key signaling adaptors - TRAF3 and TRAF6 to enhance its replication capacity in the cell. HIV-1 Vpr and Vpu proteins are involved in this modulation which down-regulate TRAF3 and up-regulate TRAF6 to a similar extent, thereby creating a pro-inflamatory environment which enables the virus to have a much more productive replication.

P.D4.11.03

Suppressor of cytokine signaling-3 and control of progression towards liver fibrosis and hepatocellular carcinoma in chronic HCV-infected patients

F. JADID[1,2], *H. Chihab*[1], *H. Salih Alj*[2], *R. Elfihry*[1], *I. zaidane*[1], *S. Tazi*[1], *W. Badre*[3], *A. Marchio*[4], *M. Tahiri*[3], *R. Saile*[2], *P. Pineau*[4], *S. Ezzikouri*[1], *S. Benjelloun*[1];
[1]*Institut Pasteur du Maroc, Casablanca, Morocco,* [2]*Université Hassan II de Casablanca, Casablanca, Morocco,* [3]*CHU Ibn Rochd de Casablanca, Casablanca, Morocco,* [4]*Institut Pasteur de Paris, Paris, France.*

Chronic Hepatitis C is one of the most important risk factors of liver cirrhosis and hepatocellular carcinoma. Before reaching these ultimate steps, insulin resistance triggered by hepatitis C virus infection is known to participate in the progression of liver disease. The present study aims to investigate the influence of two functional polymorphisms on *SOCS3* mRNA expression and on the outcomes of CHC progression in a North African context. In this case-control study, 601 Moroccan subjects composed of 200 healthy controls, 101 resolvers and 300 patients with persistent HCV infection including 95 mild chronic hepatitis, 131 Advanced Liver Diseases and 74 HCC were enrolled. They were genotyped for the 4874 A/G (rs4969170) and A+930-->G (rs4969168) *SOCS3* variants using TaqMan SNPs assays. SOCS3 mRNA expression was assessed using Real Time PCR technique. Logistic regression analysis showed that variation at rs4969168 was associated with spontaneous clearance of HCV (P<0.05). In addition, minor allele frequencies were significantly higher in AdLD patients when compared to the mCHC group both for rs4969168 (P=7.0 E-04) and rs4969170 (P=4.0 E-05). A significant association between haplotype and liver disease progression was also found. Moreover, SOCS3 mRNA was significantly more expressed in peripheral leukocytes from patients with HCC than in those from mCHC. Finally, rs4969170 was significantly associated with LDL-lipoprotein (P=0.04), total cholesterol (P=5.0 E-04), and higher fasting glucose levels (P=0.005) in patients with persistent HCV infection. Our results underline the importance of the functional SOCS3 polymorphisms in the modulation of CHC progression and suggest their contribution to HCC development by affecting its mRNA expression and perturbing key metabolic parameters.

P.D4.11.04

PIP_3 induces phagocytosis of non-motile *Pseudomonas aeruginosa*

S. Demirdjian*, D. Hopkins, H. Sanchez, B. Berwin;*
Dartmouth College, New Hampshire, United States.

Pathogenic bacteria that establish chronic infections in immunocompromised patients frequently undergo adaptation or selection for traits that are advantageous for their growth and survival. Clinical isolates of *Pseudomonas aeruginosa*, a gram-negative, opportunistic bacterial pathogen, exhibit a temporal transition from a motile to a non-motile phenotype through loss of flagellar motility during the course of chronic infection. This progressive loss of motility is associated with increased resistance to both antibiotic and immune clearance. We have previously shown that loss of bacterial motility enables *P. aeruginosa* to evade phagocytic clearance both *in vitro* and *in vivo* and fails to activate the phosphatidylinositol 3-kinase (PI3K)/Akt-dependent phagocytic pathway. Therefore, we tested the hypothesis that clearance of phagocytosis-resistant bacteria could be induced by exogenously pre-treating innate immune cells with the Akt activating molecule phosphatidylinositol-(3,4,5)-trisphosphate (PIP_3). Here we demonstrate that PIP_3 induces the uptake of non-motile *P. aeruginosa* by primary human neutrophils >25-fold, and this effect is phenocopied with the use of murine phagocytes. However, surprisingly, mechanistic studies revealed that the induction of phagocytosis by PIP_3 occurs because polyphosphoinositides promote bacterial binding by the phagocytes rather than bypassing the requirement for PI3K. Moreover, this induction was selective, since the uptake of other non-motile gram-negative, but not gram-positive bacteria, can also be induced by PIP_3. Since there is currently no treatment that effectively eradicates chronic *P. aeruginosa* infections, these findings provide novel insights into a potential methodology by which to induce clearance of non-motile pathogenic bacteria and into the endogenous determinants of phagocytic recognition of *P. aeruginosa*.

Estrogen stimulates phagocytosis by macrophages in both *in vitro* and *ex vivo* models of age-related impaired healing via the estrogen-receptor alpha

M. El Mohtadi*, K. Whitehead, A. Fadel, J. Ashworth;*
School of Healthcare Science, Manchester, United Kingdom.

Annual expenditure for the treatment of chronic wounds in the elderly exceeds $9 billion. Chronic wounds are frequently colonised by opportunistic pathogens such as *Staphylococcus aureus* and *Pseudomonas aeruginosa*, and declining levels of estrogen with increasing age delays healing. This study investigated the effect of hormonal aging (estrogen deprivation) on the clearance of methicillin-resistant *S. aureus* (MRSA) and *P. aeruginosa* by macrophages derived from U937 and human primary $CD14^+$ monocytes. Concentrations of 17β-estradiol were used to model estrogen levels found in the elderly (estrogen deprivation: absolute absence and $1x10^{-9}$M), young adults ($1x10^{-8}$M) and following exogenous supplementation ($1x10^{-7}$M). The estrogen receptor (ER) isoform(s) involved in bacterial clearance were determined using selective ER modulators.
Estrogen at concentrations typical of youth or supraphysiological levels significantly ($P<0.05$; n=24) increased the phagocytosis of MRSA and *P. aeruginosa* in a concentration-dependent manner compared to estrogen deprivation. Confocal and scanning electron microscopy confirmed estrogen increases co-localisation of fluorescent GFP-*S. aureus* or mCherry-*P. aeruginosa* with macrophages and promotes bacterial internalisation. ER-alpha (ERα) activation mirrored the stimulatory effect of estrogen on phagocytosis whilst ERα antagonism completely blocked the effect of estrogen. In contrast, activation or antagonism of ER-beta (ERβ) had no effect on phagocytosis, confirming estrogen mediates bacterial clearance via ERα alone.
These findings suggest estrogen promotes the resolution of wound bacteria during youth but this protection is lost as estrogen levels decline with increasing age. Novel dressings that provide estrogen supplementation or selective activation of ERα may be an effective treatment option for colonised wounds in the elderly.

Chlamydial co-infection boosts the CTL-stimulatory capacity of HIV-1-exposed DCs in a time-dependent manner

M. Schönfeld[1], *U. Knackmuss*[1], *P. Chandorkar*[1], *P. Hörtnagl*[2], *T. J. Hope*[3], *A. Moris*[4], *R. Bellmann-Weiler*[5], *C. Lass-Flörl*[1], *D. Wilflingseder*[1], ***W. Posch***[1];
[1]*Division of Hygiene and Medical Microbiology, Medical University Innsbruck, Innsbruck, Austria,* [2]*Central Institute for Blood Transfusion & Immunological Department, Innsbruck, Austria,* [3]*Department of Cell & Molecular Biology, Feinberg School of Medicine, Northwestern University, Chicago, United States,* [4]*Centre d'Immunologie et des Maladies Infectieuses-Paris, Pierre and Marie Curie University UMRS C7, INSERM U1135, CNRS ERL 8255, Paris, France,* [5]*University Hospital for Internal Medicine II, Medical University of Innsbruck, Innsbruck, Austria.*

Pathogenic bacteria and their microbial products activate dendritic cells (DCs) at mucosal surfaces during sexually transmitted infections (STIs) and might also modulate their functions during co-infections with HIV-1. We recently illustrated that complement (C) coating of HIV-1 (HIV-C) as found during the acute phase of infection by-passed SAMHD1-mediated restriction in DCs and thereby mediated an increased DC activation and antiviral capacity. To determine whether the superior antiviral effects of HIV-C-exposed DCs also apply during bacterial co-infection, we developed a super-infection model in which DCs were infected with *Chlamydia spp.* simultaneously (HIV+Chlam-DCs) or followed by HIV-1 infection (Chlam-DCs). Simultaneous infection of DCs with HIV-1 and *Chlamydia* significantly boosted the CTL-stimulatory capacity compared to HIV-C-loaded iDCs. This protective effect was lost upon pre-infection with *Chlamydia* 3h or 24h prior addition of opsonized HIV-1. The reduction in the CTL-stimulatory capacity was not due to lower HIV-1 binding, internalization or infection of Chlam-DCs compared to iDCs or HIV+Chlam-DCs, but due to altered fusion and internalization mechanisms within DCs. CTL-stimulatory capacity of HIV-C in Chlam-DCs correlated with significantly reduced viral fusion than iDCs and HIV+Chlam-DCs and illustrated considerably increased numbers of HIV-C-containing vacuoles compared to iDCs. These data indicate that *Chlamydia* super-infection of DCs mediates a transient boost of their HIV-specific CTL-stimulatory and antiviral capacity, which is reversed in a time-dependent manner.

P.D4.11.07

Hyperinduction of Interferon Lambda and proinflammatory cytokines upon infection of neural cells with Zika virus

A. S. M. SELIM*, S. M. Lee;*
The University of Hong Kong, Hong Kong, Hong Kong.

In Feb, 2016, The WHO has declared Zika virus as a "Public Health emergency of international concern" after the outbreak in Brazil where numerous cases of microcephaly in newborns of Zika infected mothers as well as acute myelitis in adults. Zika is an enveloped, non-segmented, positive sense, single stranded RNA arbovirus. Here we investigated the viral replication kinetics and the host immune response in human neural cells after Zika virus infection. Human differentiated astrocytes (d T98G), neuronal (d SH-SY5Y) and microglial (Immortalized Human Microglia-SV40) cells were infected with Zika virus at MOI of 4. TCID50 was used to measure the viral replication kinetics. We found that Zika replicated efficiently in the neuronal and microglial cells but to a lesser extent in astrocytes. RT-qPCR was used to measure the host immune gene response after infection. We found that Zika induced type I interferon represented in IFN-beta induction in microglial and astrocytic cells. Interestingly, we found that Zika induced the expression of type III interferons, IL29 in astrocytic and microglial cells and IL28a/b in neuronal and microglial cells as well as IFN λ receptor (IL10RB). Proinflammatory cytokines and chemokines hyper inductions were sparking with RANTES, IP10, IL8, IL6 and COX2. Hyperinductions of pattern recognition receptors involved in viral recognition were identified with TLR3 and RIG-I. Our results demonstrated that three of the main neural cell types are susceptible to Zika virus infection. The hyper- induction of IL-29 in astrocytic and microglial cells opens new insights for Zika host antiviral response.

Introduction: Meningitis can be caused by several viruses and bacteria. Identifying the specific pathogen as fast as possible is crucial to initiate the most optimal therapy, as acute bacterial meningitis can be fatal. Bacterial meningitis requires antibiotics, as opposed to enteroviral meningitis, which only requires supportive therapy. Clinical presentation is mostly not sufficient to differentiate between viral and bacterial meningitis, thereby necessitating cerebrospinal fluid (CSF) analysis by PCR and/or time-consuming bacterial cultures. However, collecting CSF in children is not without risk.
Methods: In 11 Belgian hospitals, we obtained acute blood samples from children with signs of meningitis (3 months – 16 years). When meningitis was confirmed on CSF, the patient was asked to give a convalescence sample after recovery. 3'mRNA sequencing was performed to determine differential expressed genes to create a host transcriptomic profile. Gene ontology analysis was used for further interpretations.
Results: Enteroviral meningitis cases displayed the largest upregulated fold change enrichment in interferon production (especially interferon-alpha), response and signaling pathways when comparing acute with convalescence samples. Furthermore, we noted an upregulation of expression of different other cytokines, activation and degranulation of leukocytes, including neutrophil mediated immunity. We compared enteroviral against bacterial meningitis data and built a random forest classifier with feature selection with an AUC of 0,957.
Conclusion: Enteroviral meningitis has a clear innate immunity signature with type 1 interferons as key players, as expected in a viral infection. Our classifier, based on the host transcriptomic profiles of different meningitis cases, is able to select for enteroviral meningitis.

P.D4.11.09

Dissecting the molecular mechanisms underpinning T cell help for dendritic cell

E. Gressier[1,2], *P. G. Whitney*[1], *W. Kastenmuller*[2], *S. Bedoui*[1];
[1]*The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia,* [2]*Institute of Experimental Immunology, Bonn, Germany.*

$CD8^+$T cell priming relies on the ability of dendritic cells (DC) to present antigen as well as recognizing, processing and communicating contextual cues associated with antigen acquisition to $CD8^+$T cells. DC often require CD40-CD40L-mediated interactions with helper $CD4^+$T cells to generate an efficient $CD8^+$T cell response. Precisely how such 'T cell help' is delivered *in vivo* and how it optimizes the priming capacity of DC remains unclear. Previous work conducted by the team showed that $CD4^+$T cell help amplifies the capacity of DCs to generate efficient priming of $CD8^+$T cell in response to suboptimal innate stimuli. Focusing on the CD40-driven amplification of innate pathways induced in IFN-α/β-stimulated DC, this study was designed to explore the molecular mechanisms underpinning such help phenotype. We have observed distinct patterns and dynamics of a fast amplification of various cytokines such as IL-15, IL-6 and IL-12p40, amplification induced by CD40 treatment following IFN-α stimulation. Moreover, transcriptomics, proteomics and protein phosphorylation analysis suggest that this crosstalk between interferon and T cell help signal was integrated through the distinct stimulation of particular aspects of the NF-κB pathways. These findings argue for a complex synergism between CD40 signaling and innate stimuli that enable DCs to flexibly adjust cytokine secretion to the strength of inflammatory responses that accompany the acquisition of antigen. By dissecting how T cell help amplifies innate signals required for $CD8^+$T cell priming, this work will assist in the development of more targeted T-cell-based therapeutic strategies.

Adrenal hormones mediate disease tolerance in malaria

L. Vandermosten[1], *T. Pham*[1], *S. Knoops*[1], *C. De Geest*[1], *N. Lays*[1], *K. Van der Molen*[1], *C. J. Kenyon*[2], *M. Verma*[2], *K. E. Chapman*[2], *F. Schuit*[3], *K. De Bosscher*[4], *G. Opdenakker*[1], ***P. E. Van den Steen***[1];
[1]*Rega Institute for Medical Research, KU Leuven - University of Leuven, Leuven, Belgium,* [2]*The Queen's Medical Research Institute, University of Edinburgh, Edinburgh, United Kingdom,* [3]*KU Leuven - University of Leuven, Leuven, Belgium,* [4]*VIB Center for Medical Biotechnology, Ghent University, Ghent, Belgium.*

Malaria, a global parasitic disease with severe complications, reduces host fitness and survival by pathogen-mediated damage and/or exaggerated host inflammation. Disease tolerance mechanisms counter these negative effects without interfering with pathogen load and thereby improve host survival. Adrenal hormones, including glucocorticoids (GCs) and adrenalin, have several homeostatic functions. GC levels are increased in patients with malaria, but their precise role remains unknown. In four different mouse models of malaria, we demonstrated that adrenal hormones protect mice against early death during infection, independent of parasitemia and parasite-mouse strain combinations. Adrenal hormones thus confer disease tolerance in malaria. Surprisingly, adrenalectomy differentially affected malaria-induced inflammation by increasing circulating cytokine levels and inflammatory activity in the brain, but not in the liver or lungs. Furthermore, without effects on the hepatic gluconeogenic enzyme transcription and the free fatty acid levels in plasma, adrenalectomy caused lethal hypoglycemia upon infection, independently from TNF-α and insulin. Glucose administration did not prevent or reverse lethal hypoglycemia. In contrast, treatment with a synthetic GC (dexamethasone) prevented the hypoglycemia, lowered cerebral cytokine expression and significantly increased the survival rates. Overall, we conclude that adrenal hormones do not protect against lung and liver inflammation in malaria, but instead protect against systemic and brain inflammation and severe hypoglycemia.

P.D4.11.11

TOB1 inhibits IRF3-directed antiviral responses by recruiting HDAC8 to specifically suppress IFN-β expression

Z. Yu, M. Jia, ***W. Zhao****;*
Department of Immunology,School of Basic Medical Science, Shandong University, China, Jinan, China.

Innate immunity is the first line of host to defense against viral invasion and need to be precisely controlled. Viral infection induced type I interferons (IFNs) production play fundamental roles in innate immunity against virus and maintain immune homeostasis. However, the epigenetic regulatory mechanisms of type I IFNs production is unclear. The transducer of ErbB-2.1 (TOB1) is a member of the anti-proliferative family of BTG/TOB (B cell migration factor/erbB2). TOB1 plays crucial regulatory roles in T cell activation and cancer, via interacting with SMAD4 or SMAD2. However, its potential roles in innate immunity is unknown. In the present study, we found that the crystal structures of SMAD and IRF3 are very similar, and TOB1 could interact with IRF3. TOB1 expression could be markedly induced during viral infection in macrophages. TOB1 deficiency enhances both RNA and DNA viral-induced IFN-β production, and inhibits viral replication in macrophages. Mechanistically, TOB1 associates with IRF3, recruits HDAC8, and promotes HDAC8 binding to IFN-β promoter. Thus, TOB1 attenuates the acetylation of histone in the IFN-β promoter region, and thus inhibiting IFN-β transcription. Therefore, we identified TOB1 as a negative regulator of IFN-β production and outlined a new feedback mechanism for the epigenetic control of antiviral immune responses.

P.D4.11.12

Schlafen 14 (SLFN14) is a novel antiviral factor involved in the control of viral replication

O. Shin*;*
Korea University School of Medicine, Seoul, Korea, Republic of.

Schlafen (SLFN) proteins have been suggested to play important functions in cell proliferation and immune cell development. In this study, we determined the antiviral activities of putative RNA-helicase domain-containing SLFN14. Murine SLFN14 expression was specifically induced by TLR3-mediated pathways and type I interferon (IFN) in RAW264.7 mouse macrophages. To examine the role of SLFN during viral infection, cells were infected with either wild-type PR8 or delNS1/PR8 virus. SLFN14 expression was specifically induced following influenza virus infection. Overexpression of SLFN14 in A549 cells reduced viral replication, whereas knockdown of SLFN14 in RAW264.7 cells enhanced viral titers. Furthermore, SLFN14 promoted the delay in viral NP translocation from cytoplasm to nucleus and enhanced RIG-I-mediated IFN-β signaling. In addition, SLFN14 overexpression promoted antiviral activity against varicella zoster virus (VZV), a DNA virus. In conclusion, our data suggest that SLFN14 is a novel antiviral factor for both DNA and RNA viruses.

P.D4.11.13

Th17 cells and the adaptive immunity to vulvovaginal candidiasis

R. Marzi[1], *C. Basso*[1], *C. De Gregorio*[1], *F. Kirchner*[2], *G. Gyuelveszi*[1,3], *S. Becattini*[1,4], *B. Becher*[5], *S. LeibundGut-Landmann*[2], *F. Sallusto*[1,6];
[1]*Institute for Research in Biomedicine,Università della Svizzera Italiana, Bellinzona, Switzerland,* [2]*Section of Immunology, Institute of Virology, University of Zurich, Zurich, Switzerland,* [3]*Roche Innovation Center Zurich, Zurich, Switzerland,* [4]*Memorial Sloan Kattering Cancer Center, New York, United States,* [5]*Institute of Experimental Immunology, University of Zurich, Zurich, Switzerland,* [6]*Institute of Microbiology, ETH Zurich, Zurich, Switzerland.*

Vulvovaginal candidiasis (VVC) is the most common manifestation of *C. albicans* infection. Chronic mucocutaneous candidiasis (CMC) patients with mutations in genes associated with the IL-17 pathway display symptoms of VVC, but whether the disruption of the IL-17 pathway is a direct cause for VVC or rather an indirect effect due to the general increase in fungal colonization in these patients is unclear. Mice lacking IL-23, either IL-17R subunit or the adaptor Act1, are susceptible to oral and dermal candidiasis. These previous studies analyzed only the early phases of the host-pathogens interplay, which is generally life-long in humans. In our study, we set out kinetic experiments to assess the relative contribution of Th17 cells in persistent VVC. We found that WT mice and μMT mice survived even at later time points and completely recovering from the infection, while CD3ε$^{-/-}$ mice succumbed to the challenge. In order to define the mechanism of T cell-mediated protections, we adoptively transferred CD3ε$^{-/-}$ mice with *Candida*-specific TCR-transgenic T cells. *Candida*-specific CD4$^+$ *in vitro* polarized Th17 cells confer protection to VVC and using IL-17A$^{-/-}$ mice we highlighted that IL-17A, produced by T cells, is required for long-term containment of infection. On the contrary, Th2 cells have a detrimental effect on Th17 cells affecting their expansion, probably through IL-4 production since anti-IL-4 treatment restores Th17 ability to control infection. Our results suggest that CD4$^+$ T cells are required for long-term control of VVC and in particular only IL-17-producing Th17 cells confer protection against *C. albicans* infection.

P.D4.11.14

Androgens inhibit phagocytosis by macrophages via the androgen receptor

C. Parry, ***M. El Mohtadi****, K. Whitehead, J. Ashworth;*
School of Healthcare Science, Manchester, United Kingdom.

The cost to healthcare services for the treatment of chronic wounds in the elderly exceeds $9 billion per annum. Chronic wounds are frequently colonised by opportunistic nosocomial pathogens such as *Staphylococcus aureus*. Endogenous androgens are known to contribute to delayed healing whilst in contrast, estrogen accelerates healing. Healing in the elderly is impaired, particularly in elderly males due to the concomitant decline in estrogen levels yet largely unchanged levels of circulating androgens. This study investigated the effect of the two main endogenous androgens, testosterone (T) and dihydrotestosterone (DHT), on the clearance of methicillin-resistant *S. aureus* (MRSA) by macrophages derived from U937 monocytes. Concentrations of T and DHT were chosen to model adult physiological ranges of androgen levels (1x10^{-9}M, 1x10^{-8}M, 1x10^{-7}M) and supraphysiological levels following exogenous supplementation (1x10^{-6}M). The involvement of androgen receptor (AR) activation in bacterial clearance was confirmed using AR antagonists. Concentrations of T and DHT typical of adults or supraphysiological levels significantly ($P<0.05$; n=30) inhibited phagocytosis of MRSA in a concentration-dependent manner compared to untreated controls. Confocal and scanning electron microscopy confirmed androgens decrease the co-localisation of fluorescent GFP-*S. aureus* with macrophages and inhibit bacterial internalisation. AR antagonism reversed the effect of T and DHT, significantly ($P<0.05$) enhancing phagocytosis. These findings suggest androgens inhibit the resolution of wound bacteria. Novel dressings that induce local blockade of the AR may be an effective treatment option to promote the bacterial clearance of colonised wounds, particularly in elderly males.

P.D4.11.15

Effect of BCG and rBCGmIL-18 on central and effector memory T cells in C57BL/6 mice in the model of immunosuppression induced by cyclophosphamide

M. Kowalewicz-Kulbat*, K. Krawczyk, M. Wlodarczyk, M. Druszczynska, W. Rudnicka, M. Fol;*
Department of Immunology and Infectious Biology, Lodz, Poland.

Introduction Memory T cells can provide long-term immunity. Cyclophosphamide (CTX) is an immunosuppressive agent used in cancer therapy. Still little is known how CTX may act on the memory T-cell population and whether BCG bacilli can modify this process. **Aim** The aim of our study was to compare the response of central (T_{CM}) and effector memory T cells (T_{EM}) in immunized with *Mycobacterium bovis* BCG and recombinant BCG producing murine IL-18 (rBCGmIL-18) C57BL/6 mice (sensitive to mycobacterial infection), under immunosuppressive conditions. **Materials and methods** Mice were intradermally immunized with BCG or rBCGmIL-18 and after 6 and 12 weeks intraperitoneally treated with CTX (50μg/g b.w.) for 7 days. The splenocytes were isolated and stained with the monoclonal antibodies to determine the expansion of T_{CM} expressing CD62L$^+$CD44$^{+/-}$ CD127$^+$CD4$^+$ and T_{EM} with phenotype CD62L$^-$CD44$^+$CD127$^{+/-}$CD4$^+$. The percentage of the T_{CM} and T_{EM} was determined by flow cytometry. **Results** We observed a strong inhibition of CD4$^+$ T cell population in immunosuppressed mice immunized for 12 weeks with BCG and rBCGmIL-18 compared to mice immunized for 6 weeks. Interestingly, rBCGmIL-18 in immunosuppressed mice significantly increased the amount of CD4$^+$ CM compared to BCG in mice immunized for 12 weeks but not 6 weeks. This effect was not observed in CD4$^+$EM population in mice immunized with mycobacteria for 6 and 12 weeks. **Conclusion:** Our results indicate that under immunosuppressed conditions, rBCGmIL-18 displayed better ability than BCG to increase the percentage the CD4$^+$$T_{CM}$ without an effect on CD4$^+$$T_{EM}$ cells what may extend the knowledge in understanding the protective response of memory T cells in immunosuppressed conditions. Introduction: Influenza virus infection (IVI) outbreaks are associated to high morbidity and complications. Coinfection is a risk factor for mortality in IVI. Immune dysregulation secondary to IVI is known to play a role in Acute Respiratory Distress Syndrome (ARDS) and mortality, but its role in coinfection has not been sufficiently explored. This study aimed at characterizing the differential immune phenotype of patients admitted to the emergency department (ED) for IVI according to associated coinfection. **Methods:** A prospective, observational study was performed in adult patients admitted to our ED with IVI confirmed by PCR from nasopharyngeal swabs between January and March 2018. Patients with history of malignancies or immunosuppression were excluded. Flow cytometry from peripheral blood was performed to determine T cell, monocyte and granulocyte subsets and activation status at admission. **Results:** 26 patients with Influenza A pdm2009H1 (65%) or Influenza B (35%) (54.5 years old, IQR 39.3-62; 10 men) were included. 50% required ICU admission and 31% had pulmonary coinfection during hospital stay. 4 patients (15%) died, all of them with documented coinfection. At admission, lymphocytes (1.08 vs. 2.57 G/L; p=0.004), HLA-DR+ monocytes (22.28% vs. 61.94%; p=0.006 and 0.0023 vs. 0.1982 G/L; p=0.007), and activated monocytes (0.045 vs. 0.1892 G/L; p=0.009) were decreased in later coinfected patients; while immature granulocytes (26.52% vs. 4.06%; p=0.049), and M-MDSC (65.54% vs. 31.99%; p=0.016) were increased. **Conclusions:** Innate and adaptive immune dysregulation related to IVI leads to decreased mature, effective lymphocyte, monocyte and granulocytes counts. It seems to be a mechanism facilitating coinfection, and could serve as early predictor of such outcome.

P.D4.11.17

Deregulation of monocyte related cytokine/chemokine profile in serum milieu during Puumala virus infection

L. Cvetko Krajinovic[1], *P. Svoboda*[1], *A. Topić*[1], *P. Čikeš*[1], *M. Bosnar*[2], *V. Eraković Haber*[2], *A. Markotić*[1];
[1]*University Hospital for Infectious Diseases, Zagreb, Croatia,* [2]*Fidelta Ltd, Zagreb, Croatia.*

Changes in circulating cytokine and chemokine levels have been associated with many human diseases, and thus understanding the relationships between these changes and disease is an important. Hemorrhagic fever with renal syndrome (HFRS) is a viral disease caused by hantaviruses, however, it is primarily considered as an immune-mediated disease. Several studies have shown deregulated pro- and anti-inflammatory cytokine/chemokine production during the acute phase of hantavirus infection in patients' sera. Monocytes/macrophages are important producers of different cytokines/chemokines significantly contributing to the status of the serum milieu.
They are also considered as one of the target cells for hantaviruses. The aim of our study was to analyze kinetics of the monocytes/macrophages related cytokines/chemokines in HFRS patients' serum during the course of disease and correlate the serum profile with the severity of the clinical outcome of Puumala virus (PUUV)-induced disease. Serum samples were collected two times during the disease course. The mean levels of 16 cytokines and chemokines were determined by multiplex immunoassay with magnetic beads. When compared to the controls, some pro-inflammatory cytokines were unaltered (IL-1β, IL-12(p70), IL-23) due to infection, whereas levels of CCL5 and TGF-β1 were significantly lower in infected cases. Significantly elevated levels of IL-15, IL-1RA, IL-18, MIF, CCL2 and CCL4 were detected in PUUV-infected individuals. We found no significant differences in the levels of cytokines/chemokines between the group of patients with moderate symptoms compared to individuals with mild symptoms but cytokines like CCL5 and TGF-β1 showed strong positive correlations with some HFRS-associated pathological laboratory findings.

P.D4.11.18

Dengue virus infects epidermal human Langerhans cells for transmission to dermal dendritic cells

***L. C. Helgers**, J. K. Sprokholt, T. B. Geijtenbeek;*
AMC, Amsterdam, Netherlands.

Dengue virus (DENV) is an enveloped positive ssRNA *flavivirus* that infects 390 million people on an annual basis. During recent years, studies have focused on DENV infection of dendritic cells (DC), macrophages and monocytes. However, DENV is introduced into the human epidermis via mosquitos bites. Therefore, a specialized subset of epidermal DCs called Langerhans cells (LCs) might be a target for DENV. Hence, this study investigates the role of LCs in DENV infection using ex vivo skin model. Isolated migratory LCs (migLCs) or sheets of epidermal human skin (ex-vivo LCs) were exposed to DENV-2 for 48h to determine infection. To research DENV-2 transmission, DENV-2 infected migLCs or ex-vivo LCs were added to DCs for another 48h. Exposure of epidermal skin to DENV-2 ex vivo led to infection of LCs. Furthermore, isolated migLCs were also efficiently infected by DENV-2. Strikingly, both migLCs and ex-vivo LCs transmitted DENV-2 to DCs, leading to high infection of DCs. Interestingly, transmission was dependent on both active DENV-2 infection of LCs and cellular interaction between LCs and DCs. These results demonstrate that LCs are not only permissive for DENV-2 infection, but also play a role in the transmission of DENV-2 to DCs. Normally, LCs fulfill a protective role against invading viruses by degrading viruses such as HIV-1. In contrast, this study provides evidence for a LC-dependent transmission route for DENV-2 infection of DCs and potentially other professional phagocytes. Therefore, preventing infection of LCs might limit dissemination of the virus throughout the host.

Molecular imaging of retargeted UniCAR T cell therapy

*N. Berndt[1], S. Albert[2], C. Arndt[3], S. Koristka[3], A. Feldmann[3], M. Bachmann[3,4,2], **R. K. Bergmann**[3];*
[1]German Cancer Consortium (DKTK), partner site Dresden and German Cancer Research Center (DKFZ), Heidelberg, Germany, [2]University Cancer Center (UCC) Dresden, Tumor Immunology, 'Carl Gustav Carus' Technische Universität Dresden, Dresden, Germany, [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, [4]German Cancer Consortium (DKTK), partner site Dresden and German Cancer Research Center (DKFZ), Heidelberg, Dresden, Germany.

The switchable UniCAR platform avoiding "off target" side effects by consisting of two components: UniCAR-modified T cells and specific targeting modules (TMs). For personalized precise immunotherapy, molecular imaging regarding *in vivo* localization and kinetics of these components is mandatory. In this presentation, we demonstrate the optical (OI), MRI and PET imaging of this therapeutic concept in a preclinical setting using EGFR positive tumors in mice.UniCAR 28/ζ T cells were labeled with fluorescent nanoparticles and the cell line A431 was transfected with the firefly luciferase. For PET imaging studies both, mono- and bivalent α-EGFR TMs were conjugated with p-SCN-Bn-NODAGA and radiolabeled with ^{64}Cu .The bivalent α-EGFR TM showed an improved redirection of UniCAR T cells against EGFR$^+$carcinoma cells and was able to bind cell lines expressing high to low levels of EGFR. The killing of the tumor cells was visualized and quantified by luminescence imaging. In biodistribution studies both, mono- and bivalent α-EGFR TMs showed specific tumor accumulation after short times and tumor to muscle ratios of more than 12, however, at the next day the tumor to background ratio of the bivalent α-EGFR was higher. The T cells were transiently accumulated in the lungs before they were distributed in the body and also accumulated in lymph nodes. The study shows, that preclinical molecular imaging of all components of the retargeted UniCAR T cell therapy is possible and has the potential to be translated into the clinic.

Neutrophil migration via lymphatic vessels in *Aspergillus fumigatus*-induced inflammation

*M. Shevchenko[1], **A. Fedorina**[1], E. Bolkhovitina[1], A. Bogorodskiy[2], V. Borshchevskiy[2], A. Sapozhnikov[1];*
[1]Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation, [2]Moscow Institute of Physics and Technology, Dolgoprudny, Moscow region, Russian Federation.

Neutrophils migrate fast from bone marrow to the site of inflammation. Recent studies have demonstrated that neutrophils can also relocate from the site of inflammation toward lymph nodes via lymphatic vessels. Here we investigate the process of neutrophil migration during *A. fumigatus* infection.
For the research we used three-dimensional visualization of whole-mount conducting airways of mice at different time points after *A. fumigatus* inhalation. Tissue samples were stained against Ly6G, Lyve-1 and CD31. Simultaneous visualization of neutrophils, lymphatic vessels and blood vessels was achieved by spectral unmixing.
The optimal sets of primary and secondary antibodies were chosen and simultaneous staining of neutrophils with rat anti-Ly6G, blood vessels with goat anti-CD31 and lymphatic vessels with rabbit anti-Lyve-1 in combination with secondary donkey anti-rat-Alexa488, donkey anti-goat-Alexa555 and donkey anti-rabbit-Alexa647 was performed. We visualized neutrophils that were associated with blood vessels in 6 hours after *A. fumigatus* conidia application. Examination of mouse bronchus in 72 hours after conidia inhalation revealed neutrophil association with lymphatic vessels.
Thus, neutrophils were detected in lymphatic vessels at the late stage of *A. fumigatus* conidia application-induced immune response. The observation confirms the ability of neutrophils to migrate from the site of inflammation via lymphatic vessels.
The study was supported by RFBR № 18-315-00166

P.E1.01.03

Time course of different apoptotic stages during target cell killing

***K. S. Friedmann**, A. Knörck, S. Zöphel, S. Renno, C. Hoxha, M. Hoth, E. C. Schwarz, C. Kummerow;*
Biophysics, CIPMM, Homburg, Germany.

Introduction: CD8$^+$ T- and NK cells are key players for elimination of cancer cells. Killing of such target cells can be induced by two pathways: either perforin-dependent via lytic granules or receptor mediated via Fas-FasL-interaction. Both pathways can lead to apoptosis, whereas only perforin can induce direct target cell lysis (necrosis). The apoptotic pathway involves the activation of caspases leading to cytoskeletal breakdown, DNA fragmentation and loss of membrane integrity. Nevertheless the kinetic progression of the different apoptotic stages during target cell killing by immune effector cells is not well understood.
Methods: We investigated apoptosis induction by primary NK cells and melanoma-specific CD8$^+$ T-cell clones in K562 and Jurkat T-cells or T2 and melanoma cells respectively. We analyzed caspase activation and membrane disruption using amongst others the FRET-based cell death sensor Casper3-GR and the phosphatidylserine sensor AnnexinV. Experiments were performed using flow cytometry and fluorescent live cell imaging.
Results: We describe different apoptotic stages induced by either chemical substances or lymphocyte-mediated killing. As expected, detection of caspase activation is an early apoptotic event. AnnexinV, commonly used as apoptosis marker, on the other hand provides signals which appear in rather late stages of targeted cell death.
Conclusion: The detection of caspase activity during target cell killing to analyze apoptosis is an earlier marker compared to AnnexinV. Moreover the cell death sensor Casper3-GR enables a specific analysis of cytotoxic mechanisms by providing information about target cell morphology and a precise discrimination of apoptotic and necrotic killing on single cell level.

P.E1.01.04

Cryoglobulin clearance after direct acting antiviral -DAA- therapy in hepatitis C virus HCV-monoinfected and HIV-HCV coinfected patients

***M. N. Kolopp Sarda**[1,2], K. Hartig-Lavie3, P. Miailhes4, A. Uhrès5, V. Virlogieux3, P. Pradat3, F. Zoulim3;*
[1]CH Lyon Sud Lab Immunology, LYON - Pierre Bénite, France, [2]EA 4130 Immunogenomic and Inflammation, Lyon Claude Bernard University, France, [3]Hepatology Dpt, Croix-Rousse Hospital, LYON, France, [4]Infectious Diseases Dpt, Croix-Rousse Hospital, LYON, France, [5]Pharmacology Dpt, Croix-Rousse Hospital, LYON - Pierre Bénite, France.

Background: Mixed cryoglobulins (MC) are found in 40-60% of patients with chronic HCV infection. The objective of this study was to evaluate the efficacy of DAA therapy on cryoglobulin clearance in patients with HCV-associated MC. Methods: HCV mono-infected and HIV-HCV co-infected patients with symptomatic or nonsymptomatic MC, who received DAA treatment, were included from 2013 to 2016. Cryoglobulins were characterized and quantified in Immunology laboratory. Results: 41 patients were analyzed: 31 HCV mono-infected patients and 10 HIV-HCV co-infected patients. MC was symptomatic in 77.4% of HCV mono-infected patients and in 10% of HIV-HCV co-infected patients. Two patients had Waldenström macroglobulinemia (WM) and 2 rheumatoid arthritis (RA). The most frequent symptoms were arthralgia, asthenia and polyneuropathy. DAA therapy was used with Ribavirin in 10 patients and all other patients received an IFN-free and Ribavirin-free DAA regimen. Median level of cryoglobulin fell from 51.8 mg/L at baseline to 6.5 mg/L at the end of DAA treatment.
Cryoglobulin clearance was obtained in 66% (n=27) of our cohort: 90% in HIV positive and 58% in HCV mono-infected patients. A partial response with a decrease of cryoglobulin level >50% without negativation was reached in 15% of patients. Cryoglobulin was persistent in patients with WM and RA. Baseline cryoglobulin level was not associated with cryoglobulin clearance at the end of treatment. Similarly, the presence of symptomatic MC, fibrosis stage and HCV genotype were not associated with cryoglobulin clearance.
Conclusions: DAA therapy allows a high rate of cryoglobulin clearance both in HCV monoinfected and HIV-HCV coinfected patients.

Natural killer (NK) cells are specialized lymphocytes with innate ability to eliminate virally infected and cancerous cells, but the mechanisms that control NK cell development and cytotoxicity are incompletely understood. We have identified novel roles for sclerostin domain containing-1 (Sostdc1) in NK cell development and function. Sostdc1-knockout (KO) mice display a progressive accumulation of transitional NK cells (CD27+CD11b+, tNK) with age, indicating a partial developmental block. We simulated developmental rates with a deterministic compartmental model under the assumption that proliferation and death rates stay consistent. Our model elucidates a requirement for Sostdc1 in NK cell development. Furthermore, we identified that Sostdc1-KO splenic tNKs express lower frequencies (%) of inhibitory Ly49G2, but higher % of activating Ly49H+ and D+ cells. However, the % of Ly49I+, G2+, H+ and D+ populations were universally decreased at the mature (CD27- CD11b+, mNK) stage. We hypothesized that the Ly49 repertoire and developmental block in Sostdc1-KO mice would correlate with NK killing ability. We observed that KO NK cells are hyporesponsive against MHC-I-deficient cell targets in vitro and in vivo, despite higher CD107a surface levels and similar IFN-gamma expression to controls. We plan to use high-dimensional flow cytometry analysis to identify specific NK cell clusters of highly active subsets based on Ly49 and activating receptor expression. Taken together, these data support a role for Sostdc1 in the regulation of NK cell development and could provide insights into novel biological parameters to increase active NK cell numbers with high killing efficiency for immunotherapies.

P.E1.01.07

Direct measurements of tumor antigen cross-presentation by dendritic cells

E. M. Muntjewerff, *F. Bianchi, G. van den Bogaart;*
Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands.

Introduction: Antigen cross-presentation is essential for the initiation of an adaptive immune response against cancer and numerous pathogens. During this process, dendritic cells (DCs) present peptides derived from ingested antigens of affected tissues in their major histocompatibility complex class I (MHC-I) to cytotoxic CD8+T cells. As a result, cognate CD8+T cells become activated, enabling them to eliminate affected cells in the human body. Aim of this study is to develop a quantitative method to measure cross-presentation of NY-ESO1, a tumour-specific antigen expressed by several cancer types.
Materials and Methods: HLA-A2+ DCs were activated and loaded with a NY-ESO1-based antigen consisting of a HLA-A2-binding epitope extended at its N- and C-termini. To measure cross-priming, these DCs were co-cultured with primary autologous CD8+T cells. These T cells were transfected with mRNA coding for a T cell receptor specific for the NY-ESO1 epitope. After incubation, the activation of the cytotoxic T cells was followed using ELISA for interferon γ and flow cytometry for T cell activation and proliferation markers. In addition, we also followed the dynamics of bio-orthogonally tagged NY-ESO1 peptides carrying a solvent-exposed propargylglycine, enabling for direct visualization of antigen cross-presentation independent of co-stimulatory signals.
Results & conclusion: This novel method allows to measure presentation of tumour antigens on MHC-I in dendritic cells. Since cross-presentation is crucial for elimination of virus-infected and malignant cells by the immune system, this knowledge could contribute to improvement of DC-based immune therapies.

The epigenetic regulation of host factors associated with in-vivo control of HIV has been little explored. To start addressing some of the gaps in our knowledge in this regard we assessed host genome methylation signatures in the peripheral blood mononuclear cells (PBMC) of untreated chronically HIV-infected subjects with high (>50000 HIVcopies/ml, n=29) or low HIV (<10000 HIVcopies/ml, n=42) plasma viral loads (VL). Differential methylated CpG sites between the two groups were determined using regression models, adjusting for methylation confounders (age, sex, PBMC cell type composition). Clustering and gene enrichment analysis were applied to identify signatures of antiviral genes putatively epigenetically regulated and which were positively (e.g.CXCR5) or negatively (e.g.MX1) correlated with viral load (Rho>0.6) and proviral reservoir (Rho>0.5) in total PBMC. Based on methylation profiles, the gene expression levels of lead candidates, including MX1, a strong antagonist of DNA- and RNA-virus replication, were determined by real-time PCR. MX1 was significantly higher expressed in individuals with elevated HIV viral load compared to low-viral load subjects. Additionally, MX1 gene expression and promoter methylation levels were inversely correlated (Rho=-0.55), further supporting a tight epigenetic regulation of the expression of this gene. Additional MX1 gene expression analyses in unrelated cohorts of individuals with chronic uncontrolled HIV infection (n=11) and HIV elite controllers (VL<50 HIVcopies/ml, n=12) validated these results. The data thus identify several epigenetically dysregulated antiviral factors, MX1 in particular, that may be employed in future immune interventions aiming at the cure of HIV infection.

P.E1.01.09

Natural Killer cells switch from Granzyme B to death receptor-mediated cytotoxicity during serial killing of tumor cells

I. Prager[1], *C. Liesche*[2], *H. van Ooijen*[3], *D. Urlaub*[1], *M. Claus*[1], *B. Önfelt*[3,4], *J. Beaudouin*[2], *C. Watzl*[1];
[1]*Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany,* [2]*Division of Theoretical Bioinformatics, German Cancer Research Center, Heidelberg, Germany,* [3]*Department of Applied Physics, Science for Life Lab, KTH – Royal Institute of Technology, Stockholm, Sweden,* [4]*Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden.*

Natural Killer (NK) cell cytotoxicity is mediated via the release of cytotoxic granules or by engaging death receptors that initiate caspase cascades. While the mechanisms of the two pathways are well understood, the orchestrated interplay between both has remained poorly defined. To visualize the granzyme B (GrzB) and Caspase-8 mediated target cell death in a time-dependent manner, we used fluorescent localization reporters that enabled us to simultaneously measure the activities of both pathways upon contact with NK cells by life cell imaging.We observed rapid target cell death which was induced by GrzB and which originated from early established NK : target contacts. In contrast, cell death mediated by Caspase-8 was a result of later target cell engagements and took much longer from contact to target cell death. We determined the amount of intracellular GrzB, perforin and of surface-FasL in NK cells that were exposed to target cells over time.
We observed a clear reduction of GrzB and perforin and an increase of surface-FasL in NK cells over time. This suggested a kinetic regulation of the two cytotoxic pathways during serial killing. By directly imaging individual NK cells during serial killing we could indeed show that NK cells switch from mediating a fast GrzB-mediated cell death in their first killing events to a more delayed death receptor-mediated cell death during subsequent tumor cell encounters. This demonstrates that the use of GrzB vs. death receptor-mediated target cell killing is differentially regulated during the serial killing activity of NK cells.

P.E1.01.10

Expression of equine interleukin (IL)-2, IL-4, IL-10, IL-18 and IFN-γ in Baculovirus expression system

S. Saini[1,2], *H. Singha*[1], *P. Siwach*[2], *B. N. Tripathi*[1];
[1]*National Research Centre on Equines, Hisar, India,* [2]*Chaudhary Devi Lal University, Department of Biotechnology, Sirsa, India.*

Recombinant cytokines are considered as valuable tools for functional studies and candidates for vaccine additives or therapeutic use in various diseases. In the present report, horse IL-2, IL-4, IL-10, IL-18 and IFN-γ were produced in insect cells using baculovirus expression system. The coding sequences of equine cytokines were cloned in gateway entry vector (pENTR™/TEV/D-TOPO vector). Subsequently, recombinant cytokines were mobilized from entry vector to baculoviral destination vector DNA (Baculodirect ™ linear DNA). Further, *Spodoptera frugiperda* (SF9) cells were transfected by baculovirus/respective cytokine ligation mix and incubated at 27^0C. Multiplicity of infection (MOI) ranging from 1-10 PFU and optimum expression time was standardized for each cytokine. After 72 h post-infection, reduced cell growth, enlargement of cell nuclei, polyhedron formation and partially detached cells were observed. Expression of recombinant horse cytokines in SF9 cells was confirmed by SDS-PAGE and western blotting. Recombinant baculovirus DNA was confirmed by PCR and sequencing cytokine insert. Recombinant horse cytokines were purified from cell pellet by using Nickel-NTA affinity chromatography. SDS-PAGE analysis displayed the molecular weight of IL-2, IL-4, IL-10, IL-18 and IFN-γ at 22, 18, 24, 23 and 24 kilo dalton (kDa), respectively. These recombinant horse cytokines will provide basic research tool for understanding their role in protective immune response, disease pathogenesis, and use as a therapeutic agent or vaccine adjuvant in horses.

P.E1.01.11

Full automated load-and-go flow cytometry in neutrophil analysis: the start of a new era

***R. Spijkerman**, L. Hesselink, P. Hellebrekers, F. Hietbrink, L. Leenen, L. Koenderman;*
UMC Utrecht, Utrecht, Netherlands.

Introduction Changes in functional phenotypes of neutrophils is an adequate measurement of the amplitude of the innate immune response. A combination of these changes can be applied to predict infectious complications. Due to technical and logistical difficulties this concept is currently not clinically applicable. A fully automated 24/7 load and go flow cytometer would provide the opportunity to design such an analysis. Therefore, the aim of this study was to investigate the applicability of 24/7 automated analysis of neutrophils by flowcytometry. **Methods** For proof of principle blood was drawn from healthy controls next to the flow-cytometer. Neutrophil activation was measured by the use of the automated AQUIOS load-and-go flowcytometer. The AQUIOS is able to pierce the tube caps, add antibodies, lyse and measure the sample within 20 minutes immediately after vena puncture. Thereafter, the *same* blood tubes were measured every 15 minutes. Measurements were done in presence or absence of the bacterial stimulus fMLF. **Results** A significant increase in MFI was detected in the activation markers CD35(174%(146%-213%),**P=0.004**), CD11b(245%(167%-524%),**P=0.009**) and CD11c(220%(153%-389%),**P=0.008**) within the first hour after vena puncture. After 3 hours an even higher increase in all activation markers was detected (CD35(222%);CD11b(378%);CD11c(316%)). Neutrophil responsiveness to fMLF was most evident at T=0 and gradually decreased over time. **Conclusion** Neutrophil activation significantly increased in the tube shortly after vena puncture particularly during the first hour. For a reproducible clinical test on neutrophil functionality it is mandatory to measure neutrophil receptor markers immediately after vena puncture in a point-of-care context.

P.E1.01.12

Identification of germline heavy chain targeted to envelope protein in acute phases of DENV2 secondary infected patients.

***N. Thammasonthijarern**;*
Tropical Medicine, Bangkok, Thailand.

Identification of germline heavy chain targeted to envelope protein in acute phases of DENV2 secondary infected patients.

N. Thammasonticharoen[1], W. Poungmanee[1], S. Benjathummarak[1], P. Ramasoota[1], P. Pitaksajjakul[1]
[1] Department of Social and Environmental Medicine, Faculty of Tropical Medicine, Mahidol University, Thailand.

Dengue is one of the most important mosquito-borne viral diseases in humans, and lacking of vaccines and therapeutics contributes to disease burden. Dengue viral infection can cause a spectrum of clinical symptoms ranges. The understanding of human immunity creating antibody response that showed protection against infectious agent can be applied for vaccine design strategy.

Antibody heavy chain genes generated at acute phase of secondary DENV-2 infected patients were studied from both human monoclonal antibodies (HuMAbs) targeted to enveloped (E) proteins by clonal sequencing, and sample of B cell repertoires by next-generation sequencing. In addition, antibody neutralizing activity was tested by foci reduction neutralization test (FRNT). Germline sequencing were analyzed either by IMGT/V-Quest or IMGT/HighV-Quest online program.

Two major germline genes derived from 25 cross-neutralizing HuMAbs were IGHV1-69 and IGHV3-23. Accordingly, IGHV1-69 is also the majority (32%) of antibody heavy chain genes derived from PBMC of acute phase dengue type 2 infected patient. It was implied that IGHV1-69 type of heavy chain was rapidly generated after DENV-2 infection at the acute phase and showed cross-neutralizing activity to 4 serotype and showed cross-protection in dengue patients. The result obtained from this study will be understanding for human antibody response correlated with further dengue vaccine design.

Identification of small molecule compounds modulating the formation of neutrophil extracellular traps (NETs)

*P. Habenberger[1], **P. Wentker**[1], R. Di Lucrezia[1], G. Sollberger[2], M. Bickle[3], J. Eickhoff[3], A. Zychlinsky[2], P. Nussbaumer[1], A. Choidas[1], B. M. Klebl[1];*
[1]Lead Discovery Center GmbH, Dortmund, Germany, [2]Max Planck Institute for Infection Biology, Berlin, Germany, [3]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany.

Formation of neutrophil extracellular traps (NETs) is a non-reversible process of subsequently appearing, distinct cellular morphological features, which includes the loss of the characteristic lobulated nucleus. Breakdown of the nuclear and cellular membranes finally leads to release of several granule proteins and DNA / chromatin forming the extracellular NET fibres. Normally functioning as defence mechanism against extracellular pathogens, NET formation was also shown to be involved in the pathogenesis of several infectious diseases, sepsis, chronic lung disease, thrombosis and autoimmune disorders (e.g. systemic lupus erythematodes). Aiming at potential therapeutic applications, we performed a high throughput screen on the basis of those neutrophilic morphological changes to identify small molecular weight inhibitors of NET formation.

Primary human neutrophils from healthy donors were stimulated with phorbol 12-myristate 13-acetate (PMA) and treated with ~180.000 compounds. After staining the DNA for fluorescence microscopy, high content analysis was used to determine the NET-related morphological changes. This phenotypic screen identified hits in several compound classes. The assay quality parameters within the screening campaign were good, especially for an assay using human primary cells. Upon hit verification, the results were clustered chemically and biologically into different groups. In parallel to hit optimization, selected compounds have been further characterized to unravel their mode of action.

In summary, we identified compounds modulating the formation of NETs by a high content screen based on phenotypic morphological changes in human primary neutrophils. Our results serve as basis of further investigation of immunomodulatory drugs and promote an innovative drug discovery program.

ACUTE AND CHRONIC INFLAMMATION AND MAST CELL ACTIVATION, IN SILICO

***A. Abdukerim**;*
VU University Amsterdam, Amsterdam, Netherlands.

Objective: An iterative process of model building is able to provide new understanding about the mechanisms of inflammation. We designed a computer model able to provide a rational explanation of the network's response to antigen in terms of acute or chronic inflammation. The model should calculate *in silico* the level of tumor necrosis factor alpha (TNF-α). It should likewise predict the effect of an *in silico* drug targeting the immunoglobulin light chain (FLC) that activates mast cells, on the outcome of an inflammation. **Modelling:** For each species in the network, a balance equation was then formulated, specifying its time dependence as the differences between the rates of the reactions synthesizing the commodity and the rates of the processes degrading it. The corresponding rate equations were integrated in time or for steady state by using the COPASI simulation software. Immunostaining on cancer biopsies, protein detection, and *in vitro* and *in vivo* studies were used for validation. **Results:** The model enabled us to 1) examine the capability of immune system to kill invading microorganisms, 2) explain the dichotomy between acute and chronic inflammation, and 3) test effect of an in silico peptidic drug that inhibits FLC. The model reproduced experimental findings and was subjected to tests for dynamic stability and to sensitivity analysis. **Conclusions:** A systems mechanism for the effects of therapeutic peptides against cancer-associated inflammation was identified and made computable in terms of personalized molecular properties. This should facilitate further testing as well as provide a platform for personalized immunology.

Tetracysteine tagged $OVA_{(323-339)}$peptide as a novel tool for visualizing peptide-MHCII complexes in primary mouse cells

***B. Akkaya**, J. Al Souz, R. Kamdar, O. Kamenyeva, E. M. Shevach, M. Akkaya;*
NIH, Bethesda, United States.

Current reagents such as peptide specific MHCII antibodies do not allow to probe peptide-MHCII dynamics during live interactions in vivo as they also block T cell- APC interactions. To address this, we aimed to design fluorescent antigenic peptides. Typically, flurorescent protein tags such as green fluorescent protein (GFP) consist of more than 200 amino acids thus have the potential of disrupting the conformation and functionality of the antigenic peptides. Therefore, we constructed an $OVA_{(323-339)}$ peptide containing a pro-fluorescent tetracysteine tag (CCPGCC) at the C-terminus with aminocaproic acid linker (OVA_{CACA}). First, we tested whether the addition of tag had an impact on T cell stimulation and found that OVA_{CACA} pulsed APCs could activate OTII cells to same degree as $OVA_{(323-339)}$. Secondly, we treated the APCs with an organoarsenic compound to switch on the fluorescence and measured the signal by flow cytometry. We showed that the fluorescent signal specifically comes from OVA_{CACA}-MHCII as neither $MHCII^{-/-}$ APCs that were pulsed with OVA_{CACA} nor $MHCII^{+/+}$ APCs that present $OVA_{(323-339)}$ produced same fluorescence. We also tracked the fluorescence in OTII- DC culture in vitro and detected that it got concentrated at the synapse over time. Altogether our findings suggest that tetracysteine tagged peptides can be used for tracking the peptide-MHCII complexes during visualizing the interactions of primary mouse T cells and APCs and they have the potential to be an alternative to MHCII tetramers to detect antigen specific T cells.

P.E1.02.03

Infiltrating T cells establish immunological synapses forming cSMAC preferentially with MHCII antigen presenting cells in human GBM.

***C. Barcia**, L. R. Diaz, E. Saavedra-Lopez, G. P. Cribaro, P. Casanova, L. Romarate;*
Institut de Neurociències, Bellaterra, Cerdanyola del Vallès, Spain.

Glioblastoma multiforme (GBM) is the highest and most aggressive grade of glioma, the most common primary brain tumor. Currently it remains incurable, as there are no effective treatments; however, the presence of an inflammatory environment characterized by immune cell infiltration and microglial activation, has suggested that its manipulation could represent a potential therapeutic strategy. In this study, immunological engagements between infiltrating T cells with tumor cells and microglia/macrophages were analyzed in detail. Our results show that 70% of T cells establish physical appositions with either tumor cells or MHCII+ cells, and that 55% of contacting T cells form features of immunological synapses, being much more likely to do so with MHCII+ cells, since the number of TCR rich central supramolecular activation clusters (cSMACs) formed with these cells doubled the cSMACs formed with tumor cells. Importantly, we demonstrate that antigen presentation mediated by MHCII takes place in the tumor parenchyma and not only in the lymph nodes, suggesting that the brain tumor could be acting as a tertiary antigen presenting tissue to downregulate the cytolytic immune response. Furthermore, we believe that the IS formation between T cells and MHCII cells may be an strategy of the tumor to escape the immune response (i.e activating antigen-specific Tregs), so the inhibition of these engagements could represent a new immune checkpoint to block for potential immunotherapy in GBM.

Real-time migratory pattern monitoring of neutrophil and macrophage toward skin melanoma microenvironment using two-photon intravital microscopy

***Y. Choe**, S. Jeong, Y. Kim, Y. Hyun;*
Department of Anatomy and Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of.

<META NAME="author" CONTENT="최영호(해부학교실)">
Recent studies revealed that recruitment of myeloid cells toward tumor microenvironment can accelerate tumor progression during tumor development. However, the initial response of neutrophils and macrophages interacting with tumor cells in early phase has not been clearly visualized.
Hereby, we investigated the crosstalk between metastatic skin melanoma and innate immune cells including neutrophils and macrophages. To directly visualize migratory pattern of neutrophils and macrophages toward melanoma microenvironment, we set up dorsal skin window chamber for two-photon intravital microscopy. In order to investigate dynamic behavior, CMFDA (green) or CMTPX (red) fluorescent probe-labeled murine melanoma cells, B16F10, were subcutaneously injected. To visualize neutrophils and macrophages, we used LysM-GFP and CX3Cr-1 GFP mice, respectively, as well as fluorescent Abs.
In this study, we will visualize each step of neutrophil infiltration toward melanoma cells at the early stage of subcutaneous injection of B16F10, and also demonstrate how to control the adhesion molecule developmental endothelial locus-1 (Del-1) affects the migration pattern of neutrophils. We hypothesized that Del-1 deficiency may be involved in the intravascular and transendothelial migration of neutrophils in the presence of B16F10 melanoma cells. However, it was supposed that absence of Del-1 may not affect the interstitial migration of neutrophil to the tumor site. In this study, we will show the effect of Del-1 in neutrophil migratory cascade toward to melanoma microenvironment in crosstalk with resident macrophages in the early phase of innate immune response.

P.E1.02.05

A comparative analysis of targeted transcriptomic techniques and immunohistochemistry for immuno-oncology biomarker profiling in humanized mice

***M. Houtkamp**, N. Pencheva, F. de Bree, P. Franken, S. Verploegen, D. Schuurhuis, J. Lammerts van Bueren;*
Genmab BV, Utrecht, Netherlands.

Traditional transcriptomic profiling techniques, such as RNA sequencing and microarrays, require relatively large sample input and their application on formalin-fixated paraffin-embedded (FFPE) samples is often hindered by RNA degradation. NanoString and HTG EdgeSeq are novel technologies that measure messenger RNA (mRNA) levels in a targeted fashion and can be applied to low amounts of FFPE samples for biomarker discovery. The ability of these targeted transcriptomic approaches to capture immune-related changes, as validated by immunohistochemistry (IHC), was assessed in human hematopoietic stem cell-reconstituted mice containing subcutaneous human tumors treated with a T-cell activating agent versus control. In addition, the NanoString PanCancer Immune Profiling Panel and the HTG immuno-oncology (IO) assay were compared for their concordance. Strong concordance (r=0.8, Pearson) between the NanoString and HTG techniques of mRNA measurements were observed. Both techniques identified a largely overlapping set of transcripts modulated upon treatment with T-cell activating agent. Importantly, both NanoString and HTG EdgeSeq mRNA measurements were further corroborated by quantitative IHC protein measurements for a selected panel of IO biomarkers modulated by T-cell activating treatment. In conclusion, both NanoString and HTG EdgeSeq are suitable technologies for transcriptomic assessment of IO biomarkers in FFPE samples. T-cell activating agent-induced transcriptomic changes, as assessed by either technology, are representative of immune alterations found by IHC - the current gold standard in the IO field.

Identification of apoptotic cells and cells carrying extracellular vesicles during LCMV infection using imaging flow cytometry

***J. Kranich**[1], N. Chlis[2], A. Latha[1], L. Rausch[1], F. Theis[2], T. Brocker[1];*
[1]Institute for Immunology, 82152 Planegg-Martinsried, Germany, [2]Helmholtz Zentrum München, 85764 Neuherberg, Germany.

Exposure of the phospholipid phosphatidylserine (PS) on the outer surface of the cell membrane is common to both, apoptotic cells and extracellular vesicles (EVs). Administration of a fluorescent version of the PS-binding protein Mfge8 (Mfge8-eGFP) *in vivo* in combination with imaging flow cytometry, allowed us to reliably detect and separate dying cells from live EV-decorated cells *ex vivo*. To discriminate both classes of Mfge8-eGFP$^+$ cells we developed a deep learning algorithm. Using this novel approach, we found only very low frequencies of dying cells in absence of infection, but EV-decoration was readily detected mainly on B cells. Upon LCMV-infection, however, we found a significant increase in cell death mainly among CD8$^+$ T_{CM} (CD44$^+$CD62L$^+$) cells as well as follicular and marginal zone B cells. In addition, the frequency of EV-decorated CD8$^+$cells increased approx. 4-fold. Here, EV-binding was found to be mostly confined on CD8$^+$ T_{CM} and T_E (CD44$^+$CD62L$^-$), but almost absent on T_N (CD44$^-$CD62L$^+$). Our data visualize and quantify the propensity of activated CD8$^+$T cells to bind EVs, opening new avenues for investigation of potential functional consequences. Our data demonstrate that Mfge8-eGFP is a valuable tool for simultaneous identification of dying and EV-decorated cells *in situ*.

P.E1.02.07

Quantifying murine myocardial infarction and immune cell infiltration via light sheet fluorescence microscopy

***S. F. Merz**[1], S. Korste[2], L. Bornemann[1], P. Stock[2], U. Hendgen-Cotta[2], T. Rassaf[2], M. Gunzer[1], M. Totzeck[2];*
[1]Institute for experimental Immunology and Imaging, University Duisburg-Essen, Essen, Germany, [2]West German Heart & Vascular Center, Department of Cardiology & Vascular Medicine, University Hospital Essen, Essen, Germany.

Myocardial infarction (MI) is one of the most lethal diseases in western industrialized countries. To investigate the underlying mechanisms and to determine effects of novel therapeutic approaches an accurate quantification of infarct sizes in experimental models is imperative. Current protocols utilize life imaging (MRT, echocardiography) or slice-based histological methods, which suffer from poor resolution or limited representation of the entire heart, respectively.
Here, we present a novel light sheet fluorescence microscopy (LSFM) approach for the precise quantification of relevant infarction model parameters including MI-size, area at risk (AAR) and heart volume in adult mice. Benefitting from ethyl cinnamate (ECi) clearing, it allows simultaneous visualization of immune cell infiltrates in the whole heart at cellular resolution via *in vivo* labeling of target structures utilizing i.v. injected conjugated antibodies and fluorochrome compatible bleaching.
Verifying its usefulness, we correlated our LSFM method with traditional TTC staining in an ischemia/reperfusion-injury mouse model. Here, TTC negative areas matched with capillary damage revealed by anti-CD31 labeling of the endothelium in the same heart slices. Furthermore, we visualized macrophages and neutrophils via antibodies against F4/80 and Ly-6G, respectively. Neutrophils (24h reperfusion) were located in the vicinity, while macrophages (5d reperfusion) were localized within the infarction volume.
Taken together, LSFM-based 3D quantification of infarction size represents a novel and precise tool to measure MI and to obtain crucial information about immune cell infiltration at the same time. This powerful approach enables multiplexing of various markers of interest to investigate myocardial damage, infiltrating immune cells and their behavior.

P.E1.02.08

High throughput sequencing of TCR repertoire after yellow fever revaccination

***A. A. Minervina**, M. V. Pogorelyy, E. A. Komech, I. Z. Mamedov, Y. B. Lebedev;*
Shemyakin–Ovchinnikov Institute of bioorganic chemistry, Moscow, Russian Federation.

Introduction: Yellow fever vaccination is a well established model of acute viral infection in human. Primary immunization elicits strong T-cell response and the formation of long-lived memory. However, little data exists on the activation of this memory and individual T-cell clones dynamics after revaccination. We applied deep TCR-profiling to quantitatively track T-cell clones after yellow fever vaccination and revaccination.
Methods: We isolated PBMCs from two donors -- one received primary vaccination, other revaccinated 30 years after -- on 5 timepoints: 0, 5, 10, 15, 45 days after YFV17D immunization. CD4+, CD8+, memory and MHC-dextramer positive subpopulations were collected on several timepoints. TCR repertoires were sequenced on Illumina platform, expanded TCR clonotypes were identified using edgeR package.

Results: We identified 1374 expanded clonotypes in first-time vaccinee and 125 in revaccinated donor. YFV17D-specificity was confirmed by TCR repertoire sequencing of MHC-dextramer positive subpopulation. In first-time vaccinee fraction of responded clones sharply peaked (6%) at day 15 after immunization. However, in revaccinated donor fraction of responded clones reached 0.3% by day 5 and slightly increased on days 10 and 15. Analysis of individual clones dynamics showed presence of two distinct groups of clones in revaccinated donor: peaking on day 5 and on day 15.
Conclusions: Second vaccination with YFV17D-vaccine, even 30 years after first, elicits T-cell response. This response differs from response to primary immunization both by intensity and dynamics. We detected early expansion of memory T-cells in response to revaccination and delayed response of putatively naive T-cells. Supported by RSF-15-15-00178 .

P.E1.02.09
Visualizing tumor cell-lymphocyte interactions in the brain using *in vivo* two photon microscopy

***M. Piechutta**, M. A. Karreman, A. S. Berghoff, K. Gunkel, W. Wick, F. Winkler;*
Neurology Clinic and National Center for Tumor Diseases, University Hospital Heidelberg; Clinical Cooperation Unit Neurooncology, German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, Germany.

Current knowledge on the immunological tumor microenvironment is gained from *in vitro*- and *ex vivo* experiments, such as flow cytometry and immunohistochemistry. However, these models fail to recapitulate the dynamic influx of lymphocytes and their interaction with tumor cells in the complex tumor microenvironment. Particularly in brain cancer, which develops in an "immune-privileged organ", a better understanding of lymphocyte recruitment, trafficking and activation *in vivo* is urgently needed to improve immunotherapeutic approaches. To characterize the adaptive immune response in brain tumors on a single cell level, we developed a unique model allowing us to monitor these processes *in vivo* over weeks using repetitive two photon intravital microscopy. Hereto, mice with a chronic cranial window were introduced with fluorescent syngeneic melanoma cells via heart injection or stereotactic injection into the cortex. Next, these mice received adoptive cell transfer of tumor-specific, fluorescently labeled T cells. We observed tumor-specific T cells crossed the brain blood barrier within a couple of hours. Notably, transferred T cells were found in the tumor margin and inside the tumor but not in healthy brain parenchyma. Furthermore, we could track lymphocytes at the site of the tumor for several days to explore their interactions with tumor cells.
Taken together, we established a novel preclinical model to study dynamic lymphocyte- tumor cell interaction *in vivo* at high resolution. This approach provides unique insights into the underlying mechanisms driving the immuno-response. Importantly, it enables to further investigate and improve immunotherapeutic approaches with respect to prevention and therapy of brain metastases.

P.E1.02.10
Alteration of TCR repertoire after tick-borne encephalitis infection in murine model

***M. A. Salnikova**[1,2], A. A. Minervina[1], M. V. Pogorelyy[1], K. K. Tuchinskaya[3], G. G. Karganova[3], Y. B. Lebedev[1], I. Z. Mamedov[1];*
[1]Shemyakin-Ovchinnikov Institute of Bioorganic chemistry, Moscow, Russian Federation, [2]Moscow State University, Moscow, Russian Federation, [3]Chumakov Institute of Poliomyelitis and Viral Encephalitides, Moscow, Russian Federation.

Introduction: Adaptive immune system is a very sophisticated mechanism, which is able to recognize great diversity of antigens. T cells play key role in adaptive immune response to tick-borne encephalitis virus. Deep TCR repertoire profiling can be performed via high-throughput sequencing. Murine models to study alterations in TCR repertoires during immune response are lacking. Here we present the method for longitudinal TCR repertoire reconstruction which identifies TCR clonotypes expanded in response to acute infection.
Materials and Methods: Peripheral murine blood was collected in two biological replicates before and after the infection with tick-borne encephalitis virus. TCRbeta cDNA libraries were prepared using custom protocol. Libraries were sequenced on Illumina platform. TCR repertoires were extracted from data using MIGEC and MiXCR software.
Results: We show good reproducibility of individual clones concentrations between biological replicates. edgeR package was used to identify significantly expanded or contracted after infection. We found 38 clones expanded and 1 contracted in response to viral infection. Most expanded clonotypes were not detected before infection, but were very abundant after, accounting for 6% of repertoire with 13 responding clones in top 20 clonotypes after the infection. Identified expanded clonotypes show considerable V-usage bias and little overlap with published tick-borne encephalitis virus specific TCRbeta sequences.
Conclusion: This approach can be used to identify statistically significant changes in murine TCR repertoire during infections, vaccinations and drug tests.
Supported by RSF15-15-00178.

P.E1.02.11
In vivo deuterium labeling of circulating immune cells: a feasibility study

***E. Veld, in 't**[1], H. W. Grievink[1], M. Baliu Pique[2], J. Drylewicz[2], F. E. Stuurman[1], T. Kolk, van der[1], G. J. Groeneveld[1], J. A. Borghans[2], K. Tesselaar[2], M. Moerland[1];*
[1]Centre for Human Drug Research, Leiden, Netherlands, [2]UMCU, Utrecht, Netherlands.

Quantification of the life span of immune cells *in vivo* by deuterium labeling may be an attractive methodology when studying disease or drug effects. It requires cell isolation, which is operationally challenging in clinical studies. Moreover, limited data are available on the variability of cellular lifespan between subjects, and the correlation with cell counts. Therefore, a feasibility study was performed in 16 volunteers (8 healthy subjects/HV, and 8 MS patients). Subjects received 70% deuterated water for 9 weeks and were followed for one year. Immune cell subsets were isolated by sequential magnetic sorting (RoboSep), phenotyped (MACSQuant10), and analyzed for deuterium incorporation (GCMS) allowing calculation of life span.
Cell count strongly influenced cell purity. For CD19+ B-cells and CD4+ T-cells, average purities were 89 and 87% (CD4+, HV and MS) and 90 and 89% (CD19+, HV and MS). Cell counts were generally exceeding $30*10^4$/subset. However, for memory and naïve CD8+ T-cells, average purities were 76 and 59% (CD8+m, HV and MS) and 73 and 68% (CD8+n, HV and MS), with counts below $15*10^4$. Average life span was 271±232 days for CD19+ cells, and 209±283 days for CD4+ cells (minimal purity 85%), not clearly correlating with circulating cell numbers.
Although the availability of automated sorters greatly facilitates cell sorting in clinical studies, our data demonstrate that the quality of the cells remains an important point-of-attention for customized isolation protocols. Life span of immune cell subsets was highly variable between subjects, complicating its use as readout in future clinical pharmacology studies.

P.E1.02.12
In vitro three dimensional vascularized skin on a chip to study of immune response

***S. Kim**;*
KIST, Seoul, Korea, Republic of.

Various kinds of human organ on a chip studies have been performed to screen the toxicity and efficacy of certain materials including drugs by various limitations of animal experiments such as the ethical and regulatory issues and the considerable difference between animals and human. Especially, skin on a chip is one of the studies that has attracted attention because it can be used for screening of cosmetics and skin detergents as well as drugs. However, most of current in vitro skin models are based on two dimensional culture of fibroblasts and keratinocytes that only simulate human epidermis and dermis. One of the most serious problems among various skin reactions caused by chemical substances and biological agents, including drugs, cosmetics and skin detergents is inflammatory skin disease. To confirm this reaction, the vascular network structures, which regulate immune response, are need as well as the epidermis and dermis structures. For this reason, we investigated the in vitro three dimensional vascularized skin on a chip to mimic the structures and functional responses of the human skin using collagen/fibrin hydrogel (CFH) for dermis and poly(l-lactide-co-caprolactone)(PLCL) nanofibrous electrospun membrane(NEM) for epidermis. To mimic vessels, we created channels in the CFH and coated with human umbilical vein endothelial cells(HUVECs). Consequently, we could find that channels coated with HUVECs formed a vessels-like structure, and microvascular networks were formed in CFH like the dermis. Moreover, it was confirmed that PLCL-NEM formed the epidermis like structure.

P.E1.02.13
Characterization of immune infiltrate and checkpoint protein expression patterns in murine syngeneic tumors via multiplex immunohistochemistry

***J. Bewsher**[1], J. Ziello[2], S. Klein[2], K. Costa[2], K. Crosby[2];*
[1]Cell Signaling Technology, Leiden, Netherlands, [2]Cell Signaling Technology, Danvers, United States.

Murine syngeneic tumor models are increasingly utilized for preclinical immuno-oncology studies as immunotherapeutic strategies continue to make clinical strides. However, the immunologic features of the tumor microenvironment (TME) in these models remain largely undefined. In this study, we applied a 7-color multiplex immunohistochemistry (mIHC) panel to visualize and quantify the immune infiltrate within formalin-fixed, paraffin-embedded (FFPE) Renca, CT26, and LL/2 tumor tissues derived from subcutaneous mouse models of renal cell carcinoma, colon carcinoma, and lung carcinoma, respectively. Additionally, we applied this panel to a 4T1 orthotopic primary mammary tumor and 4T1 lung metastasis formed via tail vein injection. The multiplex panel included antibodies detecting CD3 and CD8 as T cell markers, F4/80 as a myeloid cell marker, the immunosuppressive receptor PD-1, as well as its ligand PD-L1, pan-keratin as a tumor mask, and DAPI as a nuclear counterstain. We characterized the localization of tumor-infiltrating immune cells, as well as trends in the coexpression and frequency patterns of immunosuppressive proteins. This study strives to better understand the underlying differences in the immunologic landscapes of these tumors, which in turn has implications for researchers studying responses to immunotherapeutic approaches and combination strategies in murine models of cancer.

P.E1.02.14
REAlease® immunomagnetic separation technology with reversible labeling for positive selection of leukocytes

*P. Steinbrück, **C. Evaristo**, D. Vorholt, J. Pankratz, Z. Yu, M. Assenmacher, C. Dose;*
Miltenyi Biotec, Bergisch Gladbach, Germany.

Immunomagnetic enrichment of leukocytes is an important technique in both research and clinical applications. Current enrichment strategies using magnetic labeling of the target cells allow for highly efficient isolation, but in some instances removal of residual cell surface labeling after isolation is of high interest. To this end, we have combined the benefits of positive selection by MACS® Technology, the proven state-of-the-art method for the isolation of functional, viable cells, with a novel technology enabling the removal of both superparamagnetic beads and antibody fragments. REAlease® Technology provides an easy and fast solution for the highly specific isolation of unlabeled leukocytes directly from PBMCs. Separation based on this technology results in high purities of e.g. $CD3^+$, $CD4^+$, $CD8^+$, $CD19^+$, and $CD56^+$ cells of around 95%. Here, we present our latest results on cell separation with REAlease Technology validating activation, proliferation and re-labeling of important cell subsets such as $CD4^+$ and $CD8^+$T cells, as well as $CD19^+$ B cells. Target cell isolation did not induce cell activation while upon stimulation the cells were properly activated indicating preserved cell physiology.

Biostatistics - Association Between Age, Occupation & Morbidity, using publicly available NIH longitudinal study data

***S. H. Cho**;*
-, -, United States.

According to the NIH longitudinal study data publicly available, there has been a significant association between Age, Occupation and Profession. It has been found that those who were working as Professionals & in Related Occupations, has been found to be recorded as dead in their late 20s, while occupations such as Service Occupations, as well as, people in Office & Administrative Support Occupations, seem to have seconded the high mortality rate. Farming, Fishing, and Forestry seem to have the least number of people in the public death records. It might mean that people in these occupations were never in the public death records or there had been least number of deaths in these occupations.

On the feasibility of mining CD8+ T cell receptor patterns underlying immunogenic peptide recognition

***N. De Neuter**[1], W. Bittremieux[1], C. Beirnaert[1], B. Cuypers[1], A. Mrzic[1], P. Moris[1], A. Suls[2], V. Van Tendeloo[3], B. Ogunjimi[4], K. Laukens[1], P. Meysman[1];*
[1]Adrem Data Lab, Antwerpen, Belgium, [2]Center for Medical Genetics, Antwerpen, Belgium, [3]Laboratory of Experimental Hematology, Antwerpen, Belgium, [4]Centre for Health Economics Research & Modeling Infectious Diseases Lab, Antwerpen, Belgium.

Current T cell epitope prediction tools are a valuable resource in designing targeted immunogenicity experiments. They typically focus on, and are able to, accurately predict peptide binding and presentation by major histocompatibility complex (MHC) molecules on the surface of antigen-presenting cells. However, recognition of the peptide-MHC complex by a T cell receptor is often not included in these tools.
We developed a classification approach based on random forest classifiers to predict recognition of a peptide by a T cell and discover patterns that contribute to recognition. We considered two approaches to solve this problem: (1) distinguishing between two sets of T cell receptors that each bind to a known peptide and (2) retrieving T cell receptors that bind to a given peptide from a large pool of T cell receptors.
Evaluation of the models on two HIV-1, B*08-restricted epitopes reveals good performance and hints towards structural CDR3 features that can determine peptide immunogenicity. These results are of particular importance as they show that prediction of T cell epitope and T cell epitope recognition based on sequence data is a feasible approach. In addition, the validity of our models not only serves as a proof of concept for the prediction of immunogenic T cell epitopes but also paves the way for more general and high performing models.
This research was funded by the University of Antwerp [BOF Concerted Research Action] and the Research Foundation Flanders (FWO) [Personal PhD grants to NDN (1S29816N), PMo (1141217N), BC (11O1614N)]

P.E2.01.03
TCRex: a webtool for the prediction of TCR-epitope recognition

***S. Gielis**, N. De Neuter, W. Bittremieux, V. Van Tendeloo, B. Ogunjimi, K. Laukens, P. Meysman;*
University of Antwerp, Antwerpen, Belgium.

To date, multiple immunoinformatics tools have been created with the goal to achieve a better understanding of immunological processes. Although great tools exist for the prediction of epitopes and their binding to MHC molecules, we are still lacking useful tools for the prediction of epitope-MHC recognition by TCRs. Hence, we propose TCRex, a tool to investigate TCR recognition of epitopes.
This tool is based on our prior work related to the feasibility of predicting TCR-epitope recognition using TCRβ sequences. In this study, we showed that a random forest classifier trained to predict TCR-epitope interactions from TCR amino acid physicochemical properties can achieve a high accuracy. We are extending this work into a toolbox trained on a large dataset containing epitopes from different viruses, such as HIV-1 and EBV, and tumour cells. To this end, we collected epitope-specific human TCRβ sequence data containing information about the CDR3 sequences and the corresponding V-and J-genes. Random forest classifiers are trained on this data and kept if they report a sufficiently high performance in a cross-validation setting. These classifiers will be made freely available in a webtool, called TCRex.
TCRex will be useful to make predictions on newly gathered experimental TCRβ sequence data. As such, it will aid researchers in the development of more specific epitope-TCR binding assays and the elucidation of T cell repertoire targets.

IUPHAR Guide to IMMUNOPHARMACOLOGY

***S. D. Harding**[1], E. Faccenda[1], A. J. Pawson[1], J. L. Sharman[1], C. Southan[1], S. P. Alexander[2], S. Anderton[1], C. Bryant[3], A. Davenport[3], C. Doerig[4], D. Fabbro[5], F. Levi-Schaffer[6], M. Spedding[7], J. A. Davies[1];*
[1]University of Edinburgh, Edinburgh, United Kingdom, [2]University of Nottingham, NOttingham, United Kingdom, [3]University of Cambridge, Cambridge, United Kingdom, [4]Monash University, Melbourne, Australia, [5]PIQUR Therapeutics, Basel, Switzerland, [6]Hebrew University of Jerusalem, Jerusalem, Israel, [7]Spedding Research Solutions, Le Vesinet, France.

Immunity, inflammation and infection have become priority areas in drug discovery research. Most chronic diseases, including ageing, have an immune-inflammatory component; auto-immunity is a serious problem, and the progress of infections depends on immune and inflammatory responses.
The International Union of Basic and Clinical Pharmacology (IUPHAR) have developed a new online resource called the IUPHAR Guide to IMMUNOPHARMACOLOGY (GtoImmuPdb; www.guidetoimmunopharmacology.org) that aims to improve data exchange between immunology and pharmacology expert communities, to better support research and development of drugs targeted at modulating immune, inflammatory or infectious components of disease.
Supported by the Wellcome Trust, GtoImmuPdb is an extension to the existing IUPHAR/BPS Guide to PHARMACOLOGY (GtoPdb; www.guidetopharmacology.org), a joint initiative between IUPHAR, the British Pharmacological Society (BPS) and the University of Edinburgh. It is an open-access and regularly updated resource, providing a unique access point that is user-friendly to immunologists and pharmacologists alike. Its integration with GtoPdb comes with enhanced search mechanisms and new ways to browse and visualize immunological data. Details of the expansion are provided in our recent update in the 2018 NAR Database Issue paper (1).
The data in the IUPHAR Guide to IMMUNOPHARMACOLOGY, and its parent database, are sourced from peer-reviewed primary literature and their content is curated by committees containing >500 global expert contributors.
1. Harding SD et al. (2018). The IUPHAR/BPS Guide to PHARMACOLOGY in 2018: updates and expansion to encompass the new guide to IMMUNOPHARMACOLOGY. *Nucleic Acids Res*, 46(D1), D1091-D1106.

Computational search of active compounds for SH2

V. Hurmach[1], *A. Varnek*[2], *M. Platonov*[3], *Y. Prylutskyy*[1];
[1]*Taras Shevchenko National University of Kyiv, Kyiv, Ukraine,* [2]*University of Strasbourg, Strasbourg, France,* [3]*Institute of Molecular Biology and Genetics, NAS of Ukraine, Kyiv, Ukraine.*

Search for the new chemical structures with specific biological activity is a problem, which requires usage of the latest achievements in molecular modeling technologies. It is well known that SH2 domains are involved in intracellular signaling pathways. Their dysfunction is related with such cancer diseases as Basal cell carcinoma, T cell acute lymphoblastic leukemia and B cell lymphoma. The aim of this work - investigation of SH2 domain binding properties and searching for new potential active compounds in the whole SH2 domains class. All available structures of SH2 domain were divided to six groups with high/average level of conservation (group 1 - 91.25%, group 2 - 78%, group 3 - 47%, group 4 - 32%, group 5 - 39%, group 6 - 45%) and not significant Rmsd difference (0.8 Å, 1.16 Å, 1.6 Å, 1.9 Å, 2 Å, 1.4 Å).
Structure analysis showed that binding pocket contains 20-24 main amino acids: FLVRESETT (pTyr binding part), βB-sheet; KHYKIR (central part), βD-sheet; ITSR and ADGLC (hydrophobic pocket), βG-sheet and αB-helix. Seven most representative pockets were selected based on those sequences, and used for docking and pharmacophore study of the entire Enamine Ltd database (> 1 M compounds). The outcome of this stage is selection of 10463 compounds. To conclude, specific scaffolds have been identified as pTyr substitutes. In almost all cases the ligand tightly fills the phosphotyrosine binding site and creates hydrogen bonds with the key amino acids Arg and Lys.

REAfinity recombinant antibodies can be used for Immunofluorescence staining of fixed mouse and human cells and tissues

A. Kinkhabwala, ***W. Muller****, T. D. Rockel;*
Miltenyi Biotec GmbH, Bergisch Gladback, Germany.

REAfinity™ recombinant antibodies are available from Miltenyi-Biotec conjugated to various fluorochromes. The main advantage of recombinant antibodies compared to hybridoma derived monoclonal antibodies is their reproducibility in their staining performance. One of the research areas in which monoclonal antibodies are utilised are multicolour immunofluorescence images from fixed cells or tissues. Here we show that REAfinity™ recombinant Antibodies can be used to stain various tissues and cells from mouse or human origin fixed by two fixation method and that they can be used in a multiplex manner. Examples of fixed tissue sections and single cell mixtures will be shown for a selected subset of REAfinity™ antibody staining demonstrating that REAfinity™ recombinant Antibodies can be used not only for flow cytometry but also for immunofluorescence staining of fixed cells and tissues.

P.E2.01.07

Robust prediction of peptide-MHC binding affinity with deep neural networks

V. I. Nazarov[1], *V. Tsvetkov*[2,1], *E. Ofitserov*[3];
[1]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, RAS, Moscow, Russian Federation,* [2]*Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [3]*Tula State University, Tula, Russian Federation.*

Current adaptive immunity research pose significant challenges to data analysis. One of the major challenges toward personalized vaccine design and other applications is the prediction of interaction between major histocompatibility complexes and their ligands. The emerging field of mass spectrometry immunopeptidomics complements existing binding affinity data, although common machine learning models are trained mostly on binding affinity data alone. Moreover, available data is often noisy and redundant. Therefore models inferenced from this data don't reach high accuracy due to data bias and corruption. In order to address both issues deep neural network was designed and trained on both binding affinity and mass spectrometry data. Specific architecture and learning process modifications were introduced to increase model robustness and to handle corrupt data. Altogether these advantages of designed deep learning algorithm allowed us to compete with state-of-the-art models, e.g. netMHCpan, and achieve comparable performance in at least 10 times less computation time.

P.E2.01.08

Identification of mutations associated with autoinflammatory diseases by Next Generation Sequencing

I. Olivas Martinez*, M. Montes Cano, L. Gonzalez Garcia, J. Bernabeu Wittel, L. Fernandez Silveiro, M. Camacho Lovillo;*
Hospital Virgen del Rocio, Sevilla, Spain.

The aim was to evaluate a patient with inflammatory symptoms and mild immune disorders using *Next Generation Sequencing* (NGS). Patient is a 27-year-old man with chilblain lesions that appear in winter and recurrent febrile episodes who was subjected to biochemical analysis, imaging techniques (Pulmonary CT scan) and autoimmunity studies (ANA, ANCA). A genetic study was also performed by NGS with a panel of 12 genes related to autoinflammatory diseases: *NLRP3*, *TNFRSF1A*, *MVK*, *PSTPIP1*, *MEFV*, *NOD2*, *CECR1*, *TMEM173*, *IL1RN*, *IL36RN*, *LPIN2* and *NLRP12*. Patient's DNA was amplified by multiplex PCR and sequenced using Ion Torrent platform. Mutations identified were confirmed by Sanger methodology. Imaging and autoimmunity studies were negative, but the presence of characteristic lesions, hepatic enzymes increased, neutrophilia and lymphopenia, made clinicians suspect an autoinflammatory SAVI-like syndrome (STING-Associated Vasculopathy with onset in Infancy). Four heterozygous mutations associated with autoinflammatory diseases were found: in exon 9 of *MEFV* gene with amino acid change I591T, in exon 11 of *MVK* gene with change V377I, in exon 7 of *LPIN2* gene with change A331S and in exon 5 of *TMEM173* gene, producing the change F153V. All these mutations were classified as non-pathogenic by the statistical analysis tool PolyPhen-2. F153V had not been described before, being located next to a pathogenic mutation (N154S), so we can't rule out its possible role in the above-mentioned pathology. Identification through NGS of 4 different mutations related to autoinflammatory syndromes in the same patient allows to extend the spectrum of mutations and phenotypes associated with these immune disorders.

P.E2.01.09

Novel miRNAs revealed in bovine macrophages stimulated with pathogen associated molecular patterns

F. N. Toka[1,2], *F. Smaltz*[1], *L. Szulc-Dabrowska*[2], *M. B. Mielcarska*[2], *P. Nielsen*[1], *M. Bossowska-Nowicka*[2];
[1]*Ross University School of Veterinary Medicine, Bassesterre, Saint Kitts and Nevis,* [2]*Faculty of Veterinary Medicine, SGGW, Warsaw, Poland.*

Introduction: MicroRNAs influence biological processes during development, cell differentiation and infection. We have mimicked bacterial and viral infection with pathogen associated molecular patterns to assess the early phase expression of miRNAs in a bovine macrophage cell line Bomac.
Material and Methods: Cells were stimulated with CpG or poly(I:C) for 6 h, and miRNAs isolated using an enrichment protocol and sequenced in Illumina system. Data were analyzed in miRDeep2. Read counts for mature miRNAs were input into R for data pre-processing and statistical analysis using Bioconductor.
Results: The 9 samples had 18-31 million reads. MiRNAs with 0.5 CPM in at least 3 samples were filtered out, leaving 1,318 miRNAs, comprised of 671 novel miRNAs, 564 known miRNAs that mapped to the genome and 83 known miRNAs that could not be mapped to the genome. Nine miRNAs were compared with the mRNAs; the overall FDR threshold was 0.35. Of these nine, seven were upregulated by CpG only and two were upregulated by poly(I:C) only. MiRNAs negatively regulate their targets, we looked for mRNAs with ≤ -0.75 Pearson correlation coefficients between mRNA expression and miRNA expression. 580 mRNAs were negatively correlated with one or more of the 7 CpG miRNAs and 507 mRNAs were negatively correlated with one or more of the 2 poly(I:C) miRNAs. Nine novel miRNAs were validated by Taqman small RNA assays and found to be expressed at levels that correlated with sequencing data.
Conclusion: We have discovered novel bovine miRNAs that may influence gene expression in infected bovine macrophages.

P.E2.01.10

The prediction of specific antibody- and cell-mediated responses using baseline immune status parameters of individuals received measles-mumps-rubella vaccine.

D. Grebennikov[1,2], ***A. Toptygina***[3,4], *G. Bocharov*[2];
[1]*Moscow Institute of Physics and Technology (State University), Moscow, Russian Federation,* [2]*Marchuk Institute of Numerical Mathematics of the Russian Academy of Sciences, Moscow, Russian Federation,* [3]*G.N.Gabrichevsky Research Institute for Epidemiology and Microbiology, Moscow, Russian Federation,* [4]*Lomonosov Moscow State University, Moscow, Russian Federation.*

The successful vaccination implies the induction of effective specific immune responses. We intend to find biomarkers among various immune cell subsets, cytokines and antibodies which could be used to predict the levels of specific antibody- and cell-mediated responses after measles-mumps-rubella vaccination. To do this, we measured 59 baseline immune status parameters (frequencies of 42 immune cell subsets, levels of 13 cytokines, immunoglobulins) before vaccination and 13 response variables (specific IgA and IgG, antigen-induced IFN-γ production, CD107a expression on CD8+ T-lymphocytes, and cellular proliferation levels by CFSE dilution) 6 weeks after vaccination for 19 individuals. Statistically significant Spearman correlations between some baseline parameters and response variables were found for each response variable ($p<0.05$). Due to the low number of observations relative to the number of baseline parameters and missing data for some observations, the automatic stepwise procedure of minimal adequate multivariable linear regression selection without overparameterization is unfeasible. To reduce the number of candidate parameters, we manually selected for each response variable 5 parameters among the parameters which correlated with response variable with $p<0.2$, and which were as much as possible uncorrelated between each other. Given the manually chosen candidate parameters, we managed to identify the minimal adequate predictive multivariable linear regression models of post-vaccination antibody- and cell-mediated responses with up to 5 predictors in each model. The work is supported by the Russian Foundation for Basic Research (grant 17-01-00636).

P.E2.01.11

Exploring large-scale flow cytometry data for identification of immune-related genes

I. Treise[1,2], *Y. Cho*[1], *G. Miller*[1], *H. Fuchs*[1], *V. Gailus-Durner*[1], *M. Hrabě de Angelis*[1], *D. H. Busch*[2];
[1]*Institute of Experimental Genetics, München/Neuherberg, Germany,* [2]*Institut für Medizinische Mikrobiologie, Immunologie und Hygiene, München, Germany.*

Immune-related diseases such as autoimmune or inflammatory disorders are a common clinical problem, but the underlying genetic factors are not yet fully understood. A large-scale approach is required to characterize protein-coding genes, their functional evidence and their relevance for immune system-related diseases. The International Mouse Phenotyping Consortium (IMPC) aims at generation and phenotypic characterization of knockout mouse lines of all coding genes. Within the Immunology Unit of the German Mouse Clinic, we systematically analyzed flow cytometry data of mice from the IMPC resource for abnormalities in the immune cell composition of the spleen. Multicolor flow cytometry is a powerful tool for simultaneous acquisition of a vast diversity of immune cell populations.
Components of both the innate and adaptive immunity were assessed: T, B, and NK lymphocytes and their respective subpopulations, as well as myeloid cell subsets, e.g. monocytes, granulocytes, macrophages and dendritic cells. Here, we show multiparametric analysis of large-scale flow cytometry data of more than 150 mutant mouse lines. We use statistical tools to visualize relations of the different immune cell subpopulations and to identify genes relevant for immune disorders.

P.E2.01.12

T- and B-cell receptor repertoire sequencing: quality control and clone identification

B. D. C. van Schaik[1], *P. L. Klarenbeek*[1], *M. E. Doorenspleet*[1], *S. Pollastro*[1], *A. Musters*[1], *G. Balzaretti*[1], *R. E. Esveldt*[1], *F. Baas*[2], *N. de Vries*[1], *A. H. van Kampen*[1,3];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Leiden University Medical Center, Leiden, Netherlands,* [3]*University of Amsterdam, Amsterdam, Netherlands.*

Next-generation sequencing (NGS) of T- and B-cell receptor repertoires was introduced in 2009 as a new powerful tool in immunology research. Repertoire sequencing has found various applications such as the elucidation of plasmablast antibody response to influenza vaccination, the analysis of T-cell receptor diversity in systemic lupus erythematosus, and discovery of invariant T cells. Sequencing of repertoires has specialized experimental protocols and subsequent bioinformatics analysis of the data.
We have developed a data analysis strategy to analyse lymphocyte repertoires of (clinical) samples. To identify clones from this NGS data we use a set of sequence motifs, instead of the Cys104 and Phe/Trp118 to determine the CDR3 region and, subsequently, assign the V and J genes. After each sequence run and for every project we check for sample contamination by comparing the top 10, 25 and 100 most abundant clones between all samples.
In the past ten years we have performed ~90 NGS experiments with 100-200 samples per run. The data analysis is performed on a community cloud and the process is automated using a pilot job framework. Meta data is kept about the samples and is stored together with the data in a research data management system to enable reuse of these samples in future projects.
Grants: This work was carried out on the Dutch national e-infrastructure with the support of SURF Cooperative. P.L.K. was funded by a PhD scholarship of the AMC Graduate School.

Arbitrary transformation of flow cytometry data for multivariate analysis may produce misleading immunological information

S. van Staveren[1,2], *G. H. Tinnevelt*[3,2], *R. Folcarelli*[3], *E. Cadot*[3], *J. J. Jansen*[3], *N. Vrisekoop*[1], *L. Koenderman*[1], *O. F. van den Brink*[2];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*TA-COAST, Amsterdam, Netherlands,* [3]*Radboud University, Nijmegen, Netherlands.*

Introduction: The flow cytometry field has evolved rapidly, allowing the measurement of 30-50 parameters per cell. This has led to a tremendous increase in multivariate information. Manual gating is insufficient to extract all this information. Therefore, multivariate analysis (MVA) methods have been developed like cluster methods SPADE and FlowSOM and dimensionality reduction methods viSNE, FLOOD, DAMACY and ECLIPSE. To aid interpretation, the data are often transformed logarithmically before MVA.
Rationale: We studied the consequences of different transformations of flow data in datasets containing negative intensities caused by background subtractions and compensation, as logarithmic transformation of negative data is not possible. Alternative transformations such as biexponential, or logicle, and hyperbolic arcsine transformations allow linearity around zero, whereas higher (positive and negative) intensities are logarithmically transformed.
Results: To define the linear range, a parameter (or co-factor) must be chosen. The type of transformation and the concomitant chosen parameter have great impact on the MVA results. In some cases, peak-splitting is observed, producing two distributions in an actual homogeneous population around 0. This may be misinterpreted as the presence of multiple cell populations. We applied various statistical methods to optimally choose the parameter of the transformation used.
Conclusion: Arbitrary or unconsidered transformation can lead to wrong conclusions for cluster methods as well as dimensionality reduction methods. Importantly, it should be noted that some MVA methods only support one transformation option with a pre-set parameter in their algorithms. We recommend to transform flow cytometry data separately per channel, to prevent peak-splitting.

P.E2.01.14

Knowing what is what: Artificial Intelligence for cell classification in cytometry

J. Verhoeff[1], *J. J. Garcia-Vallejo*[1], *S. Abeln*[2];
[1]*Cancer Center Amsterdam, Amsterdam, Netherlands,* [2]*VU university Amsterdam, Amsterdam, Netherlands.*

The advent of high parametric cytometry systems (10+ color flow cytometry and mass cytometry) has greatly increased the amount of data gathered from single cell suspensions. Classical gating misses out on multi-parametric relations not visible on sequential biaxial plots, leading to the creation of computational tools, capable of clustering cells in an unsupervised manner. However the identified clusters would still need interpretation by a skilled immunologist to label them. This work details our strategy to develop a cell classifier, suited for mass cytometry data. We hypothesize a supervised approach is preferable over the laborious process of identifying unknown clusters. By identifying known subsets the process of cluster analysis can be expedited. This information is then implemented in metaclustering steps to reach biologically relevant clusters. We developed a neural network logistical regression model based on softmax regression. Softmax regression is a generalized logistic function. This model took as input a small set of classically gated and labeled cells (500 of each label) from 1 sample per batch. Initial results indicate a success rate of >95% in training, test and validation sets. The abundance of subsets does not affect identification rate. Our current work has shown to accurately classify cells within a single batch of mass cytometry data, with a high success rate. Future efforts will be focused on implementing different information sources, such as gene expression data in the classifier. This could eliminate the necessity of expert gating in mass cytometry analysis.

P.E2.01.16

BRepertoire: A user-friendly webserver for analysing antibody repertoire data

D. Dunn-Walters[1], *C. Margreitter*[2], *F. Fraternali*[2];
[1]*University of Surrey, Guildford, United Kingdom,* [2]*King's College London, London, United Kingdom.*

The major goal of BRepertoire is to facilitate easily accessible, fast and responsive data partition comparisons in the analysis of the antibody repertoire. A powerful data preparation pipeline and a set of analysis functionalities including PCA, V(D)J gene usage and statistical comparisons enables the investigation of repertoires in many different ways and ultimately the identification of distinguishing features between sub-groups of data. As most functions provide plots in addition to the text results, a quick screening of the data and visual inspection of the results is also possible. We believe BRepertoire to be an invaluable tool for experimental immunologists who study immune repertoires. A unique functionality is flexible analysis of physico-chemical properties of amino acid sequences, moving towards a better understanding of receptor-antigen interactions. Since flexibility has been a major design target, BRepertoire will prove useful in a variety of applications as it does not rely on pre-defined format conventions and tries to make as few assumptions on the data as possible. Plots and data generated may be downloaded as image files and data tables in different formats. The server is accessible under http://mabra.biomed.kcl.ac.uk/BRepertoire.

Single cell multidimensional analysis reveals activation-induced generation and maintenance of regulatory T cells during homeostasis and in tumour microenvironments

A. Bradley[1], *T. Hashimoto*[1], ***M. Ono***[2];
[1]*University of Tsukuba, Tsukuba, Japan,* [2]*Department of Life Sciences, London, United Kingdom.*

Background: T cell receptor (TCR) signalling initiates downstream transcriptional mechanisms for T cell activation and differentiation. FoxP3-expressing regulatory T cells (Treg) require TCR signals for their suppressive function and maintenance in the periphery. It is, however, unclear how TCR signalling controls the transcriptional programme of Treg, and whether and how Treg are generated from activated T cells.
Results: Here we dissect the transcriptomes of various T cell subsets using multidimensional and single cell analysis methods. We show that Treg are as activated as memory-phenotype T cells (Tmem) and effector T cells (Teff) at the transcriptomic level, and identify the common activation-dependent gene modules for these T cell subsets. Importantly, the major feature of Treg is that Foxp3 represses Runx1-associated, Tmem-specific activation-dependent genes, while Foxp3 sustains or enhances the expression of the common activation genes. Furthermore, by analysing single cell RNA-seq data of tumour-infiltrating T cells from melanoma patients, we show that activated T cells in the tumour microenvironments dynamically differentiate into two lineages of cells: Treg and T follicular helper (Tfh)-like cells. We identify the bifurcation point of Treg and Tfh-like differentiation, which specifically contains *IL2* producing cells. Notably, *CTLA4* is induced in both the Treg and Tfh-like lineages upon activation, while *PDCD1* is induced in the Tfh-like lineage only. We identify marker genes to distinguish these new populations.

Conclusion: Our study establishes the new model that Treg are dynamically generated from activated T cells in tumour microenvironments and during homeostasis. Future studies should analyse the temporal dynamics of Treg differentiation and T cell activation in vivo.

Memory T-cell kinetics: do long-lived memory T-cells exist?

*M. Baliu-Piqué[1], J. Drylewicz[1], L. Ravesloot[2], S. Otto[1], L. Borkner[3], X. Zheng[3], L. Cicin-Sain[3], A. Koets[2], K. Tesselaar[1], **J. A. M. Borghans**[1];*
[1]Laboratory of Translational Immunology, University Medical Center Utrecht, Netherlands, [2]Central Veterinary Institute, Wageningen UR, Netherlands, [3]Helmholtz Center for Infection Research, Braunschweig, Germany.

Immunological memory, a hallmark of adaptive immunity, can last for decades, but it remains controversial whether long-lived T-cells contribute to this long-lasting memory. It has been shown that memory T-cells from blood and lymph nodes maintain themselves through proliferation, and not by longevity of the individual cells. Until now, however, most knowledge on memory T-cell dynamics is based on circulating T-cells and using phenotypic memory markers. It has been argued that *antigen-specific* memory T-cells may be longer-lived than the bulk of memory-phenotype T-cells, and that memory T-cells with long lifespans may be located in the bone marrow (BM), and hence go unnoticed in studies based on blood. We investigated the maintenance of memory T-cells against mouse cytomegalovirus (mCMV) using *in vivo* deuterium labelling. Since mCMV induces not only contracting but also inflating T-cell responses, which continue to expand over time, we could investigate whether *antigen-specific* memory responses, and in particular inflating responses, consist of long-lived memory T-cells. We found that the lifespans of antigen-experienced and memory-phenotype T-cells are comparable, and that even inflating T-cell responses are maintained by continuous cell renewal. We also investigated whether long-lived memory T-cells may be stored in the BM, by quantifying the *in vivo* dynamics of memory T-cells in BM, secondary lymphoid organs and blood of goats using deuterium labelling, and found that T-cells in BM are as short-lived as those in circulation. Taken together, our data support a dynamic model in which T-cell memory is maintained by homeostatic proliferation of relatively short-lived cells.

P.E3E4.01.02
Role of interleukin (IL)-12/15/18 and ruxolitinib in the phenotype, proliferation and polyfunctionality of human cytokine-preactivated NK cells.

*I. Terrén[1], I. Mikelez[1,2], I. Odriozola[1], A. Gredilla[1], J. González[1], A. Orrantia[1], O. Zenarruzabeitia[1], J. Vitallé[1], **F. Borrego**[1,3,4];*
[1]Biocruces Health Research Institute, Barakaldo, Spain, [2]CIC biomaGUNE, Donostia-San Sebastián, Spain, [3]Ikerbasque, basque Foundation for Science, Bilbao, Spain, [4]Basque Centre for Transfusion and HUman Tissues, Galdakao, Spain.

Interleukin (IL)-12, IL-15 and IL-18 preactivated NK cells, also known as cytokine-induced memory-like (CIML) NK cells, are a promising tool in cancer immunotherapy. We have studied the effect that combinations of IL-12, IL-15 and IL-18 have on the generation of human CIML NK cells. Our data points toward a major contribution of IL-15 to CIML NK cell mediated cytotoxicity, although the synergistic effect of the three cytokines grant them the best polyfunctional profile, that is, cells that simultaneously produce multiple cytokines such as interferon (IFN)γ, tumor necrosis factor (TNF)α and C-C motif chemokine ligand (CCL)3 and degranulate (CD107a). We have also analyzed the involvement of each cytokine and their combinations in the expression of homing receptors CXCR4 and CD62L, as well as the expression of CD25 and IL-2-induced proliferation. Furthermore, we have checked the effects of the Jak1/2 inhibitor ruxolitinib in the generation of CIML NK cells. We found that ruxolitinib-treated CIML NK cells express lower levels of CD25 than non-treated CIML NK cells, but show similar IL-2-induced proliferation. Moreover, we have also found that ruxolitinib-treated NK cells show reduced effector functions after the preactivation, and that these functions can be recovered after an expansion period of 4 days in the presence of low doses of IL-2. Altogether, our results describe the impact that each cytokine and the Jak1/2 pathway have in the phenotype, IL-2 induced proliferation and effector functions of human CIML NK cells. **Funding:** AECC-Spanish Association Against Cancer (PROYE16074BORR) and BIOEF-Basque Foundation for Research and Innovation-EiTB Maratoia (BIO14/TP/003).

P.E3E4.01.03
Characterizing the human Yellow Fever Vaccine immune response by gene expression profiling at single-cell resolution

***J. J. A. Calis**[1,2], S. A. Uhl[2], R. Caron[2], B. R. Rosenberg[2];*
[1]The Rockefeller University, New York, United States, [2]Icahn School of Medicine at Mount Sinai, New York, United States.

Introduction. An effective immune response relies on the coordinated activity of many cell types and associated functions. Transcriptomics methods enable detailed characterizations of these complex and dynamic processes. RNA-Seq and microarray studies of peripheral blood samples from human volunteers have revealed numerous gene expression networks and corresponding cellular functions that contribute to effective immunity. Recently developed high-throughput single cell RNA-Seq (scRNA-Seq) technologies offer great potential for further characterization of immune function at increased resolution. In measuring gene expression in individual cells, these methods can resolve different cell types in complex mixtures, to analyze gene expression of many cell types without *a priori* selection, and assess cell-to-cell heterogeneity.
Methods. We applied high-throughput scRNA-seq to characterize the human immune response to Yellow Fever Vaccine (YFV). YFV was administered to healthy volunteers and peripheral blood mononuclear cells (PBMC) were analyzed at 0, 3, 7, 14 and 42 days post-vaccination by scRNA-seq. We analyzed approximately 75,000 total immune cells using unsupervised clustering methods to identify different cell types and assess vaccine-elicited changes in gene expression.
Results. Preliminary results include a robust Interferon response at days 3 and 7 post-vaccination, with distinct interferon-stimulated gene (ISG) expression programs induced in different cell types. At later time points, we observed activated T and B cell expansions characteristic of the adaptive immune response to vaccination. Additional analyses have revealed numerous cell type-specific gene expression programs in the response to this highly effective and clinically important vaccine.

Dietary lipids can modify the immune-related transcriptome in Atlantic salmon: a model organism

***M. Jalili**[1], Y. Jing[1], Y. Olsen[1], A. Bones[1], M. Ostensen[1], F. Buonocore[2], M. Gerdel[3], A. Pallavicini[3], G. Scapigliati[2];*
[1]NTNU, Trondheim, Norway, [2]University of Tuscia, Viterbo, Italy, [3]University of Trieste, Trieste, Italy.

Background Aquaculture nutrition has an important determining role in fish and human health. The type and amount of fatty acids may affect the immune response and there is a knowledge gap in this area. Our objective was to investigate the immunomodulatory effects of fish oil (FO), vegetable oil (VO) and phospholipid (PL) rich feedings in farmed Atlantic salmon juveniles. Methods and Materials After 12 weeks at aquaculture facility, pyloric caeca (PC) and liver (LV) tissues were dissected from fishes and RNA was extracted, cDNA libraries were prepared and sequenced according to standard protocols. The raw data were processed, mapped, quality-checked and analyzed statistically to compare different sampling time points (Day0, Day48 and Day94) and feedings (FO, VO and PL) in two type of tissues (PC, LV) in order to determine the significantly up- and down-regulated immune related genes and relative pathways. Results and discussion With regard to immunological related transcripts, there were limited differences among the diets and the immune modulation was very similar comparing the three different dietary interventions. Taking into account the sampling at Day48 and Day0, the highest up-regulated genes were related to complement system and immunoglobulins chains. The moderate modulated genes were of pathogen recognition receptors and triggering receptor expressed in myeloid cells (TREM-1). Although transcriptome of all markers and receptors was not changed, there was a remarkable evidence for modulation of gene networks and pathways related to innate (TLRs, NLRs, complement C1q and C3) and adaptive immunity (immunoglobulins, T cell receptors, phagocytes and opsonization factors).

P.E3E4.01.05
Defining the memory T cell cytotoxic mode of action with a high-resolution immune cell cytotoxicity assay on single cell level

***A. Knörck**, K. S. Friedmann, C. Backes, C. Kummerow, D. Alansary, G. Schwär, S. Renno, S. Zoephel, M. Hoth, E. C. Schwarz;*
Biophysics, Homburg, Germany.

Introduction: Following antigen recognition cytotoxic T lymphocytes (CTLs) undergo differentiation into various subtypes of effector and memory T cells. Effector Memory (T_{EM}) and Central Memory (T_{CM}) T cell subsets induce target cell death by at least two different lytic mechanisms. Death receptor mediated- or perforin/granzymeB mediated mechanisms induce target cell apoptosis and/or necrosis. Apoptotic and necrotic target cell death can be distinguished by a pCasper 3GR single immune cell cytotoxicity assay, which was used to identify the preferred mechanisms of target cell lysis of T_{EM} and T_{CM}.
Methods: Human $CD8^+$ T cells were isolated out of a SEA-stimulated PBMC population and sorted into $CD45RO^+/CD62L^-$ TEM, $CD45RO^+/CD62L^-$ TCM subpopulations. The cytotoxic repertoire and signaling of CTL subpopulations were characterized by qRT-PCR, intracellular perforin staining, calcium imaging and a multiplex bead array assay. The cytotoxic effector functions of these CTL subpopulations were further analyzed by a population based real-time killing assay and high-resolution cytotoxicity assay on single cell level.
Results: After in vitro SEA-stimulation of CTLs 15% of the $CD8^+$ population show a T_{EM} and 50% a T_{CM} phenotype. Although T_{EM} display a highly increased cytotoxicity and elevated expression of Perforin and other effector molecules, both subpopulations mainly rely on a perforin/granzymeB mediated killing mechanisms. Perforin mediated primary necrosis and slower apoptotic events were of less importance for both subpopulations.
Conclusion: Using a high-resolution immune cell cytotoxicity assay on single cell level sheds light on the kinetics, efficiency, and mode of T_{EM} or T_{CM} induced target cell lysis in great detail.

P.E3E4.01.06

Comparative analysis of transcriptomic data obtained from SCLC cells upon IFN-gamma response display great heterogeneity

A. M. KURSUNEL[1], *E. Z. TASKIRAN*[2], *G. ESENDAGLI*[1];
[1]*Department of Basic Oncology, Hacettepe University Cancer Institute, Ankara, Turkey,* [2]*Department of Medical Genetics, Hacettepe University Faculty of Medicine, Ankara, Turkey.*

Introduction: Small cell lung cancer (SCLC) which comprises 13% of all lung cancer cases is associated with aggressive tumor growth together with a tendency to early dissemination and distant metastasis. IFN-γ is the uppermost cytokine implicated in anti-tumor immunity. Although it plays a central role in the recognition and elimination of transformed cells, many immune regulatory pathways can also be induced. The aim of this project is to determine whether an IFN-γ-related immune activation occurs against SCLC cells and how SCLC cells cope with anti-tumor effects of IFN-γ. **Materials&Methods:** SCLC cell lines were co-cultured with PBMCs. T-cell proliferation, IFN-γ and IL-2 secretion were determined. Additionally, SCLC cell lines were exposed to recombinant IFN-γ and total RNA was extracted. RNA-seq library preparation and next-generation sequencing (NGS) were performed. NGS data were analyzed using various approaches (STRING, KEGG). **Results:** SCLC cells promoted the proliferation of T-cells within the PBMCs. IL-2 and IFN-γ levels were also elevated in supernatants collected from the SCLC:PBMC co-cultures. Differential effects of IFN-γ on each SCLC cell line was observed. Especially major immune regulatory pathways (such as PD-L1 and IDO1) were heterogeneously modulated. **Discussion:** These data indicates an adaptive resistance mechanism for SCLC since these cells initially allow T-cell activation and IFN-γ secretion. SCLC cells are responsive to IFN-γ while different immune regulatory pathways were induced. Thus, exposure to IFN-γ revealed alternative mechanisms employed by SCLC cells to cope with immune responses. These data might provide new insights for cancer biology and immune intervention therapies.

Characterising the functional and genomic profile of CAR CD19 T cells using single cell analyses

F. Luciani[1], *L. Clancy*[2], *C. Cai*[1], *H. McGuire*[3], *E. Keoshkerian*[4], *D. Koppstein*[4], *E. Blyth*[2], *D. Gottlieb*[2], *K. Micklethwaite*[2];
[1]*School of Medical Sciences, Sydney, Australia,* [2]*Westmead Institute for Medical Research, University of Sydney, Sydney, Australia,* [3]*University of Sydney, Australia, Sydney, Australia,* [4]*Kirby Institute, UNSW Sydney, Sydney, Australia.*

Despite the great success of CAR T-cells in the treatment of blood malignancies the mechanisms underpinning long-term persistence and limited toxicity remain unknown. The presence of less-differentiated T-cells such as T-stem-cell-memory (T_{SCM}) have been correlated to long-term persistence and limited toxicity. A single cell (sc)RNAseq approach has been developed to identify and track post-infusion the transcriptional signatures and endogenous TCR of CAR-T cell subsets and to link these profiles to clinical data. Three CAR-T products have been administered with complete molecular remission in two patients with acute lymphoblastic leukaemia and complete metabolic remission in a third with diffuse large B-cell lymphoma. CAR-T cells generated using thePiggyBac transposon-system with IL-15 and co-cultured with peripheral-blood mononuclear cells showed between 5-10% of T_{SCM}cells. CAR-T cells expanded in blood, produced cytokine-mediated toxicities commensurate to tumour-burden, and had up to 200 CAR-T/µl blood at 3-months follow-up. scRNAseq from the total $CD3^+$or $CD8^+T_{SCM}$($CD45RA^+CD95^+CXCR3^+$) compartments had a median of 858-950 genes per cell, with multiple gene-clusters identified. T_{SCM}showed 4 clusters, one with gene profile consistent with long-term memory and enhanced respiratory capacity and fatty-acid oxidation, in line with recent findings on 4-1BB CAR-T compared to CD28CAR-T cells. Full-length TCR was identified in 20% of the cells, and at least one chain in 75% of the cells. Ongoing research on post-infusion blood samples seeks identification of T_{SCM}clones that are maintained in the blood. This study reveals heterogeneous population of cells in the CAR T product, which can confer long-term survival of cells in the patient and minimise toxicity

P.E3E4.01.08

TCR sequence motif based classification of CD4-CD8 cells

E. Ofitserov[1], *V. Tsvetkov*[2,3], *V. I. Nazarov*[3];
[1]*Tula State University, Tula, Russian Federation,* [2]*Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [3]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, RAS, Moscow, Russian Federation.*

The field of immunology has witnessed an exponential growth of data. For instance, accumulation of TCR sequencing data allowed classification of CMV status in patients. This is the very point where big data algorithms should step in. Nevertheless, conventional deep neural networks (NN) lack of interpretability due to poor algorithmic transparency. In order to combine interpretability and performance we sought to develop a comprehensive NN training algorithm for motif-based sequence classification. It incorporates differential sequence alignment that provides end-to-end learning without preprocessing. Short substrings with gaps - TCR motifs - are generated during model training that constitute the features for the classification. In other words generated sequences are the cell type associated motifs as well as a part of NN classification model. The method was applied to human TCR sequencing data to classify CD4 and CD8 cell subsets. This analysis revealed the CD4 and CD8 associated motifs with the mean accuracy of prediction at least 70% across all repertoires. Thus it is an intelligible way to discern the measurable difference between cell subsets.

P.E3E4.01.09

HLA Frequencies in a a population of Barranquilla, Colombia

C. H. Parga Lozano[1,2], *F. Torres*[1], *A. García*[1];
[1]*Universidad Libre, Barranquilla, Colombia,* [2]*Universidad del Atlántico, Barranquilla, Colombia.*

Introduction: Barranquilla is a city in northern Colombia. The city had high immigration in the last 200 years, mainly from Central Asia, Africa and Europe. That caused a significant miscegenation of the population along with native Amerindians in the region. Materials and methods: 43 individuals from Barranquilla were typed for the detection of the HLA-DRB1 and DQB1 alleles. The HLA allele frequencies of 738 chromosomes were analyzed and compared these with 9 Colombian Amerindian populations using genetic distances, neighborjoining dendrograms (NJ) and correspondence analysis. Results: The most frequent alleles were DRB1 * 15: 01(0,088889), DRB1 * 01: 01(0,077778), DRB1 * 04: 01(0,077778) and DQB1 * 06: 01(0,16667), DQB1 * 03: 02(0,15556), DQB1 * 05: 01(0,13333). Several new haplotypes were obtained. Of which the most frequent were DRB1 * 01: 01-DQB1 * 05: 01 and DRB1 * 04: 01-DQB1 * 03: 02. According to the NJ results and correspondence analysis, the population is not related to the Amerindians, due to its presence as a group in the NJ phylogenetic tree. Discussion: Based on these analyzes it was found that there is a close relationship between the indigenous people from Colombia, mainly with the indigenous from Sierra Nevada de Santa Marta. Several DRB1/DQB1 haplotypes were not reported previously and this population from Barranquilla, moreover this population is not related to any of the Amerindians directly, which suggests a miscegenation and therefore in future studies should be included mestizo, Caucasian, Asian and Black populations to obtain a better phylogenetic relationship.

P.E3E4.01.10

A novel statistical approach to monitor clonal antigen-specific T-cell responses using targeted RNA-seq

S. Pollastro[1], *M. De Bourayne*[2], *B. van Schaik*[1], *A. van Kampen*[1], *A. van Kampen*[1], *B. Maillère*[2], *N. de Vries*[1];
[1]*AMC, Amsterdam, Netherlands,* [2]*SIMOPRO, CEA, Saclay, France.*

Introduction: *In vitro* T cell stimulation assays are basic immunological tools used to investigate antigen-specific T cell responses. Here we explored different experimental set-ups to take this tool to the single clone level using next generation sequencing (NGS) based technologies and novel statistical approaches. **Methods:** We analyzed sequential samples - taken in triplicate - during 10 day peptide-based *in vitro* T cell stimulation assays using NGS-based T-cell receptor (TCR) repertoire analysis (NGS-TCR-RA) to identify, fingerprint and monitor antigen-specific T cell responses at the clonal level. **Results:** Reproducible gradual expansion of initially low-frequency T-cell clones was observed during the cultures. We developed a statistical approach to identify differentially expanded, candidate antigen-specific TCR clones by comparing the pre-stimulation and day 10 post-stimulation repertoire. We confirmed antigen-specificity of most significantly expanding clones using NGS-TCR-RA of T-cells sorted on CD40L expression upon short antigen re-challenge. **Conclusion:** NGS-TCR-RA is a robust, sensitive and reproducible tool for identification and monitoring of antigen-specific T-cell responses, performing statistical evaluation at the single clone level. Furthermore, based on clonal fingerprinting it is able to link *in vitro* analysis of clones to *in vivo* observations on T-cell responses. As such it constitutes a novel, powerful “omics” tool to fingerprint relevant B- and T-cells in adaptive immune responses.

P.E3E4.01.11

Communicome analyses identify the TNF/TRAIL receptor family as a potential determinant of virus control and CD4 T cells counts in natural chronic HIV infection.

M. Ruiz-Riol[1], *B. Oriol-Tordera*[1], *A. Llano*[1], *B. Mothe*[1,2], *P. Susana*[1], *C. Galvez*[1], *D. Berdnik*[3], *J. Martinez-Picado*[1,2,4], *C. Ganoza*[5], *J. Sánchez*[5], *G. Gómez*[6], *B. Clotet*[1,2], *T. Wyss-Coray*[3], *C. Brander*[1,4,7];
[1]*IrsiCaixa, AIDS Research Institute, Badalona, Spain,* [2]*Universitat de Vic - Universitat Central de Catalunya (UVic-UCC), Vic, Spain,* [3]*Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, United States,* [4]*Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain,* [5]*IMPACTA, Lima, Peru,* [6]*Universitat Politècnica de Catalunya-Barcelona Tech, Barcelona, Spain,* [7]*Aelix Therapeutics, Barcelona, Spain.*

The progressive loss of CD4 T cells in untreated HIV infection is incompletely understood. Apart from direct cytolytic effects of viral replication, “bystander” apoptosis triggered by soluble factors or membrane-bound host immune factors also contribute to cell death of infected and uninfected cells. To identify soluble plasma factors driving cell-death during chronic HIV infection, “communicome” profiles were assessed in HIV-infected, treatment-naïve individuals with high (>50,000, n=47) or low (<10,000 HIV RNA copies/ml, n=49) viral loads. Multivariate classificatory and regression model analyses for CD4 count prediction revealed that plasma levels of soluble death factors, most of them involved in TRAIL (tumor necrosis factor (TNF)-related apoptosis-inducing ligand) signaling, are critical for control of virus replication and CD4 loss.

In particular, plasma concentrations of two TRAIL decoy receptors (TRAILR3 and TRAILR4) were significantly correlated with peripheral blood CD4 T cell counts as well as viral load and proviral HIV-DNA copies (all p<0.01).
Total PBMC-based gene expression levels supported these associations further. An additional TNF ligand (TL1A; TNFSF15) and TNF receptor (DR3; TNFRSF25), were strongly related with CD4 counts. These results were validated in unrelated cohorts of seronegatives, recently HIV infected subjects (3-6 months post-seroconversion), longitudinally followed individuals tested 1 year before and after cART initiation and HIV controllers. The data identify several soluble plasma markers of the TNFR family that are related to HIV disease progression and which are involved in "bystander" cell death, thereby opening potential new targets for immune-based therapeutic interventions in HIV infection.

P.E3E4.01.12
A mathematical model of TCR signaling and its information transmission in a pool of low affinity ligands

***K. Saeki**, R. J. de Boer;*
Utrecht University, Utrecht, Netherlands.

T cells scan the surface of antigen presenting cells to detect foreign peptides on major histocompatibility complex (MHC). Recognition takes place via the binding of T cell receptor (TCR) to peptide-MHC and the transduction of downstream signaling cascades. To induce a proper immune response, it is essential that T cells are activated when they bind to foreign peptides and not when confronted with self-peptides. Although T cells that have high affinity to self-peptides are deleted during development in the thymus, T cells in the periphery should still discriminate foreign peptides with high affinity to its TCR from the many and abundant low affinity self peptides. Failures in this discrimination result in either infection or autoimmune diseases.Many models have been suggested to explain this, however, it is not clear that how peptide discrimination by TCRs is disturbed in the background of many low affinity self-peptides that could antagonize signaling. Here we simulate the TCR signaling model developed by Francois et al. 2013 *PNAS* with low affinity ligands, and quantify the ability of ligand discrimination using mutual information. The mutual information indicates the maximum number of input signal values that a signaling pathway can reliably resolve. The results show that ligand discrimination works only in the presence of antagonists with very low affinity, which suggests that negative selection of immature T cells should be very strict. We will also discuss how the selection of immature T cells with different strength of TCR signaling results in different T cell differentiation.

P.E3E4.01.13
Development of recombinant antibodies: highly reproducible with tailored specificity

***M. Sassi**, A. Wittmann, A. Symonds, R. Adams, A. Solache, B. Hamilton;*
Abcam plc, Cambridge, United Kingdom.

Recombinant Antibodies are fundamental tools in both basic and clinical research of Immunological targets. However, an increasing number of studies have shown that not all antibodies are specific, which leads to a lack of experimental reproducibility.
To provide antibodies that have excellent specificity and reproducibility, we have engineered recombinant versions of our RabMAb® rabbit monoclonal antibodies. Recombinant antibodies are manufactured by cloning the immune-specific heavy and light antibody chains into a high-yield mammalian expression vector or they can be produced from an existing hybridoma.
The technology combines the superior antigen recognition of a rabbit immune system with the specificity and consistency of a monoclonal antibody. Our RabMAb® products are validated in key applications (western blot, IHC, ICC/IF, IP, and flow cytometry) and include several relevant targets in immunology and immuno-oncology research. Successfully validated products will be produced in numerous formats (Fluorescent conjugates, PBS formulations) to allow their use in many types of in vivo and in vitro studies.
Our phage display technology is an alternative method to generate high-affinity binders against difficult proteins, small molecules, and toxins. This *in vitro* approach is based upon a large library of bacteriophage particles, each carrying the genetic information and the unique phenotypic binding function of one antibody clone.
Utilizing both *in vivo* and *in vitro* technologies, we can deliver high quality antibodies to all targets. The advantages of recombinant antibodies over both traditional monoclonal and polyclonal antibodies are increased in consistency and reproducibility, high affinity and specificity, ease of scalability.

P.E3E4.01.14
Quantifying immune cell subsets in living cultures over time using IncuCyte® live-cell analysis

***C. Szybut**[1], N. Bevan[1], H. Campwala[1], L. Kelsey[1], N. Dana[2], T. Jackson[2], N. Holtz[2], E. Endsley[2], T. Dale[1], D. Trezise[1];*
[1]Essen BioScience, a Sartorius Company, Welwyn Garden City, United Kingdom, [2]Essen BioScience, a Sartorius Company, Ann Arbor, United States.

CD surface markers have long been used to identify immune cell subsets and associate cells with certain immune functions. Typically, flow cytometry and specific fluorescently-labelled anti-CD antibodies are used for these analyses. Whilst extremely powerful, this approach does not readily afford insight into temporal changes or spatial interactions between cell populations in heterogeneous systems. Here we describe a novel labelling and analysis strategy to enable long-term, non-invasive quantification of immune cells based on IncuCyte® live-cell imaging.
An Fc-targeted anti-mouse Fab fragment conjugated to a green-emitting fluoroprobe (IncuCyte FabFluor-488) was used to tag antibodies to cell surface markers. Addition of the FabFluor488-antibody complex to living cells, including OptiGreen background suppressor, produced fluorescent labelling that was sufficiently bright and stable to allow repeated measurements for >4 days without perturbing cell morphology or growth. With new image analysis and visualisation tools, individual cells were segmented from the phase-contrast image and quantified cell by cell for fluorescence. The method was validated by comparing the phase cell counts over time with nuclear fluorescence values in proliferating Jurkat-Nuclight RFP cells. In PBMCs, the anticipated frequencies of lymphocyte subpopulations (CD4, CD8, CD45) were detected using this method. Cell subsets can be gated for further analysis determining dynamic changes in response to stimuli, e.g. increase in CD71+ cells following anti-CD3/IL-2 activation.
FabFluor antibody labelling and live-cell imaging enables long-term tracking and analysis of immune cell subsets in living cultures over time. This method should prove powerful in analyses on dynamic heterogeneous cell models and for studying cell-cell interactions.

P.E3E4.01.15
Define the dynamic protein landscape during early of human Th17 cell differentiation

***S. K. Tripathi**, T. Välikangas, M. Khan, A. Shetty, S. D. Bhosale, R. Moulder, E. Komsi, V. Salo, R. De Albuquerque, O. Rasool, L. E. Elo, R. Lahesmaa;*
Turku Centre for Biotechnology, Turku, Finland.

Th17 cells play key role in the pathogenesis of inflammatory and autoimmune diseases and in various cancer. Hence, it is critical to unveil molecular signatures driving the differentiation of Th17 cells in order to understand their regulation during diseased state. We performed label-free mass spectrometry based quantitative proteomics analyses to reveal the Th17 cell-specific proteomic signature regulating Th17 cell differentiation and function in human. We compared the human Th17 proteomics data generated in this study with our previously published data on the transcriptomic profiles during human Th17 differentiation that revealed the degree of similarities and differences between the transcript and the protein levels. Furthermore, we validated a panel of selected proteins with known and unknown functions in Th17 cell differentiation. To our knowledge, this study is the first to map the global protein landscape during early human Th17 cell differentiation.

P.E3E4.01.16
Inflamed tissue contributes to the emergence of auto-reactivity in granulomatosis with polyangiitis

***G. Weppner**[1], O. Ohlei[2], C. Hammers[3], K. Holl-Ulrich[4], K. Hasselbacher[5], G. Riemekasten[1], S. Ibrahim[3], A. Recke[3], P. Lamprecht[1], A. Müller[1];*
[1]Department of Rheumatology & Clinical Immunology, Lübeck, Germany, [2]LIGA, Lübeck, Germany, [3]Department of Dermatology, Lübeck, Germany, [4]Institute of Pathology, Marienkrankenhaus, Hamburg, Germany, [5]Department of of Otorhinolaryngology, Lübeck, Germany.

Circulating anti-neutrophilic cytoplasmic autoantibodies targeting proteinase 3 (PR3-ANCA) are a diagnostic and pathogenic hallmark of granulomatosis with polyangiitis (GPA). It is, however, incompletely understood if inflamed tissue supports presence and emergence of PR3-ANCA$^+$ B-cells. In search of such cells in inflamed tissue of GPA, immunofluorescence staining for IgG and a common PR3-ANCA idiotype (5/7 Id) was undertaken. To gain insight into surrogate markers possibly indicative of a PR3-driven antibody response at inflamed sites, a meta-analysis comprising IGVH and IGVL genes derived from respiratory tract tissue of GPA (231 clones) was performed.
Next generation sequencing-based IGHV genes derived from peripheral blood of healthy donors (244.353 clones) and previously published IGLV genes (148 clones) served as controls. For comparison, Ig genes of murine and known human monoclonal anti-PR3 antibodies were analyzed. Few 5/7 Id$^+$ / IgG$^+$ B-cells were detected in inflamed tissue of GPA. IGHV and IGLV genes derived from inflamed tissue of GPA displayed altered V(D)J usage, contributing to prolonged complementarity determining region 3 (CDR3) in the IGHV genes. Further, selection against amino acid exchanges was prominent in the framework region of IGHV genes derived from inflamed tissue of GPA. Comparing V(D)J rearrangements and deduced amino acid sequences of the CDR3 between anti-PR3 antibodies and Ig clones derived from inflamed tissue of GPA, yielded no identities and few similarities. Thus, few PR3-ANCA$^+$ B-cells were found in inflamed tissue of GPA. Notably, the search for clones producing PR3-ANCA IgG in inflamed tissue might require methods that can detect rare clones.

P.E3E4.01.18

Extracellular Vesicles Derived From Mesenchymal Stromal Cells Modulate Immune Cells generating a Regulatory Profile

F. Franco da Cunha[1], *V. Andrade-Oliveira*[2], *D. Candido de Almeida*[1], *T. Borges da Silva*[1], *M. Cenedeze*[1], *M. Ioshie Hiyane*[2], *R. Aparecida Cavinato*[2], *N. Olsen Saraiva Camara*[2];
[1]*Federal University of São Paulo- Unifesp, SAO PAULO, Brazil,* [2]*University of Sao Paulo, SAO PAULO, Brazil.*

Mesenchymal Stromal Cells (MSC) can generate immune tolerance due to their inhibitory activity toward T and B cells, dendritic cells (DC) and natural killer cells. Extracellular vesicles (EVs) are one of the main mechanisms by which MSC exert their actions. In this study, we hypothesize that EVs from MSC can, by themselves, modulate the immune response, generating a regulatory profile.EVs were obtained by ultracentifugation. DCs from bone marrow were expanded with GM-CSF. The incorporation by DCs and Tcells was detected by confocal captures. EVs-treated DC were used as stimulus for Tcell differentiation assay. Tcell proliferation assay was performed with anti-CD3 and anti-CD28 antibodies. Tcell polarization was evaluated in naïve TCD4 proliferation with specific cytokines. The expression of surface markers was detected by flow cytometry (FACS) and the cytokines were detected by RT-PCR, ELISA, FACS and confocal microscopy. A miRNA PCR array was performed to evaluate miRNA profile. EVs were incorporated by DCs and lymphocytes. EVs treatment didn't affect the expression of surface markers on DCs, but altered their function. TCD4 cells in the presence of EVs-treated DCs demonstrated lower differentiation toward Th1 cells. EVs led to lower Tcell proliferation and lower Th1 differentiation. Interestingly, the addition of EVs in a Th1 polarization increased the expression of Foxp3, generating some $IFNg^{+}FoxP3^{+}$ cells. The treatment of EVs with Rnase abolished some effects, suggesting a role of RNAs/miRNAs in this regulation. Some miRNAs were regulated after EVs treatment. Our data suggests that MSC-EVs are able to manipulate immune cells, generating a regulatory profile, specially in Tcells. Support by CNPq, FAPESP.

P.E3E4.01.19

Myeloid cells mediates the accelerated growth of tumor in high-fat diet-fed mice

T. Tran, M. Montabord, B. Esposito, E. Tartour, ***S. Potteaux****;*
INSERM U970, Paris, France.

Cancer and cardiovascular diseases (CVDs) are the leading causes of mortality worldwide. Components of the metabolic syndrome have been shown to aggravate both disease conditions. Here, we investigated the role of early dyslipidemia on melanoma development in mice with or without pre-atherosclerosis conditions. C57Bl6J mice were fed with a pro-atherogenic high fat diet (HFD: 15% FAT and 1.25% cholesterol) or a control chow diet starting two weeks before subcutaneous injection of B16-F10 melanoma cells. Our data showed that mice on a HFD displayed accelerated melanoma progression independently of cholesterol levels and insulino-resistance. Kinetic analysis revealed an increase of systemic inflammation and accumulation of myeloid cells in the growing tumor, in mice on HFD. Transcriptome analysis showed a switch in immune responses in the tumor microenvironment. Leukocytes isolated from the tumor of HFD-treated mice had lost their capacity to inhibit tumor cell proliferation as compared with chow diet-fed mice. Selective depletion of monocytes/macrophages with clodronate liposomes, or myeloid-derived suppressor cells with an anti-Gr1 antibody partially protected against melanoma progression under HFD. Mechanistic analysis demonstrated the implication of VEGF and IL-1beta in the protumoral effect of myeloid cells under HFD. Current experiments are now being performed to identify the implication of specific fatty acid in the immuno-metabolic switches orchestrated in myeloid cells infiltrating the tumor at early time points. In conclusion, this transversal study should help understand in more details the communication between free fatty acids, immune cell activation and tumor development. It should as well allow proposing new therapeutic strategies to limit tumor growth in patients with metabolic syndrome.

P.E3E4.01.20

Deep phenotyping approach to reveal the novel platelet interaction with immunological cells

S. Kalyan*;*
ARUP Laboratories, Salt Lake City, United States.

In this study we have used the mass cytometry (Helios CyTOF) technique combined by the dimensionality reduction analytical approach (utilizing R/Bioconductor) to reveal novel interaction between platelets and several immunological cells in normal healthy donors whole blood. Using the power of CyTOF we first identified expression of novel surface marker on platelets. These expression were compared with the platelet expression data base and RNA-Seq data. We later explored the already known physical interaction between platelets and immunological cells such as monocytes, dendritic cells and NK cells, albeit at the subtype level. Platelets prefer classical monocytes and myeloid dendritic cells over non-classical sub-types for physical interaction. We also identified physical interaction between platelets and T and B lymphocytes. The study revealed that platelets prefer naive T and B cells over active and memory T and B cells. Our study also revealed novel subtypes in NK cells, T and B lymphocytes based on the t-SNE analysis of our chosen surface markers. These novel immunological T and B cell subtypes also showed varying degree of physical interaction with the platelets. These study open new possibilities of development of disease marker and therapeutic approaches as evidenced by previously ongoing clinical trials exploiting platelets and monocyte interaction in diseases such as HIV and CVID.

P.E3E4.01.21

MAE versus IP: a comparison of two methods of HLA class I peptide isolation

R. Farriol Duran[1,2], *G. Janssen*[2], *A. de Ru*[2], *Y. Arribas*[1], *L. Labeur*[1], *D. Jaraquemada*[1], *P. Van Veelen*[2];
[1]*Institute of Biomedicine and Biotechnology, Autonomous University of Barcelona, Cerdanyola del Vallès, Spain,* [2]*Center for Proteomics and Metabolomics, Leiden University Medical Center, PO Box 9600, 2300 RC Leiden, The Netherlands., Leiden, Netherlands.*

The most commonly applied method for HLA Class I peptide isolation is immunoprecipitation (IP). However, the method has a limited yield, which affects the HLA-peptidome coverage, requiring relatively large amounts of starting material (cells or tissues) to obtain a deep HLA-peptidome. Alternatively, mild acid elution (MAE) is the other established technique that can be applied. MAE is based on a citrate shock that disrupts HLA Class I complexes liberating peptides to the supernatant. The simplicity and time-efficiency of MAE comes at the expense of the (co)isolation of non-HLA-binding peptides. Our current experiments showed a relatively high fraction of HLA-binding peptides (77%), higher than generally reported, but not as good as IP (90%). Parallel elutions (with IP and MAE) of the EBV-transformed B cell line JY showed a similar HLA-binding affinity distribution for MAE and IP-derived peptides, which seems to imply that not many weak binders are lost during IP.

TotalSeq™ , Standardized oligonucleotide barcode antibody conjugates for multiplex immunophenotyping by single cell sequencing

M. Li*, B. Yeung, K. Nazor, X. Zhao, X. Yang;*
BioLegend, San Diego, United States.

The combination of nucleic acid sequencing and protein expression profiling is a recent advance in single cell sequencing (scSeq) technologies. For instance, the CITE-Seq or REAP-Seq combined measurements of cellular proteins and transcriptomes. This advance will potentially transform how complex cell populations are studied. Published data, as well as those from our own studies, indicated that scSeq analysis on cell surface marker expression are comparable to multi-color flow cytometry, but provides superior capacity in multiplexing to the latter. To support application of the new technologies and enable reliable comparison of data across longitudinal and multi-site studies, we provide standardized oligonucleotide barcode-labeled antibodies. After assigning a unique oligo barcode to each of our monoclonal antibodies, we prepared the conjugated reagents; we name it TotalSeq™ product line. In addition, we attempted to assign/conjugate a series of oligonucleotide barcodes to select clones of antibodies specific to "universally" expressed cell surface molecules. These products , the Hashtags, can be used to label cells from different sources, or experiments, etc, in multiplex analysis. We will show data from our studies validating the application of these products.

The dopaminergic agonist Pramipexol enhances regulatory T cell response after one-year treatment in Parkinson disease patients

L. Adalid-Peralta[1], *D. D. Álvarez Luquín*[1], *A. Arce Sillas*[1], *J. Leyva Hernández*[1], *E. Montes Moratilla*[1], *V. Vivas Almazán*[1], *C. Pérez Correa*[1], *U. Rodríguez Ortiz*[1], *M. C. Boll*[2], *G. Fragoso*[3], *E. Sciutto*[3];
[1]*Instituto Nacional de Neurología y Neurocirugía, Mexico DF, Mexico,* [2]*Instituto Nacional de Neurología y Neurocirugía, Mexico City, Mexico,* [3]*Instituto de Investigaciones Biomédicas, UNAM, Mexico City, Mexico.*

Introduction: Parkinson disease (PD) is the second most frequent neurodegenerative disease, only after Alzheimer. PD is characterized by the loss of dopaminergic neurons in the substantia nigra and by the presence of α-synuclein aggregates. PD-associated neuroinflammation contributes to neurodegeneration. The dopaminergic agonist Pramipexol has shown a neuroprotective effect by mechanisms yet unknown. Meanwhile, both inflammatory and anti-inflammatory immune cells could be stimulated by dopamine and dopaminergic agonists. Regulatory T cells (Tregs), critical in restraining inflammation, express dopamine receptors. This work is aimed to determine the effect of Pramipexol on Treg-mediated immunoregulatory responses.
Materials and Methods: 30 untreated PD patients (scoring 1-2 in the H&Y scale) and 22 healthy controls were included. Peripheral blood samples were taken at inclusion and one year after treatment with pramipexol, either alone or combined with levodopa. The levels of classical CD4+CD25+FOXP3+CD127low/-, resting CD4+CD45RO-FOXP3low, non-Treg CD4+CD45RO+FOXP3med, activated CD4+CD45RO+FOXP3hi, Tr1 CD4+CD25hiIL-10+, and Th3 CD4+CD25hiTGF-beta+ Treg cells were determined. Patient status was assessed by the UPDRS and H&Y scales.

Results: At inclusion, PD patients showed significantly lower levels of classical, activated, and Tr1 Tregs than controls. No post-treatment differences were found in these populations between patients and controls. The levels of classical, activated, and Tr1 cells showed a significant increase in patients after treatment. A decrease in UPDRS and H&Y scores was also observed.
Conclusions: The increase in Treg levels promoted by treatment suggests a recovery in the regulatory immune response that could contribute to suppress neurodegeneration-related inflammation. Treg recovery coincided with decreased UPDRS and H&Y scores.

P.E4.01.02
Binding between recombinant Phospholipases D from the venom of Loxosceles laeta and "Lipid Rafts" from the membrane of human monocyte THP-1 activates the PI3k /Akt pathway.

***T. A. Arán-Sekul**, J. M. Rojas, J. E. Araya, A. Catalán;*
Universidad de Antofagasta, Antofagasta, Chile.

Introduction: The Lipid Rafts are dynamic complexes, located on the cell surface, mainly composed of cholesterol, sphingolipids and proteins. It's believed that its most important role is to participate in the transduction of signals into the cell. Studies in mouse T cells have shown an association between the Lipid Rafts and the PI3k /Akt pathway, facilitating membrane recruitment, and activation of Akt. **Aim**: Demonstrate that the association between recombinant Phospholipases D of the venom *Loxosceles laeta* and Lipid Rafts of the monocyte membrane is able to activate the PI3k/Akt pathway. **Methodology**: Using recombinant isoforms of the *Loxosceles laeta* venom, the interaction between our proteins with Lipid Rafts of the monocyte THP-1 membrane was evaluated by immunofluorescence. Also, activation of the PI3k/Akt pathway was evaluated by Western Blot of proteins from THP-1 cells incubated with our recombinant proteins. **Results**: From the incubation with antibodies specific for Lipids Rafts, recombinant Phospholipases, marked with fluorophores, it was possible to demonstrate co-localization between our recombinant proteins and the Lipid rafts from THP-1 cells. . Also, this cell line, when incubated with recombinant Phospholipases, exhibits activation of PI3k/Akt pathway evaluated by Western Blot.**Conclusion**: No previous report has addressed the possible association of Lipid Rafts to the signals induced by Phospholipases D of *Loxosceles* spiders. In addition, its role in the activation of the PI3k/Akt signaling pathway related to the production of cytokines and chemokines associated with the inflammatory response to *Loxosceles* venom its unknown. So, according to the results, our work contributes to the understanding of this problem.

P.E4.01.03
Polymorphism analysis of TLR7 (rs179008) and TLR9 (rs352140) genes in systemic lupus erythematosus patients

***M. A. Bashir**, N. Afzal, R. Tahir, F. Shahzad, K. Javaid, M. Kashif, S. Jahan;*
University of Health Sciences, Lahore, Pakistan.

Background: Systemic Lupus Erythematosus (SLE) is an inflammatory autoimmune disease characterized by production of autoantibodies and subsequent damage to multiple organs. In SLE, various antibodies are formed and mostly anti-dsDNA levels are raised in serum of SLE patients. Various genome wide studies have shown association of TLR7 and TLR9 genes with SLE. Therefore, this study was designed to determine and compare single nucleotide polymorphism (SNP) at restriction sites of TLR7 gene (rs179008) and TLR9 gene (rs352140) between local population of SLE patients (Group-1) and healthy controls (Group-2). **Method:** It was a case control study. Eighty samples were recruited for each of the two study groups. Three ml of EDTA blood from patients and control was collected and processed for the analysis of gene polymorphism of TLR7 (rs179008) and TLR9 (rs352140) by PCR-RFLP after DNA extraction. Chi-square test was used to analyze polymorphism analysis and allele frequencies between two groups. Associations of TLR 7 and TLR 9 gene polymorphism with SLE and with its clinical parameter were analyzed. **Results:** In TLR7 genotype AT and TT are not significantly associated with SLE while TLR9 CT genotype and TT genotype and especially T allele are significantly associated with SLE showing significant interdependence of TLR9 gene polymorphism with SLE patients. **Conclusion:** Genetic variation in TLR9 may be a key part in pathogenesis of SLE; therefore and TT genotype and T allele is associated with SLE so further studies are needed to establish this genetic factor as biomarker for local population.

N-3PUFAs reduce CD4+ T-cell distribution to adipose tissue via both cellular & systemic effects

***D. Cucchi**[1], M. D. Camacho-Munoz[2], J. Smith[3], A. Nicolaou[2], C. Mauro[1,4];*
[1]William Harvey Research Institute, London, United Kingdom, [2]Faculty of Biology, Medicine and Health, The University of Manchester, Manchester, United Kingdom, [3]The Institute of Cancer Research, London, United Kingdom, [4]Institute of Inflammation and Ageing, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom.

The lipid imbalance observed in cardiovascular metabolic disorders (CVMD) alters T-cell membrane lipid composition, mediator production and related signalling cascades, leading to unwanted inflammatory responses. We postulated that these alterations may be corrected by omega-3-polyunsaturated fatty acids (n-3PUFAs). Indeed we show that exposure of activated T-cells to bioactive lipids can modify migratory patterns in vitro and in vivo and we investigate their mechanisms of actions. In mice fed n-3PUFA-enriched diet for 3 weeks, we found a significant reduction in the numbers of pro-inflammatory CD4+ T-cells in adipose tissue, as well as significant changes in the lipids profile in plasma and adipose tissues, consistent with an anti-inflammatory signature. To better understand the effect of n-3PUFA on T-cell motility, we assessed CD4+ T-cell migratory capabilities in vitro upon treatment with EPA and DHA in a trans-endothelial migration assay, observing a significant reduction of migration. Furthermore, when T-cells were pre-treated with EPA and DHA in vitro and then implanted in mice, they migrated to the inflamed peritoneum at much lower numbers. In line with this, we found that EPA and DHA treatments are able to reduce the number of polarised T-cells in vitro, alter membrane microdomains and decrease the activity of small Rho GTPases, such as Rhoα and Rac1, whose role in cytoskeletal dynamics is crucial. These findings show that the two principle n-3PUFA, EPA and DHA are active in reducing the motility of CD4+ T cells and their ability to reach target tissues through changes in the cytoskeleton.

P.E4.01.05
Exploring miR-34c-5p modulation of effector CD4 T cell differentiation through logical modelling

***N. Domingues**[1], F. C. Pinto[1], A. E. Sousa[2], M. Gama-Carvalho[1];*
[1]BioISI - Biosystems and integrative sciences institute, Faculty of Sciences, University of Lisbon, Lisbon, Portugal, [2]Molecular Medicine Institute, Faculty of Medicine, University of Lisbon, Lisbon, Portugal.

miRNAs are essential for proper immune cell development and function. miR-34c-5p is upregulated in naïve CD4 T cells 72 hours after in vitro stimulation, but its role in activated T cells remains unknown. The already complex signalling aspects of the immune system are exacerbated by miRNA regulation. Modelling approaches can be extremely useful for immunologists to predict system behaviours.
To address the functions of miR-34c-5p in CD4 T cell activation and differentiation, available logical models were expanded to include miRNA regulation. Validated and predicted targets for miR-34c-5p and miR-155-5p were taken from databases and acquired through prediction algorithms. Transcription factor regulation for these miRNAs was retrieved, including TSSs and TFBSs for promoter regions. Based on the obtained data, a new model was constructed to simulate the potential effects of miR-34c-5p in anti-CD3 and anti-CD28 stimulated naive CD4 T cells in the presence of IL2, using an asynchronous updating scheme. Using a specific set of logical rules, we identified GATA3, FOS and MYC, in addition to miR-34c described TFs TP53 and FOXO3, as the most likely modulators of miR-34c transcription given their ability to reproduce the experimentally observed miRNA expression patterns. Our results further suggest that miR-34c is expressed during effector Th2 differentiation.
Our in silico modelling approach provides new insights into the potential functions of miR-34c-5p in TCR-stimulated T cells, suggesting a role in the promotion of anergy or subtype plasticity, which we are currently validating experimentally.

P.E4.01.06
The role of integrins in serine protease activated protein C signalling in T-cell

***D. GUPTA**[1], S. Ranjan[1], S. Kohli[1], R. Rana[1], A. Müller[2], B. Schraven[2], B. Isermann[1];*
[1]Department of Clinical Chemistry and Pathobiochemistry, Magdeburg, Germany, [2]Institute for Molecular and Clinical Immunology, Magdeburg, Germany.

Introduction: The serine protease activated protein C (aPC) is an anticoagulant, which conveys intracellular signals *via* protease activated receptors (PARs). The function of aPC in innate immunity through both its anticoagulant and signalling properties is established. Using a mice model of GvHD, we have recently established a function of aPC and one of its receptors (PAR3) in adaptive immunity. Integrin activation and signaling has been shown to regulate T-cell activation and adhesion. Here we test the hypothesis if aPC regulates T-cell activation and adhesion via integrins on T-cells.
Material and Methods: GvHD was induced in APC^{high}, RGE-APC^{high} and C57BL/6 (WT) mice by transplanting $2x10^6$ T-cells with $5x10^6$ bone marrow cells from BALB/c mice. Survival, clinical scores and apoptosis in gut were used as parameters to study disease severity. T-cell activation,adhesion and trans-migration were studied *in vitro*. The effect of aPC on integrin signaling was studied using immunoblotting.
Results: *In-vivo* we observed that mice with endogenous high levels of aPC (APC^{high}) were protective against GvHD compared to WT mice. However, mice expressing a mutant aPC lacking the integrin binding site (RGE-APC^{high}) failed to be protective indicating that interaction of aPC with integrin is required for its immunomodulatory function in GvHD. *In-vitro,* aPC preincubation reduced T-cell activation, adhesion to ICAM1 and fibronectin, trans-migration in the presence of SDF-1 and phosphorylation of FAK and Ezrin.
Conclusion: These data demonstrate that aPC modulates T-cell activation and adhesion. *In vivo* results suggest that aPC interacts with integrins to mediate its protective effect in GvHD.

The role of ROS hyperproduction in murine model of autoinflammatory osteomyelitis

J. Kralova[1], *A. Drobek*[1], *J. Prochazka*[2], *F. Spoutil*[2], *D. Glatzova*[1,3], *S. Borna*[1], *P. Angelisova*[1], *T. Skopcova*[1], *J. Pokorna*[1], *R. Sedlacek*[1,2], *T. Brdicka*[1];
[1]*Institute of Molecular Genetics of the ASCR, Prague, Czech Republic, Prague 4, Czech Republic,* [2]*Czech Centre for Phenogenomics, hosted by the Institute of Molecular Genetics ASCR, Vestec, Czech Republic,* [3]*J. Heyrovsky Institute of Physical Chemistry ASCR, Prague, Czech Republic.*

PSTPIP2 is an adaptor protein expressed in the myeloid cells and its deficiency leads to the development of auto-inflammatory disease in mice. This disease has been designated chronic multifocal osteomyelitis (CMO) as the main manifestation is sterile inflammation of the bones accompanied by inflammation of the soft tissues in the external parts of the body. Enhanced production of pro-inflammatory cytokine IL-1β by murine neutrophils is the main factor driving CMO development and progression. In addition, hyper-activation of various signaling pathways in CMO neutrophils has been observed. The negative regulatory effect of PSTPIP2 protein on signaling pathways and IL-1β production is likely mediated by its interacting partners. These include inhibitory molecules, such as CSK, SHIP1 and protein tyrosine phosphatases from the proline-, glutamic acid-, serine- and threonine-rich (PEST) family. However, the exact mechanism of how PSTPIP2 inhibits signaling is not known. Here we describe deregulated ROS production in CMO bone marrow cells and purified neutrophils. To investigate the role of ROS in CMO disease development and progression, CMO mice with non-functional phagocytic NADPH oxidase (Nox-2$^{-/-}$) were generated. Detailed analysis of this mouse strain including disease free curves, CT scans and IL-1β production was performed and data will be presented showing partial alleviation of the disease symptoms.

RNAseq for novel sialic acid inhibitory signalling via Siglecs in moDC

J. Lübbers[1], *E. R. Li*[1], *A. Gallagher*[1], *S. C. Bruijns*[1], *D. Molenaar*[2], *S. van Vliet*[1], *Y. van Kooyk*[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*VU, Amsterdam, Netherlands.*

Cancer cells and pathogens, use sialic acids to actively inhibit the immune system by binding Sialic-acid binding immunoglobulin type lectins (Siglecs) with an ITIM motif. This motif becomes phosphorylated; SHP binds and phosphorylates downstream targets, triggering inhibitory processes. In mice bone marrow-derived DC, we have shown that sialic acid modified antigens are internalized and impose a regulatory program on DCs, inducing Tregs and inhibit generation of Teffector cells. To study whether similar inhibitory processes are initiated by sialic acids on human monocyte-derived DCs (moDCs), displaying Siglec 1, 7 and 9, we generated α2,3 and α2,6 sialic acids on dendrimers (sia-dendrimers). MoDC binding of these sia-dendrimers enhanced IL-10 and reduced IL-12p70 production, pointing towards a more tolerogenic phenotype. To explore the pathways induced by these sialic acids, we performed an unbiased screen of RNAseq data from moDCs treated with α2,3 and α2,6 sia-dendrimers.
α2,3 sia-dendrimer binding to moDCs uncovered 867 unique differentially expressed genes (DEGs) and α2,6 sia-dendrimer revealed 47 DEGs. Gene Set Enrichment Analysis (GSEA) of α2,3 sia-dendrimer revealed enrichment in many pathways including the high-level pathway immune system. The sub-pathways cytokine signalling and antigen processing and proteasome degradation were enriched, especially the ubiquitination sub-pathway were most pathway hubs were changed. In the α2,6 sia-dendrimer only half of the hubs in this sub-pathway were changed. This indicates that sialylated antigens are processed differently and thereby influence antigen processing and presentation leading to changes in T cell polarisation.

Granzyme B in the cell line NK-92: novel approaches and old routines

A. V. Korenevsky, Y. P. Milyutina, A. A. Zhdanova, A. D. Shcherbitskaya, V. A. Semyonov, ***V. A. Mikhailova****, D. I. Sokolov, S. A. Selkov;*
FSBSI "The Research Institute of Obstetrics, Gynecology and Reproductology named after D.O.Ott", Saint-Petersburg, Russian Federation.

Introduction: At present, a variety of routine methods is used for the proteome evaluation. In this study, we have focused on the search for granzyme B in the cell line NK-92 using combination of novel approaches. Material and Methods: The cell line NK-92; 2D-electrophoresis (Protean i12 IEF Cell, PowerPac HC; BioRad, USA), isoelectric focusing (3100 OFFGEL fractionator; Agilent Technologies, USA), on-chip electrophoresis (bioanalyzer 2100; Agilent Technologies, USA), Western blotting. Results: The routine 2D-electrophoresis followed by MS/MS identification was accompanied by a long search for granzyme B and was no success, as staining with Coomassie had not visualized the relevant spot. Therefore, the proteins were subjected to 1D-electrophoresis followed by Western blotting to discover the target protein. The novel approach was that the cell lysate was divided into 24 soluble fractions depending on isoelectrical point, which allowed for 1D-electrophoresis followed by Western blotting and subsequent identification of the fraction containing the highest amount of granzyme B. Additionally, the protein profiles of the obtained fractions were then compared using on-chip electrophoresis. The advantage of this approach is significant timesaving, when compared to the Laemmli method. Besides, the remaining fractions allows performing straight mass-spectrometry or separating proteins using micropreparative HPLC with subsequent MS/MS identification. Conclusions: The combination of novel approaches using routine methods allow for more valid granzyme B identification in the cell line NK-92. Supported by RFBR grant #17-04-00679 and President's grant NSh-2873.2018.7. The study was performed using equipment of the SPbSU Science Park resource center "Development of molecular and cellular technologies."

Mesenchymal stem cells from healthy human gingiva produce lower levels of IL-6 compared to their counterpart from chronic periodontitis

M. Milinković[1], *M. Markovic*[2], *I. Majstorovic*[2], *M. Milanovic*[2], *S. Zečević*[1], *S. Todorovic*[1], *M. Colic*[3];
[1]*University of East Sarajevo, Medical Faculty Foca, R.Srpska, BiH, Foca, Bosnia and Herzegovina,* [2]*University od Defence in Belgrade, Medical Faculty of the Military Medical Academy, Belgrade, Serbia, Belgrade, Serbia,* [3]*University of East Sarajevo, Medical Faculty Foca, R.Srpska, BiH. University od Defence in Belgrade, Medical Faculty of the Military Medical Academy, Belgrade, Serbia, University of Belgrade. Institute for Application of Nuclear Energy, Belgrade, Serbi, Belgrade, Serbia.*

Mesenchymal stem cells (MSCs) have been isolated and characterized from different dental tissues, including gingiva. However, litle is know whether and how chronic inflammation changes their functions. The aim of this study was to compare phenotypic profile, differentiation potential and cytokine production between MSCs isolated from human healthy gingiva and gingiva from chronic periodontitis patients. We showed that 90-98% of both types of MSCs expressed typical markers such as CD90, CD73 and CD105 and were able to differentiate into osteoblasts, chondroblasts and adipocytes under specific cell culture conditions. The expression of other markers, including CD146, CD56, STRO-1 and PDGF-R was lower on MSCs from healthy gingiva, but their proportion in both groups was variable, depending on the donor and number of culture passages. By using fluorescent and confocal microscopy, we demonstrated that pericytes, supposed to be the dominant source of these MSCs *in vivo*, expressed strongly NG2, PDGFR, CD146, CD105 and CD166, but not CD34 and CD31, the markers of endothelial cells. The relative number of pericytes was higher in disseased gingiva. Both types of MSCs produced IL-6, but its level was significantly lower in cultures of MSCs from healthy gingiva. The addition of conditioned medium from the tissue explant of gingival biopsies from chronic periodontitis augmented the production of IL-6 by MSCs from healthy gingiva, suggesting that gingival MSCs during periodontitis , through enhanced production of IL-6, could have a proinflammatory role.

Immunophenotyping extracellular vesicles using Amnis imaging technology

H. R. Pugsley*, B. R. Davidson, P. Morrissey;*
Merck, Seattle, United States.

Only recently has the importance of extracellular vesicles (EVs) as key mediators of intercellular communication been appreciated. EVs are membrane derived structures that include exosomes, microvesicles and apoptotic bodies. Exosomes have been shown to transfer molecules between cells and have the potential to transfer signals between cells. Exosomes are released under normal physiological conditions; however, they are also believed to serve as mediators in the pathogenesis of neurological, vascular, hematological and autoimmune diseases as well as cancer. Quantifying and characterizing EVs in a reproducible and reliable manner has been difficult due to their small size (exosomes range from 30 - 100 nm in diameter). EV analysis can be performed using high-magnification microscopy however this technique has a very low throughput. Attempts to analyze EVs using traditional PMT based flow cytometers has been hampered by the limit of detection of such small particles and low refractive index. To overcome these limitations we have employed the recently developed CellStream flow cytometer. The CellStream utilizes the Amnis imaging technology, having the advantage of high throughput flow cytometry with higher sensitivity to small particles due to the time-delay-integration image capturing system. In this study, the CellStream was used to immunophenotype EVs derived from red blood cells and platelets.

P.E4.01.13

Identifying exosome binding and internalization in blood cell subsets by multispectral imaging flow cytometry

H. R. Pugsley*, S. L. Friend, B. E. Hall, P. Morrissey;*
Merck, Seattle, United States.

Exosomes have been shown to transfer molecules between cells and have the potential to transfer signals between cells. To study how exosomes are interacting with white blood cells high-magnification microscopy can be used; however, this technique has very low throughput. In addition, these events are rare and therefore difficult to analyze objectively and statistically by traditional microscopy methods. To overcome these limitations we have employed multispectral imaging flow cytometry that has the advantage of combining high throughput flow cytometry with high sensitivity fluorescence microscopy. In this study we use multispectral imaging flow cytometry to investigate the interaction of exosomes with white blood cells. Exosomes derived from Jurkat cells were labeled with anti-human CD63-AF647 and added to human white blood cells.

The cells were labeled for immunophenotyping, fixed, and then labeled with anti-human CD63-PE to identify external exosomes.
Plotting Internalization vs Bright Detail Similarity facilitated the identity 3 populations: Internal Exosomes, External/Internal Exosomes, and External Exosomes. Neutrophils, monocytes, and lymphocytes were identified by immunophenotyping; the % of each blood cell subset associated with the CD63-AF647 labeled exosomes and whether the exosomes were internalized or external was investigated. The monocytes had the highest % of cell associated with CD63-AF647 labeled exosomes. And in all of the cell types the majority of the cells associated with CD63-AF647 labeled exosomes were either internalized or partially internalized.

Establishment of an engineered antigen presenting cell platform to study antigen specific human CD8 T cell responses *in vitro*

M. Reithofer[1]*, S. Rosskopf*[2]*, C. Battin*[3]*, J. Leitner*[3]*, B. Bohle*[4]*, B. Jahn-Schmid*[4]*, P. Steinberger*[3]*;*
[1]*Institute for Pathophysiology and Allergyresearch, MCCA PhD Programme, Medical University, Vienna, Austria,* [2]*Institute of Immunology, MCCA PhD Programme, Medical University, Vienna, Austria,* [3]*Institute of Immunology, Medical University, Vienna, Austria,* [4]*Institute for Pathophysiology and Allergyresearch, Medical University, Vienna, Austria.*

Studies on antigen-specific human CD8 T cells are hampered by their low frequency in the peripheral blood. Expansion of these cells in vitro by antigenic peptide is inefficient and often precludes a thorough characterization. Here we describe a cellular platform which allows to efficiently stimulate and expand antigen-specific human CD8 T cells. HLA-A201, the most common MHC class I molecule in the Western population was expressed on human K562 cells. In addition, we introduced an artificial gene encoding five major HLA-A2 restricted viral peptides targeted into the proteasomal degradation and antigen processing pathway. Upon coculture with PBMCs of HLA-A2 positive human donors, these eAPC efficiently expanded virus-specific T cells. Additionally generated eAPC expressing costimulatory ligands like CD80, CD86 or 4-1BBL had augmented capacity to stimulate antigen-specific T cells. Cytotoxicity assays confirmed that stimulation with eAPC yielded potent CD8 effector T cells. MHC class I tetramer staining experiments were performed to identify stimulation conditions that promoted the expansion of antigen-specific T cells and prevented bystander T cell activation. Taken together, our results indicate that we successfully established an eAPC platform that allows to evaluate the function of accessory molecules in the expansion of antigen-specific human $CD8^+$T cells. This system may be applied for the development of improved protocols for *in vitro* generation of virus and tumour-specific T cells for adoptive therapy.

Analysis of miRNA involvement in CD4+T cell differentiation

G. A. Rockinger[1]*, P. Roelli*[2]*, D. Zehn*[2]*, G. Scholz*[3]*, P. Romero*[1]*, C. Jandus*[1]*;*
[1]*University of Lausanne, Epalinges, Switzerland,* [2]*Technical University of Munich, Munich, Germany,* [3]*University Hospital of Bern, Bern, Germany.*

Introduction: in contrast to CD8+T cell, CD4+ T have only recently gained increasing importance in tumor immunity as studies showed their therapeutic relevance, including the recognition of neo-antigens. A key to CD4+ T cell usage in immunotherapy will depend on a better understanding of the regulation of CD4+ T cell differentiation, to promote stem cell memory (SCM) and central memory (CM) phenotypes.
Material and methods: we performed a mRNA sequencing and a microRNA (miR) array of highly-pure sorted naïve (N), SCM, CM and effector memory (EM) CD4+ T cell subsets from peripheral blood of 4 healthy donors, followed by in depth Bioinformatic analysis and in vitro target validation.
Results: we identified differential expression between N, SCM, CM and EM cells of known miR such as miR-146a-5p and miR-155-5p and of previously undescribed miR. Further investigations in additional healthy donors' samples confirmed by qPCR the differential expression of these miR. Further, we were able to correlate the expression of candidate miRs with up or downregulation of target genes within the CD4+ T cell subset of interest.
Conclusion: we are presently investigating miR and target mRNA expression in vitro and in vivo using TCR transgenic mouse models. We aim at identifying optimal miR candidates that could be therapeutically targeted to influence the differentiation of a Naïve CD4+T cells into SCM or CM CD4+ T cells capable of targeting tumor cells.

T cell cooperativity shapes antigen-specific immune responses

S. Zenke[1]*, J. Braun*[1]*, J. Beltman*[2]*, A. Gavrilov*[3]*, N. Beyersdorf*[4]*, P. Aichele*[5]*, T. Lämmermann*[3]*, T. Schumacher*[6]*,* ***J. Rohr***[1]*;*
[1]*Center for Chronic Immunodeficiency, Freiburg, Germany,* [2]*Leiden Academic Centre for Drug Research, Leiden, Netherlands,* [3]*Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany,* [4]*Institute for Virology and Immunobiology, Würzburg, Germany,* [5]*University Medical Center Freiburg, Institute of Immunology, Freiburg, Germany,* [6]*The Netherlands Cancer Institute, Amsterdam, Netherlands.*

Upon activation T lymphocytes rapidly aggregate and form cell clusters both *in vitro* and *in vivo* in an LFA1:ICAM1 dependent manner. The close proximity of cells within clusters provides ample opportunity for T cells to communicate their activation state to each other – via paracrine messengers and/or direct cell interaction. We hypothesized that within clusters activated T cells mutually regulate their behaviors and subsequent differentiation akin to quorum-regulation of bacteria. In order to identify molecules involved in such crosstalk, we have developed a bioinformatics-approach allowing us to identify receptor-ligand pairs co-expressed on activated T cells. We then characterized selected interactions and revealed that within clusters cellular crosstalk sustains T cell expansion by limiting activation-induced cell death. Furthermore, we found evidence for an additional related counter-regulatory signaling circuit which limits further T cell expansion. Competition between these two signaling circuits shapes the outcome of T cell activation. In summary, our results indicate that T cell clusters serve as hubs for mutual regulation of activated T cells. Such behavioral coordination within a defined spatiotemporal framework enables the generation of robust yet flexible immune responses at the population level.

P.E4.01.17

***Loxosceles' spider* phospholipases D activates the PI3K/Akt signaling pathway, and join to lipid raft present in human skin fibroblasts.**

J. M. Rojas Morales*, T. Arán Sekul, J. E. Araya, A. Catalán;*
Universidad de Antofagasta, Antofagasta, Chile.

Introduction: Phospholipase D (PLD) family enzymes from *Loxoceles* spider venom, are responsible of dermonecrosis during human spider envenomation. On human skin fibroblasts, different recombinant isoforms of PLDs from *L. laeta*, induced IL-6, IL-8, CXCL1 and CCL2/MCP-1 production. However, the signaling pathway implicated in this process is unknown. **Aim:** Evaluate the signaling pathway involved in chemokines production mediated by *Loxosceles* PLDs on skin fibroblast. **Methodology:** Human skin fibroblasts HHF-1 cultures were incubated with recombinant PLDs from *L. laeta* (rLlPLD1 and rLlPLD2), and the mutant isoforms of rLlPLD1 (rLlPLD1-D259G and rLlPLD1-W256S), and the Akt activation were evaluated by western blot, using an anti-phospho-Akt1/PKBα (Ser473) monoclonal antibody. Additionally, PI3K participation was determined by Western Blot of phosphorylated Akt in presence or absence of PLDs plus wortmannin. The PLDs-lipid raft binding was evaluated by immunofluorescence using kit Vybrant® Lipid Raft labeling kit (Molecular Probes Inc,). The phospholipase D activity of rPLDs was determinates by Amplex Red Sphingomyelinase Assay.
Results: The recombinant PLDs from *L. laeta* activate Akt between 5-15 min in fibroblast cultures. This effect was decreased in cultures treated with rLlPLDs and wortmannin. Also, the substrate deficient rLlPLD1 mutants, showed a lower activation of PI3K/Akt pathway compared to native protein. Also, PLD binding to lipid rafts from fibroblasts plasmatic membrane seem to be involved in PI3K/Akt pathway activation. **Conclusion:** PI3K/Akt signaling pathway is activated by rLlPLDs, involved binding to lipid rafts present in the plasma membrane of skin fibroblasts, suggesting a role of the latters in the chemokines expression during *Loxosceles* envenomation.

P.E4.01.18

Lymphocyte-specific tyrosine-protein kinase Lck homo-dimers in the complex control of T-cell receptor signaling

P. Schatzlmaier[1]*, F. Baumgart*[2]*, P. Eckerstorfer*[1]*, S. Kraupp*[1]*, G. Schütz*[2]*, H. Stockinger*[1]*;*
[1]*Medical University of Vienna, Vienna, Austria,* [2]*Vienna University of Technology, Vienna, Austria.*

Engagement of the T-cell antigen receptor (TCR) initiates a signaling cascade resulting in T-cell activation, proliferation and differentiation. Intracellular lymphocyte-specific kinase (Lck) plays a pivotal role in this process, transducing initial TCR/CD3 stimulation into tyrosine phosphorylation, calcium fluxing, synapse formation, and altered gene expression. Lck activity is regulated on multiple intercalated levels, including its subcellular localization (by transporters), 2D nano-domain distribution within the plasma membrane, and its phosphorylation status that is directly linked to its enzymatic activity. A potential mechanism of Lck regulation not investigated so far is its homo-dimerization. Noteworthy, ligand-induced homo-association followed by trans-activatory auto-phosphorylation is an established principle for transmembrane receptor tyrosine kinases.
Employing a super-resolution imaging technique - Thinning Out Clusters while Conserving the Stoichiometry of Labeling - we identified a significant amount of Lck dimers in living T-cells. Furthermore, homo-association of membrane-anchored Lck was confirmed by co-immunoprecipitation. To investigate the role of Lck homo-dimers in T-cell signaling, we established an inducible Lck-dimerization system in human Jurkat T-cells after CRISPR/Cas9 knock-out of endogenous Lck. Controlled and specific dimerization of Lck by a membrane-permeable X-linking agent significantly altered its phospho-status and enzymatic activity in a titratable fashion, modulating early as well as late TCR signaling events. In conclusion, homo-dimerization of Lck represents a novel regulatory mechanism controlling Lck kinase activity and thus stimulatory thresholds for T-cell activation.

P.E4.01.20

HyperIgM syndrome caused by defect in CD40

N. kechout[1], *S. Khalissa*[1], *L. Smati*[2], *R. Yahi*[1], *S. Otsmane*[1], *F. Benhassine*[2], *N. Attal*[1];
[1]*Institut Pasteur d'Algérie, Algiers, Algeria,* [2]*Department of Pediatrics, EPH Bologhine, Algiers, Algeria.*

Introduction: Hyper IgM Syndrome (HIGM) is a rare primary immunodeficiency with defects in immunoglobulin (Ig) class switch recombination . So, the affected patients have low levels of IgG and IgA and normal or elevated IgM, resulting in high susceptibility to infections. This defect can be caused by alteration in T-B (CD40-CD40L) interaction or by intrinsic B cell abnormalities. Germinal center can not be formed. The most common form is X-linked inherited and is due to mutations in CD40 ligand (CD40L) gene. In this study we report the first case of Algerian patient with HIGM caused by defect in CD40.
Materials/Methods: A male patient aged of 10 months referred us for exploration. Immunological techniques used are: measurement of IgG, IgA and IgM by nephelometry; T, B, NK immunophenotyping , evaluation of CD40, CD40 L expression and numeration of CD27 + memory B cells by flow cytometry.
Results: The patient had a medical history of pneumonia, recurrent otitis until 8 months. Studying his medical documents revealed an episode of Pneumocystis jiroveci pneumonia. He also suffer from persistent oral candidiasis. He has low levels of IgG, IgA, normal levels of IgM and normal expression of CD40L. Furthermore, he has decreased memory B cells and lack of CD40 expression on monocytes and B lymphocytes.
Conclusion: The clinical phenotype of our patient is that of a combined immunodeficiency similar to patients with CD40L defect. Lack of CD40 enables us to confirm the diagnosis of hyper IgM syndrome and consequently its autosomal recessive inheritance.

P.E4.01.21

Toll-like receptor activation by lipid nanoparticle delivered messenger RNA

S. Bates[1], *M. Ingelsten*[2], *M. Beano*[1], *M. Fellows*[2], *N. Gay*[3], *C. Betts*[1];
[1]*Pathology, Drug Safety and Metabolism, IMED Biotech Unit, AstraZeneca, Cambridge, United Kingdom,* [2]*New Modalities, Drug Safety and Metabolism, IMED Biotech Unit, AstraZeneca, Cambridge, United Kingdom,* [3]*Department of Biochemistry, University of Cambridge, Cambridge, United Kingdom.*

Lipid nanoparticles (LNPs) are the most developed delivery formulations for messenger RNA (mRNA) therapy. They aid cellular delivery of mRNA and prevent extracellular degradation with proven efficacy, both *in vivo* and *in vitro*. A key safety issue is the activation of an innate immune response. Understanding the cellular mechanisms and activated inflammatory pathways are key to improving mRNA/LNP design, and hence their therapeutic potential. Here we investigate if mRNA/LNP delivery activates pattern recognition receptors such as Toll-like receptors (TLRs). Primary human dermal fibroblasts were treated with different TLR and cellular pathway inhibitors 30 mins prior to LNP treatment for 24 hours. The effect on proinflammatory cytokines and exogenous mRNA protein expression (luciferase) were measured. Of eight cytokines assessed, only G-CSF, IP-10, IL-8 and IL-6 were detectable. Whilst TLR4 inhibition did not impact cytokine release induced by this LNP, inhibition of downstream proteins such as IRAK4 and MyD88 led to significant drops in cytokine levels. Additionally, inhibition of endosomal formation by dynamin inhibition resulted in the largest drop in all detected cytokines, suggesting that endosomal uptake of LNP/mRNA is required to induce inflammation. This initial data supports a role for TLR signaling in mRNA/LNP activation of fibroblasts and work is ongoing to further define the mechanisms of activation and the specific TLR receptors involved.

P.E4.01.22

The ERBB-STAT3 Axis Drives Tasmanian Devil Facial Tumor Disease

L. Kosack[1], *A. Popa*[1], *B. Wingelhofer*[2], *A. Orlova*[2], ***B. Agerer***[1], *B. Vilagos*[1], *P. Majek*[1], *K. Parapatics*[1], *A. Lercher*[1], *A. Ringler*[1], *J. Klughammer*[1], *M. The marsupial Tasmanian devil (Sarcophilus harrisii) faces extinction due to transmissible devil facial tumor disease (DFTD). To unveil the molecular underpinnings of DFTD, we designed an approach that combines sensitivity to drugs with an integrated systems-biology characterization. Sensitivity to inhibitors of the ERBB family of receptor tyrosine kinases correlated with their overexpression, suggesting a causative link. Proteomic and DNA methylation analyses revealed tumor-specific signatures linked to oncogenic signaling hubs including evolutionary conserved STAT3. Indeed, ERBB inhibition blocked phosphorylation of STAT3 and arrested cancer cells. Pharmacological blockade of ERBB signaling prevented tumor growth in a xenograft model and resulted in recovery of MHC class I gene expression. This link between the hyperactive ERBB-STAT3 axis and MHC class I mediated tumor immunosurveillance provides mechanistic insights into horizontal transmissibility and led us to the proposition of a dual chemo-immunotherapeutic strategy to save Tasmanian devils from DFTD.

The purpose of this study was attempted to evaluate the efficiency of ascorbic acid (AA) on the effects on cardiomyogenic differentiation of human amniotic fluid mesenchymal stem cells (hAF-MSCs). The result of immunofluorescence and immunoenzymatic staining of the AA combined with 5-aza treatment group revealed the highest expression of cardiac specific proteins including GATA4, cTnT, Cx43 and Nkx2.5. It could be concluded that AA might be a cardiomyogenic inducing factor for mesenchymal stem cells and may open new insights into future biomedical applications for cardiomyogenic differentiation.

Hyperpigmentation of the skin results from excessive melanin formation in melanocytes, and over production of melanin frequently leads to melanoma. The aim of this study was to investigate the potential of *Rhinacanthus nasutus* (L.) Kurz leaf water extract on inhibition of melanin formation or melanogenesis. *R. nasutus* leaf water extract was evaluated *in vitro* for its inhibitory effect on mushroom tyrosinase activity and cellular tyrosinase activity. B16F10 mouse melanoma cells were cultured with *R. nasutus* leaf extract and their tyrosinase activity and melanin content was compared with kojic acid, a known tyrosinase inhibitor. Moreover, the level of expression of melanogenesis related genes and proteins were determined by quantitative RT-PCR and enzyme-linked immunosorbent assay (ELISA), respectively. The result showed that *R. nasutus* leaf extract had no inhibitory effect on mushroom tyrosinase activity. However, *R. nasutus* leaf extract significantly suppressed cellular tyrosinase activity and melanin production in B16F10 melanoma cells without any apparent cytotoxicity. Quantitative RT-PCR and ELISA revealed that *R. nasutus* leaf extract downregulated the expression of microphthalmia-associated transcription factor (MITF) and tyrosinase mRNA and proteins. Taken together, the data suggest that *R. nasutus* leaf extract may act as an anti-melanogenic agent by inhibiting the expression of MITF and cellular tyrosinase activity. *R. nasutus* leaf extract may show potential as an ingredient in skin-whitening cosmetics or as a topical agent for the treatment of hyperpigmentation disorders.
